Getting enough sleep is a fundamental biological need. Extensive medical research has demonstrated the significant effects of sleep deprivation on physical health, mental conditions, and cognitive functioning (Cappuccio et al., 2010; Ferrie et al., 2011; Hale et al., 2020). Parallel to this, economic research highlights how inadequate sleep affects financial market returns (Kamstra et al., 2000), academic performance (Avery et al., 2022; Jagnani, 2024), and labor market outcomes (Gibson et al., 2018; Giuntella et al., 2019; Costa et al., 2020; Bessone et al., 2021; Kajitani et al., 2021; Costa, 2024). This body of research acknowledges sleep duration as a choice influenced by economic incentives (Biddle & Hamermesh, 1990) and addresses endogeneity concerns by leveraging variations in natural light at time-zone boundaries, changes in sunset timing, daylight-saving time, disruptions from household babies, and interventions like monetary incentives to promote sleep. However, even with randomized sleep allocation, the binding time budget constraint complicates identification. More sleep means less time for other activities, making it challenging to isolate the impact of sleep on economic outcomes. The effect of one more hour of sleep may partly be due to reduced work, leisure, or other activities, and ignoring the substitution of activities has significant implications. Eventually, different activities impact outcomes differently, so the benefits of increasing sleep depend on what activity is reduced. Thus, analysing sleep in isolation, without characteristing time substitutions, complicates interpretation of results. What can instead be identified are relative effects of time allocation across activities (Fiorini and Keane, 2014), and a way to isolate the impact of a specific time trade-off is to control for time allocated in all the activities but one. This enables to estimate the effect of an increase in the activity of interest relative to the omitted time use category, which necessarily decreases in substitution, holding all the other activities fixed. This paper contributes to the literature on the economic impacts of sleep by integrating techniques from time use research. We use complete time diary data from the American Time Use Survey (ATUS) to estimate sleep vs. non-work activities' effect on labor productivity, proxied by weekly earnings, while controlling for work time. We address time use endogeneity with longitudinal productivity data in a VA specification, comparing productivity of workers with similar characteristics, work hours, and lagged productivity, but different sleep durations. Our main results indicate that, once work time is held constant, trading sleep for non-work activities does not significantly affect earnings. Further results show that increased sleep leads to a smaller decrease in work hours compared to other activities. When not controlling for work time, sleep's unconditional effect on earnings is negative, due to a weighted average of zero substitution effect with non-work activities and a negative substitution effect with work. These findings highlight the negative bias in sleep's marginal effect estimates when work-time adjustments are free. They underscore the importance of considering substitution patterns in sleep impact studies, as relative effects vary based on substituted activities.

Ind-758 Illness and Income: Quantifying Long-Term Effects of 20 Prevalent Diseases in Denmark

PRESENTER: **Emily K Johnson**
AUTHORS: Angela Chang, Liza Sopina

0.1 Background

Comparative disease burden estimation is a longstanding topic of research in epidemiology, and health policymakers depend on comparative information to prioritize efforts across diseases towards those at greatest disadvantage. In health economics, similar comparative estimation of the economic burden of disease is useful to understand how different disease burdens affect personal and population level productivity. In this study, we compare the comparative long-term income losses experienced by individuals diagnosed with 20 of the most prevalent diseases across the population in Denmark. We seek to identify who is most affected by income loss due to incident disease, and whether different diseases show different gradients of income loss across socioeconomic and demographic stratifications.

0.2. Methods

We adopt a cohort study design using Danish register data to estimate the causal effect of disease incidence on income loss across 20 diseases in Denmark from 2000 to 2018. We match individuals with incident disease burden to a control population by age, sex, region, baseline income, employment status, baseline health, education history, household size, and relationship status and follow outcomes for 10 years following diagnosis or until censorship. For diseases with acute onset such as cancer or stroke, we match in the year before diagnosis, and for diseases that

present slowly over time such as depression we match to control 5 years before incident diagnosis. Personal and household equivalized income loss over the whole period is estimated for each disease, along with the mortality rate in each cohort. Results are stratified by age, employment status, education, and region in Denmark.

0.3 Results

Income loss over 10 years varies vastly by disease in Denmark. For example, breast cancer, stroke and depression have similar prevalence rates in Denmark, but average 10-year personal income losses per incident case in the working population total €10,130 (€9570 - €10,690) for breast cancer, €34,070 (€33,660 - €34,490) for stroke and €79,300 (€78,880 - €79,720) for depression. With most diseases, individuals with higher education and higher baseline income levels suffer greater income loss in absolute terms but smaller relative loss as a proportion of the control income with the same education and baseline income. Regional variation in income loss is different for each disease, despite the same national sick leave and disability policies available across the country for all diseases measured.

0.4 Interpretation

Just as healthcare needs differ for different diseases in a population, so do the economic protections necessary to mitigate illness-related income loss. Though matching estimation of income loss by disease cannot fully account for confounding which may differentially impact different disease estimates, a comparative accounting of total income loss is crucial information to inform health and economic policy. In Denmark, a subset of the 20 measured diseases produces outsized income loss across the population, and these conditions deserve special attention to protect individuals and bolster population-level economic output.

Ind-2078 Economic Burden of Breast Cancer in Chinese Women: Analysis from 2016 to 2018 Using National Health Insurance Data

PRESENTER: **Yumeng Lv**
AUTHORS: Li Yang, Yu Qi, Yaqun Fu

Background: Breast cancer is the fourth leading cause of cancer death globally, with about 665,684 related deaths in 2022, representing 15.4% of the total female cancer deaths. In China, there were 0.36 million new cases and 75,000 deaths due to breast cancer of women in 2022. Although some previous studies have reported the economic burden of breast cancer treatment among Chinese patients, few of them were based on multiple annual national-level claim data. **Objectives**: This study aimed to analyze the costs associated with female breast cancer patients in China using data from the China Health Insurance Research Association (CHIRA) and to explore the factors influencing total and out-of-pocket costs. **Methods**: Female breast cancer patients aged over 16 years were included in the CHIRA database between 2016 and 2018. CHIRA is a national sampling database that collects hospital claim records of patients covered by either the Urban Employee Basic Medical Insurance (EBMI) or the Urban and Rural Resident Basic Medical Insurance (RBMI). Descriptive, subgroup (age, insurance type, medical service type, and regions), and log-linear analyses were performed to assess breast cancer treatments. Statistical analyses were conducted using STATA 17.0 and Microsoft Excel. **Results**: This study analyzed 166,956 claims from 28,464 women from 2016 to 2018, with an average age of 54.49. Most (72.54%) were covered by EBMI, with 82.07% treated at tertiary hospitals. The analysis revealed significant differences by insurance type, hospital level, and region. The annual total median costs for patients covered by the RBMI and the EBMI were $2141.40 and $1716.87, with RBMI had a statistically significant higher out-of-pocket (OOP) ratios (48.83%) than EBMI patients (33.21%). Specialized hospitals had higher annual and OOP median costs ($1893.16 and $517.45) than general hospitals ($1819.90 and $517.45). Regionally, central China had the highest total and OOP costs ($2346.30 and $722.63), with lower financial burdens generally in eastern and western regions. Log-linear regression showed that outpatient costs decreased while inpatient costs rose from 2016 to 2018. For older patients, total outpatient costs tended to be higher, but OOP and inpatient costs declined. Insurance differences were evident, with employees showing higher inpatient costs but a lower outpatient OOP ratio, reflecting better financial protection under EBMI. Patients in secondary hospitals faced lower costs, suggesting advantages in seeking care at lower-level hospitals, though tertiary hospitals remained most used. **Conclusions**: The mean age of Chinese patients is significantly younger compared to those in other countries, while the costs of breast cancer patients in China exhibit significant regional and demographic differences. Although the national basic health insurance has significantly reduced the economic burden on patients, it has also introduced inequalities among different beneficiary groups. Efforts in expanding breast cancer screening are necessary to reduce the financial burden, and reallocating funding across regions and different levels of hospitals should be encouraged to address financial inequities. 2

Ind-2792 Cost-of-Illness of Diarrhoea and Pneumonia Among Children Under Five in Urban Slums, Non-Slums, and Rural Areas of Bangladesh

PRESENTER: **Md Zahid Hasan**
AUTHORS: Gatien de Broucker, Deborah Oidhi, Bryan Patenaude, Himel Das, Jasim Uddin, Sayem Ahmed, Zerin Zannat

Introduction: Diarrhoea and pneumonia continue to impose a substantial burden on public health, particularly among children under the age of five. Limited research exists on the economic impact of these disease in slum, non-slum, and rural areas of Bangladesh. This study presents a comprehensive analysis of the economic burden of treating diarrhoea and pneumonia diseases among children under-five in the urban slum, non-slum, and rural areas.

Methods: A cross-sectional study was conducted in 13 healthcare facilities in urban and rural areas of Bangladesh. An ingredient-based costing approach was applied to estimate the societal costs for one episode of pneumonia and diarrhoea in children under-five. To estimate the average costs per patient, a minimum of 30 caregivers of under five patients were planned to interview from each facility following the central limit theorem. Considering 10% non-response rate, around 534 patients were planned to be randomly selected for interview. However, an interviewer spent least 15 days in each facility to capture the required number of cases. If the number of cases were not fulfilled, the interviewer moved to the next facility. A total of 680 caregivers of pneumonia patients and 533 caregivers of diarrhoea patients were interviewed during the time frame. To estimate provider cost, health facility survey was conducted with the facility managers and relevant personnel e.g., medical staff,

accountant, and head assistants and relevant documents were reviewed. Data collection spanned from September 2021 to August 2022. Societal costs were estimated using the caregiver costs per patient and provider costs for treating a diarrhoea or pneumonia patient at public facilities. The incidence of catastrophic health expenditure (CHE) was estimated considering 10% and 25% income as thresholds. Statistical differences in costs and incidence of CHE were analysis using Kruskal Walis, Mann Witney U, and chi-square tests by different characteristics.

Results: The societal costs per patient were US$102.01 for pneumonia and US$40.67 for diarrhoea in non-slum areas, US$100.34 for pneumonia and US$37.37 for diarrhoea in slum areas, and US$58.50 for pneumonia and US$25.90 for diarrhoea in rural areas. The total caregiver costs of illness were significantly higher for pneumonia patients (p <0.001) in non-slum areas compared to the slum and rural areas. Despite having significantly lower cost-of-illness among slum residents, incidence of CHE resulting from cases of diarrhoea and pneumonia were significantly higher in slums, with nearly double the percentage of slum dwellers (100%, 36.8%) facing CHE as a result of inpatient episodes of pneumonia and diarrhoea, respectively, compared to rural residents (42.9%, 18.0%) and urban non-slum residents (57.1%, 17.7%).

Conclusion: The study provides a nuanced understanding of the economic impact of childhood diarrhoea and pneumonia in Bangladesh by different areas. The findings demonstrate significant economic burden borne by caregivers in treating diarrhoea and pneumonia among under-five patients. Understanding these costs is crucial for healthcare policy and resource allocation, emphasizing the need for large scale targeted interventions such as vaccination to alleviate the financial strain on affected households, even those that currently face lower costs of care.

Drugs, Tests and Vaccines

MODERATOR: **Jeffrey McCullough**, University of Michigan

Ind-266 Antibiotic Resistance, Drug Prices, and Entry

PRESENTER: **Miaoqing Jia**
AUTHOR: Ching-to Albert Ma

Antibiotic drug resistance is modeled by an increase in future drug cost (or equivalently a decrease in drug quality) due to current consumption. Competition in the medicine market leads to maximum consumption, and results in inefficiency. A single consumer cannot affect future drug cost, so might as well choose to consume; a free-riding, inefficient outcome. Drug plans with a centralized way to ration medicine can alleviate free riding. A monopoly will dampen the market failure because the monopolist internalizes cost increase. However, consumers may not benefit from a monopoly; prices remain high despite reduction of cost increase due to internalization. If innovation is possible, a potential entrant must consider competing with an incumbent upon entry. Under Cournot competition, entry deterrence occurs when the incumbent restricts consumption to reduce its own future cost so the entrant cannot earn enough post entry. Entry deterrence by the incumbent can happen; this results in lower drug consumption and reduces resistance. Entry accommodation may actually exacerbate drug resistance because the incumbent has less incentive to internalize the cost increase.

Ind-1596 Disinvestment in Pharmaceuticals: A Survey

PRESENTER: **Smriti Raichand**
AUTHORS: Bonny Parkinson, Gabriella Hirang, Alicia Norman

Background: Among health technologies, pharmaceutical costs are one of the largest contributors to healthcare expenditures. The expenditure on subsidised pharmaceuticals in Australia was $17 billion, about 16% of total government healthcare expenditure in 2022-23. However, spending in lower-income countries often amounts to a higher share of health spending relative to other services. With the changing pressures on healthcare budgets and increasing prices of new pharmaceuticals, countries have employed disinvestment strategies for pharmaceuticals. Disinvestment in healthcare refers to “judicious investment in new healthcare technology with strategies to reduce the unnecessary, ineffective, inefficient or harmful care”, i.e. low-value healthcare services. Following up to a previous publication, we anticipate that newer strategies might have replaced the ones described previously. Further, little is known about how countries with emerging health technology assessment (HTA) processes make disinvestment decisions for pharmaceuticals. **Aim:** This study will provide an update on a previous study to examine what has changed in terms of disinvestment for the countries with well-established HTA processes, and document and summarise how countries with emerging HTA processes make reimbursement and disinvestment decisions in pharmaceuticals. **Method:** We are currently surveying key experts from the HTA community from countries with established HTA processes (UK, France, Canada, Australia and New Zealand), and experts from the HTA community in countries with newly established and emerging HTA processes. Our survey questions are based on the framework described in published literature on disinvestment strategies in pharmaceuticals, enquiring on all aspects of these strategies. We will describe the findings narratively. We will also explore the international differences in disinvestment strategies. **Findings:** We will summarise updates to disinvestment strategies in the countries with established HTA processes and highlight the distinct, and sometimes ‘borrowed/ inspired/traditional’ methods of disinvesting in the countries where HTA processes have recently been introduced. **Conclusions**: The study will potentially benefit the policy makers, pharmaceutical companies and researchers globally. The findings of this study will provide an insight into currently used methods of disinvestment, and the pros and cons of the approaches. The study will also provide an update on a previous study investigating disinvestment strategies. These insights will help shape future research and policy decisions regarding investment in pharmaceuticals. The study will also provide useful examples for other countries considering disinvestment in pharmaceuticals.

Ind-1476 Stocking Under the Influence: Spillovers from Commercial Drug Coverage to Medicare Utilization

PRESENTER: **Emma Dean**
AUTHORS: Luca Maini, Josh Feng

Background

The U.S. health insurance market consists of both public and commercial segments, with physicians and facilities treating patients across both. Studies have documented “spillovers” from U.S. public to commercial segments, focusing on how policies governing the public side of the market affect competition and outcomes in the commercial market. However, the mechanisms driving spillovers from the commercial to public segments remain underexplored.

We highlight a novel channel of commercial-to-public spillovers, driven by outpatient facilities standardizing certain aspects of care across all patients. We focus specifically on physician-administered drugs, including infusions like chemotherapies. In public Medicare insurance, which is provided to all citizens over 65, nearly all physician-administered approved drugs are covered for enrollees. In contrast, patients with commercial insurance plans only have access to a restricted list of covered medications. Though not restricted by insurance coverage, access to medications for Medicare patients may still be limited by facilities, which determine the drugs stocked and made available to physicians. Facilities limit the number of drugs stocked to simplify inventory management and secure better pricing from manufacturers. Because these facilities serve both publicly and commercially insured patients, they may prioritize stocking drugs broadly covered by commercial insurance formularies.

Methods

To establish a causal link between Medicare drug utilization and commercial formulary exclusion rates, we employ a shift-share instrumental variables research design based on variation across U.S. states in exposure to commercial insurance plans. We utilize a 20% random sample of Medicare claims data to estimate state-level drug utilization in the Medicare program. We merge this with data on commercial insurance coverage of drug brands from MMIT Network Solutions, which tracks coverage of different drugs for all commercial insurance plans.XX% of individuals covered by commercial insurance are on a plan that uses a national formulary. We then use variation in state-level exposure to different commercial insurance plans to translate changes in commercial coverage into state-level changes in Medicare drug utilization.

We then provide evidence that facility stocking decisions serve as a key transmission mechanism for this spillover. By focusing on physicians who prescribe medications across multiple facilities, we use a design inspired by Finkelstein et al. (2021) to decompose prescribing variation into physician- and facility-driven factors.

Results

Our results show that a 10% higher exclusion rate from commercial formularies for a given brand results in a 3% lower utilization rate among Medicare beneficiaries. Facility-level factors account for 80% of prescribing variation for clinically similar medications, but less than 50% for physician-preference items. These findings suggest that facility stocking decisions are key in transmitting spillovers from commercial insurance coverage.

Significance

Our results suggest that commercial market inefficiencies can affect government spending and support the idea that facilities can directly influence quality of care. Our findings generalize to other insurance-distribution settings in health care where different entities make insurance and distribution decisions. The spillover we document is difficult to address through regulation and may diminish the impact of proposed Medicare payment changes

Ind-1404 How Uncertainty Affects Physicians' Decision-Making: Evidence From Coronary Stenosis Management in China

PRESENTER: **Chenzhou Wang**
AUTHOR: ZHANG YAN

Background* Inappropriate medical decision-making leading to the waste of resources is an important issue in health economics. Overuse exists and has raised concerns, making the public realize that more is not always better. Uncertainty, as a unique attribute of the medical field, poses a challenge in identifying overmedicalization. Although current research pays attention to uncertainty, there is less exploration into the relationship between uncertainty and physicians’ decision-making. Evidence shows that up to one-third of coronary stenosis treatment involve inappropriate percutaneous coronary intervention (PCI) surgeries and expensive high-level examinations, making it an appropriate scenario for studying the relationship between uncertainty and physicians’ decision-making.

Objective To explore the relationship between uncertainty and medical decision-making in the context of coronary artery stenosis treatment. The decisions here include treatment based on visual assessment of angiography results and additional testing. Treatment based on visual assessment can lead to unreasonable care, while additional testing incurs a significant cost.

Methods (1) **Design**: Retrospectively collect imaging data from 10 patients with varying degrees of stenosis who were admitted for coronary heart disease and underwent coronary angiography at a tertiary hospital in Wuhan, China, assuming all other conditions of the cases are identical. Use these 10 sets of imaging data as hypothetical cases to design a scenario simulation test tool. (2) **Survey**: Recruit eligible physicians from the cardiology department of a tertiary hospital in Wuhan to conduct ten trials, ultimately including 74 valid participants,

resulting in 740 valid observation samples. (3) **Data Analysis**: Use fixed-effects logistic regression to analyze the effect of the perceived uncertainty in the visual assessment of coronary angiography by the participating physicians on the decision to perform additional high-level tests (FFR). Further, use a threshold regression model to analyze the non-linear relationship of this effect.

Results In 740 observations, 300 (40.54%) chose to add FFR, while among the remaining decisions made based on visual assessment, 5.68% involved under-treatment, and 19.77% resulted in unnecessary PCI. The surveyed physicians tended to overestimate the degree of stenosis overall. The mean level of uncertainty was 15.92 (SD = 9.77). The fixed-effects logistic regression model shows a strong association, with a one-unit increase in uncertainty leading to a 98.7% increase in the odds of FFR decision-making (OR = 1.987, $P < 0.001$). There is a double-threshold effect between physicians' uncertainty and FFR decision-making. When the level of uncertainty is between 16.5 and 34.5, the effect is maximized ($\beta = 0.038$, $P < 0.001$).

Conclusion Uncertainty increases the probability of opting for additional high-level tests, with a double-threshold effect observed. Physicians performed more high-level tests, unnecessary PCIs, and under-treatment decisions for cases close to the decision benchmark (stenosis degree of 70%). After removing external stimuli, the primary reason for physicians making inappropriate medical decisions is estimation bias during the diagnostic process, while uncertainty leads to increased testing costs. For controlling overmedicalization, it is necessary to focus on borderline lesions, and there exists an uncertainty response threshold for reducing testing costs.

abs-os370 Domestic Volume-based Procurement and Foreign Market Expansion: An Analysis of Chinese Pharmaceutical Industry

PRESENTER: **ZHEN WANG**
AUTHORS: Fanghao Chen, Lai Yi

Since 2018, Chinese government has launched several rounds of national volume-based procurement (NVBP) to cut prices and increase the accessibility of drugs for patients. While most literature are confined to the effects NVBP caused onto the domestic market, little is known about how firms respond to NVBP in the foreign markets. Combining firm-level data on NVBP and overseas foreign direct investment (OFDI) decisions, and adopting a generalized difference-in-differences (DID) design, we find that the affected firms responded strategically by increasing their overseas projects. The effects are more pronounced among private firms and firms more specialized in developing innovator drugs. Our findings suggest that NVBP acts not only as a cost-containment measure but also as a catalyst for pharmaceutical firms' international expansion, advocating for a nuanced understanding of policy interplays in international business dynamics.

Ind-2749 Comparative Analysis of the Economic Impact of Substandard Uterotonics on Post-Partum Hemorrhage & Maternal Mortality in Ghana, Nigeria, and Senegal

PRESENTER: **Sachiko Ozawa**, University of North Carolina at Chapel Hill
AUTHORS: Lester Chinery, Metin Gülmezoglu, Colleen Higgins, Ashley Yi-Fang Lee, Sara Rushwan, Petra Proctor

Background: Uterotonic medications, such as oxytocin and misoprostol, are vital in preventing postpartum hemorrhage (PPH), a leading cause of maternal mortality. However, in many low- and middle-income countries, substandard uterotonics undermine their effectiveness, posing significant health and economic challenges. Uterotonics have found to have some of the highest failure rates in quality testing among essential medicines. This study examines the implications of poor-quality uterotonics in three West African countries: Ghana, Nigeria, and Senegal.

Methods: A decision-tree model was developed to simulate the outcomes of substandard uterotonic use, including PPH incidence and associated economic costs, across 100,000 births in each country. The model incorporated country-specific data on delivery settings, uterotonic quality and usage, and maternal health outcomes. Data were derived from Demographic and Health Surveys and existing literature. The prevalence of substandard oxytocin and misoprostol was modeled across healthcare facilities in each country. National-level projections were calculated based on population size.

Results: Ghana demonstrated the greatest potential benefits from improving uterotonic quality, with annual cost savings of $2 million (13%) and 2,200 PPH cases (11%) avoided per 100,000 births. In Nigeria, cost savings were estimated at $1.1 million (7%), with 944 PPH cases (4%) avoided per 100,000 births. Senegal showed annual cost savings of $224,000 (7%) and 875 PPH cases (6%) avoided per 100,000 births. When scaled to national populations, improving uterotonic quality could result in annual savings of $89 million in Nigeria, $18.8 million in Ghana, and $1.3 million in Senegal, with 100,000 fewer PPH cases collectively. Key drivers of these outcomes included high levels of facility-based deliveries and poor uterotonic quality in Ghana, a high proportion of home births in Nigeria, and use of substandard misoprostol in Senegal.

Conclusions: Improving uterotonic quality offers significant economic and health benefits across the three countries. The greatest impact may be achieved through country-specific strategies: enhancing quality assurance in healthcare facilities in Ghana, increasing access to high-quality uterotonics and reducing home births in Nigeria, and addressing misoprostol quality issues in Senegal. Ensuring the quality of uterotonics not only reduces maternal mortality but also supports efforts toward Universal Health Coverage by improving medicine access and equity.

Ind-1882 Evidence use in the Decision-making Stages for Vaccine Introduction and Roll-out in Kenya's Public Health Sector

PRESENTER: **Dennis Wambiri Waithaka**, KEMRI-Wellcome Trust Research Programme/ Open University
AUTHORS: Jacinta Nzinga, Simon Lewin, Benjamin Tsofa, Edwine Barasa, Unni Gopinathan

Background: Most low-and middle-income countries (LMICs) have established technical advisory bodies to assist policymakers in making evidence-informed decisions on introducing and/or implementing new health programmes and commodities including vaccines. However, we know little about how policymakers and their technical advisory bodies contextualise and use global guidance documents and evidence as well as how they elicit and use local evidence, including the knowledge of stakeholders such as civil society groups, which is key in centring people

during policymaking processes for sustainable health systems in LMICs. **Objectives:** To investigate how health system policymakers and their technical advisory bodies use global and local evidence and include stakeholders in decision-making processes for the introduction and roll-out of HPV and malaria vaccines at the national level in Kenya. **Methods**: We employed a qualitative multiple case study design. Data were collected through document review (n=52), observations, and in-depth interviews of national and county level government officials, and other stakeholders such as partners and local civil society organisations (n=30). Modified framework analysis was used to analyse data and generate findings. **Results:** The World Health Organization's (WHO) global guidance and Ministry of Health (MOH) *programmatic data* were the most used explicit evidence. These two sources of evidence were perceived by decision-makers within the National Vaccines and Immunisation Programme's officials as legitimate sources of sufficient and readily available evidence to inform health systems and policy decisions. The consistent involvement of WHO and MOH officials in these decision spaces allowed them to easily share the information required to inform decisions. In contrast, the use of *local primary research findings* largely occurred when imposed by donors as part of funding requirements, and when non-government actors represented in the decision-making process had earlier on conducted research specifically to inform these decisions. *Local tacit evidence* from the MOH and partners involved in the decision-making was used largely to interpret and contextualise WHO guidance documents. Specifically, these actors used their local contextual and programmatic knowledge and experiences to make broad WHO recommendations relevant to local needs. **Conclusions**: While both global and local evidence can play key roles in informing decisions on implementing health interventions, the range of stakeholders represented in these decision-making spaces influences the diversity of global and local evidence that is available. Wider stakeholder involvement, including civil society is key in centring people in the policy making process for building fair and just health systems in LMICs.

Ind-517 Traditional Vaccine Platforms: Lessons Learned from the COVID-19 Pandemic

PRESENTER: **Veronica Vargas**, Universidad Alberto Hurtado

Abstract **Background:**The COVID-19 pandemic catalyzed unprecedented vaccine development, with traditional platforms, including inactivated and protein subunit vaccines, relying on established, non-genetic technologies, and modern platforms, such as mRNA and viral vector vaccines. Inactivated and protein subunit vaccines—often more affordable and accessible—were fundamental, particularly in low- and middle-income countries. Inactivated vaccines developed in China and India accounted for 42% of global deployment, compared to 33% for mRNA and 25% for viral vector vaccines. Despite extensive research and development, protein subunit vaccines experienced limited global rollout..**Objectives:** Analyze the R&D and authorization timeline (domestic and WHO) of inactivated and protein subunit COVID-19 vaccines from 2020 to 2024, identifying how funding, partnerships, and scientific evidence influenced approvals to guide future policy and innovation.**Methods:**We conducted a systematic literature review and statistical analysis of all authorized COVID-19 vaccines by national authorities and World Health Organization Emergency Use Listing (WHO-EUL) in the period 2020–2025. Variables analyzed included country of origin, technology, authorization timelines, partnership scope, and funding source (e.g., public, public-private, international) and scientific evidence supporting clinical and real-world data. **Results:** From July 2020 to March 2024, 28 traditional vaccines (39% inactivated, 61% protein-based) gained national domestic approval, mainly in Asia, the Middle East, and the Americas. Inactivated vaccines, led by domestic partnerships in China and India, were approved earlier (May 2021) than protein-based vaccines (February 2022), using more clinical and real-world studies. Only one-third achieved WHO EUL, with international partnerships boosting EUL likelihood (Spearman's $\rho = 0.5812$, $p = 0.0015$ **). Domestic funding drove inactivated vaccines. IP/manufacturing barriers delayed protein-based vaccines.**Conclusion:**Although mRNA vaccines dominated global attention during the COVID-19 pandemic, traditional platforms—particularly inactivated vaccines—played a vital role, especially in low- and middle-income countries. In countries like China and India, state-led initiatives facilitated the rapid domestic approval and rollout of these vaccines. In contrast, protein subunit vaccines, which pursued international distribution via the WHO Emergency Use Listing, faced significant delays. These delays were largely due to the complexities of multi-partner agreements, particularly around intellectual property and manufacturing capacity. However, Cuba's centralized and vertically integrated vaccine infrastructure proved to be an exception, enabling earlier development and deployment. To ensure equitable global access, WHO should streamline the EUL process, harmonizing IP policies across platforms such as the WHO's Technology Access Pool, the U.S. NIH, and academic institutions to accelerate vaccine availability.

Ind-989 What Role Does Equity Play in Australia's HTA processes? A Review of the Pharmaceutical Benefit Advisory Committee Recommendations Regarding Vaccines

PRESENTER: **Ms. Marie-Anne Boujaoude**

AUTHORS: Natalie Carvalho, Kim Dalziel, Mackenzie Bourke, Nancy Devlin

Background and Objective: PBAC makes recommendations to government on which vaccines to include in the National Immunisation Program. Vaccines can have important benefits in terms of reducing health inequalities, which produces benefit to society. It has been argued that these benefits are not adequately accounted for in evidence and decision-making. This study aimed at determining if and how equity is considered in the PBAC evaluation of vaccines.

Methods: A comprehensive evaluation of each vaccine including economic evaluation, financial implications, and other criteria, are published in Public Summary Documents (PSDs). All PBAC PSDs evaluating vaccines were reviewed. An Excel-based equity-focused framework for data extraction was developed through a literature review and included: (1) general variables containing details on the vaccine and economic evaluation, (2) equity specific variables reflecting equity dimensions and any equity-informative methods used.

Results: 70 PSDs from 2005 to 2024 capturing 37 vaccines were included. The equity relevant dimensions commonly mentioned within the documents were presence of comorbidities (48%), Indigenous status (38%), gender (19%), parental status (4%), geographic location (3%), socioeconomic status (1%) and refugee status (1%). Fewer equity-relevant dimensions were incorporated in the final PBAC recommendations and proposed listing of the vaccines. An even smaller number of evaluations included equity dimensions explicitly within the analysis. Subgroup analysis (40% of PSDs) was the only method used showing distributional concerns. There was no evidence of any equity-informative economic evaluation used.

Discussion: Although specific groups (ex: Indigenous adults) were targeted in the evaluations and/or recommendations, equity-informative

economic evaluation evidence supporting these decisions was scarce. In some cases, a description of health inequity was presented through subgroup analysis. However, equity in the distribution of health and opportunity costs was not included. Equity informative economic evaluation methods offer a way of strengthening this aspect of PBAC decisions and could offer lessons to other settings.

Ind-225 Optimal Pricing of Diagnostic Tests: How Much Money to Compensate for the Incurability of a Disease

PRESENTER: **Bruno Ventelou**, CNRS - Aix Marseille Univ
AUTHOR: antoine lacombe

Objectives – When it comes to patients' decision to undergo testing, two characteristics are involved in the decision to take test for a given disease: the "transmissible" nature of a disease, which will push the patient to be screened/tested to avoid being a vector of the disease in those around them (prosocial motive), and its "curable" nature, which will give the patient personal motivation for screening/testing (individual benefit).

Methods - We conducted an online survey on a representative sample of the French population in September 2021 (n=1017). Using a contingent valuation methodology, we studied the impact of these two characteristics on the propensity to be screened and tested (for the case of a disabling respiratory disease). We applied a two-part model to account for a partition of the population in our data between absolute refusal screening and screening hesitancy. We sought to estimate the effect of the two characteristics on the "willingness to pay" for tests and to quantify precisely how (much) the incurable nature of a disease could be a disincentive to screening/testing.

Results –We determined that the optimal subsidy to compensate for the incurability of an illness must decrease the price of the test by 39% (95% CI: [28.42%;52.11%]). This figure can be studied for different population strata (gender, age, level of income, health status etc.) and, due to the parallel collection of behavioural data, for different psychological profiles of people (risk aversion, cooperativeness, and trust-in-science, etc.).

Discussion - The behaviour of access to care and in particular of diagnostic tests utilisation is decisive for the success of epidemic prevention and control strategies (the famous test and treat policies). Even in the absence of current treatments, early detection may facilitate proactive measures, emphasizing the need for optimal pricing strategies to promote the adoption of tests. This study brings new insights on that topic.

Public Insurance for Vulnerable Populations: Access and Utilization

MODERATOR: **Damien de Walque**,

Ind-1225 Public Health Insurance and Healthcare Utilisation Decisions of Young Adults

PRESENTER: **Muhammad Fikru Rizal**

Background: Low- and middle-income countries (LMICs) are home to 90% of the world's young adult population, who face higher morbidity and mortality risks compared to their counterparts in higher-income countries, yet have poorer access to healthcare services. To address these issues, LMICs are expanding public health insurance coverage, commonly through fully subsidised schemes for the poor and contributory mechanisms for the non-poor. While the impact of public health insurance on healthcare access in these settings is relatively well-studied, research has generally focused on subsidised schemes, and studies specifically targeting young adults are lacking. Inadequate medical treatment for this population may lead to long-term health and economic consequences.

Objective: This paper examines how non-subsidised public health insurance coverage affects the health and healthcare-seeking decisions of young adults in Indonesia.

Methods: The study exploits a sharp change in insurance coverage caused by an age-eligibility rule within Indonesia's National Health Insurance (NHI) programme, which states that individuals older than 21 are no longer covered by their parents' employer-sponsored, non-subsidised NHI scheme. A regression discontinuity design (RDD) is used to estimate the impact on health-seeking behaviours and health outcomes among young adults aged 19 to 23. Data are drawn from two sources: (1) the NHI sample dataset containing 1.7 million individuals representative of all NHI enrolees by the end of December 2018, and (2) the 2018 wave of the Indonesia National Socioeconomic Survey (Susenas), a nationally representative household survey of 1 million respondents.

Results: The age-eligibility rule caused a sudden 14.6 percentage point reduction in NHI coverage among young adults. While this sharp change does not affect self-reported health status, significant impacts on healthcare-seeking decisions are observed. Among those reporting illness in the past month, the age cut-off abruptly reduces the probability of an outpatient visit by 5.3 percentage points. This reduction is mainly driven by decreased utilisation of primary care services rather than specialist or hospital outpatient visits. The age limit also leads to substitution in treatment-seeking behaviour, increasing the likelihood of self-treatment and the use of traditional healers. Further analysis suggests that the age threshold has larger impacts on healthcare-seeking decisions among individuals who are poorer, less educated, and those living in regions with above-median average outpatient costs.

Conclusions: This is the first study to document the effects of a dependent coverage age-eligibility rule on young adults in Indonesia. The findings suggest that the government's efforts to increase insurance uptake among the young population should target young adults who were

previously insured through their parents' coverage, with a particular focus on the relatively poor and less educated subgroups. Policymakers should also anticipate additional costs incurred by increased NHI uptake on this cohort's healthcare service utilisation.

Ind-2462 Impact of Long-term Care Insurance on Healthcare Utilization and Expenditures: Evidence Using an Insurance Claim Dataset in City A, China

PRESENTER: **Xiaoyu Wang**
AUTHORS: Yunting Zheng, Min Chen, Yanming Lin

Background: The effects of long-term care insurance (LTCI) on healthcare utilization and expenditures in developing countries is limited, and existing findings remain inconclusive. Previous studies have identified both a "release effect" and a "substitute effect" of LTCI on health service use and costs. City A, one of 49 LTCI pilot sites in China, known for its dynamic private sector and strong philanthropic culture, launched a distinct LTCI program in August 2020 to address the challenges posed by a rapidly aging population. This study aims to assess impacts of LTCI on healthcare utilization and expenditures. **Methods:** This study analyzed outpatient and inpatient medical insurance claim data from 4,624 individuals covered by urban employee basic medical insurance between 2018 and 2023 in City A. LTCI eligibility required a disability assessment, eligible disabled enrollees received LTCI benefits in a staggered manner. To address potential biases in traditional two-way fixed effects (TWFE) methods for estimating causal effects in staggered implementations, we applied an updated staggered Difference-in-Differences (DID) approach, accounting for treatment effect variations by calendar time, entry cohorts, and exposure length, allowing for a precise estimation of the LTCI's impact on healthcare utilization and expenditures. Patients who completed disability assessments were defined as the treatment group (1,020 individuals), with the assessment completion date marking the start of their LTCI benefits. **Results:** The average annual hospitalization cost is 22,000 yuan, and the average quarterly outpatient cost is 740 yuan. The baseline regression results show that, aside from a significant decrease in outpatient visits, there was no notable reduction in inpatient admissions or medical expenses. According to the staggered DID analysis, after the introduction of LTCI, patients with LTCI coverage experienced a sustained reduction in hospital admissions compared to those without coverage, with annual hospital admissions decreasing by 0.8 visits. In the first year of LTCI benefits, inpatient expenses and out-of-pocket costs for inpatient care increased by 30.1% and 29.6%, respectively, with no significant changes observed thereafter. Outpatient visits also showed a sustained decrease beginning four quarters post-implementation, ranging from 0.4 to 1.0 visit per quarter. Additionally, quarterly outpatient expenditures decreased by approximately 15% starting in the third quarter. However, changes in patients' out-of-pocket costs for outpatient services were not statistically significant, likely due to the deductible threshold in outpatient reimbursement policies. **Conclusions:** The implementation of LTCI in city A initially increased inpatient expenditures and out-of-pocket costs, likely due to a release effect. However, in long-run, it may reduce hospital admissions and outpatient visits through a substitution effect, with unsignificant impact observed on healthcare expenditures. This study underscores the importance of adequately preparing medical insurance funds at the outset of LTCI implementation and establishing a robust supply system for long-term care to meet healthcare needs. These insights are essential for policymakers considering LTCI in developing contexts, highlighting the need for a balanced approach that addresses both immediate and long-term impacts on healthcare utilization and spending.

Ind-2627 The Impact of Indonesia's National Health Insurance (JKN) on Healthcare Utilization Among the Elderly: A Decade of Implementation

PRESENTER: **Mr. Antokalina Sari Verdiana**
AUTHORS: Rizal Mansur, Mitha Cerinda, Yenny Yenny, Fentya Yumna Cahyani, Mr. Benjamin Saut Parulian Simanjuntak, Mahlil Ruby

Background: Indonesia is entering an aging population phase, with the elderly (aged 60+) comprising more than 7% of the total population by 2023. This demographic shift presents significant challenges for the healthcare system, particularly in ensuring equitable access to healthcare services for the elderly. The introduction of Sustainable Development Goal (SDG) 3.8, supported by the National Health Insurance (*Jaminan Kesehatan Nasional*/JKN) program, aims to improve healthcare access. With 98% of the population now enrolled, JKN's decade-long implementation provides a unique opportunity to evaluate its impact on healthcare utilization among the elderly. **Methodology:** This study analyzed data from Susenas 2013 and 2023, focusing on individuals aged 60 and older (95,464 respondents in 2013 and 129,234 respondents in 2023). Using the Andersen Behavioral Model, predisposing (age, gender, marital status, education), enabling (urban/rural residence, internet access, asset index), and need factors (health complaints, disruptive conditions) were examined. Logistic regression was employed to assess the factors influencing healthcare utilization in insured populations. Propensity Score Matching (PSM) with nearest neighbor matching (caliper 0.05) was used to reduce bias between insured and uninsured groups, followed by Difference-in-Differences (DID) analysis to evaluate JKN's impact over the decade. Additionally, the Concentration Index (CI) was calculated to analyze inequality in healthcare utilization based on asset index for 2013 and 2023. **Results:** The study revealed significant changes in factors influencing JKN participation between 2013 and 2023. Education's influence on insurance ownership increased from 16.22% to 23.72%, and urban residency's impact rose from 11.14% to 46.93%. Internet access, while still significant, saw a decline from 40.82% to 34.94%, and the influence of health complaints decreased from 22.56% to 12.47%. Matching results showed that in 2013, the ATT was 1.86% and not statistically significant, indicating minimal impact of insurance ownership on healthcare utilization before JKN. By 2023, the ATT increased to 7.71% and was statistically significant, highlighting JKN's role in improving healthcare access for the elderly. The DID analysis demonstrated a 5.85% increase in the probability of healthcare utilization attributable to JKN implementation. The CI for healthcare utilization based on asset index was 0.065 in 2013 and decreased to 0.041 in 2023, indicating reduced inequality in access to healthcare between wealthier and poorer groups after JKN's implementation. **Conclusion:** The JKN program positively impacted healthcare utilization among the elderly, improving access and reducing inequalities. The 5.85% increase in healthcare utilization probability and the reduction in Concentration Index (0.065 to 0.041) demonstrate JKN's success in addressing financial and structural barriers. However, to maximize its impact, regional governments should focus on enhancing healthcare accessibility for elderly populations, particularly in underserved areas and eliminating remaining financial barriers. Policies should prioritize expanding quality healthcare services in rural and lower-income areas while promoting awareness and utilization of JKN among the elderly. These measures can further strengthen the program's effectiveness and ensure equitable healthcare access for Indonesia's aging population.

Ind-1526 Urban-rural Critical Illness Insurance and Forgone Healthcare Utilization

PRESENTER: **Jiyuan Wang**
AUTHORS: Ya Gao, Yi Zhang

Over the past decades, many countries have invested heavily in expanding public health coverage and improving access to healthcare. In China, near-universal coverage of basic public medical insurance has been achieved. To further protect vulnerable households from catastrophic health expenditures, China introduced Critical Medical Insurance (CMI) as a supplementary scheme to its basic resident medical insurance. While CMI aims to reduce forgone care by alleviating out-of-pocket expenses, concerns about potential moral hazard persist, and its effectiveness, particularly in reducing forgone healthcare, remains unclear. This study examines the impact of CMI implementation on forgone healthcare, leveraging a staggered policy rollout that began in 2012. Unlike previous studies that primarily focus on insurance expansions for risk reduction or welfare improvement, this research evaluates a unique supplementary insurance scheme, offering insights for public health policy design. Our analysis employ a difference-in-differences (DID) approach with data from the 2011–2015 China Health and Retirement Longitudinal Study (CHARLS), CMI implementation timelines from government websites, and city-level socio-economic data from the *China City Statistical Yearbook*. These datasets allow us to compare cities with different CMI adoption dates while accounting for local development trends. Our findings indicate that exposure to CMI reform reduces the probability of forgoing inpatient care by 1 percentage point (pp) and outpatient care by 2 pp—approximately 20% reductions relative to baseline rates of 5.6% and 10.4%, respectively. Notably, CMI reform primarily reduces the likelihood of forgoing inpatient care due to financial constraints, suggesting that CMI effectively alleviates disease-induced financial burdens. An event study analysis further reveals that the reduction in forgone inpatient care persists for up to four years after the reform. These results remain robust across different estimation methods. Additionally, we find that the effects are more pronounced among households with non-agricultural *hukou*, females, and individuals with higher baseline health risks. Regarding mechanisms, we find no evidence of overtreatment or moral hazard but observe improved health outcomes and more cost-effective use of healthcare services. These findings suggest that CMI not only improves healthcare access but also enhances the efficiency of healthcare utilization by reducing financial barriers without encouraging excessive medical consumption. In summary, this study highlights the crucial role of supplementary insurance in addressing unmet healthcare needs among vulnerable populations. By alleviating financial constraints and promoting cost-effective care, CMI contributes to a more equitable and sustainable healthcare system, providing valuable insights for future policy design.

abs-os256 Achieving UHC with Disability Inclusion in Indonesia: A Mixed-Method Study to Explore People with Disability's Access to Healthcare

PRESENTER: **Relmbuss Biljers Fanda**
AUTHORS: Shita Listyadewi, Ardhina Nugraheni, Retna Siwi Padmawati, Tri Muhartini, Muhamad Faozi Kurniawan, Ika Septiana Eryani

Background: In Indonesia, universal health coverage called *Jaminan Kesehatan Nasional*, or the JKN, has promised free access to healthcare for everyone, including people with disabilities, since 2014. However, little is known about the health-seeking behaviours of these individuals, particularly their use of this JKN scheme. This convergent mixed-method study explored the JKN coverage rate for people with disabilities and their use of the JKN.

Method: For the qualitative component, we interviewed participants from national, provincial, and district governments, primary health centres (PHCs), and associations for people with disabilities. We conducted a total of 19 focus group discussions with 167 participants. For the quantitative component, we carried out a household survey involving 2,666 individuals with physical and sensory disabilities across three provinces and six districts: the Special Region of Yogyakarta (Yogyakarta Urban and Bantul districts), Bali (Denpasar and Buleleng districts), and East Nusa Tenggara (Kupang Urban and Kupang Rural districts). Descriptive, bivariate, and logistic regression analyses were performed to examine JKN utilisation among individuals with disabilities experiencing illness symptoms within the past year. We integrated the findings by triangulating the quantitative data with qualitative insights.

Results: The JKN insurance coverage rate for all survey respondents was 89%. Around 85 % of the population received premium subsidies because they were coming from families with limited income. The national, provincial and district governments have made multiple efforts to ensure that all people with disabilities are enrolled in JKN, such as providing population data and paying their premiums. Those who are not insured reported that they had a lack of information on the registration process (46%), financial constraints (18%), and a preference to remain uninsured (9%). Regarding health-seeking behaviour, although 35% of them have utilised the JKN when looking for a health service, others (65%) did not use it. Even more concerning, 7 % of the population who needed health services lived without any needed treatment. In addition, our logistic regression showed that the respondents tended to use the JKN if they were self-employed, had guardians, visited primary health centres and visited hospitals. In terms of out-of-pocket payments, variations in the health service costs ranged from 0.05 to 103 times the daily minimum wage, which can be catastrophic for these individuals. In our interviews, participants mentioned that the JKN scheme only covers a partial health benefits package, including medications in hospitals. In another case, they had to pay since their JKN registration status was inactive. Their premiums were not paid because they were excluded from the list of the JKN participant groups that received a premium subsidy.

Conclusion: Although Indonesia has succeeded in ensuring high coverage of all individuals with physical and sensory disabilities registered in the JKN program, these individuals still tend not to utilise it when needed. To prevent catastrophic payments in this community, the Indonesian government should expand healthcare design to achieve universal health coverage by increasing the JKN benefit package in the hospital and maintaining their activated status.

Dietary Behavior of Children and Adolescents: Evidence from Behavioral Experiments in Indonesia and Vietnam

MODERATOR: **Igna Bonfrer**, Erasmus School of Health Policy & Management

CONVENER: **Robert Sparrow**, Wageningen University

DISCUSSANT: **Hien Nguyen**, Erasmus University Rotterdam; **Puguh Prasetyoputra**, National Research and Innovation Agency; **Tri Mulyaningsih**, Universitas Sebelas Maret

abs-os393 Adolescent Girls, Agency and Appetite: Evidence from a Food Voucher Experiment

PRESENTER: **Ms. Tri Mulyaningsih**

AUTHORS: Mr. Robert Sparrow, Matthias Rieger, Amalina Shabrina

Nutrition during adolescence is increasingly recognized as a key to a healthy and productive life for women and their children. Nutrition policies and advocacy in the Global South have traditionally focused on mothers and their children under five years of age, because the first years of life are often characterized by growth faltering and stunting, offering a “first window of opportunity” for interventions. However, there is a “second window of opportunity” that is particularly relevant for adolescent girls as the growth velocity is intense again. This second window is behaviorally complex as girls undergo important cognitive and emotional changes. We explore the role of agency in improving nutritional behavior among adolescent girls in Indonesia, by testing the effectiveness of food vouchers in altering dietary behavior, leveraging agency to enhance outcomes. We hypothesize that food vouchers can encourage healthier eating habits and that agency — exercised through choice — improves the efficacy of interventions, as agency may foster patience and goal-oriented decision-making, critical for adopting healthier diets. We test this with a randomized controlled trial involving 1,011 girls aged 12-16 in Solo, Indonesia. We compare three groups: a group with restricted vouchers for healthy foods (paternalistic treatment), a group with vouchers offering a choice between healthy and unhealthy options (agency treatment), and a control group receiving vouchers for stationery. The choice (in the agency treatment) was made salient through information on healthy diets, provided to all groups. Vouchers were personalized and handed out over three weeks (2 times a week), and could be redeemed at food stalls on school grounds. Baseline and follow-up surveys track food choices and preferences, complemented by food diaries and anthropometric measurements. We find that the healthy (restricted) and the choice (agency) vouchers reduced consumption of the number of unhealthy food items relative to the control group, but the treatment effects of both food vouchers were statistically equivalent. There were no statistically significant effects of either voucher on the primary outcome variable (a free healthy versus unhealthy meal choice in a controlled setting), suggesting that preferences were on average unaffected by our short-term intervention. But we do observe substantial heterogeneity by age, as the choice voucher increased healthy meal choice by a third (relative to the restricted voucher) for the youngest half of the sample, but there is no statistically significant effect for the older group. There was also qualitative evidence that effects vary across schools and BMI status. Our findings contribute to the literature by demonstrating the role of agency in shaping dietary preferences and behaviors.

abs-os414 Information Provision, Research Participation, and Altruism: Evidence From a Field Experiment

PRESENTER: **Hien Nguyen**

Research participants are often neglected in the process of sharing research findings and do not receive detailed information stemming from the research data to which they contributed. Although there is qualitative evidence on the effects of sharing research findings with participants, there is very little experimental evidence in the economics domain. We are among the first in the literature to develop and implement a field experiment that randomized the provision of different types of research findings involving 1,734 research participants. In one experimental condition, treated parents received general findings from the child health and nutrition literature and in another experimental condition treated parents received general research findings plus personalized research findings from the survey they completed. In the context of research related to the health and nutrition perceptions of parents and their children in Vietnam, we estimated the effects of sharing these research findings on knowledge, research uptake, perception of research usefulness, and willingness to support research. For example, we estimated the impacts of sharing research findings on donations to fund a follow-up study and to disseminate research findings via controlled and incentivized dictator games. Our results show that participants who received research findings–especially coupled with personalized survey data–donated more money to fund a follow-up study and to disseminate the research findings. We interpret these results within the qualitative literature on research participation in the health domain. One implication of our results is that policies to share research findings with research participants may increase support for future scientific investigations and broader dissemination of scientific findings, which may promote scientific discoveries and progress.

abs-os398 Interpretive Nutrition Labels, Parent-Child Interactions, and Food Choices in Indonesia

PRESENTER: **Margarita de Vries Mecheva**

AUTHORS: Mr. Robert Sparrow, Matthias Rieger, Mr. Puguh Prasetyoputra, Rika Rachmalina

Diets in many countries in the Global South are moving towards more processed, unhealthy foods. One popular policy response to tackle the growing consumption of unhealthy food in the Global North has been the introduction of interpretive nutrition labels. Experimental evidence from the Global South and contexts undergoing a nutrition transition remains scant. We conduct a series of lab-in-the-field experiments with parents and children in public primary schools in Bogor, Indonesia (n = 900 parent-child dyads). We use an online experimental supermarket

(for parents) and a table with snacks and drinks (for children) to investigate if a nudge in the form of "traffic lights" labels (green "Healthier choice", yellow "OK choice", red "Less healthy choice") may potentially improve the healthiness of parents' and children's food and snack consumption. In post-experimental surveys we explore the participants' perceptions of the nutrition labels and motivation of choosing the foods/snacks. We also record whether a parent approves/disapproves the snack choice of her child and whether a child accepts/rejects it. We compare the proportions of healthy/unhealthy foods and snacks chosen by the participants in treatment ("traffic lights" labels) and control (no labels) groups.

abs-os405 Sharing Research Results and Correcting Nutritional Perceptions and Behavior: Evidence From a Field Experiment

PRESENTER: **Hien Nguyen**

To contribute to the scarce literature on the effects of sharing research results with study participants, we conducted an RCT in which parents received research data and findings about childhood obesity and healthy lifestyles through virtual workshops, videos, and written reports. The primary goal of this information intervention was to empower parents with an updated information set to achieve more accurate perceptions about their child's weight status, diets, and exercise levels. A total of 1,734 parents were randomly assigned to three groups: (1) a control group; (2) a treatment group receiving general research findings from the child health and nutrition literature plus aggregate data from our baseline survey; and (3) a treatment group receiving general research findings from the child health and nutrition literature, aggregate data from our baseline survey, and personalized data from our baseline survey. Our findings indicate that the receipt of research information, especially personalized survey data, led to improvements in both perceptions and behaviors after about 1 month. Treated parents receiving personalized research data and findings were more likely to correctly categorize their child's weight status, declare that they would like their child to be at a healthy weight, and express more accurate assessments regarding their child's food consumption and exercise levels. Moreover, treated parents receiving personalized information also reported increases in their child's consumption of healthy foods and physical activity levels. We find that these improvements in perceptions and behaviors were partly driven by increases in concerns about their child's weight status, with treated parents who received personalized research data and findings being more likely to express concern about their child eating too much unhealthy food and needing to change their diet to maintain a desirable weight, being overweight as an adult, and developing diabetes and cancer later in life. Overall, our findings indicate that, compared with traditional modes of information provision, personalized research findings sourced from the participants themselves may be one potential solution to improve health perceptions and behaviors in the short term.

Bridging the Gap Between R and Excel for Health Economic Modelling

MODERATOR: **Aaron Winn**, University of Illinois at Chicago

CONVENER: **Howard Thom**, University of Bristol

DISCUSSANT: **Rob Smith**, Dark Peak Analytics; **Yun-Ting Wang**, Clifton Insight

abs-os432 AssertHE: An R Package to Improve Quality Assurance of HTA Models

PRESENTER: **Mr. Rob Smith**

Summary: The growing use of health economic models to inform resource allocation in healthcare underscores the need for rigorous quality assurance processes to ensure model reliability and robustness. Traditional approaches to quality assurance rely on both technical and non-technical experts manually reviewing various model components, which can be time-consuming and resource-intensive. This process often requires an extensive understanding of how model components interact, and it is sometimes not feasible to thoroughly test each part within available timeframes. Addressing this gap, we introduce the *assertHE* package, an open-source tool for the R programming environment aimed at enhancing the quality assurance of health economic models.

Methods: The *assertHE* package offers a suite of testing functionalities that can be integrated directly into the health economic model development workflow. The package features multiple automated checks designed to reduce the likelihood of common modelling errors, aiding both model builders and reviewers. Additionally, *assertHE* includes functions that allow users to explore the network of R functions within a model, detailing where each function is defined, if and where it has been tested, and the test coverage of tested functions. An added feature is the package's ability to generate summaries of functions using a Generative Pretrained Transformer Large Language Model (LLM), providing a clear overview of complex model components.

Results: We applied the *assertHE* package to three open-source health economic models built in R, demonstrating its application in real-world settings. This use case involved embedding assertHE's check functions within model code to automate error detection, as well as using its visualisation capabilities to map the interconnections among model functions. This network visualisation also enabled users to identify untested functions and assess overall test coverage comprehensively. The LLM-generated summaries facilitated a quicker understanding of each function's purpose within the model, enhancing usability for reviewers with varying levels of technical expertise. Throughout *assertHE's* development, we collaborated with industry partners, regulatory bodies, and academic institutions to ensure its applicability across diverse modelling frameworks. Feedback from these collaborators informed adjustments to the source code, making *assertHE* adaptable to a wide range of health economic models.

Conclusions: The *assertHE* package provides an effective toolkit for both developing and reviewing health economic models, streamlining the

quality assurance process and promoting model reliability. By automating routine checks, enabling detailed function mapping, and offering AI-generated summaries, *assertHE* helps reduce the resource demands of traditional manual reviews. This, in turn, could improve model validation efficiency and effectiveness, especially in settings where time or expertise constraints hinder thorough quality checks. The package's open-source nature and adaptability further allow it to be widely applicable, supporting best practices in health economic modelling. Through *assertHE*, we aim to contribute to a more rigorous, consistent, and accessible quality assurance framework for health economic models, with implications for enhanced policy decisions based on well-validated, reliable models.

abs-os427 Automatic Conversion from Excel to R Using the Reliable and Efficient Estimation of the Economic Value of Medical Research (REEEVR) Tool

PRESENTER: **Mr. Howard Thom**

SUMMARY: Complex models build in Microsoft Excel for health technology assessment (HTA) can suffer from long run times when performing probabilistic sensitivity analysis (PSA). This makes it difficult to fully explore parameter uncertainty and often limits the base case and scenario analyses to be deterministic. It also prevents the conduct of value of information (VOI) analysis, which quantifies the value of further medical research. A solution is provided by the R statistical programming language but expertise with R is limited and its learning curve is steep. We present an alternative method for Excel users to benefit from the greater speed of R by providing a tool to convert Excel models into R automatically. The converted model enables the calculation of VOI and the tool is named Reliable and Efficient Estimation of the Economic Value of medical Research (REEEVR).

METHODS: REEEVR requires users to specify the output cells of the Excel workbook, for example the incremental net monetary benefit or incremental cost-effectiveness ratio, but the conversion process is otherwise automatics. Using concepts drawn from interpreters and auto-coding REEEVR then parses, tokenises, generates abstract syntax trees (ASTs), and translates each cell of the Excel workbook. The ASTs are a language agnostic representation of the logic of the Excel workbook and theoretically facilitate conversion to any language. The exported R code is then ordered and redundant code which is not linked to the specified output cells is culled. Finally, libraries, extraneous code, and the program itself are output, along with an RShiny graphical user interface.

RESULTS: REEEVR is tested with deterministic and probabilistic decision trees and probabilistic Markov models. Exemplar tests comparing implants for hip replacement surgery demonstrated improvement in runtime from 95±2.1s in Excel to 0.323±0.02s in converted output for 3500 iterations. We require 106 iterations to yield run-times comparable to Excel, 34±2.5s. Due to loop unrolling used in the conversion, we also demonstrate speed improvement over the exemplar R model, 13.6±0.68s for R and 0.53±0.03s for the Excel-to-R conversion at 103 iterations. This work is achieved without additional improvements due to the use of RCpp, leaving avenues for further improvement.

CONCLUSIONS: The REEEVR converter has been developed using models from academia, industry, and with input from UK National Institute for Health and Care Excellence (NICE) Guidelines Development Group, which has lead to a variety of models that have been explicitly tested and demonstrated to be successfully converted from Excel to R , while also demonstrating a significant increase in PSA run-time performance.

abs-os428 Proof-of-Concept of a Process for Automatically Generating Excel Implementations of R Cost-Effectiveness Models

PRESENTER: **Ms. Yun-Ting Wang**

SUMMARY: The spreadsheet software Microsoft Excel is the dominant tool for health economic model development, with the majority of submissions to the Health Technology Assessment (HTA) agencies being developed in Excel. It is widely accepted that the R statistical programming language has much greater computational efficiency than Excel and can handle more complex and realistic models. However, only a subset of global HTA agencies accept R submissions from manufacturers, while others require Excel. Experience with R is also limited to specialists, restricting the transparency and usability of models build in R. We aim to overcome these barriers to the wider adoption of R by developing a framework for R modelling that enables the automatic export of Excel versions of the model. We prove that this concept is possible by implementing it for probabilistic Markov multistate cost-effectiveness models.

METHODS: We develop a template for Markov multistate models in R that represents cohort vectors and transition matrices with multidimensional arrays. This template also stores all samples of the input parameters but also specifies the distribution for these input parameters and the relation of the parameters to the transition matrices, state costs, and state utilities. The template is general so that users can specify the numbers of states, treatments and cycles; the allowed transitions between states; and the distribution for the input parameters. Sophisticated string manipulation functions are used to generate the Excel formulae for the Markov trace by linking the input parameters in a way that reproduces the matrix multiplication of the transition matrices with the cohort vector. String manipulation is also used to generate the Excel formulae for the total cost and quality adjusted life years (QALYs). These various formulae are then exported to an Excel sheet with a pre-built Visual Basic for Applications (VBA) macro that enables probabilistic sensitivity analysis.

We tested our template on a Markov model for smoking cessation with two states and two treatments, and a Markov model for hip replacement surgery with four states and four treatments.

RESULTS: The tests on the smoking cessation and hip replacement surgery examples indicated that the model logic was reproduced exactly. Results differed to a small extent due to differences in random number generation between Excel and R. The incremental cost-effectiveness ratio (ICER) for the two treatment smoking cessation model was approximately £3900/QALY in both the original R and exported Excel model. The incremental net benefit for the four treatment hip replacement surgery model model also approximately matched.

CONCLUSIONS: Our proof-of-concept study has demonstrated that it is possible to build a template for cost-effectiveness modelling in R that can automatically export an Excel version of the model. The concept could be used by manufacturers to develop a 'Global' R model that still allows county affiliates to submit an Excel version to HTA agencies that do not yet accept R. The concept could be extended to other model types such as partitioned survival models, semi-Markov models, and microsimulations.

abs-os654 Primary Care Provider Engagement Postpartum and the Reduction of Emergency Department and Urgent Care Center Visits

PRESENTER: **Anjelica Gangaram**

AUTHORS: Ishani Ganguli, Mark Clapp, Jessica Cohen

Background & Aim

In the United States, approximately 30% of emergency department visits are classified as non-urgent. Non-urgent emergency department visits are visits for conditions that do not require an immediate resolution, delaying the treatment of these conditions for several hours would not result in negative health consequences for patients. In addition to seeking non-urgent care at emergency departments, patients may also seek non-urgent care at urgent care centers. Urgent care centers are walk-in clinics for minor illnesses and injuries. When non-urgent care is obtained at emergency departments and urgent care centers, it is more expensive than if the analogous care was obtained at primary care physician offices. In addition to the increased financial costs, the dependence on emergency departments and urgent care centers for non-urgent care reduces the likelihood that patients develop relationships with their primary care providers and in turn diminishes patients' care coordination. Reduced care coordination can negatively affect the quality of care a patient receives. Substituting away from receiving care at emergency departments and urgent care centers and towards primary care physician offices may result in a variety of health and financial benefits for patients.

Socioeconomically disadvantaged, postpartum patients are more likely to obtain emergency department care relative to their more advantaged peers. The postpartum period is a medically complex time one where patients could benefit from engaging with their primary care providers. In our paper, we examine the effect of primary care provider engagement on emergency department and urgent care center utilization among postpartum patients.

Methodology

In our analyses, we use data from a randomized clinical trial that scheduled patients visits with their primary care provider within four months postpartum. We assess the effect of primary care provider engagement on having: an emergency department visit, an urgent care center visit, an emergency department or urgent care visit within one year postpartum. We also assess the effect primary care provider engagement has on the number of emergency department and urgent care center visits obtained during this period. To do so, we conduct instrumental variable and reduced form analyses.

Results

Preliminary results indicate that primary care engagement early in the postpartum period reduces emergency department and urgent care center utilization for up to a year postpartum. These results remain qualitatively unchanged in both the instrumental variable and reduced form analyses. Early postpartum primary care provider engagement results in heterogenous utilization effects by patient race suggesting that that provider engagement may have particularly salient effects among the disadvantaged. Our results tentatively suggest that increasing primary care engagement may improve postpartum health and well-being beyond the initial visit and have medium-term effects on health.

abs-os643 Protective and Preventive Tools for a Good Start: Supporting Families During Pregnancy Through a WhatsApp Chatbot

PRESENTER: **Ana Balsa**

AUTHORS: Juanita Bloomfield, Alejandro Cid

As early as the prenatal period, brain structure and function are sensitive to environmental influences. The formation of neural processing capacities depends directly on experiences in the womb that are affected by maternal stress, nutrition deficits, intake of toxic substances, maternal health problems, lack of exercise, or infections, among others. Despite this knowledge, most programs targeting early childhood development begin usually after pregnancy.

In this paper we report on the design, implementation and evaluation of an intervention aimed at optimizing the pregnant woman's health, fetus development, and pregnancy outcomes through the delivery of information, the administration of screening tools, and the provision of support. The intervention takes advantage of mobile technology and leverages behavioral science in its design. The program functions as a complement to the regular obstetric care received by pregnant women and is initially advertised through the primary care provider. The content is based on three pillars: (i) promoting healthy habits (physical activity, eating healthy, avoiding toxic substances), (ii) helping women maintain a healthy mental and emotional state, and (iii) encouraging father's involvement.

We assess the impact of the program by using a randomized controlled design on 1,190 pregnant women recruited from public and private healthcare providers in Uruguay. We find moderately sized improvements in pregnancy-related wellbeing for women at risk of depression at baseline, more engagement in self-care activities, and weak evidence of effects on diet and physical activity. We also observe signs of increased paternal involvement, as captured by a higher likelihood of assisting to prenatal controls and an increased intention of taking paternity leave days. On the other hand, results show that treated women with no risk of depression at baseline increase their depression symptoms and the risk of depression by the end of the pregnancy. The culprit does not appear to be increases in distress due to more demanding reference norms or an excess of cognitive load. Instead, we hypothesize that it is due to a higher awareness about emotions. Finally, we find, based on administrative data, that the intervention did not affect birth outcomes. (JEL: I12, I31, J13, H43)

abs-os655 When Abortion is Illegal: The Effects of Access to Medication

PRESENTER: **Azka Imran**
AUTHOR: Partha Deb

In countries where abortion is illegal, "do-it-yourself" abortions, which once involved wire-coat hangers, are becoming safer. Misoprostol, a stomach-ulcer pill which can be used to induce abortions, is making it easier for women to end unwanted pregnancies. Women are obtaining the drug on the black market and its use is developing primarily on a trial-and-error basis. As women have begun to experiment with the drug, doctors have sought to reach them with information on proper use.

In 2006, in Peru, clinicians in five of the country's twenty-five departments, adopted a so called harm reduction approach and began disseminating information on the use of misoprostol pills with detailed directions of dosage after confirming a woman's pregnancy. All women are encouraged to come in for an "after visit" for post-abortion care. If misoprostol is properly used, women present as if they are having a miscarriage, allowing physicians to complete termination and address complications with complete confidentiality.

We exploit the geographic variation in the implementation of the harm reduction program in Peru and use a difference-in-differences design to estimate the effects of the program on the rate of self-induced abortions, abortion related complications, pregnancy care practices, infant health outcomes, and women's labor market and educational outcomes.

We use three data sources: (1) The Perinatal Information System in Peru that collect clinical records on live births, infant health outcomes and information on the number of women receiving abortion related care (2) The Peruvian Demographic and Health Survey and (3) Encuesta Nacional de Hogares Survey. The former survey is a nationally representative cross-sectional household survey that collects data on self-induced abortions, and pregnancy care practices** and the latter is a nationally representative household survey that collects information on employment and education.**

Our analysis reveals that the rate of self-induced abortion increased by 1.7 percentage points, and the rate of adequate antenatal care increases by 1.4 percentage points (defined by the WHO organization as at least 4 antenatal visits) in treated regions.

Statistics on how many women take abortion pills without medical care are patchy. Still less is known about how they fared. Unsafe abortions claim the lives of 22,800–31,000 women (depending on the data source) annually, posing a serious public health issue. It is important to understand whether abortion harm reduction models can be used to mitigate harm in restrictive environments.

Breaking the Cycle: Economic Costs, Prevention, and Intergenerational Impacts of Child Maltreatment

MODERATOR: **Nicole Black**, Centre for Health Economics, Monash University

CONVENER: **Gabriella Conti**, UCL

DISCUSSANT: **David Johnston**, Monash University

abs-os764 The Architecture of Care: Professional Models in Early Home Visiting and Child Maltreatment

PRESENTER: **Gabriella Conti**, Department of Economics and Social Research Institute, University College London
AUTHORS: Tilman Brand, Malte Sandner, Soren Kliem

Background: Home visiting programs have shown promise in supporting disadvantaged families and preventing adverse childhood outcomes.

However, questions remain about optimal delivery models. This study examines the efficacy of two different delivery models of the ProKind intervention, a German adaptation of the evidence-based Nurse-Family Partnership (NFP) program. We compare two approaches: a continuous model (CM) where NFP-trained midwives deliver all visits from pregnancy through the child's second year, and a tandem model (TM) where visits are delivered by midwives during pregnancy and transition to social workers for postnatal care. This comparison addresses the critical question of whether professional continuity matters for program effectiveness.

Objective: Our primary aim is to evaluate the relative effectiveness of these delivery models in reducing three key outcomes that signal family adversity: surveillance by child protection services (CPS), foster care placements, and pediatric medical incidents. These outcomes were chosen as objective measures of child wellbeing and family functioning that can be tracked through administrative data.

Participants and Setting: The study recruited 755 pregnant women facing multiple disadvantages (including low income, limited education, and social isolation) from multiple centers across Germany. Participants were randomly assigned to either intervention (n=394) or control (n=361) groups. The intervention began during pregnancy and continued until the child's second birthday, with follow-up extending to the child's seventh year.

Methods: We conducted a longitudinal multicenter randomized controlled trial with two distinct follow-up phases: Phase I covered birth to 36 months, capturing immediate program impacts, while Phase II extended to approximately the child's 7th birthday, allowing assessment of sustained effects. To estimate average treatment effects (ATE), we employed augmented inverse probability weighting (AIPW), an innovative approach that combines outcome regression and propensity score methods. We enhanced this analysis by using lasso techniques to select relevant control variables, ensuring robust and precise effect estimation.

Results: The continuous midwife-led model demonstrated significant positive impacts across multiple outcomes. Most notably, it reduced hospital visits across both phases (ATE = -7.20, $p<.001$), suggesting improved child health and parental healthcare utilization. By Phase II, we observed promising trends toward reduced CPS surveillance (ATE = -5.24 percentage points, $p=.10$) and fewer foster care placements (ATE = -2.25 percentage points, $p=.09$). In contrast, the tandem model showed no significant effects on any outcome measure. Analysis of the combined intervention group revealed significant reductions in hospital visits during Phase II (ATE = -3.58, $p<.005$), though effects were smaller than for the CM alone.

Conclusions: Our findings demonstrate that delivery model choice significantly influences program effectiveness. The continuous midwife-led model shows superior outcomes, particularly in reducing healthcare utilization and trending toward decreased child protection involvement. These results suggest that professional continuity may be a crucial element in home visiting programs, potentially due to stronger therapeutic relationships and more consistent support. The sustained effects visible at age 7 indicate that early intervention through midwife-led home visiting can achieve long-term benefits for high-risk families. These findings have important implications for the design and implementation of home visiting programs internationally.

abs-os762 The Economic Burden of Child Maltreatment in Italy

PRESENTER: **Gabriella Conti**, Department of Economics and Social Research Institute, University College London
AUTHORS: Elena Pizzo, Francesca Marazzi, Emma Scandolo, Flavia Bustreo

Child maltreatment is a major public health problem in Italy, with significant consequences for victims and society. About 27% of adults recall experiencing physical harm during childhood, and 50% report having experienced harm, neglect, or poor parental relationships. The last comprehensive study on the cost of child maltreatment (Bocconi for Terres des Hommes & CISMAI, 2013) is more than ten years old, does not include some costs due to data unavailability and lacks econometric modelling; hence, there is a need to compute updated and more comprehensive estimates of the costs of this phenomenon. In this paper, we provide comprehensive updated estimates of the economic costs of child maltreatment in Italy, in relation to several long-term outcomes, ranging from physical and mental health problems to labour market outcomes and welfare use.

To compute the costs of child maltreatment on health and socio-economic outcomes, we adopt the two-step procedure of Conti et al. (*Health Economics,* 2021), which can be summarized as follows: (i) we perform econometric analysis using OLS and logit models to estimate the impact of child maltreatment on health and socio-economic outcomes, holding constant background characteristics; (ii) we perform the cost analysis using the regression results from step (i) and best-published evidence on the cost of each outcome. To estimate step (i), we use rich data from the 7th wave of the Survey of Health, Ageing and Retirement in Europe (SHARE) and the EU Agency for Fundamental Rights (EU-FRA) Violence Against Women Survey, which collect retrospective information on childhood. We complement our analysis with data on Italian hospital discharges for the period 2004-2016 to estimate the average cost per hospital admission associated with child maltreatment. We identify diagnoses related to violence and abuse via the associated ICD-9 codes; and we then compute the average cost for the NHS using the national tariffs, which are associated with every hospital admission via the DRG (HRG) codes.

Following previous work, we construct a global measure of child maltreatment as physical abuse, neglect, and a poor parental relationship. Assuming that the average age at which children are maltreated is 6 years old, on the basis of the survey data analysis, we find that child maltreatment: (a) increases the likelihood of experiencing depression in adulthood by 2.4pp, which translates into a discounted cost per victim of €5,973.29; (b) increases the likelihood of smoking by 6.6pp, which translates into a discounted cost per victim of €4,539.53; (c) increases the probability of receiving disability benefits by 2pp, amounting to a discounted cost of €3,133.96 per victim; (d) is associated with a productivity loss from reduced daily activities of €49,591.97. Additionally, using hospital registry data, we estimate that the average cost per hospital admission associated with child maltreatment is €1,418 per child (inflated to 2024).

Our estimates provide the first comprehensive benchmark to quantify the cost of child maltreatment in Italy and suggests more coordination is needed between health (GPs), social services and law enforcement to improve surveillance of child maltreatment and so reduce a substantial economic burden.

abs-os664 The Impact of Compulsory Schooling on Teen Fertility and the Intergenerational Transmission of Maltreatment

PRESENTER: **Adam Akmal Dzulkipli**
AUTHORS: Nicole Black, David Johnston, Leonie Segal

Background and Research Aim:

Victims of child maltreatment tend to suffer from a variety of adverse outcomes throughout the lifecycle, including poor educational attainment, poor health, and self-destructive behaviours. Maltreated females in particular are at higher risk of experiencing teenage pregnancies, which may negatively impact their future health and economic outcomes. Additionally, mothers who are exposed to abuse and neglect during their childhood have a higher risk of maltreating their own children, leading to the pervasive cycle of violence.

In this paper, we use a raising of the school-leaving age (RoSLA) reform in South Australia to examine the impact of schooling on teenage fertility outcomes and the intergenerational consequences of maltreatment. While economists have long documented a negative relationship between schooling and teenage fertility, whether these findings apply to maltreated children is an open question. We further contribute by examining the impact of schooling on the intergenerational transmission of maltreatment, which remains relatively unexplored in the literature.

Methodology:

In 2009, the South Australian government implemented new laws that mandated children to remain in education between the ages of 16 and 17. We use this reform in a regression discontinuity (RD) design to identify the impact of schooling on teenage fertility and intergenerational maltreatment, by comparing children born just before the reform cut-off (i.e. 1 January 1993) to children born shortly thereafter. Our analysis uses data from the Impacts of Child Abuse and Neglect study, which linked records from multiple government and semi-government agencies in South Australia to create a large dataset of the universe of children born in the state from 1986 to 2017.

Preliminary Results:

Preliminary analyses indicate that the RoSLA reform led to a 6.3 percentage point increase in school enrolment at age 16 among females with a history of Child Protection Services (CPS) involvement. Correspondingly, we find that these children are less likely to experience a pregnancy-related event at age 16. In particular, the reform led to a 43% reduction in teenage pregnancies and a 47% reduction in abortions. Effects for fertility-related outcomes in the five years after the new mandatory school-leaving age (between ages 17 and 21) were much weaker in comparison. This is consistent with an 'incapacitation' effect, whereby being in the school environment reduces children's propensity to engage in risky sexual behaviours. Tracking these females into the future, we find no significant difference in the birth outcomes of children born to mothers who were affected by the reform versus children born to unaffected mothers.

Conclusion:

We find that compulsory schooling policies play an important role in the lives of maltreated females by reducing their risk of teenage pregnancies. This is likely to have positive implications for these children's health and economic outcomes in the future. More generally, our results suggest that encouraging maltreated children to remain in school may remediate some of the adverse outcomes that these children face.

abs-os94 Episode-Based Cost-Sharing for Childbirth in the Privately Insured Population in the United States: Quantifying the Out-of-Pocket Cost Redistribution

PRESENTER: **Michal Horný**, University of Massachusetts Amherst

Background: In most clinical circumstances, patients in the United States do not know how much they will have to pay for their medical care until after that care is delivered. Consequently, many patients are forced into medical debt, even for planned health care encounters. The episode-based cost-sharing model—under which patient cost-sharing obligation is derived from the expected rather than the realized treatment intensity—was developed to provide patients with reliable, upfront out-of-pocket cost information while preserving mechanisms to contain moral hazard and sustaining premiums. Given the novelty of this model, evidence on its consequences is sparse.

Research question: The goal of this research was to quantify the cost redistribution under the episode-based cost-sharing model from patients who receive less than the statistically expected amount of treatment intensity to those who receive more in the setting of inpatient admissions for childbirth—a common and shoppable health-care-related episode—in the privately insured population in the United States.

Methods: Using health insurance claims from the 2021 Merative MarketScan Commercial Database, we identified inpatient admissions for childbirth and all associated health care services. For each childbirth encounter, we quantified the realized treatment intensity by aggregating services provided to both the birthing person and newborn(s) weighted by their respective national mean prices and estimated a price scale factor by dividing the total cost of care and the realized treatment intensity to measure the episode-specific price level at the given provider. We estimated patients' out-of-pocket costs under the episode-based cost-sharing model by applying each patient's insurance benefit design parameters to the product of the statistical expectation of treatment intensity and the estimated price scale factor. Finally, we compared the observed patient cost-sharing to the estimated amounts under the episode-based cost-sharing model using descriptive statistics.

Results: The study sample consisted of 98,635 inpatient admissions for childbirth. Mean patient cost-sharing was $2,783 (SD = 2,167) per episode. Under the episode-based cost-sharing model, patients would incur lower cost-sharing than under the status quo in 22,136 (22.4%) encounters, with a mean reduction of $793 (standard deviation [SD] = 1,233). At the same time, patients would incur higher cost-sharing than under the status quo in 63,683 (64.6%), with a mean increase of $754 (SD = 635).

Conclusion: By design, episode-based cost-sharing would reduce the financial burden for the minority of patients who have the bad luck of experiencing clinical complications during a planned episode of care and simultaneously increase the financial burden for the majority of patients who experience no—or only minor—complications. Notably, patients who would financially benefit from episode-based cost-sharing would experience a greater reduction in out-of-pocket costs than the amount by which out-of-pocket costs would increase for the majority of patients. As such, episode-based cost-sharing would introduce further redistribution of resources within a pool of insured individuals. Policymakers can use these findings to make better-informed decisions regarding potential implementation of the episode-based cost-sharing model. Future research should assess patients' preferences for this cost-sharing model and its impact on the incidence of medical debt.

abs-os95 Reduced Mortality and Admissions Through Integrated Care: Evidence from Taiwan's Family Doctor Program

PRESENTER: **Li-Lin Liang**, National Yang Ming Chiao Tung University
AUTHOR: Ms. Jui-fen Rachel Lu

Background:

Integrated care (IC) addresses fragmented health systems through a primary healthcare approach, targeting the triple aims of improving health outcomes, reducing costs, and enhancing patient experience. While its effectiveness is well-documented for single-disease management, its impact on multimorbid patients remains unclear. Over 70% of IC research focuses on North American and European models, where patient registration with family physicians is mandatory or incentivized. However, there is limited evidence on the design and implementation of IC in health systems where primary care delivery is weakly integrated into broader healthcare systems. This study addresses this gap by evaluating Taiwan's Family Doctor Program (FDP), a nationwide IC initiative introduced by the National Health Insurance (NHI) Administration to enhance care for high-cost, multimorbid chronic patients.

Research question:

What are the effects of the FDP on avoidable hospital admissions and all-cause mortality?

Methods:

We conducted survival analysis using nationwide data from the Taiwan NHI Research Database. Eligible patients were identified from the annual roster and assigned to FDP or non-FDP groups using a one-to-one matching method. Matching criteria included demographics, health status, healthcare utilization patterns, and attributes of the clinic most frequently visited. The study period spanned from 2013 to 2020, divided into baseline (2013–2016) and follow-up (2017–2020) phases. Analyses focused on hospital admissions and all-cause mortality, with final matched samples of 484,644 individuals for admissions and 826,996 for mortality. We employed multivariable modified Cox proportional hazards models and stratified analyses to assess FDP effectiveness.

Results:

FDP participants exhibited a 1.88% lower 4-year cumulative mortality incidence compared to non-participants (7.94% vs. 9.82%; $P<0.001$). After multivariable adjustments, FDP participants had a 3% lower risk of hospital admissions (adjusted hazard ratio [AHR]: 0.97; 95% CI: 0.95–0.98; $P<0.001$) and a 13% lower risk of death (AHR: 0.87; 95% CI: 0.86–0.89; $P<0.001$) than non-participants. The reduction in admission risk was most notable among patients under 65 and those with hyperlipidemia or diabetes (AHR: 0.95–0.96, $P<0.05$). All-cause mortality risk was significantly lower across all subgroups (AHR: 0.84–0.89, all $P<0.005$).

Conclusion:

The FDP's multifaceted IC approach—comprising case management, clinic-hospital care pathways, and team-based care—may explain its association with improved outcomes. Performance payments in the FDP are directed to primary care teams, who may share these payments with hospitals, thereby incentivizing hospital engagement in IC initiatives. This mechanism highlights the critical role of primary care coordination in achieving improved outcomes while fostering hospital collaboration. Taiwan's experience provides valuable insights for countries seeking to establish IC models in systems with less integrated primary care delivery.

abs-os93 The Performance Paradox: Longitudinal Payment Disparities for Safety-Net Providers in a U.S. Value-Based Payment Model

PRESENTER: **Ms. Meng-Yun Lin**, Wake Forest School of Medicine
AUTHORS: Amresh Hanchate, Zhang Zhang

Background

In an effort to shift the focus of Medicare payments from volume to quality, the United States implemented the Medicare Access and CHIP Reauthorization Act (MACRA) in 2015. This act introduced the Medicare Merit-Based Incentive Payment System (MIPS), which adjusts payments to clinicians based on performance across four domains: quality, cost, improvement activities, and promoting interoperability (use of electronic health records). Payment adjustments under MIPS range from negative to positive, with the potential to increase or decrease Medicare payments by up to 9% starting in 2020.

While MIPS aims to incentivize higher-quality care, it does not account for patient social determinants of health, raising concerns for clinicians who serve socially disadvantaged populations—often referred to as safety-net providers (SNPs). These providers, who are critical in delivering care to underserved communities, may face resource limitations and workforce shortages that could affect their ability to achieve higher MIPS scores and payment rewards.

Research Question

This study aims to assess how SNPs have fared under MIPS compared to non-SNPs over a four-year period (2018-2021). Specifically, we examine whether there are disparities in performance scores and payment adjustments that may disadvantage providers serving vulnerable populations.

Methods

The study identified 329,657 clinicians who participated in MIPS from 2018 to 2021. We defined SNPs as clinicians affiliated with safety-net hospitals (those in the highest quartile of Medicare Disproportionate Share Hospital payments) or outpatient providers serving communities with high rates of uninsured or Medicaid-covered residents. Our study focused on three key outcomes: (1) the likelihood of receiving positive payment adjustments ("rewards") consistently over four years; (2) changes in payment adjustments between the early (2018-2019) and later (2020-2021) years of the program; and (3) the cumulative impact on payment adjustments over the four-year period.

We employed multivariable regression analyses, adjusting for provider characteristics (sex, specialty, practice years), practice settings (practice size, health system affiliation), and patient risk factors (average clinical complexity and proportion of dual-eligible patients).

Results

Among the study cohort, 95,317 (29%) were identified as SNPs. Over the four-year period, SNPs consistently achieved slightly higher performance scores than non-SNPs, with average scores increasing from 90.6 in 2018 to 91.9 in 2021, compared to a rise from 88.7 to 90.4 for non-SNPs.

SNPs were 14.5% more likely ($p<0.001$) than non-SNPs to receive positive payment adjustments consistently throughout the study period. Additionally, SNPs were 16.6% more likely ($p<0.001$) to achieve improved adjustments in the later years (2020-2021) compared to the earlier years (2018-2019). However, despite their better performance, SNPs received lower cumulative dollar adjustments, with a net difference of \$0.39 less per patient served ($p=0.006$) relative to non-SNPs. Sensitivity analyses using matched samples, based on 2018 performance scores, yielded consistent results.

Conclusions and Policy Implications

Our study reveals a paradox in the MIPS program: although safety-net providers serving disadvantaged populations consistently performed well, they received lower cumulative financial adjustments compared to their non-SNP counterparts. This discrepancy may impose an unintended financial burden on SNPs, potentially undermining their ability to sustain care for underserved communities in the long term.

The Hidden Costs of Caring: Unseen Economic, Health, and Quality of Life Impacts on Informal Carers.

SESSION CHAIR: **Hareth Al-Janabi**, Health Economics Unit, Institute of Applied Health Research, University of Birmingham

CONVENER: **Ann Livingstone**, Deakin University

abs-os23 Exploring Variations in Carer Quality of Life and Health Status Across Differing Health Conditions of Care Recipients.

PRESENTER: **Ann Livingstone**
AUTHORS: Jessica Bucholc, Lidia Engel, Clement Wong, Ms. Nikki McCaffrey

Background As the number of informal carers continues to rise, understanding the impact of informal caregiving, both economically and from a quality-of-life perspective, remains challenging. Many instruments have been developed and validated to measure carer quality-of-life impacts. However, how these tools compare across those caring for people with differing health conditions is unclear. **Objectives** This research aimed to compare the impact on quality of life for carers of people with various health conditions using three carer-specific preference-based measures: ASCOT-Carer, Carer Experience Scale (CES), and CarerQol; two preference-based health-related quality of life (HRQoL) tools: AQoL-8D and the EQ-5D-5L; and the Caregiver Reaction Assessment (CRA). **Methods** Data were collected through an online survey of 500 Australian informal carers. Participants completed three carer-specific preference-based measures (CES, ASCOT-Carer, CarerQol) in randomised order, two HRQoL tools (AQoL-8D, EQ-5D-5L), and the five domains of the Caregiver Reaction Assessment (CRA: self-esteem, schedule, family support, finances, and health). Preference-based instruments were scored using UK algorithms, while the AQoL-8D used the Australian value set. Total mean scores were estimated for the carer-related and health-related preference-based measures and CRA domains, and a linear regression model was used to compare the scores across the care recipient's different health conditions (temporary disease, chronic disease, dementia, mental health, intellectual disability, aging-related issues, terminal illness, and other illnesses). Sociodemographic characteristics were summarised using descriptive statistics. **Results** The analyses suggest there are significant differences ($p \leq 0.05$) in mean CES scores (N=375) for all health conditions except terminal illness compared with temporary disease, with mental health showing the largest difference (Coefficient 22.26, SE 4.20). There was also a statistically significant difference in mean AQoL-8D score (N=469) for chronic disease, mental health, intellectual disability, and terminal illness versus temporary disease. Mental health again showed the greatest difference (Coefficient 0.15, SE 0.04). Compared to temporary disease, carers of individuals with intellectual disability and other illnesses showed significant differences across four CRA domains (self-esteem (N=473), schedule (N=475), finances (N=474), and health (N=474)), carers of people with chronic disease, across all domains except self-esteem, and carers of individuals with dementia and mental health conditions just two domains, finances and health. **Conclusions** Meaningful differences in carer-related and health-related quality of life emerged across assessment tools and health conditions. Carers of individuals with mental health issues reported greater negative impacts on care-related and health-related quality of life. In contrast, carers of individuals with chronic diseases, intellectual disability, and other illnesses experienced a higher burden compared to the reference group temporary disease as measured by the CRA. These findings offer valuable insights into the diverse impacts of providing informal care, with the potential to guide the development of tailored support and services for informal carers globally.

abs-os323 How Well do Generic Preference-Based Measures Perform in Informal Carers: a Psychometric Study in Australia

PRESENTER: **Jan Faller**, Monash University
AUTHORS: Gang Chen, Lidia Engel, Cathy Mihalopoulos, Ms. Nikki McCaffrey, Brendan Mulhern

Background: Using generic preference-based measures (GPBMs) to capture informal care outcomes provides consistency across economic evaluations and facilitates combining patient and carer quality-adjusted life years. However, it is currently unknown how well GPBMs perform in informal carers. This study assesses the psychometric performance and dimensionality of the 5-level EQ-5D (EQ-5D-5L) and the Assessment of Quality of Life 8 Dimension (AQoL-8D) among Australian informal carers. Objective: To assess the psychometric performance of the EQ-5D-5L (the most commonly used measure in economic evaluation) and the AQoL-8D (a measure with a broader coverage of psycho-social domains of quality of life) among Australian informal carers. Methods: This was a secondary data analysis with data derived from an online survey administered to 500 informal carers across Australia. The online survey contained three carer-related measures (CES, CarerQol, ASCOT-Carer) and GPBMs (EQ-5D-5L, AQoL-8D). Descriptive analysis was conducted, including ceiling and floor effects analysis. Convergent validity was assessed through correlations (Spearman's rank) analyses with the three carer-related measures and discriminative validity tested using Mann-Whitney U and Kruskal-Wallis tests based on a priori hypothesised relationships between the EQ-5D-5L, AQoL-8D and the informal care situation. Test-retest reliability was assessed for respondents who self-reported 'no change' in their quality of life as a carer over two weeks using the EQ-5D-5L. An exploratory factor analysis (EFA) was conducted to understand the conceptual overlap between the AQoL-8D, EQ-5D-5L and the three carer-related measures. Ethics approval were secured from Deakin University (HEAG-H 91_2018) and Monash University (39031). Results: Mean informal carer utilities were 0.819 and 0.604 for the EQ-5D-5L and AQoL-8D respectively. Both did not show any ceiling or floor effects (threshold >15%). Test-retest reliability, which was only available for the EQ-5D-5L, revealed good agreement (ICC=0.825) with moderate (usual activities, pain and discomfort, anxiety and depression) to substantial (mobility, self-care) agreement on domains. Convergent validity analysis showed that both EQ-5D-5L and AQoL-8D had moderate correlations with the three carer-specific measures. Known-group validity suggested that the GPBMs had the ability to discriminate based on hours of care, number of tasks, number of care recipient diagnoses, number of recipients cared for, sharing a household and duration of care. EFA identified 9 factors with minimal overlap between the carer-related measures and the GPBMs. Discussion: The GPBMs tested are all acceptable for use in informal carers, and the choice of instrument to use will depend on the constructs to be measured. The inclusion of both generic and carer measures during outcome assessment may still be warranted to understand carer wellbeing and burden. Further research is still needed to examine responsiveness of the respective measures.

abs-os330 Developing a New Preference-Based Measure of Quality of Life for Carers of People with Dementia: Results From the COCOON Study

PRESENTER: **Lidia Engel**, Deakin University

Background: Providing informal care to a person with dementia can affect carers' quality of life. While existing generic preference-based measures (e.g., EQ-5D) may not be able to fully capture the caring experience, carer-specific measures (e.g, CarerQol), whilst preference-based,

are not anchored onto the dead-full-health scale to derive quality-adjusted life years (QALYs) in cost-utility analysis. Aim: The aim of the COCOON project was to develop a new preference-based quality of life questionnaire for carers of people living with dementia that can be used in cost-utility analysis. Methods: The development of the descriptive system was informed by: (1) interviews with 10 carers of people with dementia, assessing the face validity of candidate items; (2) an online survey of 202 carers of people with dementia, evaluating the psychometric performance of candidate items (missing data, floor-and ceiling effects, known-group difference, convergent validity, exploratory factor analysis and item response theory analysis); and (3) engagement with an Advisory Group. To derive preference weights for the new measure, a discrete choice experiment (DCE) with duration was constructed in an online survey and administered to a representative sample of the Australian general population (n=1000). A partial subset DCE design was used with 3 fixed attributes and 5 varying attributes, containing 240 choice tasks that were blocked, so that each respondent completed 12 choice tasks. A conditional logit model was used to generate an anchored model (anchored on the 0 to 1 dead-full health QALY scale). Results: From the initial pool of 60 candidate items, the advisory group selected 44 items for further testing in qualitative interviews with carers. These interviews helped identify and remove inappropriate items, ultimately reducing the total number to 35. Based on the psychometric analysis of candidate items and a final consultation with the Advisory Group, the final descriptive system of the quality of life measure comprised seven items: (1) emotional health; (2) physical health; (3) loss and grief; (4) loss of freedom; (5) loneliness; (6) support; and (7) financial burden. Each item is measured on a 5-point frequency scale, ranging from ‘never’ to ‘always’. For the development of the value set, several models were tested to smooth out the disordering of the utility estimates, with the final value set reflecting the monotonic nature of the descriptive system. Conclusion: The new developed COCOON measure of carers quality of life will enable the inclusion of carer outcomes in future cost-utility analysis in dementia, leading to more equitable and efficient resource allocation decisions.

abs-os333 Evaluating Methods for Including Caregiver QALYs in Economic Assessments: Impacts of Treatment Effects on Patient Cure, Morbidity, and Mortality

PRESENTER: **Holly Cranmer**
AUTHORS: Becky Pennington, Sarah Davis

Background: Traditionally, health technology assessments (HTAs) and economic evaluations have focused on patient outcomes, but there is increasing recognition of the broader impact of disease on the patient's support network. Including caregiver quality-adjusted life years (QALYs) can provide a more comprehensive picture of a treatment’s value, especially in conditions that require significant caregiving, such as chronic, progressive, or severe diseases. However, there are ongoing debates regarding the approach to incorporating caregiver QALYs into economic evaluations. **Aim:** To assess and compare five different approaches for incorporating caregiver QALYs into economic evaluations across six hypothetical interventions, each with varying effects on cure, mortality, and morbidity. **Methods:** Building on established methods from the literature, we examine five different approaches to modelling caregiver QALYs in a hypothetical disease setting characterised by mild, moderate, and severe health states. Additionally, we explore the impact of incorporating caregiver QALYs in the patient cure and patient death states. The five approaches are: (1) caregiver utilities, (2) caregiver disutilities, (3) increments relative to the best health state, (4) increments relative to the worst health state, and (5) increments relative to the midway health state. We examine how these approaches affect the incremental QALYs across the six interventions and under what conditions they are consistent with each other. **Results:** Incremental QALYs are consistent across all approaches when caregiver QALYs are included for both the patient cure and death states. Caregiver QALY gains are observed in scenarios where the intervention improves morbidity without curing patients, where the intervention cures all patients without affecting mortality, and where the intervention improves cures all patients and extends survival. Conversely, caregiver QALY losses occur in scenarios where the intervention improves mortality but does not cure patients. When caregiver QALYs are excluded for the patient cure and death states, the only scenario where incremental QALYs remain consistent across all approaches is when the intervention improves morbidity without curing patients and does not affect mortality. When caregiver QALYs are included for the patient cure state but excluded for the death state, the only scenario where incremental QALYs remain consistent across all approaches is when the intervention cures all patients but does not impact mortality. **Conclusions:** Where caregiver QALYs are relevant for inclusion in economic evaluations, including them for both patient cure and patient death ensures consistency across modelling methods. Nevertheless, there are still challenges in ensuring the validity of the results that require further exploration. One key consideration is whether caregiver QALYs would be affected by extending mortality in the cured health state. Another important question is how caregiver QALYs would be impacted following the death of a patient. Ongoing research aims to engage caregivers and stakeholders in discussions around key questions, with the goal to advance the methods for including caregiver QALYs in economic evaluations.

abs-os117 Developing a Consolidated Conceptual Framework for Understanding Physicians Choice of Specialization Throughout Their Medical Careers

PRESENTER: **Ms. Amy T. Hsu**

Background and Aim: There is a significant shortage of geriatricians worldwide, with the demand far outpacing current supply. In the United States alone, it's estimated that about 30,000 geriatricians will be needed by 2030; yet, less than 7,300 certified geriatricians currently practice

nationwide. Studying motivating factors can help develop strategies to attract more physicians to this specialty. Many existing studies have examined the factors medical trainees and professionals consider when choosing a specialty or sub-specialty. However, no single conceptual framework currently consolidates all these factors and determinants into one relational system to provide a comprehensive overview of how decisions concerning a career in a specific medical specialty or sub-specialty are made.

The aim of this scoping review was to, first, identify conceptual frameworks and models that summarize factors influencing the decisions of medical students, residents, and physicians when selecting a medical specialty or sub-specialty. Then, individual factors and their associated domains from the identified conceptual frameworks are compiled into a consolidated framework. Finally, we applied the consolidated framework to understand the motivating factors for choosing a career in geriatric medicine.

Method: We developed a search strategy with a medical information scientist and searched six databases, including MEDLINE, Embase, PsycINFO, CINAHL, Web of Science, and ProQuest Dissertations & Theses Global. We considered all study designs but only included studies that presented a multifactorial conceptual or theoretical framework summarizing the determinants of medical trainees and physicians' pursuit of a specialty or sub-specialty. Studies that do not focus on careers in allopathic medicine or focused on medical education systems outside of North America were excluded, given our focus on application towards North American medical education and training. Articles were independently screened by at least two reviewers. Data from included studies were charted, and results were described narratively.

Results: A total of 5,469 abstracts and titles were retrieved, with 839 selected for full-text review (ongoing). We anticipate that broader domains, including student and medical school characteristics, attitude towards specialty, specialty profile, personal values, and career needs will be significant determinants in choosing a medical specialty.

Implications: Conceptual frameworks are crucial for understanding career decision-making, shaping educational policies and programs, and identifying gaps in the literature to inform future research in medical education. As the global population ages, the demand for geriatric care is increasing rapidly. Understanding what draws physicians to geriatric medicine can help healthcare systems and policymakers create incentives and programs to ensure adequate care for older adults.

abs-os312 Gender Mix Prescription: Is it the Cure for GPs Job Satisfaction and Retention?

PRESENTER: **Martina Repetto**
AUTHOR: Margherita Agnoletto

Background: Job satisfaction is a critical component of worker well-being, significantly impacting turnover rates, absenteeism, and productivity. Although previous research highlights the influence of workplace gender composition on job satisfaction, most studies focus on large, hierarchical, male-dominated firms. This study examines the effect of gender composition among general practitioners (GPs) in Australia —a setting characterized by small to medium-sized practices, frequent coworker interactions, high earnings, limited promotion opportunities, and a balanced gender distribution.

Objectives: We investigate how changes in the proportion of female GPs within a practice affect overall job satisfaction, various lower-level satisfaction domains (e.g., satisfaction with colleagues, recognition at work, freedom in work methods), intentions to quit medical work, and the service quality of "stayer" GPs—those who remain at the same practice over time.

Methodology: Using data from the Medicine in Australia: Balancing Employment and Life (MABEL) longitudinal survey, which includes approximately 3,500 GPs over 11 annual waves from 2008 to 2018, we employ individual fixed-effects models to control for unobservable time-invariant characteristics, dealing with potential endogeneity concerns in several ways. Among others: we focus on GPs who remain in the same practice over time, excluding them when they change practices to mitigate future self-selection. We also exclude GP principals to mitigate biases related to hiring preferences and we conduct additional randomness checks on our independent variable.

Key findings: Our findings reveal that an increase in the proportion of female GPs within a practice positively affects overall job satisfaction and specific components such as satisfaction with colleagues, recognition received for good work, and with working hours. These effects are driven by female GPs, who exhibit increased satisfaction across all areas and greater freedom to choose their own working methods. We do not observe significant effects on service quality, except for a decrease in consultations with others among male GPs and a decrease in patients seen per hour among female GPs. Additionally, intentions to quit medical work decrease. We find support for some mechanisms to explain the role of gender composition on job satisfaction. GPs are less likely to report having a poor support network at work when the proportion of women increases. They also experience lower stress in managing the practice and face a reduced probability of aggression from colleagues or supervisors. Furthermore, we investigate the role of gender balance and discover that the effects of increasing the proportion of female GPs are moderated when accompanied by a decline in gender diversity within the practice. This suggests that diversity itself enhances job satisfaction.

Conclusions: These findings contribute to the understanding of how gender composition affects job satisfaction and retention in a high-skilled, gender-balanced workforce. They have important implications for policy and practice, highlighting the potential benefits of promoting gender diversity within healthcare settings to enhance worker well-being and reduce turnover intentions. Our results are robust to multiple sensitivity checks, including the Oster test and assessments of the randomness of the independent variable.

abs-os160 Homecare Labour Supply: Modelling Determinants of Homecare Personal Support Worker Exit

PRESENTER: **Katherine A.P. Zagrodney**, University of Toronto
AUTHORS: Emily King, Rachael Jaffe, Sandra McKay
Background: Inadequate health workforce supply is one of the most pressing challenges facing healthcare systems worldwide. In homecare, there is a mismatch between chronic shortages of personal support workers (PSWs) and the growing demand for PSW services to support an aging population. Despite many healthcare systems' expanding reliance on homecare PSWs, literature applying quantitative methods

to examine homecare PSW exit from employment (turnover) is relatively limited. Insight into factors influencing homecare PSW turnover are essential to building sustainable healthcare systems that meet population needs. **Objectives:** 1) Describe turnover rates of homecare personal support workers (PSWs) in Ontario, Canada 2) Determine the relative effects of demographic and workplace factors on homecare PSW decisions to take long-term absence or exit from employment. **Data:** The study used longitudinal, individual-level, retrospective administrative data of over 2,704 PSWs providing over 6.6 million hours of publicly funded care within a homecare organization in Ontario, Canada over the last three years (April 2021 - May 2024). **Statistical Analysis:** Multilevel multinomial logistic regressions estimated the effect of a PSW exiting employment or a long-term absence from work relative to working in a given week across two stratified models (late- and post- COVID-19 pandemic). The models were adjusted for individual-level heterogeneity, demographic factors (e.g. age, gender), and workplace factors (e.g., income, distance travelled between homecare visits, and job tenure). **Results:** The majority of the PSW sample (n = 2,704) were female (96%) with an average age of 44 years. Approximately one-sixth of the sample exited employment within the study period (18%) and one-third experienced a long-term absence at some point over the three years (28%). Higher income significantly decreased the odds of a long-term absence or turnover across all models while longer distances between visits increased the odds of turnover during the pandemic. Each additional year of employment tenure was associated with a decrease in the odds of leaving their job. **Conclusions:** Findings from this research provide insight into the increasingly critical topic of homecare labour supply. Utilizing an individual-level and longitudinal dataset, preliminary findings suggest that key determinants of homecare PSW turnover were lower income, further travel distance between visits, and higher localized demand-to-supply ratios. Targeted policies such as improved financial remuneration and reduced travel between visits can be expected to improve retention for this increasingly vital workforce. As demand for homecare PSWs is forecasted to rise over the coming years, improving homecare access and PSW workforce stability will be critical to meet the needs of those relying on care at home.

Inequity in Access to Health Care Services

MODERATOR: **Jacob Novignon**, University of Ghana

Ind-571 Treatment Preferences and Their Determinants Among Adults With Depression or Anxiety in Outpatient Mental Health Care: A Systematic Review

PRESENTER: **Lara Lenz**

AUTHORS: Hans-Helmut König, Melanie Leitner, André Hajek

Background:

Due to rising prevalence of depressive and anxiety disorders, we experience a growing demand for mental health care. However, treatment gaps, long waiting times for psychotherapy and high rates of treatment drop-outs show that the system is overwhelmed and better allocation of resources is needed to secure timely and effective mental health care. Accommodation of treatment preferences is known to improve treatment outcomes and increase patient satisfaction.

Aim:

The aim of this study was to systematically review studies that elicited treatment preferences and their determinants among adults with depressive or anxiety disorder for outpatient mental health care.

Methods:

The study was registered in PROSPERO and followed the PRISMA guidelines. Studies were systematically retrieved from four databases (Web of Science, PubMed, CINAHL, PsycInfo) from inception to May 2024. Study screening was performed in a three-step process (title, abstract, full-text) in duplicate. We included studies of all types that assessed and reported treatment preferences of adults with depressive or anxiety disorder for outpatient mental health care, and that were published in English or German. We made no restrictions regarding geographical

location or year of publication. We did not review grey literature. Extracted data on preferences and determinants was summarized. Preferences were categorized into *treatment approaches*, *psychotherapy delivery and setting*, and *psychotherapy parameters*. Determinants were grouped into *sociodemographic* and *health-related factors*. Study quality was assessed with the Mixed-Methods Appraisal Tool (MMAT).

Results:

Of 14,035 identified records, 19 studies were finally included in the review for qualitative synthesis. The studies were conducted in Europe (n=8), the United States (n=8) and Australia (n=3). Seventeen studies were quantitative and two used a mixed-methods approach. Depressive disorder alone was examined in 14 studies, anxiety disorder alone in four studies and one study observed both disorders. The overall quality of the studies was moderate, with main issues concerning nonresponse bias, preference elicitation and statistical methods. Preference elicitation methods ranged from simple (single or multiple choice) questions to discrete choice experiments. Types of preferences examined relate to *treatment approaches* (n=13), *psychotherapy delivery and setting* (n=10) and *psychotherapy parameters* (n=7). Despite high heterogeneity in terms of statistical methods and preference types, three main findings were identified: 1) psychotherapy was preferred over medication, 2) face-to-face treatment was preferred over digital treatment, and 3) individual therapy was preferred over group therapy. Regarding determinants, results were highly diverse and many findings derived from single studies.

Discussion:

Our review synthesized existing evidence on treatment preferences and associated determinants in outpatient mental health care. Results showed considerable heterogeneity regarding preference types, determinants and statistical methods. We highly recommend to develop and use standardized instruments to assess treatment preferences to enhance comparability of studies and thus, strengthen the evidence. In terms of clinical implications, providers should be aware that preferences can be diverse, which highlights the importance of assessment and integration of treatment preferences into care planning to provide individualized mental health care.

Ind-664 The Impact of Free Care on Health Care Use and Financial Protection Among Vulnerable Women: Evidence from a Randomised Controlled Trial in Cameroon

PRESENTER: **Kasim Allel**, Centre for Global Health Economics, UCL
AUTHORS: Aurelia Lepine, Stephanie Moyoum, Tamoufe Ubald, Iliassou Mfochive-njindam, Sandie Szawlowski, Eric Defo Tamgno, Emilemichel Nitcheu

Background User fees in low-income countries have been linked to health inequalities, particularly among vulnerable populations. Removing these fees is anticipated to improve health service utilization and provide financial protection, though recent studies present mixed results. This study aims to assess the impact of free health care on health service use and financial protection for a vulnerable population in Cameroon.

Method A randomized controlled trial was conducted in Yaoundé, Cameroon, with 1,147 women and girls involved in transactional and commercial sex. Participants were randomly assigned to a treatment group, which received free health care for themselves and up to six dependents over 12 months, or a control group, which received no intervention. Data on health care use and out-of-pocket expenditures were collected at 6 and 12 months through surveys and hospital records.

Results The free care intervention led to a moderate increase in health care use and a substantial improvement in financial protection. However, out-of-pocket expenses during the last illness decreased by 98.3% ($p < 0.01$), the likelihood of experiencing a health-related economic shock reduced by 8.75 percentage points (14.4%, $p < 0.05$), and the incidence of catastrophic health expenditures fell by more than 30% ($p < 0.05$).

Conclusion This study highlights both the challenges and benefits of removing user fees in a low-income setting. While the intervention improved financial protection significantly, it only moderately increased health care utilization, likely due to barriers such as self-medication preferences, stigma, and supply-side issues like drug shortages. Nonetheless, the findings demonstrate the potential for health insurance models to enhance financial protection among vulnerable groups in low-income countries

Ind-1189 Assessment and Optimization of the Spatial Accessibility of Pediatric Healthcare Resources in Beijing,China

PRESENTER: **Jiawei Zhang**, Peking University
AUTHORS: Zhihu Xu, Peien Han, Chao Gong, Li Yang

Background: In recent years, the demand for pediatric services has surged, particularly during peak seasons for respiratory infectious diseases. This surge has often led to overcrowding in care facilities, straining the healthcare system and exposing systemic vulnerabilities. Addressing these challenges requires a focus on equitable access to healthcare for children, which is essential for reducing health disparities.

Objectives: This study aims to investigate the allocation of pediatric resources in Beijing, analyze disparities in the distribution of pediatric physicians and beds, and propose optimization strategies to enhance accessibility.

Methods: This study summarized the issues in pediatric resource allocation in Beijing through key informant interviews. Data pertaining to hospitals and the population for 2022 were sourced from the Beijing Municipal Health Commission. Initially, spatial accessibility to pediatric physicians and beds for resident children was analyzed using the modified two-step floating catchment area method. Subsequently, birth rates and population growth rates by district were used to predict the number of children in 2025. Finally, an optimization model was applied to determine the additional pediatric beds required to maximize equity across districts.

Results: In 2022, Beijing had a total of 4,704 pediatric beds, falling short of national standards by 1,104 beds (the national target for 2020 was

2.2 beds per 1,000 children), and 4,011 pediatric physicians, exceeding the national standard of 0.69 physicians per 1,000 children. The opinions of 11 experts emphasized three major challenges: (1) difficulties in training paediatricians, (2) insufficient pediatric bed capacity, and (3) uneven resource distribution across administrative districts.

We then calculated the spatial accessibility of pediatric physicians and beds in Beijing and optimized their spatial distribution. Across 7,184 communities, the average accessibility of pediatric physicians and beds was 0.97 physicians and 1.17 beds per 1,000 children, respectively. Notably, 45.28% of communities had fewer than 0.3 physicians per 1,000 children, 36.26% of communities exhibited bed accessibility below 0.3. In an optimized setting, Daxing District (requiring an additional 245 beds), Tongzhou District (203 beds), and Mentougou District (203 beds) emerged as the top three districts, all of which are non-central urban districts, are most in need of augmented bed capacity. With resource optimization, the average accessibility of pediatric beds improved to 1.68, with 2,076 communities (28.90%) having bed accessibility below 0.3, which represented a significant improvement.

Conclusions: There were significant spatial disparities in the accessibility of pediatric physicians and beds across Beijing. The central urban districts had better access, while the northern and southern suburban districts faced greater challenges. Focusing resources on areas with low accessibility can enhance service accessibility and reduce cross-district healthcare seeking. Compared to increases in pediatric beds based on population and policy target values, this optimized allocation methodology enabled a more equitable distribution, prioritizing healthcare accessibility over population size. These findings underscore the importance of incorporating accessibility considerations into healthcare planning to ensure equitable provision, guiding future strategies for allocating pediatric physicians and bed capacity upgrades aligned with broader health policy goals.

Ind-1704 Exploring Potential and Challenges of Cost-Sharing Policy Initiatives in Indonesia: Reflection from Global Experiences and Stakeholders Perspectives

PRESENTER: **Zahrina Laborahima**
AUTHORS: Pujiyanto Pujiyanto, Gemala Chairunnisa P, Budi Hidayat, Khairun Nisa'il Hulwah, Atmi Roseva, Mahlil Ruby, Arif Budiman, Sarah Dewi Mustika, Atik Nurwahyuni, Amila Megraini, Ibnu Susanto, Adang Bachtiar

Background: The Social Security Fund for the National Health Insurance Program (JKN) in Indonesia is projected to face a deficit of up to IDR 18 trillion by 2027. To address this, cost containment policies are necessary, including interventions on the demand side through the implementation of cost-sharing mechanisms. Indonesian regulations have outlined the need for cost-sharing policies, particularly for conditions susceptible to participant misuse. This study aims to explore the implementation and impact of cost-sharing policies in various countries and assess stakeholder perspectives on the potential introduction of cost-sharing in Indonesia.

Methods: A scoping review approach was used to systematically and iteratively synthesize relevant journal articles, reports, and regulations on cost-sharing. The analysis focused on the impact of cost-sharing on health service utilization, economic impact, and patient health outcomes. Additionally, this study used the Analytic Hierarchy Process (AHP), in-depth interviews, and focus group discussions (FGDs) to capture stakeholder views and preferences regarding the potential adoption of cost-sharing policies.

Results: Of a total of 865 articles in the review, 38 were included. These articles highlighted the diverse implementation of cost-sharing across different types of services, target populations, amounts, and payment methods. The copayments ranged from IDR 17,000 to IDR 231,000, while coinsurance rates ranged from 7% to 30%. In terms of clinical impacts, 82% of studies found no significant evidence, 13% indicated negative impacts, and 5% were neutral. Regarding economic impacts, 18% reported positive effects, while 11% noted adverse outcomes. For utilization impacts, most studies (34%) indicated a reduction in service utilization. Standard services subject to cost-sharing included childbirth, physiotherapy, dental care, and cataract surgeries. Key stakeholders agreed that cost-sharing policies should be implemented to ensure the sustainability of the JKN program and regulate participant behavior.

Conclusion: Any cost-sharing model to be implemented in Indonesia must carefully consider public acceptance, ease of implementation, and the long-term sustainability of the JKN program. The types of services included and the amount of cost-sharing should align with the principles of financial protection, considering the ability to pay (ATP) while excluding catastrophic or life-saving services from the cost-sharing scheme.

Ind-838 Partial Change in Patient Cost-sharing Affects All? Evidence from National Health Insurance Reform in Korea

PRESENTER: **Yuichi Watanabe**

Background:

The price sensitivity of health care consumption and the effect of change in patient cost-sharing on health care utilization have been one of the major concerns in health economics with the wide coverage of public health insurance throughout the world. Recent studies focus more on the elderly population due to a growing interest in aging society worldwide. Nevertheless, relatively little is known about how patient demand for health care varies by price range and types of healthcare facilities among the elderly. This study is expected to fill the gap by analyzing the quasi-experimental policy reform in Korea.

Objective:

Korean government reformed the national health insurance (NHI) scheme in 2017; out-of-pocket expenses for the elderly (over 65 years of age) outpatient care costing from 15,000 to 25,000 KRW in (dental) clinics were reduced from 30% to 10% or 20% of total spending since 2018 to alleviate their financial burden of having a minor illness and induce them to go to clinics rather than large hospitals, while their copayments for other price levels or those in the case of hospital visits were not changed. We aim to examine the causal impacts of this partial change in patient

cost-sharing among the elderly on outpatient care use and spending in clinics, allowing for a deeper investigation into the heterogenous and spillover effects across demographic groups and disease classification.

Data and Methods:

We use the sample cohort database from 2016 to 2019, provided by the National Health Insurance Service. It represents a patient sample of 2% randomly extracted from qualified NHI subscribers and medical aid recipients, including individual medical claims records and additional information on demographics and socioeconomic status. We employ a difference-in-differences (DID) estimation with fixed-effects according to price range of total expenses, where the treatment (control) group is defined as outpatient visits to clinics (primary hospitals). Primary hospitals are assumed to be a counterpart of clinics in Korea when patients with mild disease use outpatient services.

Results and Implications:

Our DID estimation for the entire sample shows that partial reduction in the copayment rate decreases overall out-of-pocket expenses in clinics by approximately 1,600 KRW per episode without significant increase in outpatient visits, while the reduction in out-of-pocket payments by 2,000 to 4,000 KRW on average and an increase in visits to clinics are found in the targeted price range as expected. We also demonstrate a significant decrease by around 1,000 KRW per episode even in the untargeted price level (over 25,000 KRW) as a spillover effect. These overall and spillover impacts are larger for females and the richer group as well as in disease areas of the eye, ear and circulatory system. However, we do not observe these effects in dental clinics. Our findings imply that partial change in patient cost-sharing applicable to clinics helps to lead the elderly in mild condition to go there at a lower cost on average rather than to primary hospitals that should treat more severe patients, contributing to the efficient allocation of healthcare resources.

Ind-1759 Patient Preferences for Centralisation of Surgical Services for Oesophageal Cancer: a Discrete Choice Experiment

PRESENTER: **Norma Bulamu**, Flinders University
AUTHORS: Gang Chen, Josipa Petric, David Watson, Tim Bright

Background and Aims: Surgery for oesophageal cancer (OAC) in a centralised high-volume centre has significant benefits to outcomes for patients including lower mortality and shorter length of stay, compared to localised low volume centres. However, patients may value and perceive these benefits differently and may be willing to make trade-offs for access to localised services. This may be due to a lack of a support network associated with a centralised high-volume centre, the need to travel further, or the costs associated with travel. The aim of this study was to understand whether these factors are important to patients, and how they influence the choice of surgical services.

Methods: A discrete choice experiment (DCE) was conducted to investigate the preferences for localised low volume centres or centralised surgical services in a high-volume centre. Attributes included were distance travelled to hospital (<10km, 50km,

400km, >1000km), risk of in-hospital mortality (1%, 3%, 8%), length of hospital stay (7-10 days, 11-20 days, >20 days), out-of-pocket cost ($0, $1-$1000, $1001 - $5000,

>$5000) and five-year survival (30%, 40%, 50%). Four respondent groups from metropolitan and rural/remote areas were recruited: patients under surveillance, OAC survivors, doctors, and the general population. Data was analysed using the framework of random utility theory.

Results: The DCE was completed by 85 surveillance patients, 30 cancer survivors, 80 clinicians, and 100 from the general population.

Significant preference was observed for travel distance of >10km (except survivors), risk of hospital death under 3% (survivors and clinicians), hospital stay under 11 days (survivors and general population), out-of-pocket costs under $1000 and 5-year survival over 40% (clinicians and general population). Similar trend of significant preference was observed when disaggregated by residence (metropolitan vs rural/remote), however, preference for lower risk of hospital death (1%) and higher 5-year survival (50%) was not significant for the rural/remote respondents.

All respondent groups had >50% probability of choosing a centralised service (reference: distance= 400km, risk of mortality=3%, hospital stay=11-20 days, out-of-pocket cost=$1-$1000, 5-year survival=40%) over a localised service (reference: distance= 50km, risk of mortality=8%, hospital stay=>20days, out-of-pocket cost=$0, survival=30%) across all attribute levels except the general population.

The probability of choosing a centralised service was most affected by higher risk of hospital death (from 83% at 1% risk to 70.2% at 8% risk) and out-of-pocket costs (from 75.9% at $0 to 62.6% at >$5000). This was also observed when disaggregated by residence. The general population switched preference to a localised service if the centralised service cost $1000-$5000 (58%) or >$5000 (62.8%) out-of-pocket.

Conclusions and Significance/Impact: Surgical services for oesophageal cancer are centralised in most parts of Europe but only in a few Australian states. With proven clinical benefits of a centralised service, this study provides the necessary patient perspective indicating that centralised surgical services are acceptable to clinicians and patients regardless of residence in metropolitan or rural/remote areas.

Ind-2249 Learning, But Not Paying: The Effect of Free Health Insurance on its Willingness to Pay

PRESENTER: **Henry Cust**
AUTHORS: Mingxuan Wu, Julienne Noo, Serge Billong, Aurelia Lepine, Iliassou Mfochive-njindam, Tamoufe Ubald, Emilemichel Nitcheu, Eric Defo Tamgno, Sandie Szawlowski

Abstract

Background: In sub-Saharan Africa, where the burden of HIV is disproportionately high among young women, improving access to health services is critical for reducing gender health disparities. Health insurance schemes have been promoted as a means to increase healthcare access, and as recent evidence finds to protect against risky behaviour and HIV infection, particularly for vulnerable populations. However, little is known about how receiving health insurance impacts the willingness of high-risk groups, such as women at high risk of HIV, to pay for such services in the future.

Aim: This study aims to examine the effect of receiving health insurance on the willingness to pay for continued coverage among women at high risk of HIV in Cameroon, a country where HIV prevalence remains significant and free health insurance has been found to effectively prevent HIV.

Methods: This study utilizes data from the POWER randomized controlled trial (RCT) in which health insurance was randomly allocated to women at high risk of HIV and their economic dependents. Data from the endline survey were used to assess the willingness to pay (WTP) for health insurance. WTP was elicited through bidding games with dichotomous choice questions, recorded as the switch point value, the amount stated in an open-ended question, or zero if all bids were rejected. Tobit models were employed to identify the effect of receiving health insurance on the WTP while controlling for socioeconomic determinants at baseline. To adjust for non-compliance, health insurance utilisation was instrumented using treatment assignment, and the local average treatment effect (LATE) was estimated via two-stage least squares (2SLS) models.

Results: The average willingness to pay (WTP) for health insurance was 42,579.40 FCFA (approximately 76.75 USD in 2021), with 89.57% of participants expressing a willingness to pay a non-zero amount. The experience of receiving health insurance did not significantly affect WTP, even when accounting for outliers and non-compliance. To scale up the intervention and uptake to be successful, our findings suggest an additional subsidy of $38 to $52 per capita would be required. Socioeconomic factors linked to higher risk of illness, such as being in transactional sex, younger age, and higher past health expenditures, were found significantly correlated with higher WTP and can be used to stratify targeted subsidies.

Conclusion: We show that whilst willingness to pay for health insurance is insufficient to cover the incurred costs, the amount of subsidy needed is relatively small and could be reduced with careful targeting. Receiving insurance for free for a year did not increase the WTP for health insurance, even after accounting for low compliance in treatment group, which could be due to the remaining barriers to health care and a possible anchoring effect. However, considering the vast benefits of providing health insurance to this population, subsidies represent an effective cost without burdening individuals with high out of pocket expenses.*

Ind-1517 Primary Health Care and Health-Related Quality of Life of Older Patients with One or Multiple Chronic Diseases in China

PRESENTER: **Jiajing Lee**
AUTHOR: Yongjian Guo

Background: China faces a dual challenge of rapid population aging and rising multimorbidity (≥2 chronic conditions). Primary Health Care (PHC) is positioned as the gatekeeper for chronic disease management, yet its effectiveness in improving Health-Related Quality of Life (HRQoL) among older adults with multimorbidity remains understudied.

Objective: This mixed-methods study examined the heterogeneous impact of PHC utilization on HRQoL among older adults (≥60 years) with single chronic disease versus multimorbidity in China, and identified systemic barriers to effective PHC delivery.

Methods: In quantitative study, Data from the Sixth National Health Services Survey (Shandong Province, 2018; *n*=12,938 households) were analyzed using a Simultaneous Equation Model (SEM). Outcomes included self-rated health (SRH), activities of daily living (ADL), depression/anxiety (DA), and physical pain (PP). PHC metrics included supply (doctors/beds per 10,000), accessibility (distance), and utilization (family doctor registration, chronic disease management sites).In qualitative study, semi-structured interviews (n=20 stakeholders) from an integrated multimorbidity management pilot in Sanshui District were coded using the Consolidated Framework for Implementation Research (CFIR).

Results:

1. Multimorbid older adults had significantly poorer HRQoL than single-disease peers: higher moderate/extreme DA (20% vs. <12%, $p<0.001$) and PP (>50% vs. <40%, $p<0.001$).

2. **Heterogeneous PHC effectiveness:** PHC supply/accessibility improved pain/ADL only in the single-disease group. No association was found for multimorbidity. Family doctor registration improved SRH in both groups (single: $\beta=2.929$; multimorbidity: $\beta=2.776$; $p<0.05$) but showed no association with mental health or ADL in multimorbidity. Chronic disease management reduced PP only in older people with multimorbidity ($\beta=0.092$, $p<0.01$).

3. **Systemic barriers:** Fragmented health information systems (lack of automated multimorbidity indicators, poor interoperability), unquantified PHC costs (multidisciplinary coordination, rural outreach), and digital divides hindered integrated care.

Conclusion: PHC utilization differentially impacts HRQoL in older adults with single versus multiple chronic conditions. While family doctors improve physical health perception in both groups, PHC fails to address mental health and functional limitations in multimorbidity. Reforms must prioritize integrated data systems, multimorbidity-focused performance metrics, and resource allocation for underserved populations.

Ind-2298 Health Literacy and the Use of Emergency Rooms. Experiment to Reduce Information Asymmetry By Guiding Patients with a Triage Service.

PRESENTER: **Sebastian Neumann-Böhme**, University of Hamburg
AUTHOR: Jonas Schreyögg

Introduction:
Emergency departments (EDs) are often misused for conditions that could be treated in primary care, contributing to system strain, delays, and increased costs. One contributing factor is **limited health literacy**, which impairs patients' ability to navigate the healthcare system and assess the urgency of symptoms. Patients may over- or undertreat due to uncertainty, especially in situations involving children. Building on theories of **credence goods** and **bounded rationality**, this study investigates whether targeted triage guidance can improve decision-making and reduce inappropriate ED use.

Methods:
A **vignette-based online experiment** was conducted with a representative sample of the German adult population (N=303). Participants were randomized to one of three arms: control, triage, or triage+framing. Each respondent evaluated one of two clinical scenarios describing a child with either urgent or non-urgent gastrointestinal symptoms. The triage tool offered structured advice on whether emergency care was needed; in the framed version, participants also received contextual information on ED overcrowding. Health literacy was measured using the HLS19-Q12 instrument, with particular focus on navigational aspects.

Results:
Participants with **limited navigational health literacy** were significantly more likely to opt for overtreatment in the baseline (control) condition (OR = 2.60, $p = 0.03$). Both interventions **reduced overtreatment**, with odds ratios of 0.39 ($p = 0.046$) and 0.34 ($p = 0.02$), respectively. The **framing intervention** additionally **reduced undertreatment** (OR = 0.21, $p = 0.083$), suggesting increased appropriateness in both directions. Gender and risk aversion were also significant predictors of behavior.

Discussion:
This study provides experimental evidence that **triage guidance tools** can mitigate the effects of low health literacy on emergency care decisions. While health literacy predicts overtreatment, the intervention **closes this gap**, especially among those with poor system knowledge. The vignette method allows for realistic yet controlled assessment of patient decision-making. These findings support the use of scalable, literacy-sensitive interventions to improve care navigation and reduce inappropriate ED use in the general population.

Ind-2571 Development and Validation of the Healthcare Access Barriers Scale: A Measurement Development Study Based on a Population Survey in Shanghai, China

PRESENTER: **Danyang Wei**
AUTHORS: Yusheng Jia, Jingyi Li, Min Hu, Xiaoyu Wang
Background: Access to healthcare remains a pressing global challenge, with significant implications for healthcare experience and health outcomes. Previous studies have predominantly relied on qualitative methods to examine healthcare access barriers, lacking unified theoretical frameworks and quantitative measurement tools. This study developed and validated the Healthcare Access Barriers Scale (HABS) and applied it to assess barriers by residents in Shanghai, China, providing evidence for identifying healthcare needs and designing targeted interventions.

Methods: A cross-sectional survey was conducted among 2,009 Shanghai residents. HABS was developed based on Penchansky and Thomas's Theory of Access and Saurman's modification. Exploratory and confirmatory factor analyses (EFA, CFA) assessed its structure. Reliability and validity were tested using Cronbach's alpha and model fit indices.

Results: Healthcare access barriers were conceptualized based on the theory and model of health services appropriateness， and encompassed six dimensions: unawareness, unavailability, inapproachability, adaptability, unaffordability, and unacceptability. The final 31-item HABS used a five-point Likert scale (1=strongly disagree, 5=strongly agree), with higher scores indicating greater perceived barriers. A total of 2,009 valid responses were collected and analyzed. The HABS demonstrated strong reliability (Cronbach's $\alpha = 0.974$) and a good fit for the six-factor model (CFA: Comparative Fit Index [CFI] = 0.937, Tucker-Lewis Index [TLI] = 0.930, Root Mean Square Error of Approximation [RMSEA] = 0.069). The mean score for access barriers was 3.03 (SD=5.78), with unaffordability scoring the highest (3.26, SD=1.16), followed by unawareness (3.19, SD=1.07), inadaptability (3.13, SD=1.07), unavailability (2.89, SD=1.22), unacceptability (2.87, SD=1.05), and inapproachability (2.84, SD=1.21).

Conclusion: The HABS is a valid and reliable instrument for measuring perceived healthcare access barriers in an urban population, offering a more holistic, process-integrated assessment by capturing obstacles across the full continuum of care – before, during, and after healthcare visits. This unified scale can facilitate systematic barrier assessment, comparison across settings, and identification of target areas for intervention. Future use of HABS may inform policies and programs to improve health service access and equity.

Ind-2691 Preferences for Alternative Kidney Donation Systems: Evidence From Sub-Saharan Africa

PRESENTER: **Maximilian Guigas**
AUTHOR: Jan Priebe

The shortage of donated kidneys remains a critical issue in addressing the needs of end-stage kidney disease patients, particularly in Sub-Saharan Africa, where infrastructural limitations hinder the establishment of deceased organ donation programs. Despite these challenges, progress in kidney transplantation is evident, such as successful operations by local surgeons in Ghana and availability of transplantation services at multiple centers in Nigeria. However, further advancements necessitate robust legal frameworks for transplantation practices in the

region. In the absence of deceased donations, alternative kidney procurement systems are being considered, though many of these proposals raise significant ethical and moral questions. This study aims to investigate preferences for alternative kidney procurement systems among individuals in five Sub-Saharan African countries, focusing on the impact of moral foundations and religious beliefs on support for these systems. The study deployed an online survey targeted at participants from Ghana, Nigeria, Tanzania, Uganda, and Kenya, recruited through Facebook Ads. Participants were randomly assigned to evaluate one of 16 alternative kidney procurement systems, categorized into exchange systems and undirected donation systems. The exchange systems varied by regional scope (national vs. international) and donor incentive (no incentive vs. priority on the waiting list). The undirected systems varied across three dimensions: regional scope, type, and level of incentive (no incentive, priority waiting list, low compensation, high compensation), and payment source (government vs. recipient). We further randomized into two groups, one receiving psychological primes to stimulate individuals into thinking about the role of organs in traditional African beliefs. We provide descriptive statistics to check for group balance and levels of support. To evaluate the impact of different dimensions on participants' support we use multivariate regressions (OLS). Preliminary results indicate that individuals with stronger religious beliefs show lower support for alternative kidney procurement systems, suggesting potential ethical or moral concerns. Additionally, the psychological prime further reduces support for these systems. We also find differences along personality traits (e.g. altruism). This study highlights the complex interplay of ethical, moral, financial and religious factors influencing public support for alternative donation frameworks. By integrating individual moral and religious perspectives, the research contributes to a nuanced understanding of the societal readiness for innovative organ donation methods and informs ongoing discussions on ethical transplantation practices in resource-constrained settings.

Non-Communicable Diseases in Low and Middle Income Countries

MODERATOR: **Likke Putri**,

Ind-600 Exploring the Socio-Economic Toll of Non-Communicable Diseases in Low-Resource Settings: Novel Evidence from Mozambique.

PRESENTER: **Maria Verykiou**, SDA Bocconi University
AUTHORS: Giovanni Putoto, Aleksandra Torbica, Paolo Belardi

Background: Low- and middle-income countries face increasing public health challenges, with non-communicable diseases (NCDs) like diabetes and hypertension becoming increasingly prevalent. However, there is limited data on the socio-economic burden of these conditions in low-resource settings. This study seeks to fill that gap by estimating the economic burden of type 2 diabetes (T2DM) and hypertension (HTN) for patients in selected health facilities across two provinces in Mozambique.

Methods: This is a cost-of-illness cross-sectional study measuring the societal costs of T2DM and HTN in patients enrolled in an integrated disease management program. The costs measured included program implementation costs, direct healthcare, non-healthcare costs, as well as productivity loss at patient level. Primary data was collected through direct interviews with patients attending the program and healthcare personnel involved in delivering the services, while secondary data pertained to the program's cost of implementation.

Findings: The total implementation cost of the program amounted to $1.2M, equivalent to $3.2 per patient visited. Recurrent costs were reported per month per patient across disease groups, location, sex and income group. These averaged $49.8 per month per patient, with direct non-healthcare costs as the main cost driver at 74% of the total recurrent costs. Consistently higher costs across all cost categories were reported by diabetes patients ($62.4), males ($58.5), and patients from the upper-income group ($96.7). Patients from rural locations reported higher direct costs but lower indirect costs than urban patients. The average cost from the patient's perspective incurred by the lowest income group ($44.8) accounted for the majority (71%) of their reported monthly income, while 3% of the sample indicated that the costs incurred for the management of their disease were catastrophic.

Conclusions: The study is the first attempt to measure the socio-economic burden of T2DM and HP in Mozambique. Results offer valuable insight into the disproportionate economic impact of the diseases across income groups, with those living under the poverty line, who represent a significant proportion of the Mozambican population, being most negatively affected. Further research is encouraged to investigate the implications of these diseases for health systems in low-income countries.

Ind-620 Adapting Public Health Economic Models for Low- and Middle-Income Countries: A Case Study on Hypertension Prevention Modelling in Ghana

PRESENTER: **Joseph P Mensah**, University of Sheffield
AUTHORS: Chloe Thomas, Robert Akparibo, Alan Brennan

BACKGROUND: Hypertension is a significant and growing public health issue in low- and middle-income countries (LMICs), including Ghana, where it is a leading cause of cardiovascular disease. The prevalence of severe hypertension among adults aged 18-69 in Ghana is 11.8%, posing substantial health and economic burdens. Public health economic models, typically developed in high-income settings, are valuable tools for assessing the costs, health benefits, and cost-effectiveness of interventions for conditions like hypertension. However, adapting these models for LMICs requires careful consideration of context-specific challenges and data limitations. This study aims to adapt an existing public health economic model to evaluate hypertension prevention interventions in Ghana, and to highlight the methodological and

data challenges encountered when adapting models to LMIC settings.

METHODS: We selected the School for Public Health Research (SPHR) diabetes prevention model, a microsimulation model developed in the UK which has a conceptual framework suitable for modification, and adapted it to incorporate demographic, epidemiological, and health system characteristics specific to Ghana. Using data from the Ghana WHO Study on global AGEing and adult health (SAGE) longitudinal study, we developed multistate Markov models that include key risk factors such as BMI, alcohol consumption, and salt intake, to estimate transition probabilities for the individual lifetime simulation of hypertension progression and associated cardiovascular outcomes. The model evaluates intervention impact on hypertension prevalence, cardiovascular events, healthcare cost savings, and cost-effectiveness, measured in cost per Disability-Adjusted Life Years (DALYs) averted. Cardiovascular events were estimated from the WHO CVD risk chart for Western sub-Saharan Africa. Country-specific data on disease incidence, mortality, and intervention effects were derived from the Global Burden of Disease database, supplemented by literature and expert consultation. Probabilistic sensitivity and scenario analyses were conducted to assess robustness to variations in local data inputs.

RESULTS: Base-case results estimate an average per-person cost of $4,426.00 (95% CI: 2125.06, 7660.22) associated with hypertension over a lifetime horizon, using a 3% annual discount rate, corresponding with an average of 3.51 (95% CI: 3.314, 3.733) DALYs lost due to premature death or disability. The model simulation projected a total 1099 (95% CI: 857, 1326) CVD-related deaths per 10,000, with 325 stroke cases (95% CI: 293, 359), 522 MI cases (95% CI: 484, 555), and 759 heart failures (95% CI: 506, 990) across the lifetime of the population. Behavioural interventions targeting salt and alcohol consumption have the potential to avert disability-adjusted life years (DALYs) and reduce healthcare costs. Key adaptation challenges included limited longitudinal data, missing values, and potential bias due to reliance on observational or self-reported data.

CONCLUSION: In conclusion, this study demonstrates that adapted health economic models can inform policy decisions on hypertension prevention in LMICs. However, it also highlights the complexities and data constraints involved in such adaptations. Our findings advocate for the development of tailored health economic models to support evidence-based health policy and resource allocation in Ghana and similar LMICs. Future endeavours should focus on improving data availability and quality and explore health economic model adaptations, to enhance the robustness of health economic evaluations in diverse low-income settings.

Ind-1752 Efficient Pathways for Reducing NCD Mortality and Achieving SDG 3.4 in the South-East Asia Region

PRESENTER: **David Watkins**, University of Washington
AUTHORS: Cherian Varghese, Pradeep Joshi, Nalika Gunawardena

Most countries, including in the WHO's South-East Asia Region (SEARO), are off track for Sustainable Development Goal (SDG) target 3.4, which includes a one-third reduction in noncommunicable disease (NCD) mortality by 2030. The economic and health system impacts of Covid-19 has made achieving this target more challenging. This study sought to identify efficient interventions and scale-up options for SEARO countries to get back on track for SDG 3.4.

We built our analysis around a dynamic population model developed for the NCD Countdown 2030 Collaboration, with some notable improvements. In brief, it used demographic and epidemiological modeling approaches to project NCD-specific death and case counts and total population counts over time using WHO and UN Population Division estimates. We modeled the mortality effects and costs of 10 primary healthcare (PHC) interventions, 9 secondary/tertiary care interventions, and 6 intersectoral policies using published effectiveness evidence, WHO's "Best Buys," and a costing model adapted from the Disease Control Priorities Project. We explored alternative combinations of interventions under two different scale-up assumptions: a "realistic" scenario (2% annual increase in coverage) and an "ambitious" scenario (4% annual increase in coverage). The time horizon was through 2030, the end of the SDG period, and results were not discounted. Analyses were done separately in each of the 11 SEARO countries then aggregated.

With no additional action, premature NCD death rates in the SEARO region are expected to remain relatively constant through 2030. An approach using the 10 PHC interventions could reduce NCD mortality by 8.4% (realistic scenario) to 18% (ambitious scenario) by 2030, i.e., a quarter or just over one-half (respectively) of the reduction needed to achieve the target. Within PHC, aspirin for heart attack, treatment of chronic heart failure, and primary prevention of cardiovascular disease (CVD) would all cost under US$ 500 per disability-adjusted life-year (DALY) averted. Primary and secondary prevention of cardiovascular disease (CVD) would generate the greatest overall mortality impact; diabetes treatment would incur the greatest cost. Scale-up would require an additional US$ 52 billion (realistic) or US$ 100 billion (ambitious) cumulatively by 2030. Adding 9 secondary/tertiary care interventions to the PHC interventions would reduce NCD mortality by 12% (realistic) or 18% (ambitious) but add 30-40% to the PHC costs. Within secondary/tertiary care, treatment of acute heart failure, cervical cancer, and breast cancer would all cost under US$ 500 per DALY averted. Adding 6 intersectoral policies to the 19 clinical interventions would reduce NCD mortality by 18% (realistic) or 32% (ambitious), the latter nearly reaching the 3.4 target. These policies would incur modest additional costs, since they are mostly fiscal and regulatory measures (e.g., tobacco taxes, trans fat bans).

While it will be challenging to achieve SDG 3.4, countries that choose to prioritize and scale up NCD interventions can make meaningful progress on NCD mortality and Universal Health Coverage. We identified several highly cost-effective interventions that would be feasible to implement in any health system context. We also developed a web-based tool that can help support country-level prioritization and planning (URL available on request).

Ind-2288 Addressing the Non-communicable Disease Burden in South Asia: Priority Setting through Cost-effectiveness Analysis of Essential NCD Interventions

PRESENTER: **Krishna Kumar Aryal**
AUTHORS: Tarun Shankar Choudhary, Kjell Arne Johansson

Background: Non-communicable diseases (NCDs) contribute 53% of DALYs (range: 38% Afghanistan to 72% Sri Lanka) in South Asia. Reducing the burden of NCDs requires improving the universal health coverage (UHC) service coverage index, and countries in the region lie between 41 (Afghanistan) and 67 (Sri Lanka) while the global average is 68 out of 100. Reaching the 2030 SDG 3.8.1 target will require additional efforts in expansion of essential services including that of NCDs and reducing the burden of NCDs will require focusing on interventions that are highly cost-effective. We aim to assess the health impact of the NCD interventions by 2033 along with the budget impact and opportunity cost. We further aim to compare the results with a more cost-effective package. **Method:** We used the database built in the FairChoices disease control priorities (DCP) analytics tool developed by the University of Bergen in collaboration with University of Washington and analyzed a set of major interventions recommended by DCP3 and WHO UHC compendium. The input data used for the analysis are that of burden of disease, demography, unit cost of interventions and incremental cost-effectiveness ratio sourced in the database from relevant global sources. For the set of NCD interventions we used the most recent baseline coverage and then estimated 100% coverage by 2033 and analyzed cost-effectiveness of the NCD package. The outcome indicators used are lives saved and health life years (HLYs) gained. We present a preliminary analysis for Nepal and will further refine this analysis for all 8 countries in World Bank region of South Asia with additional interventions and updated data where available subsequently. **Results:** The current health expenditure (CHE) of 58$/capita will have to be increased by $630/capita in 10 years to achieve 100% coverage of the selected NCD interventions. This will result in 333,739 lives saved and 8.5 million HLYs gained but at an opportunity cost of 69,300 lives that could be saved from using a most cost-effective package. With a more cost-effective package by limiting incremental cost-effectiveness ratio threshold to 1,000$/HLY that includes the most essential NCD interventions as well as interventions for communicable diseases and maternal and child health, we will save 273,000 lives and gain 6.8 million HLYs at just an additional cost of 38$/capita. **Conclusion:** The required per capita cost of service coverage expansion to 100% is way above the CHE per capita but will result in only a slightly higher health gains and with an opportunity cost compared to a cost-effective package still yielding similar health gains. And the results for other countries in the region are expected to be similar. This analysis will help policymakers of the countries in the region to consider using a systematic priority setting approach to select the most essential NCD interventions to achieve maximum health benefits within limited fiscal space. **Keywords:** burden of disease, essential NCD interventions, health life years, lives saved, south Asia, universal health coverage

Ind-2491 Cost of Treatment for Diabetes Mellitus with Heart Complications: Indonesian National Health Insurance Participants in 2015-2021

PRESENTER: **Pujiyanto Pujiyanto**

In 2023 BPJS Health will spend more than IDR 23 trillion to cover heart disease. One of the risk factors for heart disease is diabetes mellitus (DM). DM can cause thickening of the walls of blood vessels, which can inhibit blood flow. Therefore, diabetesee are at higher risk of developing heart disease. To reduce the pressure of increasing costs for heart treatment, efforts are needed to reduce the rate of diabetesee who suffer from heart disease complications. To increase awareness of Indonesian National Health Insurance (NHI/JKN) participants regarding the magnitude of economic losses due to the costs of treating DM and heart complications, it is necessary to study the increase in DM treatment costs if they suffer from heart complications. The research was conducted using BPJS Health (the name of Indonesian National Health Insurance/NHI carrier) sample data which is panel data on health service utilization for NHI/JKN participants starting in 2015 and every year the number of JKN participants in the sample is increased. Since 2015, there have been NHI/JKN participants suffering from DM, even until 2021, but along the way there are also DM sufferers who experience complications of heart disease (as secondary diagnosis). The total sample using secondary hospital services (outpatient and/or inpatient) includes 47,118 individuals suffering from DM and 33,576 individuals suffering from DM with heart complications. In the 7 year observation period from 2015-2021 the average duration of DM treatment was 3.22 years (SD = 1.64) and DM with heart complication was 3.19 years (SD = 1.64). The average annual cost of hospital treatment (outpatient and inpatient) for DM patients is IDR 1,814,385 (SD = 3,409,819) and for DM with heart complication patients is IDR 11,304,138 (SD = 22,647,610). Multivariate analysis results prove that total medical treatment costs per year are influenced by age, gender, heart complications, duration of treatment, treatment class, and area of residence. Treatment costs for male patients and those living outside Java Island are lower compared to women and those living in Java Island. Interestingly, we found that the older the patient and the longer the duration of treatment, the lower the cost of medical treatment. And the dominant factor that influences the total cost of treating DM patients per year is the occurrence of heart complications. The cost of treating DM patients with heart complications per year is IDR 9,450,259 more expensive than those without heart complications. Research results prove that heart complication among diabetesee cause an increase of more than IDR 9 million in medical costs per year. Therefore, it is necessary to promote every effort to prevent or at least slow down the occurrence of heart complications among diabetesee in order to save on the national health insurance funds.

Ind-1358 Understanding the Underperformance of Minority Patient Outcomes at Minority-Serving Hospitals

PRESENTER: **Shane Murphy**, University of Connecticut
AUTHOR: Angela Saquinaula

ABSTRACT With a forecasted increase in ethnic and racial diversity in the United states, hospitals will see a more diverse mix of patients. As a result, addressing the lack of health equity across race and ethnicity is critical for future healthcare reform. The purpose of this study was to identify how the role of patient ethnicity/race on inpatient mortality varies depending on changes in the racial/ethnic composition of the hospital the patient is admitted to and the racial/ethnic makeup of the neighborhood around the hospital. Using inpatient data from hospitals in New York between the years 2005-2015 and patient-level data adjusting for patient morbidity severity, we consider six conditions: acute myocardial infarction, cerebral thrombosis/embolism, pneumonia, surgical complications, intestinal obstruction, and newborn care. Controlling for a number of key variables including patient illness severity, patient insurance type, and hospital specific variation, we find evidence that Hispanic patients had worse outcomes across two of the six conditions at hospitals that serve a higher proportion of Hispanic patients. In addition, for acute myocardial infarction, Black patients had worse outcomes at hospitals that serve predominantly Black patients, but had higher rates of survival for the other five conditions at hospitals that serve a higher proportion of Hispanic patients and are located in areas that have a large Black population. This relationship is not present in economic variables; for example Medicaid patients did not see significantly different outcomes at hospitals with different patient-ethnicity-profiles. This was robust to various measures of risk-adjustment, suggesting that the difference was not due to severity of the patient. It is also robust to adjusting for multiple-hypothesis testing. An important reason this is policy relevant is because it indicates that outcome disparities may be greater in facilities most likely to treat non-white patients.

Ind-1371 The Relationship between Disease and Income Inequality: National Level Analysis Using Linked Data from New Zealand

PRESENTER: **Philip Clarke**
AUTHORS: Finn Sigglekow, Tony Blakely, Sophie Cole, Laxman Bablani

Abstract

Background: Considerable interest exists regarding the extent to which income inequalities impact both population and individual health. While it is acknowledged that patterns of disease can also affect income inequality, few attempts have been made to quantify the overall relationship at a national level.

Aims: This study aims to quantify the degree of income loss associated with 12 disease categories (cancer, cardiovascular, endocrine, gastrointestinal, genitourinary, infectious, injury, mental health, musculoskeletal, respiratory, skin, reproductive, and sensory) and to estimate their impact on income inequality at the country level.

Methods: This analysis utilized individual-level data from New Zealand's Integrated Data Infrastructure (IDI), which links whole-population health and administrative tax datasets from government agencies via a population-level spine. The study included 22.5 million person-years of data (collected from 2007 to 2016), combining administrative tax records with hospitalisation data, cancer and diabetes registries, and mental health datasets. Disease-specific income losses were estimated using panel fixed-effects regression. Simulations assessed the within-person marginal effects of income changes associated with being diagnosed with, dying from, or being otherwise affected by each disease (compared to no disease). The regressivity of income loss by disease was quantified using the Reynolds-Smolensky Index.

Results: Income losses associated with having one or more diseases were regressive, ranging from a 7.5% loss in the most deprived quintile to 2.3% in the least deprived quintile. Simulations indicated that the absence of disease was associated with a 4.43% reduction in the Gini coefficient for personal (i.e. individual) income, from 0.549 to 0.525. Mental health disorders accounted for the largest contribution to the gap between actual and counterfactual income inequality (35%), followed by cardiovascular disease and musculoskeletal disorders (both 14%).

Discussion: These findings provide a national-level measure of the association between disease and income inequality, as well as the extent to which sickness benefits mitigate the economic impact of major health conditions. The feasibility of applying similar methodologies in other countries which have integrated administrative data will also be discussed.

Ind-255 The Impact of Economic Development on Distribution of Non-communicable Diseases?A National Longitudinal Data Analysis between 1991-2020 in China

PRESENTER: **Xuemei Zhang**
AUTHORS: Tianxin Pan, Barbara McPake

Background

Non-communicable diseases (NCDs) are major contributors to health burden globally, accounting for about 74% of global deaths each year. Notably, 77% of all NCD deaths occur in low-and middle-income countries (LMICs). As countries undergo economic transition from low income to upper-middle income and further, evidence indicate that the burden of NCD shifts from the rich to the poor and exacerbates health inequalities. This reversal, influenced by complex factors such as childhood socio-economic status (SES), environmental exposures, and changing behavioural patterns, underscores the urgent need to explore how economic development impacts health disparities. If NCDs become increasingly a problem for the poor, it is crucial to deconstruct this reversal by gender and social group and analyse its drivers to better protect disadvantaged groups, from bearing major NCD burdens in the future. However, existing evidence has largely relied on cross-sectional analyses across countries, with limited analysis on the dynamic trends at the subnational level within an individual country over time by using longitudinal data. China, with its significant burden of NCDs — which accounted for 90.99% of total deaths and 86.74% of disability-adjusted life years (DALYs) in 2021 — along with its rapid economic growth, large population size, and availability of large data sets, provides promising setting to explore these dynamics and address existing gaps.

Aim

This study aims to investigate how economic development influences the distribution and burden of NCDs across different populations in China, focusing on temporal trends and demographic variations.

Methods Utilizing 16 waves longitudinal data from the China Health and Nutrition Survey (CHNS, 1991-2015) and the China Family Panel Studies (CFPS, 2010-2020), we investigate the prevalence of the 87 types of NCDs across different SES groups (proxied by education levels, income, and household expenditure), gender and age. Multivariable logistic regression and Blinder-Oaxaca decomposition models are fitted to investigate the relationship and examine the possible contributors for the relationship. We further investigate the impacts of socio-economic status mobility on the development of NCD in different populations.

Results

Our final sample size is between 10,565 (1991) and 32,522 (2020) over waves. The NCD and education level analysis results shows that the prevalence of a list of NCDs in the overall population increased from 3.52% (1991) to 13.72% (2020). The association between SES and NCDs has shifted from positive to negative over time, shifting earlier among women compared to men. For both men and women, the difference in prevalence between high and low SES groups was mostly explained by the socio-demographic and risk behaviors variables included in the models: age, being overweight, employment status, residency, and region. However, the contribution size of these factors and consistency was different by gender and changed over time.

Conclusions

China has experienced a reversal in the education level-NCD gradient which occurred first among women. The explanations of education differences are differed by gender. Policymakers should consider these shifting patterns in health inequalities to develop effective strategies. Globally, the common drivers of shifting NCD burdens should be identified and strategies that target those drivers should be developed.

Ind-1463 Does Chronic Illness Lead to Early Retirement? Insights from the Longitudinal Ageing Study of India

PRESENTER: **Amit Kumar Goyal**
AUTHOR: Shamrin Akhtar

Background: Chronic illness profoundly impacts older adults, leading to early retirement, which burdens society through productivity loss and increased healthcare costs. Employees with chronic health disorders reported reduced productivity and more absenteeism, resulting in significant economic losses for firms. Furthermore, chronic diseases can cause fatigue, pain, and cognitive impairments, all of which can interfere with concentration and focus, lowering work performance. Individuals with chronic diseases have lower motivation and involvement in their work duties.

Objective: This study aims to investigate the association between chronic illness and early retirement among Indian older adults aged 45-64 years. It focuses on identifying which chronic conditions are most significantly associated with early retirement and explores the role of sociodemographic factors in this relationship.

Data: The study utilizes cross-sectional data from the Longitudinal Ageing Study in India (LASI), Wave 1, conducted in 2017-2018. The analysis includes 5,221 early retirees and 27,246 non-retirees aged 45-64 who provided self-reported health and retirement status data.

Methods: Descriptive statistics were used to compare sociodemographic characteristics and chronic disease prevalence between early retirees and non-retirees. Chi-square tests assessed the significance of differences between groups. Multivariate logistic regression models were employed to estimate the odds of early retirement associated with various chronic conditions and sociodemographic factors, adjusting for potential confounders.

Results: 17% of the older adults aged 45-64 retire early from economic activities. The analysis revealed that early retirees had a higher prevalence of chronic diseases such as hypertension (35.43% vs. 19.79%), diabetes (17.75% vs. 9.11%), chronic lung disease (8.22% vs. 3.62%), and stroke (3.94% vs. 0.75%) compared to non-retirees. The odds of early retirement increased with the number of chronic diseases: individuals with two chronic diseases had 2.82 times higher odds (95% CI: 2.09-3.80), and those with three or more had 2.83 times higher odds (95% CI: 1.79-4.45) of retiring early. Additionally, being female, widowed, or living in urban areas was associated with higher odds of early retirement.

Conclusion: Chronic diseases significantly contribute to early retirement among older Indian adults. The study highlights the need for workplace interventions and policies that support employees with chronic conditions to extend their work life and improve their quality of life.

Ind-2194 Effects of Health Care System Consolidation on Inpatient Care Quality: Evidence from a U.S. Military Health System Study.

PRESENTER: **Seungbeen Ghim**, "Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc."
AUTHORS: Patrick Richard, Jangho Yoon, Ara Yoon, Nilam Gibson, Daniel Gedeon

Aim: The 2017 National Defense Authorization Act heralded the modernization of the U.S. Military Health System (MHS), transferring

administrative authority over all military treatment facilities (MTFs) from military branches to a single entity under the Defense Health Agency (DHA) in three implementation phases. This study examined the effect of the system consolidation under the DHA on the quality of care** among hospital inpatients.

Methods: Quarterly inpatient event data were retrieved from the 2016-2023 military healthcare claims data repository (N=56). We excluded 16 direct care hospitals outside the US and three hospitals with missing transition dates. We created a propensity score-match sample using multivariate logistic regression that matched transitioned MTFs to the 100-nearest neighbors for two types of controls: 1) not-yet-transitioned MTFs (direct care) and 2) private care hospitals (purchased care) within a 40-mile radius of the transitioned facility. We performed a staggered difference-in-difference analysis on the matched facilities. Quality of care measures included length of stay, past 30-day and 60-day mortality, and past 30-day unplanned readmissions. Because we could not observe the characteristics of private care hospitals, we additionally stratified analyses by the type of MHS beneficiary (active duty service members [ADSM]; ADSM dependents; military retirees; and military retiree and survivor dependents) to account for any potential heterogeneity among hospitals.

Results: Across all implementation phases and beneficiary types, the MHS's administrative consolidation under a single entity did not significantly alter the quality of care trends in MTFs. However, trends changed within a few waves and for a few beneficiary types for mortality and unplanned readmissions. Transferring administrative authority to the DHA in Phase-1 was associated with 1.9% ($p<0.001$) and 2.1% ($p=0.01$) decreases in past 30- and 60-day mortality rates, respectively, among ADSM. On the other hand, the Phase-1 implementation was associated with an increase in the past 30-day mortality by 1.3% ($p=0.03$) among military retirees. The Phase-0 implementation was associated with a slight increase in the past 60-day mortality by 5.5% ($p=0.05$) among military retirees and survivor dependents. However, it was associated with a decrease in past 30-day unplanned readmissions by 3.0% among ADSM.

Conclusion: Modernizing the MHS through administrative consolidation of the system under a single entity improved the quality of care metrics for ADSM but worsened the quality of care for military retirees and their dependents. Future research should systematically investigate implementation phases that may contribute the most to worsened care (e.g., comorbidity identification and complication management).

Ind-2471 What do Patients Value in Healthcare Services? Examining the Link Between Clinical Competence and Patient Satisfaction in India

PRESENTER: **Maria Cellina Wijaya**, University of Ciputra
AUTHORS: Anuska Kalita, Kirti Gupta, Nachiket Mor, Annie Haakenstad, Arpita Chakraborty, Liana Woskie, Ms. Winnie Yip, Maria Cellina Wijaya

Patient satisfaction is increasingly used as a metric for healthcare quality in many systems, including India's. However, health economics literature highlights the challenges of information asymmetry and agency problems between patients and providers that might influence patient satisfaction. Empirical evidence on whether patients can evaluate and respond to better quality care remains inconclusive. While India has seen research on patient satisfaction and clinical effectiveness independently, few studies have examined their interrelationship or how patients' expectations shape provider behavior. This study addresses these gaps with three key questions: (1) Is there an association between clinical competence of providers and patient satisfaction? (2) What aspects of care determine patient demand and satisfaction? (3) How do providers respond to patient expectations? The analysis draws on the India Health Systems Reform Project, using data from Odisha, an under-resourced Indian state. Four linked surveys informed this study: 550 clinical vignette interviews to assess provider competence, surveys with 794 public-sector providers and 685 private-sector practitioners to examine provider characteristics, and 978 patient exit interviews capturing patient experiences. Descriptive analysis and regression models were used to explore associations between variables of interest. For research question (1), we found no significant association between clinical competence and patient satisfaction. Patients often rated care quality positively, even when providers demonstrated poor clinical competence in diagnosing and treating common illnesses. For research question (2), patient satisfaction was predominantly influenced by non-clinical factors. Patients were more satisfied with private-sector providers, those requiring longer travel, providers spending more time during consultations, and those prescribing branded over generic drugs. Satisfaction followed an inverted-U pattern, with the number of prescribed drugs, peaking at an average of 2.2 drugs per visit before declining. This suggests patients perceive an "ideal" number of drugs during outpatient visits, regardless of the clinical appropriateness of prescriptions. For research question (3), patient expectations significantly shaped provider behavior. Providers prescribed an average of 2.4 drugs per consultation, aligning with patient expectations. Notably, price was not linked to provider competence, but there was a negative association between competence and consultation time, with less competent providers spending more time with patients. These findings suggest that patients often favor irrational care and less competent providers who meet their expectations for time and prescriptions. While patient satisfaction is crucial for care utilization and trust in the health system, it may not reliably reflect clinical quality or value. This study highlights the complexities of using patient satisfaction as a quality metric, particularly in low-resource settings with high information asymmetries. Addressing gaps between patient expectations and clinical quality will require systemic efforts to educate patients, align provider behavior, and ensure that satisfaction metrics incentivize high-value care.

Ind-2748 A New Healthy Ageing Score: How Chronic Diseases Influence Outcomes among Older Adults in India

PRESENTER: **Shivani Kumaria**
AUTHOR: Ramna Thakur

ABSTRACT

Introduction:

Recent times have seen a dramatic increase in life expectancy, where people all over the world can expect to live way beyond the age of 60. However, merely increasing years to life is not sufficient. Emphasis should also be put towards living a healthy life specially in older ages. This

argument has led to the concept of Healthy Ageing. Over the years, various definitions of healthy ageing have emerged and one such definition is given by World Health Organization (WHO) which focuses on functionality of older adults rather than focusing only on the presence or absence of diseases. Keeping this viewpoint, this paper has made an index of healthy ageing by taking various dimensions of health namely, functional ability, intrinsic capacity and social participation of people who are above the age of 60. These factors are recognized as key contributors to an individual's overall health and functional ability, regardless of the presence or absence of diseases. Furthermore, this paper examines how specific chronic diseases impact our index, offering insights into their influence on functional capacity and overall well-being in older adults.

Method:

We have used data from the Longitudinal Ageing Study in India (LASI), wave 1, with which we created the index using the composite index methodology. The index was developed using 49 variables divided into three domains mentioned above, and the final scores were divided into three categories, with the lower category indicating poorer outcomes. The Cronbach's alpha was 0.88, indicating high internal reliability. Furthermore, we used multinomial logistic regression (with the middle category as reference) to examine how 10 chronic conditions, including hypertension and diabetes, influence the likelihood of achieving different levels of healthy ageing. The analysis controlled for socio-economic factors such as sex, religion, caste, education, working status, and place of residence.

Results:

Chronic conditions such as Chronic Obstructive Pulmonary Disease (COPD), stroke, bone diseases, and angina significantly increase the odds of being in category 1 (lowest healthy ageing scores), with stroke (Coefficient = 1.19, $p < 0.001$) and psychological disorders (Coefficient = 0.79, $p < 0.001$) having the strongest impacts. Education reduces the odds of being in category 1, with higher educational attainment showing a stronger protective effect. For category 3 (highest healthy ageing scores), diabetes, hypertension, and COPD significantly decrease the odds of scoring higher, while urban residence (Coefficient = 0.61, $p < 0.001$), higher education, and being currently working increase the likelihood. Females are more likely to score higher.

Discussion and Conclusion:

Chronic conditions like psychological disorders, hypertension, and COPD decrease healthy ageing scores, while higher education, urban residence, and being female enhance scores. These findings highlight the critical role of socio-demographic and health factors, offering insights for future research by focusing on diseases that significantly impact healthy ageing outcomes and exploring interventions to mitigate their effects.

Ind-2839 Geographic Disparities in Stroke Mortality: Examining Rural-Urban Trends and the Impact of the Stroke Belt

PRESENTER: **Mengyuan Cheng**
AUTHORS: Nasim Ferdows, Alireza Baghbanferdows, Amit Kumar

Stroke mortality remains a significant public health challenge in the United States, with persistent geographic disparities. While previous studies have documented the rural-urban gap in stroke outcomes, limited attention has been paid to the role of the "stroke belt," a region with historically high stroke mortality rates. Understanding how these disparities evolve over time and interact with regional factors provides important insights into health equity and resource allocation. This study investigates trends in age-adjusted stroke mortality, focusing on differences between rural and urban areas, and examining how these trends vary within and outside the stroke belt region. We conducted a cross-sectional analysis using data from the Centers for Disease Control and Prevention (CDC)-WONDER database from 1999 to 2022. This dataset includes county-level mortality data across the United States. For this analysis, we extracted stroke mortality rates for individuals aged 55 and older. Stroke mortality was identified using International Classification of Diseases, Tenth Revision (ICD-10) codes. County-level socioeconomic data, including per capita income and unemployment rates, were obtained from the Area Health Resources File (AHRF). Counties were classified as rural or urban based on the U.S. Department of Agriculture Rural-Urban Continuum Codes, and further categorized as being within or outside the stroke belt region. Age-adjusted stroke mortality rates per 100,000 population were calculated using the 2000 U.S. standard population. Analytical techniques included weighted regression models with county fixed effects to examine trends and disparities, adjusted for county-level socioeconomic characteristics. Nationally, stroke mortality rates declined substantially between 1999 and 2022. However, the rural-urban gap widened over time. In 2022, stroke mortality in the rural stroke belt remained notably higher compared to other regions, with rates approximating those of urban non-stroke belt areas in the early 2000s (around 40–45 deaths per 100,000 population). Similarly, rural non-stroke belt areas in 2014 had stroke mortality rates comparable to those observed in urban stroke belt areas nearly a decade earlier. Urban non-stroke belt counties exhibited the fastest declines, maintaining the lowest mortality rates throughout the study period. Adjusting for socioeconomic characteristics partially narrowed these disparities but significant gaps persisted, particularly in rural stroke belt areas. While stroke mortality rates have declined nationwide, disparities remain stark, with rural stroke belt counties lagging significantly. The observed trends suggest that rural areas, particularly within the stroke belt, are on a slower trajectory of improvement, maintaining mortality rates similar to urban non-stroke belt areas from 10–15 years prior. These findings underscore the need for targeted policy interventions to address geographic inequities in stroke prevention, acute care, and rehabilitation services. Strengthening healthcare infrastructure and access in rural and stroke belt regions is crucial to achieving equitable health outcomes.

Ind-3 Quantifying the Impact of Incorporating Hepatitis C Virus Transmissions in Indian Punjab for Model-Based Cost-Effectiveness Analyses of Treatment

PRESENTER: **Soham Das**
AUTHOR: Varun Ramamohan

Introduction:

Hepatitis C virus (HCV) infection in the state of Punjab in India is a major health economic concern due to its high prevalence and its sizeable impact on liver-related morbidities and mortality. In 2016, highly efficacious directly-acting antivirals (DAAs) were brought under price control to boost treatment uptake. Model-based cost-effectiveness studies of HCV treatment using DAAs in the Indian context do not consider disease transmissions. Thus, quantifying the underestimation of the cost-effectiveness of treatment can help understand the appropriateness of excluding transmissions in models assessing HCV treatment decisions. In this study, we estimate the underestimation of health and cost outcomes, and cost-effectiveness of DAA-based HCV treatment due to not incorporating disease transmission in model-based analyses.

Methodology:

An agent-based simulation model for HCV transmission was developed for a dynamic cohort and coupled with a previously published disease progression discrete-time Markov chain. Treatment strategies stratified by uptake rates (10%, 30%, 50%, 70%, 90% and 95%) were tested on this model using two scenarios- one with transmissions incorporated (WT* scenario) and the other with transmissions neglected (WoT scenario). Lifetime quality-adjusted life years (QALYs) and costs were estimated using a payer's perspective. Net monetary benefits were calculated as a measure of cost-effectiveness. For either scenario, the base case was the 10% uptake rate. Cost heads included disease complications and symptoms management costs for all infected patients and DAA treatment costs for treated patients. Disease complications and symptoms management cost-related data were obtained from our clinical collaborators in Dayanand Medical College in Punjab. All other modelling input data were obtained from the literature. For assessing cost-effectiveness, outcomes were annually discounted at 3|% and the cost-effectiveness threshold was taken as INR 341901. A theoretical framework was developed for deriving analytical results to study the relation between transmission dynamics, treatment uptake rates and underestimation of treatment benefits.

Results:

We quantified underestimation of the benefits of stepping up HCV treatment using three parameters: (1) ratio of incremental per-capita cost reduction for the WT scenario to the WoT scenario (Cost-WT/Cost_WoT) (2) ratio of contribution of QALYs (in monetary values) in the NMB for the WT scenario to the WoT scenario (QALY_WT/QALY_WoT) (3) ratio of NMBs for the WT scenario to the WoT scenario (NMB_WT/NMB_WoT). As the uptake rate increases from 30% to 90%, the Cost_WT/Cost_WoT ratio decreases from 3.22 to 2.03, the QALY_WT/QALY_WoT ratio decreases from 2 to 1.06 and the NMB_WT/NMB_WoT ratio decreases from 2.09 to 1.16. Analytical results showed similar trends- neglecting transmissions led to underestimation of QALY gains and cost savings achieved by increasing treatment uptake, but the scale of underestimation decreased with increase in treatment uptake.

Conclusion

Both simulation and analytical results demonstrate underestimation of health and cost benefits, and thus of net monetary benefits as treatment uptake increases. The underestimation decreases as uptake rates increase. As treatment uptake rates are low in Indian Punjab (<30%), hence our study shows that the incorporation of HCV transmissions in models assessing outcomes of HCV treatment becomes important for decision making regarding reimbursement of treatment.

Ind-375 Cost-Effectiveness of Bubble Continuous Positive Airway Pressure in Treating Severe Pneumonia and Hypoxaemia in Under-Five Children in Ethiopia

PRESENTER: **Firew Bobo**
AUTHORS: Abdi Gari, Peter Berman, Mirkuzie Woldie, Mohammod Chisti, Tsinuel Girma, Mideksa Adugna Koricho, Meseret Gebre, Girmaye Dinsa

Background: Pneumonia is preventable and treatable, yet it remains the leading infectious cause of illness and death among under-five children. Bubble continuous positive airway pressure (bCPAP) offers a promising treatment option for oxygen therapy when combined with appropriate antibiotics and other supportive care. However, the cost-effectiveness of bCPAP in resource-limited settings such as Ethiopia is not documented. We aimed to evaluate the cost-effectiveness of bCPAP compared to low-flow oxygen therapy in treating severe pneumonia and hypoxaemia in children under-five in Ethiopia. **Methods:** We developed a decision-analytical model to determine the cost-effectiveness of a locally made bCPAP compared with the standard of care (WHO-recommended low-flow oxygen therapy) in general hospitals. We adopted a restricted societal perspective, which includes all direct medical costs regardless of the payer. Effectiveness was measured as the number of child deaths and DALYs averted. Cost data were extracted from published literature, expert opinion, and local markets. The incremental cost-

effectiveness ratio (ICER) was calculated and evaluated against the willingness-to-pay (WTP) thresholds set at multiples (0.34, 1, and 3) of Ethiopia's GDP per capita, which was $856 in 2022. Sensitivity analyses were performed to test the robustness of the results. **Results**: For every 10,000 children with severe pneumonia and hypoxaemia, providing oxygen using locally made bCPAP will save an additional 31 children compared to the low-flow oxygen therapy. A locally made bCPAP has an ICER of 139.5 USD per DALY averted. These results were robust in the sensitivity analysis performed, showing a 100% probability of being cost-effective at one times the GDP per capita of Ethiopia. **Conclusion**: A locally made bCPAP is a highly cost-effective intervention for treating severe pneumonia and hypoxaemia in under-five children in Ethiopian general hospitals. **Keywords:** Cost-effectiveness, bubble Continuous Positive Airway Pressure, bCPAP, severe pneumonia, hypoxaemia, Ethiopia**

Ind-728 A Cost-Effectiveness Analysis of Performance-Based Financing in Jimma Zone, Ethiopia

PRESENTER: **Carmen Schakel**
AUTHORS: Maarten Oranje, Kaleb Melaku Woldemariam

BACKGROUND

Performance-based financing (PBF) is a provider payment mechanism that has been applied across many sub-Saharan African (SSA) countries. The approach promotes strategic purchasing and reimburses health facilities for the provision and quality of priority health services. Evidence of the cost-effectiveness of PBF still remains limited, with full economic evaluations having only been conducted in a handful of countries including Zambia, Zimbabwe, and Nigeria. This study aims to add to this evidence by evaluating the cost-effectiveness of implementing PBF in Jimma Zone, Ethiopia. The cost-effectiveness of PBF is assessed through a comparison with status-quo financing.

PBF was initially piloted in Ethiopia in 2015 and first introduced in Jimma Zone in April 2019 (in 13 districts). Based on promising initial results, the approach was then expanded to all 521 health posts, 121 health centres and 7 hospitals of the 21 districts of the Jimma zone in 2021. The primary aim was to improve service delivery through increased utilization and improved quality of health services. Other program aims were to strengthen local governance of service delivery and improve the quality of data for better decision-making by facilities and local health authorities.

METHODS

A cost-effectiveness analysis (CEA) was conducted to measure the effects of PBF compared to status-quo financing on health service provision using a health system perspective. The study included a sample of 14 health centers implementing PBF in Jimma zone and 10 health centers implementing status-quo financing in a control zone. Costs included were PBF program costs incurred from April 2019 to August 2022. Annual service utilization data was retrospectively retrieved for pre and post-intervention periods from September 2018 to August 2022 for five services: ANC1, ANC4, Skilled Deliveries, Full Immunizations and Vitamin A Supplementation. Using sub-national health statistics, service utilization was converted to coverage rates. Net effectiveness on service coverage was measured using a difference-in-difference method and was converted to the number of Lives Saved using the Lives Saved Tool. Lastly, lives saved were converted to quality-adjusted life years (QALYs).

RESULTS

In comparison to the control group, an estimated 51 lives were saved in the 14 health centers over the PBF implementation period. Raw PBF program costs were €0,96 per capita per year. After adjustments to the study sample and the five services modelled, this translated to €0.2561 (EUR 2019) per capita/year. QALYs gained were 1,108 per million population resulting in an incremental cost-effectiveness ratio of €233 per QALY (EUR 2019) for implementing PBF.

CONCLUSION

Compared with a cost-effectiveness threshold of 1.5 times Ethiopia’s 2019 GDP (i.e. €1,126), PBF in the Jimma Zone, Ethiopia proved very cost-effective at €233/QALY. Cautiously comparing to similar CEAs in other SSA countries, PBF in Jimma Zone also appeared cost-effective, whereby lower intervention effects were compensated by significantly lower intervention costs. Incentivizing health services which suffer from low service coverage appears most cost-effective, as it may be both more effective and inherently less costly due to lower incentive payments.

Ind-1552 Economic Evaluation of Biologic Therapies for Severe Asthma in Malaysia: Cost-Effectiveness Analysis and Policy Implications

PRESENTER: **Mohamad Baihaqi Mohamad Basri**
AUTHORS: Khairil Idham Ismail, Izzuna Mudla Mohamed Ghazali

Background

Severe asthma remains a significant global health concern, with a substantial economic burden on healthcare systems, particularly in countries like Malaysia. Despite standard treatments being effective for many patients, a subset continues to experience uncontrolled symptoms, leading to frequent exacerbations and a high utilisation of healthcare resources. Biologic therapies have emerged as a promising treatment for patients with severe asthma, specifically targeting those with the Type 2 eosinophilic phenotype. However, the economic implications and cost-effectiveness of integrating these biologics into the Malaysian healthcare system remain underexplored. This study filled this gap by conducting an economic evaluation comparing the addition of biologic treatments to the standard of care (SoC) for severe asthma patients from the perspective of Ministry of Health Malaysia. The SoC followed the Malaysia’s Clinical Practice Guidelines (CPG) of Management of Asthma 2017.

Aim

The aim of this study was to estimate the cost-effectiveness of four biologics—tezepelumab, benralizumab, mepolizumab, and dupilumab—when added to the SoC for treating severe uncontrolled asthma patients, and to calculate the incremental cost-effectiveness ratios (ICERs) for each biologic compared to SoC alone.

Methods

A Markov cohort simulation model was employed to estimate the lifetime costs and quality-adjusted life years (QALYs) associated with each treatment strategy. The model included five health states: day-to-day symptoms, oral corticosteroid burst, emergency department visit, hospitalization, and death. Transition probabilities, treatment doses and effectiveness data were derived from local literature and clinical trials, while costs were estimated based on local healthcare utilisation and drug prices. In addition, deterministic and probabilistic sensitivity analyses were conducted to determine the robustness of the results. Three scenario analyses were illustrated by varying the duration of treatment, dose frequency and drug cost.

Results

The results indicated that the addition of biologics to the SoC increased both costs and QALYs gained. Among the biologics, benralizumab had the lowest ICER of $135,277 per QALY gained, followed by dupilumab ($191,632), tezepelumab ($164,598), and mepolizumab ($334,650). However, all ICERs were above the willingness-to-pay (WTP) threshold of $11,895 per QALY, suggesting that the biologics, while potentially beneficial in terms of clinical outcomes, may not be considered cost-effective in the Malaysian context without further price reductions. Both sensitivity analyses confirm the robustness of the results. A cost-effectiveness acceptability curve showed at the threshold of $216,825 (MYR 1 Million), the probability of cost-effectiveness was the highest for benralizumab (91.2%), followed by tezepelumab (88.3%), dupilumab (67.3%) and mepolizumab (3.9%). The scenario analyses demonstrated that reducing treatment duration, increasing dose intervals and significantly lowering drug costs could greatly enhance the cost-effectiveness of the biologics.

Conclusion

The findings have important policy implications, highlighting the need for further exploration of cost-reduction strategies, such as adjustments in drug pricing or treatment duration, to improve the affordability and cost-effectiveness of biologics in severe asthma treatment. Additionally, the study underscores the need for health policymakers to consider both clinical effectiveness and economic feasibility when incorporating biologics into national treatment guidelines.

Ind-316 Improved Cost-Effectiveness Thresholds for Global Health Decision-Making

PRESENTER: **Andrew Wang**
AUTHORS: Caroline Tangoren, Savannah Newman, Mark Minnery, Julianne Bruggemann, Sindhika Jai, Philip Riegert

Background: In resource-constrained settings, cost-effectiveness analysis (CEA) using averted disability-adjusted life-years (DALYs) is an important decision-making tool for prioritizing potential global health interventions, including by national governments, large-scale funders, and academic institutions. However, establishing appropriate cost-effectiveness (CE) thresholds remains challenging due to limitations in data, applicability across a wide range of contexts as a standard, and differences in perspectives. The widely used World Health Organization (WHO) Choosing Interventions that are Cost-Effective (CHOICE) initiative's approach, which defines thresholds relative to GDP per capita, has been criticized as too lenient and not applicable across diverse contexts. A more nuanced approach could improve resource allocation in low and lower-middle income countries (LICs and LMICs) by applying CE thresholds alongside a wider set of criteria for decision-making, benefiting stakeholders at all levels of global health decision-making. **Objective:** This study proposes a more conservative, geography-agnostic CE thresholding methodology for evaluating prospective health programs in LICs and LMICs, and examines the broader role of thresholds in decision-making processes across various global health sectors. **Data and methods:** We conducted a literature review to evaluate critiques of the existing WHO-CHOICE approach. Data on GDP per capita was collected across all LICs and LMICs, excluding countries determined to be infeasible for prospective program implementation at the current time. Using descriptive statistics, new thresholds based on a more conservative ½ GDP per capita metric are proposed, allowing for comprehensive evaluation across diverse contexts, interventions, and decision-making perspectives. We then evaluated prospective and ongoing interventions within our organization using CEA, validating cost per DALY averted metrics against the proposed CE thresholds. **Results:** We offer a new geography-agnostic thresholding methodology and identify potential exemptions to where the threshold cannot be rigidly applied. Exemptions include: 1) Programs with high levels of sensitivity or uncertainty; 2) Interventions likely to undergo significant design changes; 3) Programs with substantial non-health benefits; 4) Alignment with national or global health priorities; 5) Emergency response scenarios. The research emphasizes context-specific thresholding, highlighting the need for empirical estimates of opportunity cost, including willingness-to-pay (WTP) and value of statistical life (VSL) considerations. A two-step approach is recommended: first applying the geography-agnostic threshold, then considering context-specific factors. **Conclusions:** This research addresses limitations of current CE threshold approaches in global health decision-making. The proposed conservative, nuanced, and flexible methodology offers several advantages: 1) Supports improved resource allocation for large-scale funders working across a range of geographies and program areas; 2) Increases attention to context-specific factors for implementing organizations; 3) Promotes evidence-based practices in academic research and implementation. Adopting this refined approach to CE thresholds as part of a broader set of criteria for decision-making – recognizing the inherent uncertainty of CEA estimates – can help global health actors maximize the impact of limited resources, leading to more effective health interventions in LICs and LMICs.

Improving Equity in Health Care Financing

MODERATOR: **Tushar Mokashi**,

Ind-1039 Equity in Primary Care Financing: Heterogenous Benefits from Needs-Based Payments to General Practices in England, 2014-2022

PRESENTER: **Charlene Lo**
AUTHORS: Ms. Laura Anselmi, Matt Sutton

Background: Previous studies suggest that primary care provider payments should be allocated through a blended payment mechanism, with need-based capitation at its core. However, there is limited empirical evidence on whether this mechanism effectively promotes equity and whether targeting resources to areas with greater needs results in the desired outcomes. Most studies examining financing equity have assessed differential benefits as service use by socio-economic status, often overlooking patient outcomes, variations in the distribution of need and changes over time.

Objectives: We aim to (1) assess income-related horizontal equity in payments to primary care providers over time, in total and by scheme; (2) evaluate the heterogenous impact of payments on outcomes across populations with varying levels of need in the National Health Service (NHS) in England.

Methods: We used data on annual payments to 7,765 general practices in England from 2014 to 2022, linked to patient characteristics. We measured need in two ways: (i) expected utilization, based on a primary care needs index; and (ii) expected care burden from diagnosed morbidity, based on a hospital care needs index. We ranked practices by the average neighbourhood income of their patients in 2019, we computed concentration indices for both need and need-standardized payments were calculated, and we decomposed the concentration index into need, socioeconomic (income, education, ethnicity, economic activity, rurality), and supply-side factors (practice region, dispensing status, contract type). We used longitudinal regression models with Correlated Random Effects to assess the marginal effects of payment on healthcare outcomes (GP and nurse visits and patient satisfaction) across need quintiles, controlling for patient and practice characteristics.

Results: Need was concentrated among poorer populations for both measures: expected utilisation (concentration index (CI) = -0.0169) and expected care burden from diagnosed morbidity (CI = -0.0097). Total payments were consistently pro-rich, with the highest inequity when need was defined by expected utilization (horizontal inequity index (HI) = 0.0224) followed by expected care burden from diagnosed morbidity (HI = 0.0148). Inequity varied across payment schemes, ranging from pro-rich (HI = 0.0399) for the Minimum Practice Income Guarantee to pro-poor (HI = -0.0938) for the Personal Medical Services expenditure. Both socioeconomic and supply-side factors contributed to pro-rich inequalities in payments. A £1 increase in payment was associated with a reduction in GP visits (0.07%) and nurse visits (0.13%) across all five need quintiles, with these reductions being more pronounced in the higher need quintiles. The same increase in payment was associate with improvements in patient's overall experience (0.03%) and their experience of GP access (0.01%), with these positive effects being more pronounced in the higher need quintiles.

Conclusion: Populations with equal healthcare needs did not receive equal payments across income levels. To reduce horizontal inequities, resource distribution objectives should be clearly defined and harmonized across schemes. Future analysis will use more comprehensive and precise and updated need indices, additional health outcomes in a shorter time period (e.g., health status, healthcare experience).

Ind-1045 An Application of Capacity to Benefit as a Measure of Need: Equity in Payment to Primary Care Providers in England, 2019

PRESENTER: **Charlene Lo**
AUTHORS: Matt Sutton, Ms. Laura Anselmi

Background: Primary care resources should be allocated based on population healthcare needs, making it essential to explicitly recognize variations in these needs. The concept of "capacity to benefit" has been proposed as a theoretically suitable measure of need, supporting resource allocation that aligns with both equity and efficiency. This measure reflects the potential health gains an individual could achieve from healthcare services. However, it is rarely used in empirical studies to allocate resources across service delivery units based on population characteristics. Challenges include achieving consensus on its conceptual definition and identifying reliable data for measurement. As a result, studies often turn to approximate capacity to benefit using either a utilization-based or an epidemiological approach.

Objectives: We aim to (1) demonstrate a method for measuring capacity to benefit across service delivery units; (2) assess income-related inequality in capacity to benefit; (3) compare income-related inequality in capacity to benefit with inequalities in demand, utilisation, and diagnosed morbidity; (3) evaluate income-related inequity in past primary care payments. We apply these measures in an equity study in English National Health Service (NHS).

Methods: We used data on payments to 6748 general practices in England in 2019 linked to information on practice patients' average neighbourhood characteristics. We measured capacity to benefit as average health gains in terms of Quality-Adjusted Life Years (QALYs) per patient at the practice level in two steps. First, we obtained age-sex-specific prevalence of 20 diseases at the practice level. Next, we linked the health effect of these conditions (as classified by International Classification of Disease (ICD) codes) with their prevalence at each practice. We

measured income using the average neighbourhood income deprivation of practice patients. We compared the income-related inequality in capacity to benefit to that of alternative need measures used in previous studies, including (1) demand for care, (2) actual utilisation, (3) expected utilisation, (4) diagnosed morbidity, and (5) expected care burden of diagnosed morbidity. We measured horizontal inequity calculating the concentration index of indirect need-standardized payment.

Results: Of the 1,562 ICD codes, we mapped 154 to the 20 conditions monitored in primary care, capturing 16.7% of the total estimated health effect. We found that capacity to benefit was slightly concentrated among the lower-income individuals (Concentration index (CI) = -0.0179, $p < 0.0001$), making it the most pro-poor distribution among all need measures. However, payments were pro-rich when using capacity to benefit as the measure of need (CI = 0.0122, $p < 0.001$, a trend consistent across all need measures.

Conclusion: We advocate for allocating primary care payments based on individual capacity to benefit, directing resources toward those likely to experience the most significant health gains. This approach maximizes efficiency while promoting horizontal equity, ensuring that individuals with similar potential for health benefit receive equal resources regardless of socioeconomic status.

Ind-2382 Social Preferences in Health Care Financing: Evidence from the SOPHEA Survey

PRESENTER: **Florence Jusot**, Université Paris Dauphine
AUTHORS: Beka Lomidze, Clémence Thébaut, Jerome wittwer

Background Equity in healthcare financing is one of the main objectives of modern healthcare systems. In this regard, the vertical and horizontal equity are often considered as the relevant fairness principles to assess equity in healthcare financing. These equity principles come from the fiscal theory literature. horizontal equity requires that people in equal positions should be treated equally which means, in the health context, that individuals with the same ability to pay should equally contribute to health spending, independently from healthcare use. Vertical equity considers how differently should people in different positions be treated, which means that individual contributions to health spending should be related to their ability to pay. However, little literature exists on the empirical assessment of the general population's adherence to those principles of equity in healthcare financing. **Research question and aim** We aim to fill that gap by assessing the public's adherence to the principle of horizontal equity in financing (HEHF) and to the vertical equity in healthcare financing (VEHF). **Data and Methods** Using an experimental survey with 3756 respondents representative of the French population, we measure adherence of the general population to the principles of HEHF and VEHF in the fields of both healthcare and long-term care. Respondents take the role of a social arbiter and allocate the public budget among four hypothetical individuals to compensate their healthcare expenses. Due to the scarcity of the public budget, respondents have to allocate out-of-pockets between the individuals. Using the random allocation of the scenario, we test the sensitivity of their adherence to the HEHF principle to three different causes of healthcare cost: severity of health conditions, preferences on types of healthcare providers, and place of residence. We explore the respondent's heterogeneity of adherence in accordance to age, sex, political orientation, beliefs about the causes of severe illness and others. We explore the sensitivity of individuals' adherence to HEHF and VEHF to the level of income of the four hypothetical individuals. **Results** We find a strong preference for the principle of HEHF when healthcare costs differences are due to differences in severity of health status. Respondents deviate when healthcare costs differences are due to differences in hypothetical choices of providers. When hypothetical individuals differ both in healthcare costs and income we find less adherence to HEHF while a significant share of respondents prefer budget allocation favoring people with low income. We found no individual heterogeneity across gender, political beliefs and socio-economic status. **Policy Implications** This study shows that the general public do not necessarily align with normative principles proposed by the normative litterature. However public support is necessary for a welfare system to be politically supported and to thrive. Those results provides arguments for the design of healthcare financing reform in the French context, the French general public asking for a compensation of extra costs due to circumstances and for income redistribution.

Ind-1907 Can Free Healthcare Policies Sustain Equitable Public Health Spending for Primary Care in Fragile Settings? Novel Evidence from Burkina Faso

PRESENTER: **Ms. Manuela De Allegri**, University of Heidelberg
AUTHORS: Thit Thit Aye, Laurène Petitfour, Mariam Seynou, Valery Ridde, Mr. Joël Arthur Kiendrébéogo, Hoa Thi Nguyen, Emmanuel Bonnet

Background: Countries around the globe are committed to foster Universal Health Coverage through the expansion of social health protection measures, implemented either as free healthcare policies or subsidised public health insurance schemes. While evidence on the effectiveness of these policies on facilitating access to care and enhancing financial protection is increasing, limited evidence persists on how equitably governments allocate the resources earmarked for these policies. In particular, distributional incidence analyses of universal health coverage policies are particularly sparse in fragile settings, i.e. countries affected by socio-political instability and conflict. Moreover, existing analyses rely on national-level aggregated data to estimate government subsidies to UHC policies, hereby masking important underlying inequities in resource allocation across regions and districts.

Objective: To overcome existing knowledge and methodological gaps, we conducted a benefit incidence analysis of the free care policy (*gratuité*) in Burkina Faso, a country affected by socio-political instability, building on disaggregated data tracing resource allocation to the single heath facility. We examined resource allocation across regions and levels of care for both children curative health services and obstetric care.

Methods: We combined multiple secondary data sources. We computed subsidy rates using *gratuité* program database. This database contains all claims filed and all payments made from the *gratuité* program to the single facilities, allowing for later aggregation at regional level. We derived health service utilisation for both child health services and obstetric care from the latest DHS round (2023) and categorised it by socio-economic quintile. We applied standard Benefit Incidence Analysis methods to examine both resource allocation by region and by level of care and distributional benefits across socio-economics groups, separately for child curative services and obstetric services.

Results: More than 80% of the *gratuité* funding allocated to the regions for child services reached primary health facilities, while only 60% of the funding allocated for obstetric services did. We observed important variations in resource allocation across levels of care across regions. Similarly, the unit subsidies received by the single regions differed substantially, with the subsidy for a child outpatient visit ranging from 852 to 1554 CFA (1 euro = 655 CFA) and 3422 to 6779 CFA for a normal delivery. While utilisation patterns for child services did not appear to differ substantially across socio-economic groups, important differences emerged once unit subsidies were factored in, with inequities in the distributional incidence becoming apparent even at primary level (concentration index 0.0266, p-value = 0.010). Inequities in the distributional incidence of obstetric care were even more pronounced, especially at secondary level (concentration index 0.4853, p-value = 0.000).

Conclusion: While the *gratuité* policy has been praised for sustaining high coverage rates and ensuring financial protection even in times of socio-political instability, our analysis shows that the policy, based on retrospective payments, reinforced existing inequalities, especially at secondary level. Our findings speak in favour of introducing prospective payment mechanisms, with a fixed fee structure to be agreed upon ex-ante with healthcare providers as means to promote greater equity in resource allocation.

Ind-1334 Informal Payments for Healthcare at Public Health Facilities in Kenya: Influencing Factors and Effects on Equitable Access to Care

PRESENTER: **Evelyn Kabia**, KEMRI Wellcome Trust
AUTHORS: Edwine Barasa, Dina Balabanova, Eleanor Hutchinson

Background: Informal payments are payments made by a patient to a health provider in addition to the officially determined service fees. They are considered a form of petty corruption. In 2021, 15% of Kenyans had paid informally to access health services at public facilities. Informal payments slow progress toward universal health coverage because they limit access to care and expose individuals to financial hardship. The design of effective strategies to address informal payments requires a good understanding of context-specific drivers and this evidence is limited within the Kenyan context. This study examined the supply-side, demand-side, and contextual factors influencing informal payments at public health facilities in Kenya and their effects on equitable access to care.

Methods: We conducted a qualitative study at 8 public health facilities (4 hospitals and 4 health centres) in two counties (urban and rural). Study participants were identified through purposive sampling. We conducted 8 focus group discussions (4/county) with 79 patients seeking different health services, and in-depth interviews (n=35) with health workers, non-clinical staff, and county and sub-county health managers. Data were analyzed using a thematic approach.

Results: Regarding the supply-side, charging of informal payments cut across most services. However, they were more common for: services that were charged user fees compared to free services, outpatient, specialist, pregnancy termination, and non-routine/seasonal services such as voluntary medical male circumcision, especially at primary health facilities. Low, delayed, and lack of salaries for some cadres such as community health volunteers, delayed and unfair promotions, understaffing, poor working conditions such as long working hours, and individual morals were the main human resource factors reported. There was overt collaboration mainly across cadres to charge informally. We found informal charging to be more likely at health facilities with high patient workloads, long waiting lists, especially for specialized services, inadequate supervision, and those that lacked drugs/supplies/services. Informal charging was also more common at public, urban, and higher-level facilities. On the demand side, patients paid informally to access services/drugs/supplies, to receive higher quality care mainly through reduced waiting times, and to reduce financial hardship from health costs, for example, by paying reduced inpatient bills. Within the broader context, widespread corruption within the public sector, lack of/inadequate sanctions, and harsh economic times influenced informal charging. The inability to pay informally exposed patients to injustices in access such as delayed/denial/foregoing of care and discrimination based on ability to pay. Informal payments exposed vulnerable groups especially the poor and informal sector members to financial hardship.

Conclusions: Factors associated with informal payments were largely linked to health system inadequacies and inefficiencies in health financing and governance functions. Policy considerations that can reduce health inequities associated with informal charging include increasing public spending to ensure the availability of services, commodities, and human resources while ensuring fair remuneration and strengthened oversight. Enhancing public awareness of service entitlements, costs, and grievance redress mechanisms, and ensuring the latter are effective are also crucial.

1:30 PM –3:00 PM TUESDAY [Health Beyond The Health System]

Risk at the Individual and System Level - Micro and Macro Analyses

MODERATOR: **Diego Cerecero-Garcia**,

Ind-681 Transnational Lifelines: The Role of Diaspora Capital on Health System Resilience in Fragile and Shock Prone Settings

PRESENTER: **Sophie Witter**, Queen Margaret University Edinburgh
AUTHORS: Alaa Dafallah, Karin Diaconu, Ayesha Koker, Ghanshyam Gautam, Salim Adib, Kyu Kyu Than, Rouham Yamout, Thazin La, Halimatu Kamara

Introduction: Fragile and conflict-affected states face severe health system challenges that diminish the capacity of the health system to

respond and adapt in crisis to ensure delivery of essential health services. Diaspora play a significant role in supporting healthcare and health systems globally. However, their contributions to resilience of health systems, particularly in fragile and shock prone settings, remain underexplored. This study aims to explore how diaspora capital —human, social, and financial —and policy engagement influence health system functioning in fragile contexts, contributing to overall resilience.

Methods: We conducted a multi-country mixed methods study in 5 fragile and shock prone settings: Nepal, Myanmar, Lebanon, Sierra Leone and Sudan to examine the role of diaspora capital and contributions on health system resilience capabilities. In the first phase of the study, a comprehensive literature and document review was undertaken both globally and at country level, analyzing diaspora capital sources, support pathways, engagement modalities, impacts, and opportunities. The quantitative component explored associations between diaspora financial contributions, particularly remittances, and health expenditure and utilization using descriptive analysis. The qualitative phase involved 60 semi-structured interviews across the study countries with diaspora association leaders, government officials, health providers, and academics to capture insights into forms of support, engagement modalities, and perceived barriers or impacts. Additional interviews were conducted globally with subject-matter experts and representatives of multilateral organizations or think tanks working in this area. Data was analyzed using thematic framework analysis applying both deductive and inductive approaches. Findings from each stage were triangulated and synthesized, with workshops held to validate results.

Results: Our results show that diaspora have significant influence pathways that contribute to resilience of health systems both through state and non-state provision. Diaspora financial contributions through remittances are one of the largest sources of external financing for fragile states and contribute positively to household expenditure on health. Non-remittance financial contributions e.g. in-kind contributions and philanthropy such as medicines and medical supplies are equally important pathways of contribution in crisis. Other forms of diaspora capital are emerging. Diaspora human capital contribute to availability and capacity of human resources through short term missions during crisis and medical training and skill transfer programs. Similarly, diaspora yield social capital through strong social networks and values such as trust and solidarity to informally and directly support affected communities during crisis. Social media and technology facilitate diaspora contributions that leverage community capabilities and responses in crisis. We present a novel conceptual framework mapping diaspora capital flow to specific health system resilience capabilities and develop recommendations for strengthening the role of diasporas in supporting country of origin health system resilience.

Conclusion: This study highlights important resource flows through which diaspora capital —human, social, and financial — contribute to health system resilience capabilities in fragile and shock prone settings. As climate threats, epidemics, and conflicts increasingly strain health systems particularly in fragile settings, leveraging diaspora capabilities through adaptive policy is critical for progress towards universal health coverage and health security.

Ind-1240 What Explains Ethnic Inequalities in Healthcare Quality and Access? Evidence from 38 Low- and Middle-Income Countries

PRESENTER: **Diego Cerecero Garcia**
AUTHORS: Thomas Hone, Aldina Mesic, Paraskevi Seferidi

Background: Ethnic inequalities in access to high-quality health services are large and unjust. They often reflect stark inequalities in socioeconomic status. However, many health systems fail to address the specific needs of different ethnic groups, which can further contribute to poor health outcomes in more disadvantaged groups. The extent to which socioeconomic factors explain inequalities in access and quality across ethnic groups, and how much remain of these inequalities remain unexplained, has not been comprehensively explored before. **Research question:** How much do socioeconomic factors explain inequalities in healthcare quality and access in low- and middle-income countries? **Methods:** Data from 38 Demographic and Health Surveys (DHS) were compiled, including information on antenatal care use, socioeconomic factors (education, wealth quintile, urban/rural location, age, and marital status), and ethnic group. Ethnic groups were based on country-specific classifications. Antenatal care quality and access scores (ANCq) were generated (range 0-10). The ANCq scores were based on the number and timing of antenatal care visits, if visits were with skilled providers, if key tests (blood pressure) and samples (urine and blood), and if tetanus injections were given. Blinder–Oaxaca decomposition was used to quantify differences in ANCq between ethnic groups within countries and estimate how much of these inequalities were explainable by socioeconomic factors. **Results:** Responses from 270,786 mothers from 319 ethnic groups in 38 LMICs were analysed covering the period 2000-2019. The mean ANCq score was 6.03 (95%CI: 6.01-6.05) which ranged from 2.65 in Niger (2006) to 8.50 in Colombia (2015). The mean difference in ANCq scores across ethnic groups (compared to the ethnic group with the highest ANCq score in each country) was 1.13 (range:0.11-3.44). In decomposition analyses, the percentage of this difference that could be explained by socioeconomic factors was on average 47.7% (mean of ethnic groups). In 22 countries, over 50% of the ethnic inequalities in ANCq were not explainable by socioeconomic factors. **Discussion/conclusions:** Ethnic inequalities in antenatal care access and quality are large within LMICs. Over 50% of the inequalities between ethnic groups were not explainable by observed socioeconomic factors suggesting other unobserved factors, cultural factors, and structural factors (including the provision of healthcare services) play an important role in explaining ethnic inequalities in antenatal care access and quality.

Ind-1546 How Corruption Affects Population Health

PRESENTER: **Sotiris Vandoros**
AUTHORS: Elias Mossialos, Ilias Kyriopoulos, Dimitrios Minos

The role of institutions in population health has attracted a lot of attention in the literature and previous findings also suggest that there is an association between corruption and health. However, little is known on any causal effects. The objective of this study is to explore the impact of corruption on population health using an instrumental variable approach. We used annual aggregate data on mortality and other health outcomes, as well as corruption, from 104 countries over the period 2008–2018, derived from the World Bank database, and employed country-level panel data instrumental variable approach to predict contemporary corruption levels. We used an instrument designed to capture the

historical and cultural origins of corruption, derived from a novel dataset of folklore-based measures of historical attitudes, drawn from previous work in the fields of economics and anthropology. The first stage results suggest that the number of corruption-related motifs is a strong predictor of contemporary corruption levels. Our instrumental variable regressions establish a robust and significant effect of corruption on mortality and other health outcomes. Our findings are robust to a number of different specifications, health outcomes, and proxies for corruption. We additionally delve into potential mechanisms, demonstrating that corruption erodes fiscal capacity and government capability to fund healthcare, while distorting the distribution of government expenditure. Furthermore, we demonstrate that it results in the misallocation of government resources, ultimately leading to reduced public funding for healthcare. Our analysis also emphasizes the role of public goods provision, revealing a more pronounced link between corruption and mortality in countries with lower levels of public goods provision. This suggests that corruption may hinder population health through inefficiencies in the allocation of public funds, and calls for action to tackle corruption globally, as yet another means to improve population health. **JEL Classification:** I10, D73, H51 **Keywords:** mortality, population health, corruption, institutional quality, public goods**

Ind-2283 Development of the COVID-19 Health Capability Profile and Index: A Quantitative Study in Germany, South Korea, Taiwan and the United States

PRESENTER: **Marion Coste**
AUTHOR: Jennifer J Prah

Background

The global pandemic of the COVID-19 has underscored the necessity to develop a comprehensive and multidimensional inquiry into the factors that contribute to one's ability to be, and remain, healthy in the context of a global pandemic. The health capability profile (HCP) enables such an examination. It identifies eight individual abilities (internal health capabilities) and seven societal abilities or conditions (external health capabilities), which, together constitute people's ability to effectively achieve optimal potential health. Previous empirical applications of the HCP have either been incomplete (i.e. documenting only several health capabilities in India in relation to political participation) or developed at a local scale (i.e. a mixed methods study on chronic hepatitis B conducted in a rural area of Senegal). Research question/aim This study presents the development of the empirical application of the HCP to COVID-19-related health capabilities in Germany, South Korea, Taiwan, and the United States into a COVID-19 health capability profile and index.

Methods

A quantitative survey was developed to document all dimensions and factors of the HCP at the individual level, and in relation to the COVID-19 pandemic. The survey contained several questions for each of the fifteen health capabilities. Questions were designed to assess the health capabilities' levels of development, for example using Likert-type scales or through categorical variables (rather than binary ones). The survey also documented standard individual socio-demographic and economic information. The online survey was administered to a nationally representative (for age, gender, and region) sample of adults in Germany, South Korea, Taiwan and the United States (n=1,000 per country). Individual data are aggregated into (1) a **health capability profile** of scores on a scale of 0-100 for each of the 15 health capabilities, and (2) a score on a scale of 0-100 for overall **health capability index**.

Results

Preliminary results for all 4 countries are presented, including the distribution and means of the fifteen health capability scores, the distribution of these scores in terms of levels of development, and the distribution and means of the health capability profile indices. These findings reveal substantial differences in the levels and distributions of the health capability scores within and across countries and demonstrate the richness of information provided by a cross-country quantitative application of the health capability profile.

Conclusions and implications for policy and practice

This empirical application of the Health Capability Profile contributes a prototype for future applications validating multidimensional metrics and multilevel analysis. Unlike conventional metrics such as life expectancy or QALYs, the profile captures a holistic picture by integrating internal abilities and external conditions. It offers policy-relevant insights both ex-ante (identifying vulnerabilities and strengths) and ex-post (evaluating the fairness and effectiveness of interventions). This approach emphasizes individual agency while enabling international and macro-level comparisons, which could be used to inform the design of equitable health policies and track progress over time in diverse contexts.

Ind-2789 Potential Lives Saved by Vehicle Standards in G-20 countries

PRESENTER: **Andres Vecino**
AUTHORS: Safyya Cisse, Elliana McGovern, Sagnik Ray, Abdul Bachani

Background: G-20 countries account for 59% of global traffic fatalities, nearly 800,000 deaths annually. Vehicle safety standards (VSS) are one of the strategies in the Safe Systems approach toolkit to improve road safety. Despite current innovations and regulations on VSS, many vehicles produced fail to meet minimum safety standards. Several countries within the G20 have not fully applied all vehicle safety regulations to date. **Aim:** This study estimates the potential effect that introducing and implementing vehicle safety standards in G-20 countries would have in terms of lives saved. **Methods:** In this work, we 1) conducted a literature review to obtain parameters of the impact vehicle standards have on mortality and 2) developed a comparative risk assessment model to estimate the potential gains in terms of lives saved from implementing standards in G20 countries. For (1), we conducted a literature review to identify the effect sizes of the impact of each VSS on mortality. We also used data from the Global Burden of Disease study, as well as annual sales and vehicle registered data to use as inputs in the model. Then, we conducted a deterministic comparative risk assessment model to estimate the effect on lives saved that a change in the distribution of the

exposure to VSS (seat belt usage, child seats, side impact protection, frontal impact protection, pedestrian protection, automatic emergency braking, motorcycle anti-lock breaking system, intelligent speed assistance, and electronic stability control) may have towards 2030 and 2050. Some assumptions were made and are detailed in the paper. **Results:** Our results show that between 2024 and 2050, G-20 countries might surpass 1.2 million lives saved, 115,000 before the end of the decade. We provide device- and country-specific estimates Remarkably, the adoption and the implementation of pedestrian protection safety technologies could save the most total lives in G-20 countries. China, India, and South Korea benefit the most from the full implementation of these technologies. Currently, 31 countries have implemented pedestrian safety technologies. Seat-belts and side-impact protection follow as the most live-saving VSS in G-20 countries. **Conclusions and policy implications for practice:** This work identifies G-20 device- and country-specific estimates of potential lives saved attributable to vehicle standards. Our results are the first ones to our knowledge predicting the effectiveness of these strategies for G-20 nations. This work also shows the large differences in terms of lives saved across countries and VSS that save the most lives, mostly depending on the particular epidemiological profile of road mortality in each of them. Remarkably, G-20 countries have large differences in GDP per capita, that partially explain these differences. This study shows the potential impact of implementing VSS as countries approach the midst of the decade of road safety in which they expect to reduce mortality by 50% in 2030 (Sustainable Development Goal 3.6). The findings of this study will inform stakeholders about the importance of the universal adoption of minimum VSS to ensure the accessibility of vehicle safety globally.

Ind-625 Estimating the Health-Related Quality of Life Burden of Illicit Drug Use Among Australian Adults

PRESENTER: **Rezwanul Rana**
AUTHORS: Addisu Shunu Beyene, Syed Afroz Keramat, Rabeya Basri

Background: Illicit drug use presents a significant public health challenge globally, impacting quality of life and contributing to disease burden. In 2021, around 296 million people aged 15-64 reported drug use, with drug-related health issues leading to a loss of over 36 million years of healthy life measured by Disability-Adjusted Life Years (DALYs).

Objective: This study addresses a critical research gap by examining the association between illicit drugs and health-related quality of life (HRQoL) among Australian adults.

Methods: We utilised longitudinal data from the two most recent waves (wave 17 [2017] and wave 21 [2021] of the Household, Income and Labour Dynamics in Australia (HILDA) survey. We analysed a pooled dataset of 29,811 observations from 18,295 unique individuals. We measured health-related quality of life (HRQoL) through the physical component summary (PCS), the mental component summary (MCS), and the short-form six-dimension utility index (SF-6D). Using random-effects generalised least squares (GLS) estimation, we assessed the association between illicit drug use and HRQOL, focusing on the Physical Component Summary (PCS) and Mental Component Summary (MCS) scores of the SF-36 health survey and the SF-6D utility index. Statistical adjustments were made for various factors, including marital status, education level, income, employment status, Indigenous status, residence, lifestyle factors (e.g., smoking, alcohol use, physical activity), and health conditions. Additionally, we used fixed-effects panel regression models to check the within-person variation in the relationship between illicit drug use and HRQoL. We further analysed the relationships by age and gender, enhancing our understanding of the relationships across demographic subgroups.

Results: Our GLS estimation results indicated that individuals who reported illicit drug use had significantly lower MCS scores (β: -2.27, 95% CI: -2.67; -1.88) compared to non-users, indicating poorer mental health-related quality of life. Illicit drug use was also associated with a reduction in SF-6D utility values (β: -0.02, 95% CI: -0.03; -0.02), further highlighting the negative impact on overall health utility among adults. Illicit drug use significantly reduced MCS and overall HRQOL (SF-6D) scores across genders and age groups, with notable impacts on young adults (aged 15-24, MCS β: -2.24, 95% CI:-2.84; -1.62 and SF-6D β: -0.02; 95% CI: -0.03, -0.01) and male drug uses (MCS β: -2.45, 95% CI:-2.92; -1.98 and SF-6D β: -0.02; 95% CI: -0.03, -0.02).

Conclusion and Policy Implications: Our study underscores the need for comprehensive public health strategies targeting the HRQOL of illicit drug users. Policymakers should prioritise interventions that integrate mental health support with drug harm reduction programs, aiming to improve the quality of life for those affected by illicit drug use. This study adds to the limited body of literature examining the longitudinal impact of illicit drug use on HRQOL and highlights the need for targeted public health interventions that consider both mental and physical dimensions of well-being. Additionally, the SF-6D utility values provided by this study offer a basis for future economic evaluations, supporting the development of cost-effective policies to improve the well-being of illicit drug users across age and gender groups.

abs-os695 Impact of Smoking on Relative Poverty in China: A Two-wave follow-up of the China Family Panel.

PRESENTER: **Qiaoying Wei**
AUTHORS: Peipei Chai, quan wan, Hao Yang, Hewei Xiao, Liuyan Lan

Background: Smoking is harmful to health and imposes a significant economic burden on individuals and their families. Given that China is the largest consumer of tobacco in the world, smoking remains highly prevalent in the country. This study aims to examine the impact of tobacco use on the poverty status of different household types from a relative poverty perspective in China. It provides targeted insights for tobacco control and offers practical references for the development of poverty reduction policies.
Methods: The study utilized the Foster-Greer-Thorbecke Index to estimate the poverty headcount ratio, poverty gap index, and squared poverty gap index across different household types and poverty thresholds, with different poverty threshold, using data from the China Family Panel Studies (CFPS) in 2018 and 2020. It also employed a panel Logit random-effects model to identify factors associated with relative poverty and a panel regression model to assess the impact of smoking on household healthcare expenditures.
Results: When the poverty threshold was defined as half of the median household income, the relative poverty headcount ratio for Chinese households was 22.15% in 2018 and 22.54% in 2020. The poverty gap index decreased from 11.08% to 10.82%, while the squared poverty gap

index increased slightly from 7.13% to 7.17%. The relative poverty headcount ratios were 26.3% in 2018 and 26.24% in 2020 for former smoker households, 24.94% and 23.28% for current smoker households, and 22.75% and 22.37% for non-smoker households.
The Logit regression model showed that the risk of relative poverty was significantly higher for current smoker households (OR=1.643, P<0.01) and former smoker households (OR=1.991, P<0.01) compared to non-smoker households. Households with members aged 65 or older (OR=3.566, P<0.01), with members who had chronic conditions (OR=1.451, P<0.01), or with members who were sick in the past two weeks (OR=1.388, P<0.01) faced a higher risk of falling into relative poverty.
Panel regression results indicated that smoking significantly reduced household healthcare expenditures (P<0.01), with current smoker households spending 18.8% less than non-smoker households. Families with members aged 65 or older (β=0.139, P=0.012), members hospitalized within the last year (β=0.624, P<0.01), or members who were sick in the past two weeks (β=0.087, P=0.010) incurred significantly higher healthcare costs.
Conclusion: The study finds that smoking significantly contributes to the risk of relative poverty in China. It recommends increasing tobacco consumption taxes to reduce affordability, prioritizing smoking cessation interventions for rural smokers, enacting nationwide smoke-free legislation, and using tobacco tax revenue to fund cessation treatments and related interventions.

1:30 PM –3:00 PM TUESDAY [Supply And Regulation Of Health Services And Products]

Bali International Convention Centre – Jasmine

Quality of Care: Measurement and Impacts

MODERATOR: **Mihir Gandhi**,

Ind-1237 Impact of Surgical Experience on the Quality of Care: Learning-by-Doing in Cardiac Surgery

PRESENTER: **Benedikt Leonardo Langenbeck**
AUTHORS: Esra Eren Bayindir, Jonas Schreyögg

Objectives: In the context of cardiac surgery, surgical experience and specializations is a key factor for the safety and effectiveness of surgical interventions. Learning-by-doing effects are a crucial aspect for a possible reduction in mortality and perioperative complications. Previous research on the impact of surgical experience shows, that doing more surgeries in the past, have a positive effect on the quality of care. However, studies on the exact mechanisms which underly the learning effect are still scarce. Surgeons may gain experience through different learning mechanisms such as specific learning, years of experience and analogy-based learning. By analyzing a comprehensive clinical dataset, this study aims to investigate the different learning mechanisms in the context of coronary artery bypass graft (CABG), mitral valve replacement (MVR), and aortic valve replacement (AVR). This study contributes to the literature through the implementation of sophisticated risk adjustment, the observation of a large time period, and the consideration of different learning mechanisms. Method: This research project uses secondary data from a large heart surgery center in Germany covering more than 20,000 surgeries from 2010 to 2023. The dataset includes the number of heart surgeries performed by 46 surgeons, along with detailed characteristics of both surgeons and patients. We use both linear probability and logistic regression models to analyze how different learning mechanisms affect patient outcomes. The primary outcomes of interest include 30-day, 60-day, and 90-day mortality, the incidence of reoperations and complications, as well as in-hospital deaths. Results: We observe learning-by-doing effects predominantly for more complex surgeries. For AVR, we find that the number of surgeries performed in the last quarter matters most. Performing four additional AVR surgeries in the last quarter, which is the difference between the median and the first quartile, results in a significant 11% (p=0.04) reduction in 30-day mortality. When looking at the first half of the surgeon's career, the effect translates into a 25% (p=0.02) reduction in 30-day mortality. Therefore, specific learning tends to be the most important learning mechanism in cardiac surgery. For CABG and MVR, we find no evidence of learning by doing effects. Conclusion: To strengthen the results, we will work on implementing instrumental variables to move the results in a causal direction. The working days of the surgeons will be used as an instrument. If a surgeon who specializes in a certain type of surgery is absent (vacation, parental leave), other surgeons would be more likely to perform that type of surgery. Absent days of a surgeon presumably affects the surgical outcomes of others surgeons only through its effect on surgeons´ recent experience. Overall, the study highlights the importance of ongoing practice and skill development in improving surgical quality. It also suggests that by thoughtfully assigning surgeries, less experienced surgeons may gain valuable experience with complex procedures. This approach could enhance learning opportunities and improve the overall quality of care.

Ind-471 Development of the Quality of Care for Patients with Advanced Illnesses (QCPAI) Scale for Measuring the Quality of End-Of-Life Care

PRESENTER: **Mihir Gandhi**
AUTHORS: Irene Eng Ai Teo, See Mieng Tan, Yin Bun Cheung, Ravindran Kanesvaran, Shirlyn Hui Shan Neo, Jolene Wong, Eric Finkelstein, Felicia Jia Ler Ang, Alethea Yee

Background: Measuring the quality of end-of-life (EoL) care from the patient's perspective is crucial for improving healthcare delivery, yet no single comprehensive scale is available to assess key aspects of EOL care quality from the patient's perspective.

Aim: To develop and evaluate the measurement properties of the "Quality of Care for Patients with Advanced Illnesses (QCPAI)" scale and its caregiver-proxy version, designed to comprehensively assess EoL care quality from the patient's perspective.

Methods: The scale development process included five steps: (1) conducting a scoping review to identify key EOL care dimensions, (2) item development, (3) forward and backward translation from English into Mandarin Chinese, (4) cognitive debriefing with advanced cancer patients and their caregivers, and (5) item revision. The final version consisted of 15 items, representing key quality indicators. A longitudinal survey, with a baseline and follow-up assessment at 1-week, was conducted on 200 patients with advanced cancer and their caregivers to evaluate the

measurement properties of the scale, including internal consistency, criterion validity, know-group validity, test-retest reliability, and equivalence of self- and proxy-administered responses as well as two language versions. The QCPAI score was weighted based on the importance of items determined using best-worst scaling.

Results: The scoping review identified 9 key dimensions of EOL care: safety, appropriateness of care, coordination and continuity of care, health-related quality of life, dignity, empowerment, interpersonal interactions, effective communication, and access to care. After an expert review, 17 initial items were developed. These items were further revised based on feedback from cognitive debriefing sessions with 15 advanced patients and 10 family caregivers. The final version of the scale consisted of 15 items after removing four items due to overlapping concepts and adding two new items.

The patient cohort (n = 200) for assessing the measurement properties of the scale had a mean age of 62.0 years (SD 11.4), with the majority being Chinese (75.1%), followed by Malay (10.5%), Indian (9.5%), and other ethnicities (4.5%). The most common cancer types were gastrointestinal (35.0%) and lung (15.5%). Caregivers (n = 46) of these patients were typically family members directly involved in caregiving. The QCPAI demonstrated strong internal consistency (Cronbach's alpha >0.9). Test-retest reliability was confirmed with intraclass correlation coefficients between baseline and follow-up scores exceeding 0.75. Criterion validity was supported by a strong Spearman correlation ($\rho > 0.5$) between the QCPAI score and overall quality of care ratings. Known-group validity based on patients with varying quality of life demonstrated significantly different mean QCPAI scores. The scale also showed equivalence between English and Chinese versions, and between self- and caregiver-proxy responses (standardized effect sizes ≤ 0.2).

Conclusions and implications for policy and practice: The 15-item QCPAI scale is a comprehensive and reliable tool for assessing the quality of EOL care from the patient's perspective. It demonstrated acceptable measurement properties in multi-ethnic Asian patients with advanced cancer. QCPAI has the potential to be used in routine clinical practice and for quality improvement initiatives to measure and compare the quality of care delivery across healthcare settings and over time.

Ind-1818 Quality of Services Provided by Online Pharmacies in Kenya and India Findings From a Field Experiment Using Standardized Patients

PRESENTER: **Catherine Goodman**, London School of Hygiene & Tropical Medicine (LSHTM)
AUTHORS: Gautam Satheesh, Sammy Masibo, Benjamin Palafox, Irene Khayoni, Sasi Tiruttani, Francis Wafula, Abdul Salam

Background

The growth of online pharmacy in low- and middle-income countries (LMICs) presents a significant opportunity to enhance access to medicines, but concerns about inappropriate care are frequently raised. We investigated the quality of pharmaceutical care provided by e-pharmacies in Kenya and India, two countries at contrasting stages of e-pharmacy market and regulatory development. We conducted a field experiment using standardised patients (SPs), which have been widely used in health facilities and brick-and-mortar pharmacies, but rarely in LMIC e-pharmacy studies.

Methods

We identified the universe of e-pharmacies selling prescription-only medicines online using typical consumer search strings in Google, identifying 61 in India, and 28 in Kenya. SPs visits were conducted at all e-pharmacies in Jun-Nov 2024 attempting to purchase six different prescription-only medications selected to raise a range of quality of care concerns (antibiotic, antihypertensive, insulin, non-steroidal anti-inflammatory, medical abortion and opioid). We varied the SP encounter to be either (i) with a valid prescription, (ii) without a prescription, or (iii) with a prescription with an error (contraindication, overdose, bulk order). Detailed protocols were developed to ensure that SP cases were presented consistently across e-pharmacies, that risk of detection was minimized, and that the identities of research staff were protected. We classified pharmacy care as 'correct' if SP visits were handled in line with recommended care and, where applicable, government regulations: for 'valid prescription' scenarios, if the medicine delivered matched the prescription; for 'without prescription' and 'prescription with error' scenarios, if medicines were not dispensed; and for opioid cases, if the target product was not available for purchase since online opioid sale is proscribed.

Results

We attempted 1,038 SP visits, of which 499 were terminated as the target product was not stocked, leading to 539 visits completed. Of the purchases attempted without a prescription, the medicine was obtained in 38% of visits in India and 74% in Kenya. For SP visits attempted with a prescription with an error, the medicine was obtained in 59% of visits in India and 76% in Kenya. Although sale of opioids online is not permitted in either country, the target opioid was listed as available for sale in 16% of visits in India and 25% in Kenya, with SPs obtaining the opioid in 3% of visits in India and 7% in Kenya. We obtained 227 medicines, of which a high proportion had no dosing instructions (98% in India, 60% in Kenya), and did not include a product information leaflet (95% in India, 25% in Kenya). The medicines received did not match the exact product/brand/quantity ordered in just 2% of cases in India, but in 17% in Kenya. Fixed-effect logistic regression models will be presented to explore potential determinants of quality pharmacy care, including e-pharmacy website traffic, country of website server, medicine sought, and compliance with website regulations.

Discussion

The findings indicate major concerns about the quality of online pharmacy care highlighting the importance of greater enforcement of risk-based regulations on e-pharmacy practice in LMICs, and the potential for use of SPs in regulatory surveillance.

abs-os577 The Effects of Nurse Anesthesia Supervision on Surgical Quality and Access

PRESENTER: **Kevin Griffith**, Vanderbilt University
AUTHORS: Hillary Mull, Jeffrey Darna, Julia Harris

The United States is experiencing a nationwide shortage of anesthesia providers which limits patients' access to care. Scope of practice limitations for certified registered nurse anesthetists (CRNAs) may exacerbate this shortage. Twenty-six states require CRNAs to be supervised by physician anesthesiologists, and the Centers for Medicare & Medicaid Services requires hospitals to implement CRNA supervision as a condition for reimbursement. Within the U.S. Veterans Health Administration (VHA), CRNAs are often required to be supervised for invasive procedures. Further, the maximum number of CRNAs that can be supervised by a single anesthesiologist varies between states and health systems. However, there is limited evidence on the effects of CRNA scope of practice restrictions on access and quality of care. Using rich administrative data from the VHA, we assessed the effects of CRNA supervision on Veterans' access to surgery and postoperative outcomes.

We identified all invasive surgeries performed at VHA facilities during January 2016 through May 2023 (N=2,629,262). We developed three key predictors:

1) Two indicators for whether the anesthesia was performed by a CRNA under supervision or practicing independently 1) The number of concurrent cases that the supervising anesthesiologist was responsible for during each surgical case (supervision ratio)

Our outcomes included fourteen postoperative outcomes for respiratory (e.g., pneumonia, reintubation), central nervous system (e.g., nerve injury, stroke), urinary tract (e.g., renal failure, infection), and in general (e.g., post anesthesia care unit (PACU) time, readmissions). We estimated logistic regression models adjusted for patient race, ethnicity, sex, age, marital status, comorbidities, surgical complexity, anesthesia complexity, and procedure code. Models also included fixed effects for facility, year, month, specialty, and surgeon. Our unit of analysis was the individual surgery with standard errors clustered by facility and specialty. In sensitivity analyses, we estimated instrumental variable models using the daily facility-level ratio or CRNAs to physician anesthesiologists on duty.

There were few differences in outcomes when anesthesia was performed by CRNAs compared to anesthesiologists. Compared to independent physician practice, supervised CRNA practice was associated with minor increases in PACU times (+8.8 minutes, 95% CI:1.0,16.6). None of the 14 outcomes showed significant differences between independent physician or CRNA practice models.

For supervised surgeries (N=1,639,211), a one-unit increase in the supervision ratio was associated with slightly elevated rates of catheter-associated urinary tract infections (+3.9 per 10,000 surgeries, 95% CI 0.2 to 7.6). There were no significant relationships between supervision ratio and rates for the 13 other postoperative complications.

Our null results are precisely estimated, and our statistically significant findings are small and magnitude and may not be clinically meaningful. Taken together, our results demonstrate the field of anesthesia care is now remarkably safe and CRNAs provide high-quality, cost-effective care to their patients. Anesthesia-related outcomes are highly similar for CRNAs and anesthesiologists, and higher supervision ratios were generally not associated with worse outcomes. The VA and other health systems may consider expanded looser CRNA supervision or expanded scope of practice.

Ind-1721 See You at Night: Emergency Department Response to Financial Incentives in Taiwan

PRESENTER: **Chien-Tzu Cheng**
AUTHOR: Hsien-Ming Lien

Ensuring consistent performance quality within emergency departments (EDs) remains a critical challenge, particularly in the context of constrained resources. ED overcrowding has been widely associated with diminished care quality and unfavorable patient outcomes. This is exacerbated during nighttime hours, where extended wait times are more prevalent, leading to further negative consequences. Various strategies have been proposed to alleviate these challenges, including implementing wait time benchmarks and financial incentive schemes such as pay-for-performance programs. However, their effectiveness depends on hospital and provider responses, sometimes resulting in unintended consequences like gaming or effort substitution. In Taiwan, the National Health Insurance system implemented a subsidy program for 24-hour EDs, increasing diagnostic fee bonuses by 30% for admissions between 10 PM and 6 AM in 2010. Utilizing administrative data from Taiwan's National Health Insurance Research Database, we investigate the behavioral responses of EDs to the subsidy program through an event study design that compares pre- and post-policy periods. We construct a balanced panel of 59 hospitals using 3.9 million ED claims from 2009 to 2010. We ask several research questions. First, we assess whether EDs expanded their care capacity and intensity during nighttime hours. Second, we investigate the possibility of strategic manipulation by hospitals, specifically whether hospitals shifted more patients into nighttime to maximize profits. Third, we examine the substitution effects between emergency and primary care, exploring whether patients opted for ED services to benefit from the enhanced resources without incurring additional costs. Fourth, we evaluate the policy's impact on post-nighttime-ED visit health outcomes, including inpatient admission rates, length of stay, inpatient costs, and mortality rates. Finally, we consider whether hospital responses varied by ownership type. Our findings suggest a pattern consistent with manipulation. Using the number of ED physicians and total treatment expenditure as proxies for care capacity and treatment intensity, we observe no significant policy impact. However, we detect evidence of strategic behavior by hospitals—a 34% increase in the share of the least urgent patients during nighttime, while no similar increase occurred among the most urgent cases. This finding suggests that hospitals may have engaged in profit-maximizing behavior by admitting a greater number of nonurgent patients during the nighttime bonus window. Crucially, our analysis shows no evidence of patients substituting primary care with emergency care due to the policy, implying that the findings are driven by hospitals' behaviors rather than patients' decisions. We further analyze the policy's impact on health outcomes, as shifting admission times for less urgent patients could potentially strain resources for other patients arriving concurrently. However, we observe no impact on hospitalization, the length of stay, or the associated costs of these hospitalizations. Additionally, we detect no measurable impact on mortality. Lastly, we show that hospitals did not respond differently by ownership type across all examined outcomes.

Ind-148 Catastrophic Health Expenditures: Effectiveness of Nepal's National Health Insurance Program

PRESENTER: **Simrin Kafle**, "Department of Public Health, Aarhus University"
AUTHORS: Shiva Raj Adhikari, Derek Asuman, Per Kallestrup, Dinesh Neupane, Ulrika Enemark

Abstract

Introduction: Catastrophic health expenditure (CHE) is a significant public health concern worldwide, particularly in low- and middle-income countries (LMICs) such as Nepal. This study is the first to evaluate whether the National Health Insurance Program (NHIP) provides protection against catastrophic health spending among households in Nepal.

Methods: We conducted an analytical cross-sectional study in Pokhara Metropolitan City, employing a two-stage random sampling strategy to select 1,276 households from 11 wards. Data were collected through structured interviews between May and October 2023. Propensity Score Matching (PSM) was employed to address selection bias arising from voluntary enrollment, and CHE was defined as out-of-pocket expenditure (OOPE) exceeding 10% of total household consumption. The Average Treatment Effect on the Treated (ATET) was estimated using post-matching diagnostics to ensure balance in covariates, while logistic regression analyzed the association between NHIP enrollment and CHE. Sensitivity analysis, utilizing Rosenbaum bounds, assessed the robustness of results to unobserved confounding.

Results: Of the 1,276 households surveyed, 534 (42%) were enrolled in the NHIP. However, NHIP enrollment was not significantly associated with reduced odds of CHE (Adjusted Odds Ratio [AOR] = 1.174, 95% CI: 0.78–1.74), and the ATET analysis indicated a 3.1 percentage point increase in the likelihood of experiencing CHE among enrolled households. These results suggest limited effectiveness of NHIP in protecting against CHE. Barriers to enrollment and retention, such as long waiting times (64%) and medication shortages (25%), contributed to a 16% dropout rate and reflect significant accessibility and operational inefficiencies. Additionally, the NHIP's benefit package was found to be insufficient, with essential services like transportation, diagnostics, and medicines inadequately covered, leading to persistent OOPE.

Conclusion: The findings underscore the need for NHIP to expand its coverage and introduce flexible coverage limits based on income and households' healthcare needs. The implementation of strategies to mitigate adverse selection and the optimization of resource allocation and administrative processes will be critical to financing these improvements.

Ind-13 Assessing the Determinants of Out-of-pocket Health Expenditure Among Cambodian Households Without Social Health Protection Using Survey Data

PRESENTER: **Sovathiro Mao**, General Secretariat for the National Social Protection Council
AUTHORS: Andrea Hannah Kaiser, Marlaina Ross, Searivoth Vorn, Sokunthea Koy, Jesper Sundewall, Bjoern Ekman, Pichenda Koeut

Background As the deadline for the Sustainable Development Goals approaches, financial protection in Cambodia remains inadequate, especially for nonpoor informal workers lacking formal social health protection coverage or access to other prepayment schemes. This exposes them to high out-of-pocket health expenditures (OOPE) and related financial hardship. To better understand the drivers behind these expenditures, our study aims to model their healthcare, health, and social determinants and to assess their relative importance.

Methods In 2023, we conducted a cross-sectional multistage clustered sampling survey across seven Cambodian provinces, surveying 3,254 households engaged in informal employment and not covered by any formal social health protection scheme. The survey gathered information on households' use of outpatient and inpatient care and associated OOPE. We employed generalized linear models (GLMs) to analyse the healthcare, health, and social determinants of OOPE and the OOPE budget share (the proportion of total annual household consumption expenditure spent on OOPE) and applied Shapley decomposition analysis to quantify the relative contributions of these determinants to the explained variance in our outcomes.

Results Healthcare variables were the dominant contributors to the explained variance in all outcomes (41.36 50.73%), followed by health factors. While several social variables were significant, only the wealth quintile made notable contributions to explaining variance in our outcomes. The key healthcare contributors included the sector type and level of care, and the number of outpatient medications. Important health contributors included illness severity and the presence of chronic illnesses or noncommunicable diseases.

Conclusions Our findings emphasize the necessity of integrating nonpoor informal workers and their dependents into formal prepayment schemes to reduce OOPE and enhance financial protection on Cambodia's path toward universal health coverage. Strategically engaging with private providers and pharmacies to improve access to essential services and medicines, coupled with the implementation of an effective referral system are important

Ind-178 Can Long-Term Care Insurance Reduce Catastrophic Health and Long-Term Care Expenditures Among Older Adults? A Quasi-Experimental Study in China

PRESENTER: **Chengxu Long**, King's College London
AUTHORS: Wei Yang, Karen Glaser

Older adults with cognitive and/or physical limitations often face excessive health and long-term care (LTC) costs, which significantly affect their living standards. However, current measures of catastrophic health expenditure primarily focus on healthcare costs, overlooking the substantial burden of LTC costs. Our study is among the first to introduce the concept of catastrophic health and long-term care expenditures (CHLTCE) to comprehensively capture the economic burden of health and LTC costs associated with functional limitations. Drawing data from 2011, 2013, 2015, and 2018 waves of China Health and Retirement Longitudinal Study, we employed a staggered difference-in-differences approach to assess the impact of long-term care insurance (LTCI) on alleviating CHLTCE. We found that after accounting for LTC costs, both total health and LTC expenditures and CHLTCE risk significantly increased compared to when only healthcare costs were considered. Furthermore, LTCI coverage significantly reduced CHLTCE risks among older adults with cognitive and/or physical limitations. This effect was more pronounced among those with severe cognitive impairments and those with physical limitations and chronic diseases. In addition, its effectiveness in reducing CHLTCE risks for individuals with complex care needs was observed only at the high threshold, but not at lower thresholds. Our findings offer empirical contributions by incorporating both health and LTC costs into catastrophic expenditures analysis. We recommend that policymakers refine LTCI eligibility criteria and implement tiered coverage options based on various levels and dimensions of cognitive and physical function—beyond activities of daily living—to offer targeted protection for individuals with complex care needs.

Ind-987 Services and Cash: How Long-Term Care Insurance Benefit Design Affects Household Behavior in China

PRESENTER: **Mr. Terence Cheng**
AUTHORS: Minghao Wu, Miao Guo, Yang Li

Background: As populations age, the demand for long-term care (LTC) services grows, raising questions on how best to finance and deliver LTC services to meet this need. Due to the high fiscal cost of LTC and to alleviate the burden on families, there is growing recognition of the need for formal systems to finance LTC to complement the provision of informal care. In 2016, China launched a pilot program for long-term care insurance (LTCI) aimed at supporting individuals with long-term disabilities. Pilot cities offer two types of benefits: in-kind services and mixed benefits (in-kind and cash). This study examines how these designs influence household behavior, focusing on consumption patterns, financial support, and informal care.

Methods: We begin by analyzing conceptually household utility maximization decisions under the two types of LTC benefits. Building on the conceptual model, we estimate an empirical model to evaluate the impact of the two types of LTCI benefits on household consumption and intergenerational support. Our data comes from the China Health and Retirement Longitudinal Study, a nationally representative sample of residents ages 45 and older in China. Our research uses four waves of data from surveys that were conducted in 2011, 2013, 2015, and 2018. LTCI eligibility is determined by the program's introduction year in each respondent's city.

Our analysis examines two sets of outcomes: household expenditures (on clothing, food, housing, transportation, miscellaneous, and healthcare) and intergenerational support behaviors (financial transfers and informal care). We exploit the staggered roll-out of LTCI across cities and differences in benefit types to identify causal effects.

Results: Households receiving mixed benefits significantly increased spending on food and housing, while those receiving in-kind benefits increased spending on housing, transport, and clothing. Both groups reduced medical expenditures, suggesting a shift from medical services to LTC services.

In-kind benefits were associated with reduced informal care from children, indicating a substitution of formal care for family-provided care and alleviating caregiver burden. Conversely, mixed benefits led to a significant decline in financial support from children, suggesting cash benefits crowd out intergenerational financial transfers. Overall, mixed benefits promoted higher levels of non-medical consumption, enhancing household welfare.

Conclusion: Our findings highlight the need to tailor LTCI benefit designs to address the diverse needs of older adults and their families. Balancing in-kind and cash benefits can enhance household welfare, alleviate caregiving burdens, and improve the efficiency and sustainability of LTC systems in low- and middle-income countries.

Performance Evaluation of Healthcare Programs

MODERATOR: **Estela Capelas Barbosa**,

Ind-958 Assessing Health Care System Performance for Each US County Using the Triple Aim Framework

PRESENTER: **Azalea Thomson**
AUTHORS: Haley Kathryn Lescinsky, Joseph Dieleman, Maitreyi Sahu, Kayla Taylor, Max Weil, Meera Beauchamp, Drew DeJarnatt, Sawyer Crosby

The Triple Aim of healthcare systems is to provide patients with a good experience, achieve positive health outcomes, and spend relatively few resources. By many accounts, the United States health care system is failing the Triple Aim litmus test with high mortality, low healthcare access, and the highest rates of health spending per person in the world. However, there is much variation within the US. In this study, we (i) examine if any US counties are doing well by the triple aim standards, (ii) describe the populations living in exemplar counties, and (iii) identify health system characteristics and policies associated with positive county performance.

We extracted county-specific estimates of life expectancy from the Global Health Data Exchange and direct health care spending per capita, adjusted for local prices and age structure, from our previous work (under review currently). We used previous literature to identify five subdomains of patient experience: accessibility, prevention, safety, appropriateness, and patient-centeredness. We extracted county-level measures for each of the subdomains from the CMS Hospital Patient Survey (HCAHPS), the Area Health Resource File, and Mapping Medicare disparities tool and made a composite measure of patient experience using principal components analysis. Then, we assessed each county on all three aims jointly to create an exemplar score for each county from 2014 to 2019. Exemplar counties were defined as counties who were in the top quartile for each of the three triple aim indicators, in each year. We assessed if exemplar counties had statistically different population characteristics than non-exemplar counties. Finally, we measured the association between exemplar scores and relevant policy variables at the state and county level with bivariate regressions controlling for key observed exemplar characteristics.

We found that in 2019, 2% of US counties were in the top quantile of all 3 aims. The people who lived in these exemplar counties were more educated, wealthier, more urban, less black, and less obese than those who lived in non-exemplar counties. After adjusting for education, income, race, ruralness, and obesity, we found that places with higher rates of managed care for Medicaid and Medicare and places with lower market concentration of hospitals and insurers were more successful at making progress towards the triple aim. Additionally, we found that these results were robust to alternative definitions of patient experience, using all-cause mortality instead of life-expectancy, and not adjusting health expenditure for state purchasing power.

The triple aim criterion is an ambitious target that few counties in the United States have achieved. Those that have are places with high relative privilege, suggesting that our health care system is performing strongest in the counties with the greatest means. We show that expanding managed care insurance plans and increasing market competition for hospitals and insurers could improve county health system's progress towards the triple aim.

Ind-1046 Sri Lanka Hospital Efficiency Analysis

PRESENTER: **Anuji Gamage**, KDU
AUTHORS: Son Nghiem, Amala de Silva, Hideki Higashi, Deepika Attygalle, Suganya Yogeswaran, Sridharan Sathasivam

Introduction

Sri Lanka's health system is recognized as one of the most efficient among low- and middle-income countries, achieving strong health outcomes at low costs. However, the COVID-19 pandemic challenged the system's ability to maintain non-COVID care while managing the outbreak. An initial assessment by the World Bank revealed inefficiencies, with higher-level hospitals overloaded with cases manageable at primary care facilities. This study aims to estimate hospital efficiency across different levels of care, using these findings to guide policymakers in improving healthcare services.

Methods

The study employed Data Envelopment Analysis (DEA) to estimate the technical efficiency of Sri Lanka hospitals. DEA calculates the distance between observed input-output combinations and an optimal production frontier. The analysis covers three main types of hospitals: district, base, and divisional hospitals. Data on inputs (beds, doctors, and nurses) and outputs (number of discharges and outpatient visits), were collected from a random sample of 81 hospitals. We also construct a meta frontier comprising all hospitals to estimate technological gaps between types of hospitals. Bootstrap methods were used to minimize potential bias due to measurement errors. The effects of environmental factors on efficiency were analyzed using regressions.

Data

Data were collected from the Ministry of Health, encompassing hospital infrastructure, human resources, and service delivery metrics for 2020. The dataset includes 19 district hospitals, 41 base hospitals, and 29 divisional hospitals, with inputs like the number of beds and medical staff and outputs such as inpatient discharges and outpatient visits. Descriptive statistics reveal significant size differences between hospital types, with district hospitals being the largest and divisional hospitals the smallest.

Results

The DEA results indicate that district hospitals are the most efficient, with an average technical efficiency of 91%. Divisional hospitals also performed well, scoring 90%, while base hospitals lagged at 84%. On the meta-frontier, which compares all hospitals regardless of type, district hospitals remained the most efficient, achieving 85%, followed by divisional hospitals at 78% and base hospitals at 73%. Hospitals in the

Western Province were found to be the most efficient, while those in the Northern Province had the largest potential for improvement.

Discussion

The findings suggest district hospitals are more productive in inpatient services, while divisional hospitals excel in outpatient care. Differences in hospital efficiency may stem from variations in input-output structures, such as staffing levels and patient admissions. Technological gaps between hospital types indicate that significant efficiency gains can be made by adopting best practices from more efficient hospitals. Environmental factors, such as the population size of hospital locations, also play a role in determining efficiency, though the impact is modest.

Conclusion

Sri Lanka's hospitals exhibit varying levels of efficiency, with district hospitals leading in technical performance. The study highlights the importance of improving primary care to relieve the burden on higher-level hospitals, potentially increasing overall system efficiency. Future efficiency analyses should incorporate data on the quality of care and service complexity. Periodic assessments are recommended to monitor improvements and guide policy reforms in the healthcare sector.

Ind-724 Evaluation of the Priority Primary Care Centre program in the Western region of Victoria, Australia

PRESENTER: **Feby Savira**, Deakin University
AUTHORS: Sean Randall, Madison Frith, Naomi White, Andrew Giddy, Anna Peeters, Kirsty McLean, Jamie Swann, Suzanne Robinson

Introduction: The Victorian State Government of Australia has established Priority Primary Care Centers (PPCCs) to reduce the demand for Emergency Departments (EDs). PPCCs are general practitioner led, free of charge services that aim to provide care for conditions that require urgent attention, but do not require the high-acuity care of an ED. This study aims to evaluate the implementation and impact of the PPCC on ED demand in three sites within the Western region of Victoria, Australia. **Methods:** This is an observational mixed methods study. A scoping review was conducted to synthesise international literature on the effectiveness of PPCC-like services (i.e., urgent care centres). The quantitative component involved analysis of de-identified administrative data, comprising PPCC clinical records and ED presentation records, as well as patient survey. Qualitative data collection involved semi-structured interviews to understand the experiences of PPCC patients, clinical staff, managerial and administrative staff and ED clinical staff. Implementation science frameworks have been integrated within the study design. **Results:** Scoping review findings suggest while often context-specific, urgent care centres, particularly walk-in clinics and after-hour clinics, are associated with reduced ED visits and high patient satisfaction. Analysis of PPCC clinical records from 28 October 2022 until 8 June 2024 indicated 48,772 unique attendances. Most PPCC attendees in the region were either younger patients (31%) or older adults (20%), predominantly residing in regional centres (51%) and belonging to middle socioeconomic groups (33% in Quintile 3 and 26% in Quintile 4). Majority of attendances were appropriate low acuity presentations and resolved in-clinic (82%). There was no change in ED presentations across all sites, however, there was improvement in proportion of patients receiving treatment within one hour at the ED. Survey data showed that 1,161 of 2,351 respondents (49%) would have attended the ED if the PPCC were unavailable. Qualitative data suggests PPCC offers accessible, affordable, and convenient care. Facilitators to successful implementation of PPCC included experienced workforce, effective planning and resource management, and effective collaboration and leadership, while barriers included poor community awareness and interoperability issues. **Conclusion:** The PPCC has reached a broad range of patients with various demographic and socioeconomic backgrounds across the region.* *There was limited evidence on its impact in reducing ED presentations, however this should be viewed in context of ever-increasing healthcare demand. Most attendances were resolved in the clinic, suggesting the PPCC is filling a gap of unmet need for urgent but low-acuity care.**

Ind-1341 Level and Determinants of District Primary Health Care System Technical Efficiency in Ghana: Two-stage Stochastic Frontier Analysis

PRESENTER: **Beatrice Amboko**

Abstract

Background: Primary healthcare (PHC) is a fundamental component of achieving universal health coverage. In Ghana, PHC services are organized at the district level. This study aimed to estimate the level of technical efficiency and identify its determinants in the district-level PHC system across the country.

Methods: A two-step stochastic frontier analysis model was utilized, drawing on data from 181 districts in Ghana. The output variable was a composite coverage index derived from eight key PHC service indicators for the year 2021, which included the percentage of women aged 15 to 49 who had their family planning needs met using modern methods, the proportion of antenatal care (ANC) clients who completed four visits, and the percentage of deliveries attended by skilled healthcare providers. It also covered measles-rubella vaccine coverage for children aged 18 to 59 months, BCG vaccine coverage for children under one year, the proportion of children who received the DPT3 vaccine, the percentage of tuberculosis (TB) cases that completed treatment, and the share of ANC clients who received long-lasting insecticide-treated nets (LLINs). The input variables considered were district health expenditure for the fiscal year 2020/2021, the number of health facilities, and the count of clinical staff in 2021. The study further examined how technical efficiency scores were associated with various health system, socioeconomic, and demographic factors. These factors included the type of health facility, insurance coverage, literacy levels, Gini coefficient (as a measure of income inequality), poverty incidence, urbanization, and population density.

Results: The analysis revealed that the mean technical efficiency of the district PHC system in Ghana was 87%, with a standard deviation of 6.6%, ranging from 65% to 99%. The two significant predictors of technical efficiency were identified as the proportion of PHC health facilities and the Gini coefficient. A higher proportion of PHC facilities was positively associated with technical efficiency (coefficient = 0.151; 95% CI: 0.041-0.261), while higher income inequality, as indicated by the Gini coefficient, was negatively associated with efficiency (coefficient =

-0.858; 95% CI: -1.146 to -0.252).

Conclusion: The findings suggest that districts in Ghana could potentially improve their PHC outputs by an average of 13% by addressing key determinants of technical efficiency. Enhancing the proportion of PHC facilities within districts is likely to improve efficiency within the health sector. Additionally, reducing income inequality is essential for optimizing the performance of district-level PHC systems, thus contributing to better healthcare delivery and outcomes.

Ind-2358 The Impact of Supplementary Nutrition on Low Birthweight Outcomes in India: Evidence from the Integrated Child Development Services Program

PRESENTER: **Shabnam .**
AUTHOR: Mohammed Faheem Khan

Introduction: Low birthweight (LBW) is defined as a birth weight of less than 2,500 grams at the time of delivery. LBW can have significant consequences, as infants with this condition are more vulnerable to recurrent hospitalizations, neurodevelopmental disorders, chronic health issues, and higher mortality rates in children under five years old. Globally, LBW is linked to 60-80% of neonatal mortality cases, with the prevalence being highest in South Asian countries. The World Health Organization has set a target to reduce the prevalence of LBW by 30% by 2025. In India, the reported LBW prevalence is 18%, making it one of the highest in the world. The country faces substantial challenges in achieving its Sustainable Development Goal (SDG) by 2030. To address this issue, the Government of India introduced the Integrated Child Development Services (ICDS) program, which aims to provide food, preschool education, and primary healthcare to children under the age of six and their mothers.

Research Question: The objective of this study is to assess the impact of the supplementary food distribution program for pregnant women under the Integrated Child Development Services (ICDS) and Anganwadi Centers (AWC) on the incidence of low birth weight (LBW) in newborns in India. Additionally, the study aims to evaluate how this program influences the utilization of maternal and child healthcare services, such as antenatal care, institutional deliveries, and postnatal care, as well as outcomes like neonatal mortality.

Data and Method: This study uses the latest National Family Health Survey (NFHS) data to assess the impact of supplementary nutrition provided to pregnant women under the ICDS program on reducing LBW. The study links the birth weights of children born between 2014 and 2021 with their mother's status of receipt of supplementary nutrition under ICDS. However, the utilization of these ICDS services is self-selective and not entirely random. To enhance the robustness of our results and to minimize endogeneity and omitted variable bias, an econometric quasi-experimental matching approach was employed in estimating the impact of the supplementary nutrition program on the incidence of LBW at the time of birth and neonatal mortality (i.e. death of the newborn withing a month of birth).

Results: The findings indicate that receiving supplementary nutrition significantly reduces the prevalence of LBW by approximately 0.54 percentage points (β: -0.0139; 95% CI: -0.0115 to -0.0116, p: 0.003 and early neonatal mortality by 2 per 1000 live births. The mothers using ICDS services are more likely to utilize essential maternal and child health care services, including antenatal care, institutional deliveries, and postnatal care. These results indicate an urgent need for improved nutritional interventions to combat undernutrition and enhance maternal and child health outcomes in India.

Ind-1231 Effect of Hypertensive Follow-up Services on Health-related Quality of Life: Evidence From National Health Service Survey in Western China

PRESENTER: **Yan Zhuang**
AUTHORS: Chi Shen, Zhongliang Zhou

Objective

Providing health management services for patients with chronic diseases is considered as one of the most cost-effectiveness way to early detection and continuous monitoring of potential health issues and enhancement of health outcomes around the world. Since 2009, China has adopted an Essential Public Health Services Programme including providing follow-up service for hypertension patients. This study aims to provide clear and comprehensive evidence on the impact of follow-up services on and health-related quality of life (HRQoL) for patients with hypertension, contributing to improvement of health management follow-up services programme and enhancement of the overall health utility.

Methods

A total of 9,327 hypertensive patients were used in this study. The data was collected from a province in Western China as part of the 2023 National Health Services Survey (NHSS) in China. According to the "National Essential Public Health Service Standards" issued by China in 2009, patients with primary hypertension should receive at least four face-to-face follow-up visits annually. Based on this guideline, we categorized the independent variable into three groups: no follow-up; follow-up times below the standard; and follow-up times meeting the standard. For health utility outcomes, we focused on HRQoL as measured by the EQ-5D-5L scale. We applied the Utility Index(UI) score calculated from the Chinese Health Utility Score System of the EQ-5D-5L scale to proxy for HRQoL, and the UI score ranged from -0.391 to 1.000. Tobit regression, logistic regression and linear regression were employed. We further explored the impact of contents and pattern of follow-up services on HRQoL. Additionally, we investigated potential mechanisms.

Results

UFS significantly enhance the health utility of hypertensive patients. Compared to patients without follow-up utilization, those who were followed-up more than 4 time in a year experienced an increase of 0.041 units in their UI score, while patients who do not meet the criteria saw

an increase of 0.029 units. Furthermore, we found that the pattern of visiting medical institutions for follow-up is more effective than the pattern of home visits for follow-up. Among contents of the follow-up services, "blood pressure measurement" and "medication review" significantly improved UI score of hypertensive patients. Mechanism testing indicates that UFS program improved health outcomes by enhancing medication adherence and blood pressure monitoring compliance, and effectively controlling blood pressure. The results of robustness analysis are consistent.

Conclusions

This study reveals a positive association between follow-up services and the enhancement of health-related quality of life among hypertensive patients in Western China. It is crucial for the government to continue improving essential public health services, particularly follow-up services for chronic disease populations and exploring optimal delivery patterns of follow-up services. These evidences offer valuable insights for implementing essential public health programs in low- and middle-income countries.

Ind-185 The Impact of the Long-Term Care Cognitive Assistance Grade on Healthcare Utilization and Health Outcomes Among Older Adults

PRESENTER: **Hajae Jeon**
AUTHOR: Jaeyong Shin
Abstract

Background: With the rapid global aging trend, managing cognitive function and addressing the economic burden of dementia care have become critical challenges. South Korea implemented the Cognitive Assistance Grade within its Long-Term Care Insurance program in January 2018 to slow cognitive decline and improve healthcare outcomes for older adults. This study evaluates the policy's effectiveness by analyzing its impact on cognitive and physical function, healthcare utilization (outpatient visits, hospitalizations), and medical expenditures among dementia patients.

Methods: We used the National Health Information Database from National Health Insurance Service. The study included 3,766,422 individuals. Using a quasi-experimental design, this study analyzed national data spanning from 2014 to June 2024. Propensity score matching (PSM) and difference-in-differences (DID) analyses were employed to compare the outcomes of Cognitive Assistance Grade beneficiaries and non-beneficiaries.

Results: The Cognitive Assistance Grade significantly delayed cognitive decline among beneficiaries compared to non-beneficiaries (RR = 0.8552, $p < 0.0001$). However, no statistically significant difference was observed in physical function (RR = 1.0362, $p = 0.2313$). The policy also led to a reduction in outpatient visits (RR = 0.9420, $p < 0.0001$). In contrast, the policy resulted in a significant increase in inpatient length of stay (RR = 1.1990, $p < 0.0001$).

Conclusions: The Cognitive Assistance Grade policy effectively slows cognitive decline in dementia patients, emphasizing its importance in preventive dementia care. However, the lack of significant impact on physical function highlights the need for tailored interventions addressing physical activity and rehabilitation. The contrasting patterns of outpatient and inpatient service utilization suggest differing healthcare needs, underscoring the necessity of comprehensive support programs to balance healthcare service use and improve outcomes for vulnerable older adults. These findings provided valuable evidence for expanding the CAG policy to ensure broader and more equitable access to dementia care programs and support tailored interventions to improve the outcomes for at-risk older adults.

Ind-875 Mental Health Outcome and Costs associated with Intensive Community Mental Health Recovery Service Receipt among Veterans in the United States

PRESENTER: **Suja S Rajan**, University of Texas - Health Science Center at Houston
AUTHORS: Michelle Winkler, Alexander Duman

Background: In the U.S., mental illness prevalence is substantially more among veterans as compared with the general population. More than 5.2 million veterans, who form 30% of the total veteran population, experience mental illness. The federal government has recently budgeted about USD14 billion for veterans' mental health care. Given the higher mental illness prevalence among the veterans, the Veterans Health Administration (VHA) has established numerous state-of-the-art services to provide veterans with evidence-based, high-quality mental health care. The Intensive Community Mental Health Recovery (ICMHR) services are one such group of services aimed at serving veterans with serious mental illness (SMI; defined as psychoses and/or bipolar disorders) and/or severe functional impairment. ICMHR services provide clinical community-based case management to improve psychiatric symptoms, prevent mental health crisis requiring hospitalizations or emergency department visits, and enhance satisfaction and quality of life among veterans. **Study Aims:** This study, for the first time, aims to examine the association between ICMHR service receipt and 1) Mental health outcome measured using the 19-item Brief Psychiatric Rating Scale (BPRS) score; and 2) VHA inpatient and outpatient mental health care costs during the year before and after ICMHR service initiation. BPRS is the oldest and currently the most widely used score for evaluating the effectiveness of mental health interventions and treatments. These aims will help understand if ICMHR initiation is associated with psychiatric symptom improvement and reduction in mental health care costs at the VHA. The study was conducted as part of an objective external evaluation of VHA's mental health programs through an inter-institutional collaboration. **Methods:** This retrospective observational study includes veterans who enrolled in ICMHR services during October 2018-September 2021, and had a BPRS score at the time of enrollment (baseline), and at 6th and/or 12th month post-enrollment. VHA inpatient and outpatient mental health care costs were also estimated from the VHA data. Mixed effects linear regressions for panel data were used to examine the change in BPRS scores over time during the first year after ICMHR initiation, and the change in mental health care costs before

and after ICMHR initiation. **Results:** The study found a statistically significant decrease in BPRS scores during the 6th (Marginal Effect: -1.6; 95%CI: -2.2 to -1.0) and 12th month (Marginal Effect: -2.4; 95%CI: -3.0 to -1.7) follow-up, after ICMHR initiation, as compared with the baseline score, after adjusting for veteran socio-demographic and clinical characteristics. The study also found an adjusted reduction in cost of -1,248.19USD (95%CI: -2,011 to -485) and -6,574.60USD (95%CI: -7,337 to -5,812) during the first six-months and 7 to 12 months after ICMHR initiation, respectively, compared with the six months before ICMHR initiation. **Conclusion:** These results suggest that the ICMHR services are potentially effective in improving psychiatric symptoms, as measured by the BPRS scores, in veterans enrolled in these services, and reduce mental health care costs at the VHA, thereby successfully upholding VHA's directive to help veterans with SMI.

Impact and Response to Climate Change

MODERATOR: **Nicholas Stacey**,

Ind-1175 Examining the Relationship Between Climate-Induced Household Food Security and Childhood Nutritional Status in Burkina Faso Using Longitudinal Data

PRESENTER: **Edmund Yeboah**, Heidelberg Institute of Global Health, Heidelberg University
AUTHORS: Windpanga Aristide Ouédraogo, Ina Danquah, Valerie Louis, Ms. Manuela De Allegri, Ali Sie, Rainer Sauerborn

Background: The link between climate change and food security is well-established, with evidence indicating that climate change affects child nutrition mainly by exacerbating household food insecurity, especially in resource-limited, climate-sensitive agricultural settings. However, most studies are cross-sectional or rely on theoretical models, limiting causal inference. This gap highlights the need for longitudinal research to rigorously assess the causal impact of climate-induced food insecurity on undernutrition in at-risk populations. Building on a prior cross-sectional study, which found a strong association between climate variability and household food security in the study area, we use a longitudinal approach to examine the causal link between household food insecurity and child undernutrition. **Methodology**: We used three rounds of annual data from 2020 to 2022 from a dynamic cohort of 2,000 children under five and their households within the Nouna Health and Demographic Surveillance System in rural Burkina Faso. A fixed-effect (FE) model was used to explore the causal relationship between food security and childhood undernutrition (stunting and wasting). Stunting was measured by height/length-for-age z-scores, while wasting was assessed using weight-for-age z-scores. Household food security was evaluated through the Household Food Insecurity Access Scale, which captures household food access based on lived experiences. **Results**: Overall, 21% of children were stunted, while 15% were wasted. We found a decline in food security over time. In 2020, about 76% of households were food secure, but this rate dropped to 56% in 2022. Correspondingly, the proportion of households experiencing mild, moderate, and severe food insecurity increased, particularly in the "Moderately Food Insecure" category, which rose from 6% in 2020 to 25% in 2022. Household food security status was associated with stunting and wasting: children in severely food-insecure households had the highest stunting (29.4%) and wasting (21%) rates, while food-secure households had lower rates. Our FE model estimates indicated that mildly and moderately food-insecure households had significantly better height-for-age z-scores than severely food-insecure ones, indicating reduced stunting risk. However, weight-for-age z-scores did not significantly vary by food security status, suggesting no strong association with wasting. **Conclusion**: Our findings show that food insecurity is worsening, with increasing numbers of households facing moderate to severe food access issues, reflecting rising economic or environmental pressures affecting food availability. Policy interventions must address these underlying causes and support vulnerable households in securing adequate, nutritious food to help prevent stunting and improve child health outcomes.

Ind-736 Tiny Lungs, Big Costs: The Economic Burden of Air Pollution on Child Health in South Korea

PRESENTER: **Haedong Kim**
AUTHORS: Jaeyong Shin, Hee-Seung Yang, Junghwan Suh

Background:
Air pollution remains a major public health concern worldwide, with PM2.5 (particulate matter ≤ 2.5μm) recognized as one of the most harmful pollutants due to its ability to infiltrate the lungs and enter the bloodstream. While its general health impacts are well-documented, limited research has specifically examined how PM2.5 affects young children, particularly in terms of respiratory healthcare use and related expenditures. This study addresses this gap by analyzing the clinical and economic burden of PM2.5 on children's health in South Korea, a country with consistently high PM2.5 levels among OECD nations.

Objective:
The study aims to quantify the causal impact of ambient PM2.5 exposure on respiratory healthcare expenditures and medical visit frequency among children aged 0–95 months. Special focus is given to identifying age-specific vulnerability and evaluating the financial implications for the National Health Insurance Service (NHIS).

Methodology:
Using complete administrative panel data from NHIS (2015–2021), the study includes over 4.17 million children who participated in the National Health Screening Program for Infants and Children. The data captures monthly healthcare expenditures and visit frequencies. Ambient PM2.5 concentrations are merged using grid-level air quality data from Korea's National Institute of Environmental Research. To address potential endogeneity in pollution exposure, thermal inversion—a meteorological phenomenon that traps pollutants near the surface—is used as an instrumental variable. The empirical strategy employs a two-stage least squares (2SLS) fixed-effects model, controlling for individual, socioeconomic, and seasonal factors.

Key Findings:
PM2.5 exposure significantly increases respiratory-related healthcare utilization, with the effects most pronounced in early childhood. A 1 μg/m³ increase in monthly PM2.5 leads to a 0.067 rise in log monthly respiratory healthcare expenditure for children aged 0–11 months, with the magnitude declining steadily with age and becoming statistically insignificant beyond age five. When expressed in economic terms, a 0.5 standard deviation increase in PM2.5 (approximately 3.72 μg/m³) is associated with a 23.2% rise in respiratory healthcare spending for children aged 0–4. Given that this group incurred KRW 867.4 billion (approx. USD 667 million) in respiratory spending in 2019, this translates into an estimated additional annual burden of KRW 201.1 billion (approx. USD 154.7 million). Furthermore, the study finds that while healthcare visit frequency (quantity) remains elevated into later childhood, the corresponding expenditure (severity) declines more rapidly, indicating that older children may seek care with less serious symptoms, whereas infants and toddlers bear the brunt of the clinical and financial burden.

Policy Implications:
The findings highlight the urgent need for targeted air quality interventions, particularly for early childhood. Reducing PM2.5 levels can yield a dual benefit—improving health outcomes and lowering public healthcare costs. Given the disproportionately high burden on younger children, policies should prioritize emission control, air filtration in childcare facilities, and seasonal alerts during high pollution periods.

Ind-608 Effect of Financial Credit and Climate-Smart Agricultural Training on Livelihoods and Nutrition of People Living With HIV: A Cluster-Randomized Trial

PRESENTER: **Helen Harris-Fry**
AUTHORS: Edward Frongillo, Sheri Weiser, A. Rain Mocello, Craig Cohen, Suneetha Kadiyala, Tammy Nicastro, Elizabeth Bukusi, Elly Weke

Background: Despite global commitments to eliminate HIV by 2030, it is estimated that 9.2 million people living with HIV did not access antiretroviral treatment (ART) in 2022. Food insecurity is a major barrier to ART access and adherence, both because people cannot afford to buy food and cover the costs of accessing ART, and because of the adverse side effects of taking ART on an empty stomach. Recognising this, UN agencies recommend that livelihoods-based solutions should be integrated into HIV strategies, although there is limited evidence on effective models for doing so.

Methods: This is a secondary analysis of a parallel cluster-randomized controlled trial, which evaluates the effects of a climate-smart livelihoods intervention, Shamba Maisha, on agricultural production and diet quality of farmers living with HIV in Western Kenya. The intervention provided credit (175 USD) for an irrigation pump and other agricultural inputs, and a series of training sessions on climate-smart agriculture and financial management. Participants in control clinics received standard government services. Clusters were clinics in three sub-counties of Western Kenya that were providing HIV services to >350 patients. Participants were adults aged 18-60 years in a patient support group, receiving antiretroviral therapy for ≥6 months, with access to land and water source, and moderate to severe food insecurity and/or BMI <18.5 kg/m^2. Our main outcomes were dietary diversity (food groups/day) and crop diversity (unique crops/year), which we constructed using assessments at 0, 6, 12, 18, and 24 months. Secondary outcomes were underweight (mid-upper arm circumference <24.5cm), value of agricultural production (1000 KSH/year), and farmland use (hectares). Pre-planned sub-group analyses disaggregated impacts on main outcomes by season and gender. Analyses were by intention-to-treat, and used difference-in-difference linear and logistic regression models.

Results: 16 clinics were randomly allocated to intervention or control (1:1 ratio), from which 720 participants were enrolled (intervention 366; control 354) and 677 participants were evaluated (intervention 344; control 333). Relative to control, the intervention increased crop diversity (mean difference-in-difference: 1.9 crops [95% CI 1.5, 2.3]). Impacts were similar by season and gender of participant. Value of production also increased (3891 KSH [49, 7734]), while land use declined (-0.88 hectares [-1.30, -0.42]), suggesting some increases in farming efficiency. Impacts on agriculture did not translate into improvements in nutrition outcomes within the study time frame. There was no effects on diet diversity (-0.17 food groups [-0.4, 0.03]), regardless of season or gender. There was also no effect on prevalence of underweight (OR 0.8 [95% CI, 0.39, 1.5]), which was already a rare outcome at baseline.

Conclusion: Well-designed climate-smart agriculture could be an important means to improve the agricultural productivity and livelihoods of farmers living with HIV, across flood- and drought-prone seasons, and with equitable impacts for men and women. These approaches would benefit from additional nutrition-sensitive components designed to translate such benefits into improvements in nutritional outcomes.

Ind-1305 Energy Prices and Health Impacts: Light on Renewable Energy Diffusion

PRESENTER: **Yi-Chun Ko**
AUTHOR: Shinsuke Uchida

Adverse health outcomes have increased with the rise in extreme temperatures caused by climate change. According to the 2023 WHO fact sheets, health costs from temperature-related impacts are projected to reach US$2-4 billion annually by 2030. These impacts include acute conditions like hypothermia and hyperthermia, as well as chronic illnesses such as respiratory and cardiovascular diseases. Existing literature highlights a U-shaped relationship between temperatures and health risks–e.g., both extreme cold and heat increase mortality rates (Heal and Park 2016 *REEP*).

Home climate control devices, such as air conditioning, serve as a form of household self-protection against extreme temperatures (Barreca et al. 2016. *JPE*). However, their reliance on energy makes them vulnerable to rising energy costs. With global energy prices escalating due to recent inflation and geopolitical instability, insufficient indoor temperature control can worsen health outcomes. Recent studies confirm that higher energy prices are linked to increased mortality rates (Neidell et al. 2021 *J. Health Econ.*; Chirakijja et al. 2024 *Econ. J.*).

This research investigates self-sufficient renewable energy technologies as a potential solution to mitigate the health risks under the pressure of

high energy prices. Specifically, we explore the extent to which residential solar photovoltaics (PVs) can reduce the health risks. Solar PVs convert solar energy into power for household use as electricity or heat, lowering energy expenses and enabling more flexible energy use. By shifting the focus from renewable energy's environmental benefits, such as CO2 reduction, to the energy-health nexus, this study emphasizes the public health implications of sustainable energy adoption.

Using Japan's prefecture-month-level mortality data from 2009 to 2014, we evaluate our hypotheses within the context of the 2011 Great East Japan Earthquake, which triggered a sharp increase of electricity prices due to a shift away from nuclear power. Mortality and household characteristic data are sourced from He and Tanaka (2023 *AEJ: Applied Economics*), while weather data (temperature, precipitation, global solar radiation, snow depth, and wind speed) are obtained from Agro-Meteorological Grid Square Data, NARO. Residential solar PV installation data is provided by the Japan Photovoltaic Energy Association. Our baseline fixed-effects specification employs cooling degree days (CDD) and heating degree days (HDD) as measures of heat and cold exposure.

Our findings indicate that residential solar PV installations significantly reduced the adverse temperature impacts on health outcomes, particularly among individuals aged 65 and older. These results underscore the critical role of renewable energy technology in enhancing resilience to extreme temperatures and volatile energy prices.

These findings highlight the need for policies promoting renewable energy adoption, particularly in vulnerable regions and sociodemographic groups. Subsidies and incentives for residential solar PV installations could offset upfront costs, enabling broader adoption among low-income households. Governments should prioritize integrating renewable energies into public health strategies to protect at-risk populations, such as the elderly. By reducing reliance on conventional energy sources and increasing energy affordability, renewable energy diffusion can mitigate health risks linked to energy insecurity and climate change. In doing so, it offers dual benefits of improving public health and advancing energy sustainability goals. 2

Ind-167 Community Education and Surveillance of Antibiotics use: Experimental Evidence From Nepal

PRESENTER: **Prajwol Nepal**

AUTHORS: Henish Shakya, Yubraj Acharya, Anup Subedee

Abstract.

Background. Antimicrobial Resistance (AMR) poses a significant threat to global health, contributing to an estimated 4.95 million deaths in 2019. In low- and middle-income countries (LMICs), overuse of antibiotics — driven by easy access and limited public awareness — is a key factor in the rise of AMR. The World Health Organization (WHO) has called for public awareness campaigns that promote the appropriate use of antibiotics and highlight the growing risks of AMR. However, such initiatives remain scarce in LMICs, and existing efforts often lack contextual adaptation and rigorous evaluation to guide policy development. This study evaluates the impact of a targeted educational intervention aimed at reducing non-prescription antibiotics use among children in a randomized controlled trial conducted in Kathmandu, Nepal.

Methods. We enrolled 960 households across 40 wards in urban Kathmandu Valley, and randomly assigned them 50:50 to a control arm and an educational intervention aimed at enhancing parental understanding of antibiotic use in children and the associated AMR risks. The intervention included in-person sessions between parents of children under 10 years and a trained community health nurse during household visit, supplemented by periodic video messages delivered through a mobile application. The mobile application, adapted from widely used community health worker mHealth tool, also enabled households to report antibiotic use, healthcare visits, and expenditures on antibiotics and other medications, for each illness episode over a period of six months.

Key Findings. Our analytical sample** consisted of 238 illness episodes from 144 households during the six-month period. Antibiotics were used in 42% of the total illness episodes, and 65% of these were without physician prescription. The intervention reduced non-prescription antibiotic use by 41% (13.4 percentage points (pp), $p < 0.05$). Households in the intervention group were more likely to seek advice at a hospital or a clinic (29 pp, $p < 0.01$) as opposed to directly visiting a community pharmacy, incurring higher costs on medicines including antibiotics (58%, $p < 0.05$). Conditional on using antibiotics, those in the intervention arm were less likely to use Watch or Reserve categories of antibiotics (according to WHO categorization) without physician oversight (22.1 pp, $p < 0.05$). Overall antibiotics use, however, remained similar across both groups. Treatment effects on non-prescription antibiotic use were concentrated among children with a reported illness episode in the three months preceding the household visit and among parents with the lowest baseline knowledge of antibiotics and AMR.

Policy Implications. This study is among the first to evaluate the impact of public awareness campaigns on AMR in LMICs, using a phone-based application to track antibiotic consumption. We find widespread non-prescribed antibiotic use among children, but our results are encouraging — a contextually adapted, multifaceted educational intervention significantly reduced non-prescription use and increased the likelihood of households seeking care in formal health facilities. While this study informs policy efforts to reduce AMR in Nepal, both the educational intervention and the phone-based surveillance system can serve as prototypes for tackling AMR in LMICs.

Ind-969 Assessing the Role of Special Disability Schools in Shaping Labor Market Outcomes for Indonesians with Disabilities

PRESENTER: **Anu Rammohan**

AUTHORS: Mohammad Farhad, Rumayya Rumayya, Ilmiawan Auwalin

Background: Disability has the potential to exacerbate existing vulnerabilities, and previous research has found evidence of an employment gap for persons with disabilities (PwD). Indonesia has approximately 22.97 million PwDs, constituting around 8.5% of the population. Despite this significant demographic, PwDs accounted for only 0.53% of the workforce in 2022, according to the Indonesian Central Statistics Agency (BPS). Special schools, often referred to as SLBs (*Sekolah Luar Biasa*) were introduced in 2003 by the Government of Indonesia (National Education System Law No. 20/2003) to cater to students with special needs and disabilities, offering a specialised curriculum and infrastructure. International literature is ambiguous on whether Special schools or Inclusive education are better for labour market integration of PwD. However, despite special schools for PwD being an important policy initiative of the Government of Indonesia, there is no research on the labour market outcomes of PwD who attended Special Schools. **Aim and methods:** This paper uses nationally representative data on working-age PwD from the Indonesian Labor Force Survey (SAKERNAS) to empirically analyse employment outcomes of Indonesian adults who were educated in Special schools for PwD relative to their disabled counterparts who received an inclusive education. We estimate multivariate regression models for employment outcomes, controlling for an array of individual socio-economic and demographic characteristics. **Results:** Our study shows that: (i) attendance at Special schools is associated with a 3.1 percentage points lower probability of being employed relative to PwD who received an Inclusive education; (ii) those PwD with severe disabilities who attended Special Schools had a 28.3 percentage points higher probability of being employed relative to those PwD who attended General schools.

.

Ind-976 Optimising Blood Management Systems in England: Evaluating the Impact and Cost Efficiency of Electronic Blood Transfusion Systems in NHS Hospitals

PRESENTER: **Florian Tomini**, Queen Mary University of London, UK

AUTHORS: Mike Murphy, Simon Stanworth, Sophie Staples, Laura Green, Hayley Evans, Antony Palmer, Paula Dhiman, Hiro Farabi

Electronic Blood Transfusion Systems (EBTs) offer significant potential to improve patient safety, operational efficiency, and digital traceability within NHS transfusion practice. These systems include electronic bedside systems (EBSs), electronic blood ordering (EBO), electronic blood fridges (EBFs), and traceability platforms. While EBTs are increasingly adopted, their impact on blood stock management, wastage, and broader service efficiency remains under-evaluated.

This study assessed the adoption and effects of EBTs through a national survey (June–September 2023) and linked transfusion inventory data from 2000 to 2022. Difference-in-differences models with propensity score matching were used to estimate the impact of EBT implementation on red blood cell (RBC) wastage and stock indicators.

Responses were received from 55.6% (114/206) of NHS hospitals in England, with 66.7% (76/114) reporting adoption of at least one EBT component. Electronic blood fridges were the most widely implemented, adopted by 57.5% (66/114) of respondents. However, full adoption of all EBT components remained uncommon.

Matched analysis showed that EBT implementation—particularly electronic blood fridges—was associated with a 13.4% reduction in avoidable RBC wastage and a 14.8% reduction in time-expired wastage. This translates to an estimated £4.4 million annual cost saving across the NHS.

Yet the real value of EBTs extends beyond cost, in reducing pressure on limited donor blood supplies, enhancing system resilience, and supporting digital transformation. These broader clinical and operational benefits—such as improved traceability, emergency responsiveness, and staff efficiency—remain to be fully quantified.

Ind-1331 Analyzing the Efficiency of Health Systems: A Systematic Review of Literature

PRESENTER: **Rahab Mbau**

AUTHOR: Edwine Barasa

Background Efficiency refers the use of resources in ways that optimize desired outcomes. Health system efficiency is a priority concern for policy makers globally as countries aim to achieve universal health coverage and face the additional challenge of an aging population. Efficiency analysis in the health sector has typically focused on the efficiency of healthcare facilities (hospitals, primary healthcare facilities), with few studies focusing on system level (national or sub-national) efficiency. We carried out a thematic review of literature that assessed the efficiency of health systems at the national and sub-national level. **Methods** We conducted a systematic search of PubMed and Google scholar between 2000 and 2021 and a manual search of relevant papers selected from their reference lists. A total of 131 papers were included. We analyzed and synthesized evidence from the selected papers using a thematic approach (selecting, sorting, coding and charting collected data according to identified key issues and themes). **Findings** There were more publications from high- and upper middle-income countries (53%) than from low-income and lower middle-income countries. There were also more publications focusing on national level (60%) compared to sub-national health systems' efficiency. Only 6% of studies used either qualitative methods or mixed methods while 94% used quantitative approaches. Data envelopment analysis, a non-parametric method, was the most common methodological approach used, followed by stochastic frontier analysis, a parametric method. A range of regression methods were used to identify the determinants of health system efficiency. While studies used a range of inputs, these generally considered the building blocks of health systems, health risk factors, and social determinants of health. Outputs used in efficiency analysis could be classified as either intermediate health service outputs (e.g., number of health facility visits), single health outcomes (e.g., infant mortality rate) or composite indices either intermediate outputs of health outcomes (e.g., Health Adjusted Life Expectancy). Factors that were found to affect health system efficiency include demographic and socio-economic

characteristics of the population, macro-economic characteristics of the national and sub-national regions, population health and wellbeing, the governance and political characteristics of these regions, and health system characteristics. **Conclusion** This review highlights the limited evidence on health system efficiency, especially in low- and middle-income countries. It also reveals the dearth of efficiency studies that use mixed methods approaches by incorporating qualitative inquiry. The review offers insights on the drivers of the efficiency of national and sub-national health systems, and highlights potential targets for reforms to improve health system efficiency.

Ind-1567 Integrated Care as a Mean to Provide Financial Risk Protection: The Case of Integrated Community Case Management (ICCM) in Uganda

PRESENTER: **Bryan Patenaude**
AUTHORS: Gatien de Broucker, Elizabeth Ekirapa Kiracho, Anthony Ssebagereka

Background

Since 2008, in Uganda, public healthcare facilities offer healthcare free of charge to all residents. However, shortcomings in access to primary care and in care continuity marred the effectiveness of public healthcare, particularly for its poorest citizens: pneumonia, diarrhea, malaria, and malnutrition remained leading causes of morbidity and mortality in deaths in children under 5. In 2010, Uganda extended the management of these diseases with Integrated Community Case Management (ICCM) – training community health workers and deploying them as part of the healthcare force mandated to tackle these child health issues.

Although the program faces several challenges, including sometimes shifting the cost of care incurred by community health workers to users, it confers considerable benefits, easing referrals and promoting access to public healthcare services for the targeted illnesses. As ICCM targets more disadvantaged communities, this aspect is promising as these infectious diseases can pose a significant economic burden. While ICCM seems to improve how caregivers navigate the healthcare system, we don't know whether it will reduce their economic cost.

Research questions

What is the economic burden of ICCM-covered disease for poorer households? Do caregivers who follow the care-seeking pathway planned by ICCM see reduced costs? Are they less likely to experience catastrophic health expenditures?

Methods

The analysis used data collected in 2018 through the Decade of Vaccine Economics project led by Johns Hopkins and Makerere Universities, which estimated the cost of pneumonia, diarrhea, and measles treated in public and private facilities in Uganda. We ran a benefit-incidence analysis to describe the utilization of government-funded healthcare facilities compared to private facilities across patients of different wealth status and seeking care for ICCM-covered diseases. We compared the benefits and costs incurred by caregivers who followed the care-seeking pathway in ICCM guidelines against those who did not, and those who sought care for measles. Measles was also included in the analysis for comparison as a disease not covered by ICCM in Uganda.

Four outcomes were included as benefits and costs. Public healthcare expenditure (PHE), defined as the total cost incurred by public facilities to treat a case, was a measure of direct health benefit to caregivers. Out-of-pocket payments (OPP) covering medical and non-medical expenses were a measure of direct cost to caregivers. We included as measures the indirect cost to caregivers the time spent receiving healthcare and the distance traveled to a health facility.

Key results

Preliminary results show that, expectedly, poorer healthcare users benefited most from PHE for all three diseases (concentration indices from -0.169 to -0.244), while most costs (OPP, time, distance) for pneumonia and diarrhea were allocated to more affluent users (0.077 to 0.346). Not so much for measles, where highly pro-poor PHE (-0.244) failed to reduce OPP for the poorest users (0.028).

Conclusions and implications

The public sector substitutes more effectively OPP with PHE for disease covered by ICCM than for measles. Expanding ICCM to respond to disease outbreaks could complement well, and likely at low-cost, existing treatment and prevention strategies to ensure better financial risk protection for everyone.

Ind-1635 Evidence of Incentivizing Secondary Hospitals to Reduce Claims on Tertiary Hospitals in Indonesian National Health Insurance (NHI)

PRESENTER: **Diah Eva Sari Husnul Khotimah**
AUTHORS: Anastasia Susanto, Hasbullah Thabrany, Iko Safika, Riris Dian Hardiani, Yusuf Subekti, Dini Kurniawati

Background.

Health services in Indonesian hospitals under the NHI scheme are reimbursed prospectively through the Indonesia Case-Based Groups (INA-CBG) payment system. The INA-CBG tariff had remained unchanged since 2016, until January 2023, when the Ministry of Health introduced a revised tariff structure. This adjustment incorporates hospital classification, which in Indonesia is uniquely determined by the number of hospital beds. Previously, the tariff for identical procedures was higher for Class A hospitals (minimum 250 beds) compared to Class B (minimum 200 beds), Class C (minimum 100 beds), and Class D (minimum 50 beds). The 2023 revision includes a tariff increase for outpatient

services, which are now 19.1%, 37.0%, 39.7%, and 40.0% higher for tertiary (Class A) and secondary hospitals (Classes B, C, and D), respectively, reducing the disparity between these categories. Similarly, inpatient tariffs increased by 11.1%, 15.30%, 15.8%, and 11.9% for Class A, B, C, and D hospitals, respectively. This study evaluates the impact of the revised INA-CBG tariffs on hospital revenue and service utilization within the Indonesian National Health Insurance (JKN) program

Method

This study utilized e-claim data from the Ministry of Health, encompassing 232 million claims submitted by all hospitals in Indonesia contracted by the Social Insurance Administering Body for Health (BPJSK), which oversees the National Health Insurance (JKN) program. A descriptive analysis was performed to evaluate hospital revenue and service utilization before and after the 2023 tariff adjustment for both outpatient and inpatient services.

Key variables analyzed included hospital ownership (public or private), hospital location (categorized by regions 1 to 5 as defined by the Ministry of Health), and hospital ward class (Class I, II, or III). Ward classifications were based on the number of beds per room: Class I wards accommodate up to 2 beds per room, Class II up to 4 beds, and Class III up to 6 beds.

Results

There was a 24.8% increase in hospital revenue from outpatient services in Class A hospitals, which was notably lower than the increases observed in Class B, C, and D hospitals, at 43.9%, 36.5%, and 42.0%, respectively. Similarly, revenue from inpatient services increased by 37.2% in Class A hospitals, compared to 46.4%, 46.2%, and 46.2%, in Class B, C, and D hospitals, respectively.

The utilization of both outpatient and inpatient services was also considerably lower at class A hospitals than those of class B, C, and D hospitals (outpatient: 21.7% vs 35.4%, 30.4%, and 34.0%; inpatient: 26.9% vs 33.1%, 33.5%, and 34.8%, respectively).

Conclusion and recommendations

The tariff increase for secondary hospitals appears to reduce utilization at tertiary hospitals, potentially reflecting improved access to secondary care. However, cost-containment measures are needed to ensure system sustainability. Further research should explore the impact of tariff changes on health outcomes to confirm whether increased utilization aligns with improved care quality and equity.

Ind-1679 Did Incentive for Vaginal Delivery in Primary Care Settings Shift Healthcare Cost in Indonesia s National Health Insurance Program?

PRESENTER: **Aditya Darmasurya**, BPJS Kesehatan
AUTHORS: Bayu Yudanto, Rahma Anindita

Background:

Vaginal delivery referrals from primary care to hospital care shows an increasing trend in Indonesia's National Health Insurance(JKN) Program. This leads to an increase of expenditure in hospital care from 420 million USD in 2019 to 483 million USD in 2022. Urban areas show more hospital vaginal delivery utilization than that of rural areas. In January 2023, a raise in fee-for service tariff for vaginal delivery as an incentive in primary care level was issued. This was intended to reduce referrals to hospitals and prevent unnecessary healthcare costs. Was there any difference on vaginal delivery referral rates between urban and rural areas after the policy implementation? Did the incentive create cost savings hence shifting healthcare cost?

Objectives:

We investigated whether the vaginal delivery incentive in primary care settings was associated with a reduction of referral rates hence creating cost savings in urban and rural areas.

Methods:

We used a non-experimental big data analysis in this study. An observational descriptive method was applied. Healthcare data on vaginal delivery services and costs were taken from BPJS Kesehatan E-database. Serial data from 2019 to 2023 were analyzed. Healthcare data in Java, Bali, and Sumatera provinces were classified as urban data, while data in Nusa Tenggara, Kalimantan, Sulawesi, Maluku, and Papua provinces were classified as rural data.

Results:

An overall vaginal delivery data from 75 million female JKN members aged 15 to 50 years old were analyzed. In urban areas, the referral rate increased from 62 percent in 2019 to 69 percent in 2023. In rural areas, the increase was less than that of urban areas: from 63 percent in 2019 to 65 percent in 2023. However, the number of primary care vaginal delivery cases in rural areas increased compared to that of urban areas. There was an increase of 112 thousand cases per year in rural areas, while in urban areas there was a decrease of 54 thousand cases per year. Based on the number of cases in 2023, there was no cost savings made in urban areas. Even so, in rural areas the cost saving reached 2.3 million USD per year.

Conclusion:

Although the incentive policy did not show a decrease of referral rates in both urban and rural areas, the referral rate in rural areas were more

controlled than that of urban areas. Shift of healthcare costs were only seen in rural areas as indicated by the cost savings made. This was may be due to specialist care in urban areas were more accessible than that in rural areas. It was also possible that patients' perception that specialist doctors are more competent in treating vaginal delivery cases may be more apparent in urban aeas. Further studies are needed to evaluate the policy effect on behavioural characteristics. This study encourages further incentive policies to address area distinctiveness in order to shift healthcare costs to primary care settings.

Key words:

Vaginal delivery, incentive, referral rate, cost saving

Ind-2125 Impact Of Non-Specialistic Time, Age, Comorbidity, Complication (TACC) Referrals Under National Health Insurance

PRESENTER: **Khaterina Manurung**
AUTHORS: Dedy Revelino Siregar, Wan Aisyiah Baros, Donni Hendrawan, Mahlil Ruby

Backgrounds: The role of First Level Health Facilities in providing effective and efficient services is the concept of Primary Health Care in strengthening Primary Health Facilities as gatekeepers capable of handling 144 diagnoses completely and independently. TACC (Time, Age, Comorbidity, Complication) criteria are used by doctors to refer 144 types of Primary Health Facilities diagnoses which are level 4 competencies of primary doctors to advanced services. However, there is currently no evaluation of the use of TACC for Non-Specialist Referrals related to the purpose of using TACC, the appropriateness of the choice of TACC, the accuracy of the choice of diagnoses that become complications/comorbidities. Effective primary health facilities and referral systems are key to achieving better quality of health care. The aim of this study was to provide an evaluation and recommendations for improvement in TACC Non-Specialist Referrals. **Methods:** Cross sectional method with quantitative data was used in this study with variable data on demographics, visits and costs of Hospital Outpatient TACC Non-Specialist Cases and Primary Care Outpatient TACC Non-Specialist Referral visits data from 2019-September 2024. **Results:** The TACC Non-Specialist Referral rate was higher than the Non-Specialist Referral rate above the Non-Specialist Referral target of 2% with a total of 4,771,831 referrals in the period 2019-September 2024. TACC Non-Specialist Referrals in the same period, referred with the most criteria using Time at 62% and Age at 20%. The highest referrals derived from TACC Non-Specialist Referrals were made by Outpatient Primary Health Facilities amounting to 3,695,374 where 74% of all total collaborating Primary Health Facilities were Outpatient Primary Health Facilities. The Outpatient Primary Health Facilities referred with the highest Time criteria with diagnoses of Myopia and Disorder of refraction, unspecified. While on the Age criterion were the diagnoses of Essential (primary) hypertension and Non-insulin-dependent diabetes mellitus. The highest diagnoses on the Complication and Comorbidity criteria were Myopia and Disorder of refraction, unspecified and Essential (primary) hypertension. Participants who were referred to Hospitals were mostly from the Formal Sector segment (41%), followed by Contribution Beneficiary participants (27%) who came from government-owned Puskesmas (51%) and the next came from Primary Clinics (40%). The impact of health cost inefficiencies in the same period was IDR 950 billion in outpatient care which are non-specialist cases at Hospitals. **Conclusions:** Currently, TACC Non-Specialist Referrals have not been set target limits that must be referred to Hospitals because they are not yet included in the performance calculation component in Performance-Based Capitation. The selection of TACC criteria for Non-Specialist Referral diagnoses is not in accordance with the definition of the criteria so it is necessary to evaluate the use of TACC and not as a condition for passing referrals. There is potential inefficiency in the cost of health services at Hospitals, which needs to be re-evaluated.
Keywords: Non-specialist referral, gate keeper, Time, Age, Comorbidities, Complications.

Ind-2200 Quality of Service & Supply Infrastructure Financing in Increasing JKN Member Satisfaction

PRESENTER: **Mardiana Mardiana**
AUTHOR: Mr. Mahlil Ruby

Abstract

Introduction: BPJS Kesehatan, as the governing body for Indonesia's National Health Insurance (NHI) program, plays a critical role in ensuring member satisfaction to strengthen public trust in the program's implementation. Member satisfaction is a measurable indicator of health service quality, determined by comparing the expected standards of service with the members' actual experiences. Quality of service is influenced by the provider's ability to consistently meet or exceed these expectations. Beyond physical health recovery, member expectations also encompass various dimensions, including the professionalism, competence, and communication skills of service providers, the availability and accessibility of information, as well as the adequacy of facilities and the physical environment in which services are delivered.

Method: This study aims to evaluate the relationship between health facility services and the satisfaction levels of JKN members. This research uses a literature study method to obtain secondary data in the form of results from previous research and other relevant sources.

Result: A review of existing literature and an analysis of SIF implementation suggest that the quality of services provided by health facilities is a significant determinant of member satisfaction. Health facilities are required to enhance their infrastructure, increase working capital, provide comprehensive medical equipment, and expand service points to fulfill their commitment to maintaining service quality for JKN members.

Conclusion: The 2023 Member Satisfaction Survey identified key indicators of satisfaction, such as the adequacy of infrastructure, the condition of waiting areas and seating, the availability and sophistication of medical devices, and the accessibility of health facilities. To address these requirements, BPJS Kesehatan collaborates with partner banks to provide Supply Infrastructure Financing (SIF), enabling health facilities to access business development funds.

Ind-2245 Program Evaluation for Enhanced Health System Performance via District Coordination Meetings

PRESENTER: **Emilienne Carine Bieme-Ndi**, Clinton Health Access Initiative
AUTHORS: Michael Budzi, Nadege Nnang, Shalom Ndoula, Clarence Mbanga, Yauba Saidu, Choice Okoro, Sibenu Njike, Ms. Jeniffer Adungosi

Introduction: Health systems in low- and middle-income countries face significant inefficiencies that hinder equitable access to essential services, often leaving vulnerable populations underserved. In Cameroon, these challenges are exacerbated by fragmented governance, poor data quality, and limited coordination, all of which undermine efforts to achieve improved immunization coverage as well as health outcomes. Regular reviews of program data are crucial for monitoring performance and ensuring effective service delivery. Through systematic data analysis, issues such as service delivery and resource allocation disruptions can be identified and addressed, ensuring that essential services reach those in need. Despite these strategies, critical gaps remain at lower levels of the health system, particularly in district-level coordination. Monthly coordination meetings, essential for data review and decision-making, are hindered by governance, administrative, and logistical challenges. In response, the Expanded Program on Immunization (EPI), supported by CHAI, conducted a situational analysis to address these gaps by enhancing performance reviews, improving data utilization, and ensuring the timely availability of resources for informed decision-making. **Methodology:** This study, conducted from July to October 2023, aimed to evaluate the effectiveness of district-level coordination meetings in Cameroon's health districts. A **qualitative research design** was employed, utilizing key informant interviews with 10 regional EPI managers, 10 regional chief of planning and 24 District Medical Officers (DMOs) and 24 chiefs of health centers across 10 regions. Purposeful sampling was used to select participants for interviews. **Results:** Coordination meetings are essential for the efficient functioning of health districts. They facilitate data analysis, performance review, and strategic planning, leading to improved data quality, personnel management, community mobilization, and overall program effectiveness. However, challenges such as limited resources, inadequate supervision, and personnel shortages hinder the full potential of these meetings. Overlapping activities, transportation constraints, and communication issues further complicate the situation. To enhance the efficiency of coordination meetings and improve health system performance, it is crucial to address these challenges. This may involve: - Securing adequate funding to support meeting logistics, staff training, and transportation. - Implementing effective supervision mechanisms to monitor health facility performance and ensure adherence to guidelines. - Investing in staff training to improve data management, analysis, and interpretation skills. - Enhancing communication channels within the district to facilitate information sharing and collaboration. - Focusing on key priorities and avoiding overlapping activities to optimize resource utilization. **Conclusion:** District-level coordination meetings are vital for effective communication, monitoring, and addressing health system challenges at the local level. They provide a platform for stakeholders to share information, collaborate, and make data-driven decisions. **Implications for Policy and Practice:** This study underscores the importance of strengthening district-level coordination meetings to ensure effective health system performance. By addressing logistical constraints, enhancing data utilization, and integrating supply chain management into these meetings, policymakers can further optimize resources and improve healthcare delivery. Effective coordination and performance management at the district level are essential for achieving equitable health outcomes and ensuring that essential services are accessible to underserved populations.

Ind-2467 Age-friendly Neighborhood Environment and Trajectories of Multimorbidity: The Moderating Effect of Life-course Socioeconomic Status

PRESENTER: **Jing Liu**
AUTHORS: Tao Zhang, Xiaoqian Gong, Kuanlie Jiang

Background & Objectives: Limited longitudinal research exists on the combined effects of environmental factors and life-course socioeconomic status (SES) on multimorbidity in China. This study aims to explore the cumulative impact of age-friendly neighborhoods on multimorbidity over time, focusing on SES moderation. **Research Design & Methods:** Analyzing data from 10,125 participants in the China Health and Retirement Longitudinal Survey (2011-2020), this study assessed multimorbidity through self-reported chronic diseases and evaluated neighborhood environments using eight domains from the Age-Friendly Cities and Communities framework. Childhood and adulthood SES were measured using latent class analysis. Latent growth curve models examined the effects of neighborhood environment, life-course SES, and their interactions on multimorbidity. **Results:** The study found a statistically significant increase in multimorbidity over time, with an intercept of 0.514 and a slope of 0.085. Notably, government support showed an independent association with the baseline number of chronic diseases ($\beta = -0.078$, $p < 0.1$). The interaction between government support and childhood SES was also significant ($\beta = -0.183$, $p < 0.05$), suggesting that unfavorable childhood SES could reduce the protective effects of government support. Additionally, adulthood SES interacted with factors such as information infrastructure ($\beta = -0.068$, $p < 0.001$) and neighborly support ($\beta = -0.092$, $p < 0.1$), and transportation interacted with childhood SES ($\beta = -0.028$, $p < 0.05$), all negatively affecting the rate of change in multimorbidity. These findings suggest that individuals with higher SES derive greater benefits from these age-friendly neighborhood environment domains compared to their lower SES counterparts. **Discussion & Implications:** Age-friendly neighborhoods with strong government support, neighborly support, and developed infrastructure slow multimorbidity progression. However, these benefits are influenced by life-course SES. Policymakers should consider disadvantaged populations' access to environmental resources and address potential neighborhood socioeconomic health inequalities.

Ind-2562 Effect of Illinois' HBIA/HBIS Insurance Programs for Undocumented and Non-Citizen Immigrant Seniors on Hospitals' Uncompensated Care

PRESENTER: **Aresha Martinez-Cardoso**
AUTHORS: Bin Yu, Apurva Nayak

Background: Latinxs are aging faster than other racial/ethnic group in the US. By 2050, they are projected to be the largest share of the immigrant, older population. As Latinx immigrants age, however, they experience the fastest decline in health and emerging health disparities, despite having an initial health advantage. Limited access to health insurance and delayed healthcare utilization is a major determinant of health disparities in older age among Latinx immigrants. Research on how health insurance and access shape health disparities among aging Latinxs is

limited by (1) confounding between insurance and immigration and socioeconomic characteristics that shape health and (2) simultaneous changes in insurance access and lifecourse aging as Latinxs enter older adulthood.

Objective: To address these challenges, this study leveraged a policy intervention in Illinois to study changes in Illinois hospitals' uncompensated care using quasi-experimental methods. In 2020 and 2022, Illinois launched the Health Benefits for Immigrant Seniors (HBIA) and Health Benefits for Immigrant Adults (HBIA) programs, which were the first state policies that extended coverage equivalent to full-scope Medicaid to low-income undocumented immigrants and noncitizens ages 42 and older; the majority (58%) of HBIA/HBIS enrollees (n=67,310) were Latinx.

Methods: We use Medicare Costs data, HBIA/HBIS enrollment data, and county-level American Community Survey to compute annual levels of uncompensated care from 2018-2023 stratifying hospitals into high and low HBIA/HBIS enrollment counties. We then employ difference-in-differences models to study the impact of HBIA and HBIS on annual uncompensated care in Illinois hospitals, with comparisons to Indiana and Wisconsin.

Results: We find that HBIA and HBIS were associated with reductions in hospitals' charity (HBIS: $960,115, s.e. 253,405, $p<0.01$; HBIA: $1.15 million, s.e. 272,333, $p<0.01$) and total uncompensated care (HBIS: $2.73 million, s.e. 1.17 million, $p=0.02$; HBIA:$3.96 million, s.e. 1.3 million, $p=0.002$). Furthermore, counties with high proportions of immigrants experienced larger reductions in charity care associated with the policy, while counties with high proportions of enrollees relative to eligible immigrants experienced larger reductions in bad debt and charity care.

Conclusion: This study leverages a novel policy in a major immigrant state to examine how health insurance shapes healthcare delivery and costs. To our knowledge, this is the first study to examine the effects of Illinois HBIA/HBIS policies. The study contributes to scholarship on the drivers of health disparities among the growing aging immigrant population, and policy debates to expand health insurance to undocumented and noncitizens excluded from healthcare.

Ind-399 The Political Effect of Health Insurance: Evidence From the Implementation of Urban-Rural Resident Basic Medical Insurance in China

PRESENTER: **Dan Cao**, Xi'an Jiaotong University
AUTHORS: Yangling Ren, Bo Li

Background In 2016, China proposed to integrating Urban Resident Basic Medical Insurance and New Rural Cooperative Medical Insurance, and establishing urban-rural resident basic medical insurance (URRBMI). As a vital measure to break the dual division system of city and countryside, few studies examined whether the implementation of URRBMI helped build citizen trust of rural residents. In this study, we attempt to explore the political effect of URRBMI in China. **Methods** By using data from 4 waves of the China Family Panel Study, a difference-in-difference model was set and common trend test was adopted for the statistical analysis. We excluded those who weren't rural residents and who didn't participate in basic medical insurance. To ensure the sample was potential beneficiaries of URRBMI, the final sample finally included only hospitalized patients and their families, which contained 19643 respondents. **Results** We found that the trust score in local government of Chinese rural residents increased 0.374 after the implementation of URRBMI, by increasing the compensation fee of rural residents and their families, and residents' satisfaction towards health system. This study also revealed the heterogeneous effect of URRBMI on trust in local government. We found that the integration had more significant effects in people with chronic conditions, middle-aged and elderly residents, high-income residents and people with high social trust. **Conclusions** These empirical results helped people understand whether and how Chinese URRBMI policy generated political effect. It provided a comprehensive analysis of how to enhance residents' political through the reform of health insurance scheme. The mechanism and heterogeneity results implies that the basic health insurance in China need furtherly improve its compensation rate and the health resource allocation in rural area, and the disadvantaged such as chronic patients and elderly should be paid more attention to. What's more, social trust is also important to increase political trust through health insurance policy.

1:30 PM –3:00 PM TUESDAY [Evaluation Of Policy, Programs And Health System Performance]

Bali International Convention Centre – Bougainville

New Methods in Program Evaluations

MODERATOR: **Erin Strumpf**, McGill University

Ind-962 Difference-in-Differences with Unpoolable Data (UNDID)

PRESENTER: **Erin Strumpf**, McGill University
AUTHORS: Sunny Karim, Matt Webb, Nichole Austin

Difference-in-differences (DID) is commonly used to estimate treatment effects but is infeasible in settings where data are unpoolable due to privacy concerns or legal restrictions on data sharing, particularly across jurisdictions like countries or states. When treatments or policies vary at the country level, data from treatment and control units may not be able to be combined. Examples include health care data from different insurers (e.g., Canadian provinces, private and public insurers, all-payer claims databases across states), restricted-use micro-data held in secure environments (e.g., vital statistics, income tax, business data held in Statistics Canada's or the US Census Bureau's Research Data Centres), and

electronic health records federated across countries (e.g., the European Health Data Space). In this study, we identify and relax the assumption of data poolability in DID estimation. We propose an innovative approach to estimate DID with unpoolable data (UN-DID) which can accommodate covariates, multiple groups, and staggered adoption. Through analytical proofs and Monte Carlo simulations, we show that UN-DID and conventional DID estimates of the average treatment effect and standard errors are equal and unbiased in settings without covariates. With covariates, both methods produce estimates that are unbiased, equivalent, and converge to the true value. The estimates differ slightly but the statistical inference and substantive conclusions remain the same. Two empirical examples with real-world data further underscore UN-DID's utility. The UN-DID method allows the estimation of cross-jurisdictional treatment effects with unpoolable data, enabling better counterfactuals to be used and new research questions to be answered.

abs-os666 A Pooled Regression Approach to Estimating Difference-in-Difference Models With Multiple Treatments and Correlated, Staggered Timing

PRESENTER: **Partha Deb**

The difference-in-differences (DID) study design is an important tool for causal inference in economics. In recent years, there has been an extraordinary number of new theoretical papers on how to obtain DID estimates in regression-based implementations of these study designs. In particular, the discovery that the two-way fixed effects estimator of a model with a constant treatment effect can produce biased estimates of treatment effects when there is staggered treatment timing and heterogeneous treatment effects, has led to new approaches for dealing with both staggered timing and heterogeneous treatment effects (e.g. Borusyak et al, 2024, Callaway and Sant'Anna, 2021, Deb et al, 2024, and Sun and Abraham, 2021).

In many applications, however, the researcher is interested in multiple events that are related to each other and occur during the sample period with correlated, but not concurrent, timing. In other applications, while the researcher may be interested in one event, they are worried about the confounding events with correlated timing. In such circumstances, Chaisemartin and d'Haultfoeuille (2023) and Tsai (2024) show that both the TWFE regression with multiple event indicators and the staggered DID estimators designed for use with one treatment are biased in the presence of confounding events. Each develops a new approach, but both are complex to implement.

In this paper, I extend the framework in Deb et al (2024) to the case of multiple events with correlated timing. Identification of the group-time level effects of each treatment requires the existence of not-yet-treated units for each event. The regression specification turns out to be a straightforward extension of the specification in Deb et al (2024). Average treatment effects on the treated can be recovered for each event taken individually and, in principle, for all combination of the events, although these can be difficult to identify in finite samples with more than just a few event-types.

I apply this method to an examination of the effects of punitive and priority prenatal substance use policies (PSUP) for expecting mothers on their mental health outcomes. I use data from the Behavioral Risk Factor Surveillance System from 2005-2018. The representative sample of women of child-bearing age with at least one child from 34 states has 440,446 observations. There is considerable variation in the timing of the start of the policies at the state level. Between 2007 and 2018, 13 states enacted punitive PSUP. Between 2008 and 2016, 9 states enacted priority PSUP. Four states enacted both types of policies, albeit not at the same time. Finally, 18 states had no PSUP.

The results show that the TWFE estimator that simply allows for 2 policies produces biased estimates for the effects of each policy and for the effect of both policies implemented simultaneously. The staggered DID estimator that takes one treatment at a time also produces biased estimates (and cannot produce estimates for both policies together). The regression-based estimator produces intuitive estimates of a variety of ATET.

abs-os668 A New Approach to Evaluation Using Observational Data That Combines Instrumental Variable and Machine Learning Regression Models

PRESENTER: **Mr. Stephen O'Neill**, London School of Hygiene & Tropical Medicine (LSHTM)
AUTHOR: Richard Grieve

Precise subgroup-specific estimates are essential for informing targeted or personalized treatment decisions, but current approaches to generating policy-relevant evidence are inadequate. Randomized Controlled Trials (RCTs) are often underpowered for subgroups, and observational studies are vulnerable to confounding by indication (selection bias). If a valid instrumental variable (IV) is available this can reduce bias, the resultant estimates are often highly uncertain, particularly when the IV is not strong. Moreover, IV estimates may be sensitive to the choice of model specification, particularly where interest lies in estimating heterogeneous effects.

These methodological challenges are exemplified in a new evaluation of the comparative effectiveness of Surgery Or Radio-Therapy (the SORT study) for non-small cell lung cancer (NSCLC) that uses UK cancer registry data. The primary endpoint is 2-year all-cause mortality. The study considers subgroups that include age, sex, cancer stage, frailty, and performance score. The IV, historic provider preference, is expected to be relatively weak for some subgroups due to sample size constraints, exacerbating concerns about precision.

To address these challenges, we build on prior work combining IV and regression approaches by extending them with machine learning methods that are less prone to model misspecification. Specifically, we adapt the Hansen-Stein estimator (Hansen, 2017), which balances bias and efficiency by averaging OLS and 2SLS estimates, to employ forest-based approaches. We develop a novel estimator (Forest-Stein) which combines causal forests (CF) and IV forests (IVF) to enhance model robustness in the face of weak instruments and small samples, while allowing for more flexible model specification.

We conduct a Monte Carlo simulation study to assess the relative performance of our proposed estimator Forest-Stein compared to OLS, 2SLS,

Hansen-Stein, CF, and IVF estimators.. We define a simple DGP, with eight observed covariates some of which influence treatment, outcomes or them both, an unobserved confounder and a binary instrument (Z). We define a subgroup indication G that influences treatment and the outcome. The true effect is defined to differ by subgroup. We estimate an overall effect and effects for two subgroups (G=0 and G=1), varying the sample size {500, 1000, 5000} and IV strength from completely irrelevant to very strong. We report absolute bias and RMSE in training, testing and hold out samples

We show that in line with findings for Hansen-Stein approach using OLS and 2SLS, our Forest-Stein estimates tend towards the causal forest estimates as the IV becomes weaker, while tending towards the IV forest estimates as the IV becomes stronger, guarding against imprecision associated with weak instruments in smaller samples.

Ongoing work will expand the simulations study to consider non-linear outcome model specifications where we anticipate Forest-Stein will outperform Hansen-Stein, and consider different forms of effect heterogeneity and varying levels of unobserved confounding and instrument strength. Finally, we illustrate the performance of the approach in the SORT case study to address the challenge of estimating heterogeneous effects for all subgroups of policy relevance including those where there is a concern that the IV may not be strong.

Ind-2362 Revisiting the Causal Impact of Response Time on Health Outcomes in Emergency Care Using Air Temperature as an IV

PRESENTER: **Thomas Pelloquin**
AUTHOR: Pauline Chauvin

This paper examines Response Time (RT) in emergency care, focusing on Large Vessel Occlusion (LVO), the most severe form of Acute Ischemic Stroke (AIS), which is a leading cause of disability and mortality, with EU strokes projected to increase by 34% by 2035. The best treatment for LVOs (Mechanical Thrombectomy) is rare and geographically limited, highlighting the challenge of balancing centralized efficiency with timely access for acute conditions. However, linking RT to outcomes is difficult due to endogeneity from severity biases and truncated data, such as patient and emergency services responsiveness, and hospital access.

Healthcare production is not only time-dependent but also varies greatly between individuals; this heterogeneity arises from unobserved or endogenous variables, particularly the severity of the condition, the rate of health depreciation or patient health literacy. This paper leverages original large-scale individual data, containing precise time measures for 15,467 episodes of acute ischaemic strokes (AIS), starting at symptom onset, as well as precise data on patient health outcomes -transformed into a utility index-, to address this complex relationship over the complete response time segment.

By choosing an original instrument —air temperature— in a non-parametric estimation, we identify the average treatment effect (ATE) of an increase in response time, as well as the average treatment effect on the treated (ATT). Furthermore, the heterogeneity in patients' returns to reducing response time is examined. Comparing the estimates of the relationship identified using an IV method with existing results in the clinical literature highlights the value of a robust identification strategy in correcting for effects' underestimation. Our approach suggests a near-linear relationship between delays and outcomes, challenging the conventional view of bounded effects in the management of AIS. Our ATT results support existing clinical recommendations, but policy-relevant treatment effects require a more precise account of patient benefits' distribution and health loss valuations.

Ind-1908 Combining Satellite Data and Causal Machine Learning to Evaluate Brazil s Family Health Programme in Slums

PRESENTER: **Ivan Ochoa-Moreno**
AUTHORS: Akseer Hussain, Marc Suhrcke, Rodrigo Moreno-Serra, Julia Hatamyar

Background: More than 2 billion people worldwide live in informal urban settlements (slums). This study examines the effects of primary health care provided through the Family Health Strategy (ESF) in Brazil, given geographic and environmental variations in the characteristics of Brazilian slums. *Methods:* We explore the potential of satellite data to provide high-resolution spatial information on slum areas as a complement to traditional survey methods and economic indicators. Using this approach combined with double-robust machine learning of municipal-level treatment effects, our aim is to understand the heterogeneity of slum conditions – spatial and socioeconomic – and their impact on population health with a focus on healthcare interventions, specifically the Family Health Strategy and its relationship to non-communicable diseases (NCDs). *Findings:* Within municipalities, we find significant differences across a variety of health-related satellite data measures between slum and non-slum areas; for example, slums are hotter, more humid, and have poorer air quality than their surrounding areas. These environmental qualities influence the ability of the ESF to reduce NCD-related mortality: municipalities with more polluted slums experience less overall reduction in respiratory and cardiovascular mortality. *Conclusions:* These and other findings may inform targeted interventions and policies to address the unique health challenges faced by favela residents, ultimately working to reduce health disparities in urban Brazil.

Innovative Approaches for Eliciting Health Preferences in Vulnerable Groups

MODERATOR: **Robin Blythe**,

Ind-1226 Using a By Children For Children Approach to Improve Understanding and Engagement in Choice Experiments Carried Out With Children and Young People.

PRESENTER: **Lazaros Andronis**, University of Warwick
AUTHORS: Alison Pearce, Mr. Stavros Petrou, Cameron Morgan, Cam Donaldson, Emily Lancsar

Background Choice experiments are commonly employed to elicit the preferences of members of the public including, increasingly, children and young people (CYP). Emerging empirical evidence shows that older children are generally able to provide valid answers to elicitation experiments. However, a key prerequisite is that such exercises are designed appropriately, in a way that maximises understanding and engagement. **Aims** The overarching aim of this work is to identify and test ways of enhancing the understanding of and engagement with preference elicitation experiments carried out with CYP. **Methods** This work is being carried out in close collaboration with a publicly funded group of CYP in the UK (NIHR Young Research Champions), using as a vehicle an ongoing project that employs choice experiments to tease out the (monetary) value CYP put on their time. The first part of this (ongoing) work involves conducting focus group meetings during which participants (aged 8 to 18 years old) are (i) prompted to think about what understanding and engagement means to them in the context of preference elicitation exercises and, (ii) encouraged to work together to come up with strategies and 'understanding-boosted' versions of choice experiments, designed 'by children, for children'. Next, enhancements will be incorporated into the choice experiment instruments which will be subsequently tested in a series of concurrent 'think aloud' interviews. These will be conducted with a separate group of CYP, as part of the pre-testing stage of the choice experiments, with explicit feedback sought on understanding, engagement and potential improvements. Following each think aloud interview, the interviewer will also be debriefed about their perceptions of the respondents understanding and engagement. **Findings** To date, focus group sessions have offered insights into conceptualising understanding and engagement, and have given rise to various ideas about ways of enhancing choice experiments for CYP. These include suggestions about a coherent narrative that connects different parts of the experiments, short 'explainer' videos, pop-up information balloons, and built-in games). Next steps will involve embedding this input into experiments and pre-testing them with potential respondents, with findings expected in May 2025. This work and its findings will be useful in highlighting a participatory approach to designing choice experiments in CYP, as well as in pinpointing specific design characteristics that could make choice experiments more attractive to young respondents, fostering participation and improving data quality.

Ind-209 Do Child Age And Parental Status Matter in Valuing The Child Health Utility 9D (CHU9D)?

PRESENTER: **Xiuqin Xiong**
AUTHORS: Natalie Carvalho, Li Huang, Kim Dalziel, Nancy Devlin

Objectives Current value sets for child health typically only apply to children > 5 years, yet many interventions target younger children. There is mixed evidence about whether preferences for health vary by child age, most focusing on older age groups. There is also a lack of consensus about whose preferences should be obtained. Value sets are often based on preferences of the adult general public, but parents have more experience of child health. The objectives of this study are to test whether preferences for children's health states differ (a) when considering those aged 2-4 years compared to older children and (b) by parental status. Dependent on our findings from above we also aim (c) to generate a value set(s) for the CHU9D that can be applied to children from 2 years of age upwards. Methods Health states were described using the Child Health Utility 9D (CHU9D). A discrete choice experiment (DCE) survey was administered between September 2023 and March 2024 to a representative sample of the Australian general adult population which included a 20% quota of parents of 0–18-year-old children. Participants were randomly allocated to two study arms: considering the health of a 2–4-year-old or a 10-year-old child. A conditional logit model was used to obtain the latent values from the choice responses. The differences in latent values between the two ages and between parents and non-parents were analyzed using relative attribute importance (RAI), poolability test, and pooled model with interaction terms. Visual Analogue Scale (VAS) responses were used to anchor the latent values onto a 0-1 utility scale. Results 3112 participants were included. Results suggested that the preferences between the two age perspectives were similar, with only 1 out of 36 interaction terms significant. Parents' preferences differed from those of non-parents, as indicated by 3 significant interaction terms and failure in poolability test, having smaller disutility for severe health states in *pain, tired* and *join in activities* dimensions. Two value sets based on the general adult population's preferences and parents' preferences respectively were generated and compared, with slightly higher values for the value set derived from parents' preferences in severe health states of dimensions such as *tired* and *sleep*. Conclusion Considering CHU9D health states in 2–4-year-olds compared to 10-year-olds did not affect adults' preferences, although preferences differed between parents compared to non-parents. Two value sets derived from the general adult population and parents are reported.

Ind-383 Improving Digital Neurorehabilitation: Exploring Patient Preferences and Subgroup Variations

PRESENTER: **Ann-Kathrin Fischer**
AUTHORS: Andrew Sadler, Thomas Kohlmann, Dr. Axel Christian Mühlbacher

Background: Stroke is a leading cause of disability globally, driving demand for neurorehabilitation services. Digital technologies presented an opportunity to improve rehabilitation outcomes and address workforce shortages. However, patient acceptance is vital for the success of these innovations, as uptake rates depended on patients' perceived value and specific preferences. While digital technologies had been increasingly used, research had not sufficiently explored the nuances of patient preferences and subgroup-specific patterns. Identifying and understanding individuals is essential for optimizing patient engagement and promoting sustainable implementation. Previous studies had identified acceptance factors for digital innovations but lacked a detailed analysis of how preferences varied across patient subgroups. This study addressed this gap by systematically assessing factors that influenced patient acceptance, recognizing preference heterogeneity, and characterizing distinct subgroups within the patient population.

Objectives The study had three main objectives: 1) To determine the relative importance of different attributes and mean preferences for digital neurorehabilitation. 2) To derive acceptance probabilities for various digital solutions within the neurorehabilitation context. 3) To examine

preference heterogeneity through subgroup analysis.

Methods A discrete choice experiment (DCE) was conducted in 2021 with 165 stroke survivors (experimental group), and 1,094 participants from the general population (control group) focusing on seven attributes: (1) explanation and presentation of therapy exercises, (2) information provided during therapy, (3) contact with healthcare professionals, (4) patient choice in the therapy process, (5) data processing, (6) monthly copayment and (7) therapy success within six months. A fractional-factorial design was used. Initial mixed logit (MXL) analysis revealed substantial standard deviations in several attributes, indicating heterogeneity in patient preferences. This prompted further latent class analysis (LCA) to identify distinct subgroups.

Results: The MXL model showed that therapy success and copayment were primary determinants of acceptance, with technical aspects such as patient choice and information provision also playing a significant role. Three alternative digital technologies were modeled to illustrate how acceptance probabilities, ranging from 44% to 84%, varied according to changes in technical aspects. LCA identified three distinct preference classes. Class 1 (21.3%) was characterized as cost-sensitive, with a strong preference for lower copayments (ß80€ = -3.355, p > 0.001; ß0€ = 3.058, p > 0.001). Class 2 (32.2%) was outcome-oriented, prioritizing high therapy success rates (ß60% = -4.035, p > 0.001; ß100% = 3.909, p > 0.001). Class 3 (46.4%) was technology-focused, emphasizing the importance of healthcare professional contact (ßdirect = 0.941, p > 0.001) while also valuing self-determined location flexibility (ßplace = 0.632, p > 0.001) and feedback on individual progress during therapy (ßchange = 0.433, p > 0.001). These classes reflected dimensions of technology acceptance. Class 2 aligned with perceived usefulness, while class 3 emphasized perceived ease of use, underscoring the need for both technical and therapeutic benefits to drive patient engagement.

Conclusions: This study highlighted the importance of considering diverse patient preferences in digital neurorehabilitation. Acceptance was shaped by factors like cost, therapy success, and user-centered technical design. Tailoring digital interventions to subgroup preferences could enhance engagement, support more effective neurorehabilitation, and contribute to sustainable practice improvements.

Ind-994 Preferences For Accessing Pre-exposure Prophylaxis Among Men Who Have Sex in Australia; a Discrete Choice Experiment

PRESENTER: **Warittha Tieosapjaroen**
AUTHORS: Jason J. Ong, Edwina Wright, Nittaya Phanuphak, Curtis Chan, Doug Fraser, Benjamin R. Bavinton, Lei Zhang, Vincent Cornelisse, Heather-Marie Schmidt

Background:

PrEP usage remains below the national 75% coverage target. This study examined PrEP choice drivers, predictors of uptake for different program models, and identified subgroups with similar preferences among MSM in Australia.

Method:

MSM aged** >18 years with no prior HIV diagnosis and residing in Australia completed an online discrete choice experiment (DCE) between May and November 2022. They were recruited through dating apps and local MSM community organisations. We used random parameters logit (RPL) models to estimate each attribute's relative importance and predict PrEP uptake for varied program configurations. A latent class model (LCM) was used to explore sub-groups with similar preferences for PrEP programs.

Result:

Overall, 1,892 MSM participated, with a mean age of 40 (±12.7) years. Cost was the most important driver of PrEP program choice, followed by the type of PrEP, side effects, extra sexually transmitted infection (STI) testing, location and visit frequency. The least preferred PrEP program, which resulted in 48% predicted uptake, consisted of a cost of AU$100, a removable PrEP implant with potential rare kidney problems, and access to PrEP via hospital every two months without STI testing. Our model predicted that the uptake could increase up to 100% with the most preferred PrEP program, which included free long-acting oral PrEP with no side effects, accessing PrEP via a pharmacy annually, and including STI testing. The LCM identified four groups of MSM: "Long-acting oral or injectable PrEP from STI clinics" (22%), "Daily oral PrEP from pharmacy" (5%), "Long-acting oral PrEP from pharmacy" (52%), and "injectable PrEP from the hospital" (22%).

Conclusion:

There is a growing demand for alternatives to oral daily PrEP, with the majority of MSM in Australia preferring long-acting oral or injectable PrEP. Decentralising access of PrEP through pharmacies was also preferred by the majority.

Ind-1733 Healthcare-Seeking and Cost of Cancer in Kidney Transplant Recipients: A Difference-in-Differences Analysis Using Korean Administrative Claims Data

PRESENTER: **Yunji Choi**
AUTHORS: Eunjeong Kang, Hojoon Sohn, Juwon Hong, Hajeong Lee, Taewook Kang, Subin Jeong, Hyeonho Shin, Jeongin Song, Minsung Sohn

Background: Kidney transplant (KT) patients are subject to lifetime immunosuppressants, which is associated with an increased risk of cancer. Furthermore, with recent advancements in immunosuppressants, the average age of patients receiving kidney transplants has increased, which may result in higher cancer incidence and disease burden among KT patients. Improving our understanding on the patterns of healthcare use and costs post cancer diagnosis for KT patients will facilitate the design of cancer screening and care policies for this important patient group.

Objectives: We assessed the cancer treatment choices and associated costs of KT patients by exploring the differences in patterns of cancer treatment and healthcare use relative to the comparator groups: cancer patients from the end-stage kidney disease (ESKD) and the general population (GP). First, we examined whether KT patients face limitations in cancer treatment choices. Second, we investigated whether cancer diagnosis and treatment decisions have any persistent effects on cancer-specific and overall healthcare costs.

Methods: We used the Korean National Health Insurance (KNHI) claims data to identify a sub-cohort of cancer patients from those who received kidney transplant (KT), and two comparator groups. Using propensity-score matching (PSM), we constructed two different samples: (1) 1,308 KT cancer patients and a matched sample of 3,611 GP cancer patients using year of cancer diagnosis, gender, age group, socioeconomic status, and year-month of death as matching variables; (2) 1,276 KT cancer patients and a matched 2,583 ESKD cancer patients using the same matching variables plus duration of dialysis. We assessed a difference-in-differences (DD) estimates for KT cancer patients, separately for each of the two control groups, with the first date of cancer treatment defined as an event time.

Key results: Relative to GP cancer patients, KT cancer patients had 10.5% and 10.4% lower rate of chemo- and radiation therapy utilization, resulting in an average of 2.3 million KRW (approximately 1,600 USD) 5-year cumulative cancer treatment per-patient costs. However, KT patients had higher cumulative cancer treatment costs – 2.3 million KRW higher – relative to cancer-ESKD patients. Conditional on getting treated with either chemotherapy, radiation therapy or surgical procedure, the 5-year cumulative expenditure on cancer treatment increased compared to both GP and ESKD patients. The difference in monthly medical cost or number of physician visits narrowed within the first six months, largely because cancer diagnosis led to a slight decrease in overall spending for KT patients and an increase in overall spending for GP patients. Notably, KT patients exhibited reduced healthcare costs on kidney failure or hypertension.

Conclusions: Our real-world data showed that KT patients had limited cancer treatment choices compared to choices relative to those offered to the general cancer patients. Nevertheless, once the cancer treatment is initiated, the expenditure incurred on cancer treatment was larger for KT patients. Our findings suggest that the experience of kidney transplant itself may already have served as a significant health shock, thereby resulting in no notable change in care-seeking pattern of KT patients after cancer diagnosis relative to both comparator groups.

Ind-1918 Defining a Target Product Profile for [99mTc]Tc-sestaMIBI SPECT/CT in Kidney Tumor Diagnosis using DCE: Trading Certainty for Lower Risk

PRESENTER: **Siyabonga Ndwandwe**, Clinton Health Access Initiative (CHAI)
AUTHORS: William F Wildgoose, Ms. Rachael Hunter, Hannah Warren, Geraldine Fox, Maxine Tran

Background:

Over 13,000 people are diagnosed with kidney cancer annually in the UK, often by chance. Conventional imaging methods struggle to differentiate between cancerous and non-cancerous kidney tumours—up to 30% kidney tumours are non-cancerous. Currently diagnosis depends on histology from surgery or biopsy, both of which are invasive procedures with risk of complications. The [99mTc]Tc-sestaMIBI SPECT/CT (MIBI) nuclear scan has shown high diagnostic accuracy for benign tumours and there is interest in utilising this test within the UK's National Health System (NHS). However, limited research exists on patient and public preferences for this scan.

Aim: We developed a discrete choice experiment (DCE) to identify preferences for key diagnostic features and developed a target profile favouring the scan over surgical resection

Methods:

An initial list of attributes related to cancer diagnostics was identified from literature; and narrowed down to 20 then 5 items through discussion and a focus group of eight patient representatives. Appropriate attribute levels were assigned, and choice sets optimised using the D-efficiency approach, which minimised parameter estimates' variance-covariance matrix with non-informative priors. A three-part online survey was distributed nationally to members of the public through a third-party. Respondents ranked the five attributes by order of importance then completed 10 choice-tasks each with two test options. Conditional logit models quantified attributes' impact on utility and willingness to give up test certainty depicted trade-offs. Minimal and optimal criteria were defined for test attributes that could satisfy >80% and >90% of respondents as an alternative to surgery.

Results:

Of the 150 responses received, 35% (n=53) had prior experience of cancer tests, 87% (n=130) were white, 68% (n= 102) female. The risk of serious complication was ranked as the most important attribute and had the greatest impact on utility (coefficient = -2.17). Pain/discomfort

from the test was ranked lowest. No significant difference was detected between respondents younger than 55 years vs 55 years and older or between those who have tested for possible cancer and those without prior test experience. Respondents were willing to trade 32% diagnostic for 1% improvement in complication risk. To be preferred over surgery, a MIBI scan with 75% specificity, 0.75% probability of a serious complication, mild pain or discomfort and 30% of patients needing additional tests would require a minimum sensitivity of 70% and optimal sensitivity >79%. However, if the risk of serious complications was reduced to 0.3% instead of 0.75%, the minimally and optimally acceptable sensitivity for the test would decrease to 55% and 65% respectively.

Conclusions:

This study presents strong evidence for patients trading off kidney cancer diagnostic certainty to avoid the risk of complications, which is a key value-proposition for the MIBI scan. It is non-invasive whilst histology from surgery and biopsy surgery are invasive. Furthermore, our analyses highlight key consideration for future test development and patient-centred decision making in cancer diagnostics with the NHS. These findings are further strengthened by the response homogeneity, particularly by age and prior experience with cancer diagnostic tests.

Ind-305 Does Parenthood Affect Cancer Screening? Exploring the Influence of Child Age and Sex in Hepatocellular Carcinoma Screening

PRESENTER: **I-Hua Chen**
AUTHOR: Li-Lin Liang

Does Parenthood Affect Cancer Screening? Exploring the Influence of Child Age and Sex in Hepatocellular Carcinoma Screening

Background

Hepatocellular carcinoma (HCC) ranks as the second leading cause of cancer deaths in Taiwan in 2023. Biannual abdominal ultrasounds are recommended for patients with chronic hepatitis B (CHB) or C (CHC) to promote early detection. While factors such as socioeconomic status (SES), age, sex, and geographic location influence HCC screening, the impact of parental status is less understood. This study investigates whether having children, and specifically the age and sex of the youngest child, influences parental HCC screening rates.

Methods

Data were sourced from the National Health Insurance Research Database (NHIRD) and the Maternal and Child Health Database in Taiwan. We identified a cohort of 387,779 patients (52% male, 48% female) diagnosed with CHB between 2010 and 2014, with follow-up from 2015 to 2022. Patients with prior cancer diagnoses, liver operations, missing data, or fewer than two follow-up records were excluded.

We employed a panel data fixed-effects Poisson model to examine the relationship between parental status and HCC screening uptake, controlling for individual time-invariant unobserved heterogeneity to reduce potential endogeneity. To explore sex-specific patterns, separate analyses for mothers and fathers were conducted. The primary predictors were the age and sex of the youngest child, with age categorized as 0, 1-3, 4-6, 7-12, 13-15, and 16-18 years. The reference group comprised individuals without children or with all children >18 years. Control variables included parental age, SES, medical history, child's medical history, and year indicators.

Results

Parental HCC screening behaviors varied by the age and sex of their children and differed between mothers and fathers. Mothers with the youngest child aged 0 and 1-3 years had significantly lower incidence rate ratios (IRRs) for HCC screening, at 0.791 (95% CI: 0.752–0.833, $p<0.001$) and 0.916 (95% CI: 0.878–0.955, $p<0.001$), respectively.

In contrast, fathers of young children showed no significant decline in screening rates. Notably, when their youngest child was a daughter aged 4–12 years, fathers exhibited a modestly higher IRR compared with those whose youngest child was a son, whereas among mothers, screening rates did not differ by child sex.

Conclusions

Caring for young children imposes a substantial barrier to HCC screening among mothers but not fathers, reflecting a trade-off in family health capital investment. In contrast, fathers of daughters aged four to twelve demonstrate slightly higher screening uptake, suggesting a "daughter effect" that merits further investigation. These findings highlight the importance of developing policies to support parental responsibilities and promote cancer screening, especially among mothers.

Ind-2345 Willingness to Pay for a Novel Malaria Diagnostic in Five Countries in Sub-Saharan Africa

PRESENTER: **Bryony Simmons**
AUTHORS: Elisa Sicuri, Lesong Conteh

Background: The value individuals place on new diagnostic tools is important for understanding demand and guiding their adoption and integration into healthcare systems. This study investigates the willingness to pay (WTP) for a new malaria diagnostic tool across five endemic African countries: Burkina Faso, Ethiopia, Kenya, Namibia, and Sudan. The study explores individual-level determinants and potential biases in WTP valuation.

Methods: Data were collected from 2,274 participants. In four countries, respondents were individuals (or their caregivers) presenting at health facilities with fever indicated for malaria testing, while in Namibia, interviews were conducted in the community. WTP was elicited using two

stated preference elicitation methods: a bidding game format and open-ended valuation. Trivariate probit models estimated unbiased WTP while adjusting for covariates such as age, gender, symptoms, malaria test results, and risk perception. A subset of participants in Burkina Faso (n=424) participated in a follow-up assessment with modified WTP designs one week after the initial evaluation.

Results: Overall, 94% of participants were willing to pay for the diagnostic tool. WTP varied across settings, ranging from USD 0.8 in Namibia to USD 5.5 in Ethiopia (maximum WTP from open-ended response). The trivariate probit analysis estimated an average unbiased WTP of USD 0.8 (SD 0.07). Prior payment for diagnostic tests for any illness was associated with higher WTP in all settings except in Kenya. In Namibia, risk perception significantly influenced WTP, with higher levels of perceived risk correlating with increased valuations. In the Burkina Faso sub-study, follow-up assessments with modified WTP designs resulted in higher WTP compared to baseline, potentially suggesting the presence of anchoring bias.

Conclusion: The findings underscore the importance of contextual factors, such as prior diagnostic expenditure and perceived risk, in shaping WTP for malaria diagnostics. Biases in elicitation methods, particularly anchoring effects, underscore the need for robust study designs. These results offer valuable insights into the market potential for malaria diagnostics and could inform cost-effectiveness thresholds for new diagnostic tools in resource-constrained settings.

Pandemic Impacts

MODERATOR: **Mehdi Ammi**, Carleton University

Ind-1967 The Impact of H5N1 on US Domestic and International Dairy Markets

PRESENTER: **Prof. Katharina Hauck, PhD**, Imperial College London
AUTHORS: Joseph Hicks, Giovanni Forchini, Guillaume Morel, Anh Pham, Christian Morgenstern, Thomas Rawson, John Edmunds, Victoria Fan, ScD

The recent outbreak of H5N1 avian influenza in U.S. dairy cattle poses significant health and economic risks. Dairy cattle have not been identified as a host for the H5N1 virus previously, and the scale and duration of the outbreak means the risk of the emergence of a human-adapted strain is intensifying. Each time an infection occurs the virus could mutate into one that excels in transmitting between other mammals, and eventually humans.

Vigilant testing and monitoring of cattle and enhanced biosecurity practices are paramount to preventing further spread of H5N1 in the USA, and globally. Despite government subsidies, farmers are reluctant to introduce improved biosecurity measures. But failure to contain the outbreak now may result in higher costs for the industry later. Importantly, the costs of containing the outbreak now are small when contrasted against the uncertain but potentially catastrophic health and economic costs of the emergence of a H5N1 variant that is transmissible between humans.5

We use a Computable General Equilibrium model is used to assess the short-to-medium term macro-economic impact of the H5N1 outbreak amongst dairy cattle to the US economy and its key trading partners. Disruptions to the dairy sector would be expected to have ripple effects to the broader US economy, and globally. We estimate the impact of the current outbreak (Scenario S1), and of two hypothetical but plausible scenarios S2 and S3 under more stringent interventions and reductions in domestic and international demand for US milk, milk products, and beef. The magnitudes of the shocks differ by scenario and are informed by estimates of the impacts of Bovine spongiform encephalopathy (BSE) in the 1980s and 90s, and the H1N1 pandemic in 2009 on the livestock sector in the US. The H5N1 outbreak and public health measures are modelled as four exogenous shocks: Demand, supply, and international trade shocks, and subsidies to farmers.

We project that the short- to midterm loss associated with the current H5N1 outbreak is about $13.7bn in the US (based on 2023 GDP) or 0.05% of GDP. Should the US fail to contain the current outbreak, we project that the economic loss to the USA may vary between $54.7bn (0.2%, for realistic scenario S2) and $164.2bn (0.6%, for reasonable worst-case scenario S3). We evaluate the macro-economic impacts on prices, exports, outputs and employment in the agricultural and other sectors of the US, and further impact on household incomes, investments and savings. We also evaluate impacts on key trading partners Mexico, Canada, and Australasia, but find they are small.

We estimate that the current subsidies for enhanced testing and biosecurity (estimated at $98m) are covering about than 1% of the projected aggregate output loss of the dairy, cattle, and raw milk sector due to the outbreak. The currently introduced measures are disproportionately lax given the scale of the potential impact of the emergence of highly virulent H5N1 strains with pandemic potential into human populations.

Ind-2096 Association of Severe COVID-19 and Persistent COVID-19 Symptoms with Food Insecurity Among US Families with Children

PRESENTER: **Nicole L Hair**, University of South Carolina
AUTHOR: Carly J Urban

There is accumulating evidence that patients with severe COVID-19 and post-COVID-19 conditions face considerable economic consequences. In addition, prior work focused on the experiences of families, shows that families headed by an adult who had severe

COVID-19 or who was experiencing persistent COVID-19 symptoms (Long COVID) had greater odds of reporting a family member who was laid off or furloughed, lost earnings, or had any financial difficulties compared with similar families with no history of COVID-19. The economic consequences may be even more pronounced among low-income and economically vulnerable families with children; however, research focused on this population is relatively limited.

To this end, we use data from the Panel Study of Income Dynamics (PSID), a long-running, nationally representative household panel survey with interview conducted before and during the COVID-19 pandemic, to examine associations between severe or persistent COVID-19 symptoms and food insecurity in US families with children. Our sample comprised a balanced panel of families with resident children who were active in the PSID in both 2019 and 2021 (n=2268). The food security status of each sample family was measured using the USDA Household Food Security Survey Module. The COVID-19 exposure of each family was defined using information on COVID-19 diagnoses and symptoms reported for the family's reference person and, if present, their spouse/partner. Following prior work, families headed by an adult with a history of COVID-19 were assigned to ordinal exposure categories based on the duration and severity of reported COVID-19 symptoms. Families with no history of COVID-19 were assigned to a reference group. Leveraging the longitudinal structure of the PSID, logistic regression models adjusted for a range of potentially confounding characteristics, including indicators of economic hardship (e.g., food security status) measured prior to the pandemic.

Compared to families with no history of COVID-19, families headed by an adult with severe or persistent COVID-19 symptoms had a close to two-fold greater odds (1.75; 95%CI: 1.02, 3.01]) of experiencing food insecurity during the pandemic. In contrast, associations between moderate, mild, or asymptomatic COVID-19 and food insecurity were not statistically significant (0.75; 95%CI: 0.39, 1.44]). Associations between severe or persistent COVID-19 symptoms and food insecurity were strongest for families with lower income before the pandemic (e.g., pre-pandemic income below 200% of the federal poverty level).

We report greater odds of food insecurity among US families with children affected by COVID-19 symptoms despite increases to Supplemental Nutrition Assistance Program (SNAP) benefits during the pandemic. Given the prevalence of Long COVID (an estimated 17 million US adults had Long COVID in March 2024) and the lasting impact of food insecurity on children, policy actions to mitigate the economic consequences of post-COVID-19 conditions (e.g., expanded paid sick leave, improved workplace accommodations, and wider access to disability insurance) merit continued discussion.

Ind-2294 Beyond Numbers: Investigating the Impact of COVID-19 on Suicide Rates in Austria Using Regression Discontinuity in Time and Interrupted Time Series

PRESENTER: **David Roesler**

Introduction: TDuring the global COVID-19 pandemic, mental health faces substantial challenges. Although initial phases may have seen increased social cohesion potentially mitigating suicide risk, limited studies exist on the enduring effects. This study aims to comprehensively examine the impact of the pandemic on suicide rates, considering variations by gender, region and age, with a focus on Austria until December 2021. Existing research on the impact of the pandemic on suicidal behaviour provides valuable insights but does not yet allow to draw conclusions for Austria. Factors such as lockdown measures may influence suicide rates by affecting mental health conditions, altering the choice of suicide methods, diminishing help-seeking behaviours, or compromising the quality of medical care for individuals with mental disorders. In addition, this study employs a novel approach by incorporating regression discontinuity in time analysis. Unlike traditional interrupted time series analyses commonly used in previous research, this method allows for a more nuanced exploration of the temporal effects surrounding the implementation and lifting of specific pandemic-related measures. **Methods:** Utilizing real time monthly death records from January 2015 to December 2021, this study employs a regression discontinuity in time design and an interrupted time series analysis. Harmonic Fourier terms are incorporated to adjust for seasonal variations and a scaling adjustment was used to correct for overdispersion. **Results:** This study reveals a significant negative trend in Austria's suicide rates preceding the COVID-19 pandemic, coupled with an almost negligible rate change during the pandemic's onset. Notably, there were unexpectedly higher instances of suicides in Austria, indicating a deceleration in the decline of suicide numbers rather than an active increase. The study highlights the diverse impact across demographic groups, showcasing distinct trends in suicide rates based on gender, age, and regions within the same country. Particularly noteworthy is the pronounced negative effect observed among men aged 64-85, while women in the age groups 00-19, 20-34, and 65-84 experienced a small yet significant negative impact. Conversely, women in the age group 35-64 exhibited a positive impact. **Conclusion:** This study contributes to the understanding of the impact of the COVID-19 pandemic on suicide rates in Austria. The findings reveal a complex landscape of suicide trends, with higher-than-expected mortality in the pandemic period. Understanding these nuances is crucial for suicide prevention and policy decisions regarding improving health system resilience.

Ind-2439 Neighborhood Structural Racism and Its Effects on Individuals With Diabetes During the COVID-19 Public Health Emergency

PRESENTER: **Cydney M McGuire**

AUTHORS: Kosali Simon, Sih-Ting Cai

Poorly managed diabetes can lead to patients visiting the emergency department (ED) for conditions like diabetic foot ulcers (DFUs). When not properly treated, DFUs can lead to lower extremity amputation or death.1 Diabetes disproportionately impacts people from minoritized racial groups and many DFU patients face socioeconomic disadvantages posing challenges for managing their condition that exacerbate health complications. Patients with diabetes who present in the ED are highly complicated cases that may require in-person care; thus, these patients may be particularly vulnerable to disruptions in the in-person health care environment.

During the COVID-19 public health emergency (PHE), racially minoritized communities experienced greater than usual disparities in access to healthcare resources. For those living with diabetes, the impact of the PHE on access to health care could increase the likelihood of adverse health outcomes. Structural racism is one of the key drivers of inequitable access to health care. Access to health care services for patients with poorly managed diabetes may vary by neighborhood-level structural racism. The impact of COVID-19 disruptions was likely worse in

neighborhoods with higher indicators of structural racism.

The purpose of this study is to investigate the impact of the COVID-19 PHE on care in diabetes-related emergency department utilization, with particular attention to neighborhood-level structural racism and racial/ethnic disparities in access to care.

We use Medicare data from 2019-2020 and construct a cohort of individuals with diabetes who visited the emergency department. We merge this database with information on structural racism across 9 domains, estimated using census tract–level American Community Survey data. These data are compiled to produce a single summary score variable - The Structural Racism Effect Index (SREI).2

We employ a difference-in-differences design to evaluate the impact of COVID-19 PHE on Medicare beneficiaries with diabetes across neighborhoods with different structural racism scores. We identified a cohort of individuals with diabetes who visited ED in the first quarter of 2019 and followed their outcomes through the fourth quarters of 2020. The key dependent variables are DFU-related hospitalizations and mortality, and the key independent variable is the SREI summary score, which classified neighborhoods into high and low structural racism groups. We hypothesize that individuals with diabetes in high structural racism neighborhoods would experience worse health outcomes during the COVID-19 shock compared to those living in neighborhoods with low structural racism scores. We examine differences in outcomes across racial groups. We examine differences in care outcomes across those with different insurance types including Medicare Advantage, Fee-for-Service, and dual enrollment in Medicare and Medicaid.

In our preliminary analysis, we identified a total of 20,511,889 ED visits, with 38.5% involving Medicare beneficiaries diagnosed with diabetes. To ensure a complete follow-up period, we restricted our sample to those who were in the Medicare claims records in the first quarter of 2019, which included 866,754 unique Medicare beneficiaries with a diabetes diagnosis. On average, these patients had 21 diagnoses listed per ED visit. Additionally, 25% were enrolled in both Medicare and Medicaid, and they exhibited a high two-year mortality rate of 35%.

Ind-2755 The Health and Economic Impact of COVID-19 Misinformation in the United States

PRESENTER: **Sachiko Ozawa**, University of North Carolina at Chapel Hill
AUTHORS: Ashley Yi-Fang Lee, Colleen Higgins, Hui-Han Chen

Background: Misinformation is a defining issue of our times and an urgent societal concern that affects us all. Misinformation poses a significant threat to public health, contributing to preventable illnesses, deaths, and economic burden. During the COVID-19 pandemic, vaccine misinformation led to widespread vaccine hesitancy in the United States, significantly undermining vaccination efforts. This study quantifies the impact of misinformation on vaccine hesitancy, COVID-19 cases, hospitalizations, deaths, and associated costs in 2021.

Methods: A microsimulation model was developed to estimate the effects of vaccine misinformation on COVID-19 outcomes, tracking vaccinations, cases, hospitalizations, deaths, and costs across states and age groups. Vaccine hesitancy due to misinformation was modeled using age- and state-specific data, with probabilities for infection and severity differing by vaccination status. Counterfactual scenarios removed misinformation, showing increased vaccination rates and reduced hospitalizations, deaths, and associated healthcare costs. The model incorporated real-world constraints such as vaccination capacity and validated outputs against observed data. Costs were analyzed at both state and national levels, with per-person costs calculated for states with the highest burden.

Results: Vaccine misinformation in 2021 was associated with approximately 2.3 million COVID-19 cases, 66,000 hospitalizations, and 45,000 preventable deaths. Misinformation about COVID-19 vaccines cost the United States $2 Billion from hospitalizations in 2021. State-specific costs of misinformation were significant, with the highest total costs observed in California ($229 million), Texas ($173 million), Florida ($171 million), New York ($144 million), and Pennsylvania ($107 million). When adjusted for population, the highest per-person costs were found in Montana, Nevada, Colorado, Arizona, Wyoming, New Mexico, and Alaska, with an estimated $10–$14 per person in excess costs due to misinformation.

Conclusions: Misinformation about COVID-19 vaccines in 2021 led to substantial public health and economic consequences, with millions of preventable cases, tens of thousands of avoidable deaths, and billions in added healthcare costs. While the COVID-19 pandemic has waned, misinformation remains a pervasive issue with the potential to undermine future public health efforts. Comprehensive strategies to combat misinformation, rebuild trust in science, and promote evidence-based communication are critical to safeguarding population health and minimizing societal costs.

Quantifying Disease Burden Across Global Contexts

MODERATOR: **Julienne Lechuga**, University of Bologna

Ind-817 The Impact of Adult Obesity on Household Catastrophic Healthcare Expenditures

PRESENTER: **Peizhe Yan**
AUTHORS: Jialong Tan, Jian Wang

In China, obesity has emerged as a significant public health issue, imposing a substantial healthcare burden at both national and individual levels. This study aims to explore the impact of obesity on household healthcare expenses and the underlying reasons.

We examined and quantified the effect of individual obesity on household healthcare burden using data from the China Family Panel Studies (CFPS) from 2010 to 2020, encompassing 11,177 participants. To address endogeneity, we employed an Instrumental Variable Probit model, using the weight level of biological children as an instrumental variable. The children's weight levels were determined based on the sex- and age-specific growth charts provided by the World Health Organization. The household healthcare burden was assessed by measuring the risk of catastrophic medical expenditures.

The baseline regression results indicate that obese individuals are significantly more likely to incur catastrophic medical expenditures within their households compared to non-obese individuals. Additionally, the mechanism analysis revealed no significant differences in healthcare resource utilization or overall healthcare expenditures between obese individuals and their counterparts. However, obese individuals experienced notable income reductions, including decreases in both total annual income and wage income, at both the household and individual levels. This study argues that this significant income reduction is the primary reason for the increased probability of catastrophic medical expenditures in households with obese individuals.

Heterogeneity analysis further showed that obesity presents an increased risk of catastrophic medical expenditures across various subgroups, including gender, education, urban-rural residency, and health status. Men, individuals with lower education levels, and those in poorer health were more affected than their respective counterparts. Notably, only obese individuals in low-income groups faced a significantly higher risk of catastrophic medical expenditures, whereas high-income groups were largely unaffected. The findings remain robust when the sample size is expanded, alternative methods and thresholds for measuring catastrophic medical expenditures in households are applied, and individual-level expenditure controls are included.

This paper concludes that securing income stability is crucial to reducing the incidence of catastrophic medical expenditures among households with obese individuals. The findings suggest that income inequality, rather than additional medical expenses, is the primary driver of the higher healthcare burden for households with chronic disease patients. Future research should focus on addressing productivity loss due to chronic diseases and labor market inequalities to mitigate household healthcare burdens.

Ind-913 The Global, Regional, and National Burden of CKD and its Risk Factor: an Analysis of the Global Burden of Disease Study 2021 and Forecast to 2035

PRESENTER: **Jingyu Wen**
AUTHORS: Yuhang LI, Yifu Hou, Min Li

Background

Chronic Kidney Disease (CKD) poses a significant challenge to global healthcare systems, impacting patient health and highlighting issues related to socioeconomic development, healthcare accessibility, and efficiency. Prior research has been limited to specific age groups and regions, lacking a comprehensive global perspective. This study presents global, regional, and national disability-adjusted life years (DALYs) data for CKD from 1990 to 2021, emphasizing health inequality. By predicting the CKD burden in 2035, we aim to guide future medical resource allocation and health policy planning, focusing on high-burden populations and reducing disease burden.

Method

Using data from the Global Burden of Disease Study 2021, this study systematically evaluated the global, regional, and national burden of CKD and their changes. Age-standardised incidence rate (ASIR), age-standardised mortality rate (ASMR), age-standardised rate of DALYs (ASDR), and burden due to risk factors associated with CKD was analyzed. Geographical variations, the impact of the Sociodemographic Index (SDI), and trends in ASIR, ASMR, and ASDR were assessed using regression analysis and stratification by SDI quintiles. Risk factors attributable to CKD were estimated using the comparative risk assessment framework of the GBD study, and the Bayesian age-period-cohort (BAPC) model predicted future disease burden trends.

Result

In 2021, the global incidence of CKD was 19,935,037, with 1,527,638 deaths and 44,453,683 DALYs. The highest ASIR, ASMR and ASDR were observed in the middle-SDI quintile regions in 2021, Africa and Mauritius had the highest mortality rates and ASMR. From 1990 to 2021, ASIR, ASMR, and ASDR for CKD increased globally, with some regional decreases. Males had a higher burden than females, except the AAPC of ASIR (males (AAPC, 1.257(-[1.244 to 1.271]) and females (AAPC, 1.427[1.417 to 1.438])). Risk factors included Kidney dysfunction, Metabolic risks and High fasting plasma glucose with variations across SDI regions. BAPC model predictions suggested that the burden of CKD will continue to increase in the future, especially in terms of the number of new cases.

Conclusions

CKD remains a formidable public health challenge, with its burden rising consistently since 1990. This trend not only mirrors the intricate challenges confronting global health landscapes but also underscores the persistence of healthcare disparities, particularly acute in economically less developed countries and regions. Even more alarming, projections indicate a continued increase in CKD burden until 2035, exacerbating global public health pressures. Urgent attention is needed for public health interventions in less developed nations, optimizing resource allocation, enhancing infrastructure, and upgrading medical services. Deepening health education and elevating public awareness and self-management are crucial to reduce CKD incidence and progression risks.

Ind-1015 Economic Burden of Pneumonia and Invasive Pneumococcal Disease in Fiji

PRESENTER: **Fulgence Niyibitegeka**

AUTHORS: Laila Sauduadua, Fiona M Russell, Petueli Veremalumu, Natalie Carvalho, Rachel Devi, Tupou Ratou, Litiana Volavola, Ilisapeci Vereti, Stephanie Clark

Background ` `Despite progress over the past decade through pneumococcal conjugate vaccine (PCV) introduction, pneumonia remains one of the major causes of health facility-based consultations in Fiji.** Understanding the societal costs (health system plus household costs) associated with pneumonia and invasive pneumococcal diseases (IPD) can guide health strategy priorities and budget allocation and is essential for evaluating the cost-effectiveness of interventions to address this health problem. This study aimed to estimate household and health system costs associated with clinical pneumonia in children under five years, and health system cost of laboratory-confirmed IPD in all-age groups in the Fijian population. **Methods** We conducted a prospective cost-of-illness study from December 2023 to June 2024 at one tertiary hospital and two primary health facilities in Fiji. The health system cost of IPD was estimated through a retrospective review of medical records from 2013 to 2019, prior to the disruption of data entry accuracy caused by the COVID-19 pandemic. Household costs of pneumonia included all direct medical expenses (medicines, diagnostic tests, and other medical supplies and equipment), direct non-medical expenses (travel, meal, accommodation, additional communication) and indirect cost in terms of productivity lost due to absence from work by household members to take care of their children. The health system cost for both pneumonia and IPD included direct medical costs for medications, investigation tests, medical supplies and equipment, and bed days for hospitalised patients or visits costs for outpatient **Results** For the prospective study, we collected data on a total of 382 pneumonia patients under five years of age, of which 141 patients were hospitalised with an average hospital stay of 9 days. The retrospective review included a total of 66 IPD cases of which 20 patients were under-five with average hospital stay of 17 days. The household cost of outpatient pneumonia was estimated at US$120 and US$92 at heath centre and hospital level, respectively. The health system cost of outpatient pneumonia was estimated at US$13 and US$105 at heath centre and hospital level, respectively. The resulting societal cost was estimated at US$133 and US$196 for outpatient pneumonia at health centre and hospital, respectively. For inpatient pneumonia, the societal cost was estimated at US$959 consisting of US$134 in household cost and US$825 in health system cost. The health system cost for IPD was estimated at US$1,425 in children under five and US$1,189 in patients over five years. **Conclusion** Pneumonia and IPD impose a substantial economic burden to the Fijian society particularly for hospitalised episodes of which the per patient cost accounts for over 15% of Fijian gross domestic product per capita (US$5,868). The evidence from this study provides relevant estimates that can inform cost-effectiveness analysis of interventions to reduce the burden of pneumonia and IPD in Fiji.

Ind-1041 Health and Economic Burden of Disability in Bangladesh: Insights From the National Perspective

PRESENTER: **Raisul Akram**

AUTHORS: Arjan Buis, Jeremy Lauer, Alec Morton

Background: Disability became a substantial global challenge, significantly affecting social participation and economic productivity. This issue is particularly pronounced in low- and middle-income countries (LMICs) like Bangladesh. Despite the high prevalence of disability within the population, national-level insights into the health and economic burden of disability in Bangladesh are scarce, leading to the unknown need and hindering efforts to improve national initiatives on improving preventive, curative and rehabilitation services. **Aim**: This study aims to estimate the health and economic burden of disability in Bangladesh, highlighting disability prevalence, types, severity, excess healthcare costs, and the incidence of Catastrophic Health Expenditure (CHE). **Method**: This quantitative research analysed nationally representative cross-sectional data from the 2022 Household Income and Expenditure Survey (HIES) of Bangladesh. Disabilities were assessed by identifying functional difficulties in vision, hearing, mobility, cognition, self-care, and communication among 60,653 participants from 13,931 households. Disability status was determined through self-reported assessments using the Washington Group's Short Set of Questions. The incidence of catastrophic health expenditure (CHE) was defined as household healthcare costs exceeding 40% of their non-food expenditure. **Results**: National disability prevalence was estimated at 5.7% (CI: 5.48-5.85), with 4.19% reporting "some difficulty", 1.36% "severe difficulty", and 0.16% being "fully disabled". The most common disability prevalence was recorded for visual disability (2.96%, CI: 2.87-3.13), followed by mobility (2.42%, CI: 2.22-2.45), cognition (1.81%, CI: 1.65-1.86), hearing (1.55%, CI: 1.51-1.71), self-care (1.54%, CI: 1.45-1.64), and the lowest for communication-related disabilities (1.4%, CI: 1.31-1.5). Prevalence was higher among females (5.4%), rural residents (5.9%), the elderly (27.9%), among participants suffering from chronic illnesses (12.6%), and was inversely related to asset quintiles. Multiple disabilities were present in 2.44% of the population, with visual and hearing impairments frequently co-occurring (1.16%). Households with any disabled member reported higher healthcare expenditures compared to those without (37% vs. 27% of non-food expenditures) and experienced a higher incidence of CHE (15% vs. 9.6%). The primary coping strategy differed by income level: low-income households mainly relied on donations (42.7%), while higher-income households primarily used their savings (43.1%). **Conclusion**: The study highlights a higher prevalence of disabilities among specific demographic groups in Bangladesh, with the overall burden remaining higher than in many other neighbouring LMICs. Additionally, our analysis underscores the heightened vulnerability of poorer populations to disabilities, highlighting broader socioeconomic disparities. High rates of visual, mobility, cognitive, and hearing disabilities emphasise the need for extending preventive, curative and rehabilitation services and government interventions prioritising vulnerable groups within the country. The financial strain on affected households calls for expanding social safety nets and subsidies for assistive services to improve health status and reduce healthcare disparities.

Ind-1133 Persistent Inequalities in All-Cause Mortality in Taiwan: A Comprehensive Analysis of Trends and Contributing Factors (2000 2022)

PRESENTER: **Jia Wen Tay**

AUTHOR: Li-Lin Liang

Introduction

Despite Taiwan’s universal health coverage, socioeconomic health inequalities persist. All-cause mortality is a critical indicator for assessing such inequalities as it reflects overall population health, but has not been extensively studied. This study examines the trends and determinants of inequalities in all-cause mortality between 2000 and 2022, and is the first to apply the concentration index and its decomposition to Taiwanese data.

Methods

Age-standardised all-cause mortality rates (ASMRs, annual deaths per 100,000 people) were analyzed for 349 townships and stratified across five income quintiles. Joinpoint analysis was adopted to estimate the trends over 23 years till 2022. Annual percent change (APC) was calculated to evaluate the rate of change in ASMRs. Inequality in ASMRs was quantified using the concentration index (CI), decomposed by factors such as sex, socioeconomic status (annual household income, education), population density, physician supply, healthcare accessibility (travel time to the nearest academic medical centre, regional hospital, and clinic) and employment measures (non-working population, population in agriculture and construction). CI decompositions were performed for 2010, 2019 and 2022. Data sources included Taiwan Ministries of Health and Welfare, Interior and Finance.

Results

From 2000 to 2022, ASMRs were consistently higher in the poorest quintile (490.54 to 711.74) compared to the wealthiest (388.06 to 530.51), with an average ASMR ratio of 1.32:1. The ASMR for the poorest quintile decreases to a level comparable to the wealthiest quintile after approximately 13 years. Pre-COVID-19 (2000-2019), ASMRs declined across all quintiles, with the steepest decrease in the poorest quintile (average APC: -1.88%) compared to the wealthiest (-1.64%), narrowing their ASMR gap from 161.59 to 102.49. During COVID-19 (2020-2022), ASMRs increased across all quintiles, but only the increase in the wealthiest quintile was statistically significant (APC: 4.28%).

CIs revealed persistent pro-poor patterns (-0.076 to -0.060, $p<0.001$). Inequalities in household income, education, and travel time to regional hospitals were the largest contributors to ASMR inequality. Between 2010 and 2022, income inequality's contribution decreased (36.7% to 23.2%), education's contribution rose (23.3% to 28.1%), and the ranking for contribution of regional hospital accessibility fluctuated, increasing during the COVID-19 pandemic (30.1%, 24.3%, 28.3%).

Conclusions and Policy Implications

This study highlights persistent disparities in all-cause mortality rates across income quintiles. While differences between the poorest and wealthiest quintiles decreased over time, ASMRs in the poorest quintile remained significantly higher, underscoring the need for targeted efforts to address the root causes of health disparities.

The findings reveal the growing importance of educational inequality as a driver of ASMR inequality, hence policymakers should prioritize improving educational opportunities and outcomes in poorer townships. Additionally, the changing contribution of healthcare accessibility during the COVID-19 pandemic emphasizes the critical role of regional hospitals and proximity to healthcare resources in ensuring equitable health outcomes. Investments in telemedicine and other innovative healthcare delivery models could address accessibility gaps in underserved regions.

This study demonstrates that addressing income inequality alone is insufficient. A multifaceted, holistic and dynamic approach that integrates efforts to improve education, healthcare accessibility and broader socioeconomic determinants is essential for reducing mortality inequalities.

abs-os185 Blending Capitation with Performance Pay: Can It Improve Quality in Chronic Care?

PRESENTER: **Ms. Inke Mathauer**, World Health Organization (WHO)
AUTHORS: Yunguo Liu, Anja Smith, Qian Long, Megumi Rosenberg, Luca Lorenzoni, Stevie Nappoe, Sarah Barber

Background: Addressing the enormous burden of premature mortality from non-communicable diseases (NCDs) requires improving the quality of care for patients with chronic conditions. Enhancing chronic care quality is also crucial for advancing progress toward universal health coverage (UHC). Purchasing arrangements, as a key component of health financing, serve as vital policy instruments to support quality improvements. Many countries are shifting toward blended payment systems, in which a portion of payments is linked to quality targets related to care processes or patient outcomes. Capitation is often selected as the base payment model. This paper examines country reforms that combine capitation payments with performance pay and assesses their institutional design features, impact on care quality, and areas of weakness in design and implementation.

Methods: This paper synthesizes evidence from four countries (Chile, China, Indonesia, and South Africa). Country experts employed a structured data collection instrument to explore the design, implementation, and effects of these payment models based on publicly available information and key informant interviews. The authors conducted data analysis and synthesis, complemented by a scoping literature review to

consolidate the available evidence.

Results: Across all countries, the incentives in these programs were found to be insufficient to drive significant changes in provider behavior necessary for improving chronic care quality or patient outcomes. Both design and implementation challenges contributed to underperformance. For example, providers faced uncertainty regarding payment timing and amounts; payment arrangements designed as penalties for inadequate performance were less effective compared to reward-based models; and voluntary participation by both patients and providers weakened the programs' overall impact.

Conclusion: In all cases, performance payment arrangements were part of broader strategies aimed at improving chronic care quality. This underscores the importance of aligning and embedding payment mechanisms within a comprehensive framework of quality improvement measures. The study also highlights the need for adjusting performance payments based on patient health risk and case complexity to avoid "cream skimming" by providers who may prefer lower-risk patients. Moreover, setting progressive and context-sensitive quality targets, rather than fixed uniform targets, may lead to higher acceptance and effectiveness among healthcare providers. As more countries adopt such payment models, rigorous evaluation must be established to assess the effects of these arrangements, fostering cross-country learning and informing future reforms.

abs-os193 Examining the Effect of Provider Payment Mechanisms on Healthcare Quality and Equity in Tanzania

PRESENTER: **Peter Binyaruka**, Ifakara Health Institute
AUTHORS: Timothy Powell-Jackson, John Joseph Maiba, Josephine Borghi, Francis Ngadaya, Gemini Mtei

Background: Strategic healthcare purchasing, including well-designed provider payment mechanisms (PPMs), is crucial for achieving universal health coverage (UHC). Each PPM creates different incentives, influencing provider behavior and impacting healthcare delivery in intended or unintended ways. As Tanzania prepares to implement mandatory universal health insurance (UHI), effective PPM design is essential to support strategic purchasing goals. However, little evidence exist on how different PPMs, such as fee-for-service or capitation, affect provider actions, service quality, and equity in care in low-income settings. This study aims to assess the impact of current PPMs in Tanzania to guide UHI design toward high-quality and equitable healthcare.

Methods: This study uses a mixed-methods design, collecting both quantitative and qualitative data. Quantitative data were gathered through client-exit surveys in 28 primary healthcare facilities across two regions, with at least 10 insured and uninsured clients per facility from outpatient and antenatal care department (n=280). We measured quality care indicators influenced by payment methods and provider behaviors such as waiting and consultation times, interpersonal care, content of antenatal care, drug prescription patterns, C-section rates, referral practices, health promotion advice, and out-of-pocket payments. Socioeconomic status of clients used to measure equity in quality distribution. Focus group discussions and in-depth interviews were conducted with insured and uninsured clients to explore patient-provider interactions, satisfaction, and overall care experiences. Quantitative data are analysed descriptively, using equity measures (gap, ratio and concentration index) to assess equity, propensity score matching and regression analysis to quantify PPM effects on quality of care by regressing quality outcomes against insurance status with fee-for-service and capitation method, while thematic content analysis to analyse qualitative data.

Results: We expect to observe quality-of-care differences between clients of various insurance schemes (different payment methods) and uninsured, with variations in key quality indicators such as waiting times, service scope, and out-of-pocket costs. Equity analysis will indicate how socioeconomic status impacts quality distribution, while regression analysis will quantify the effects of fee-for-service, capitation and out-of-pocket payment on care quality. Qualitative findings will provide further insights into patient-provider interactions and satisfaction, highlighting how PPMs shape overall care experiences.

Conclusion: Findings will shed light on the implications of PPMs on healthcare quality and equity in Tanzania, supporting evidence-based policy decisions for UHI-related PPM reforms. This will help optimize PPM designs to promote equitable and high-quality care, advancing a fairer and more efficient healthcare system in Tanzania.

abs-os194 Healthcare Variation in Three Public Health Insurance Schemes in Thailand

PRESENTER: **Woranan Witthayapipopsakul**
AUTHORS: Anne Mills, Jan Van Der Meulen, Ipek Gurol-Urganci, Orawan Anupraiwan, Pongsun Puntachai, Gumpanart Veerakul, Apichat Asavamongkolkul, Viroj Tangcharoensathien, Kanokwaroon Watananirun

Background: Variations in medical practice can be expected because patients have different health needs and preferences. However, variations may also occur because patient groups have different health insurance arrangements which can affect quality of care, equity in health, and financial burden on health systems and individuals. Thailand introduced its Universal Health Coverage policy in 2002 through multiple public health insurance schemes led to substantial enhancements in healthcare access and outcomes. This research compares healthcare utilisation and selected outcomes in specialised care settings across Thailand's three public health insurance schemes: Civil Servant Medical Benefit Scheme (CSMBS), Social Health Insurance (SHI), and Universal Coverage Scheme (UCS). While all schemes offer comprehensive benefits, differences exist in their eligibility criteria, treatment options, provider choices and access rules, cost-sharing policies, and provider payment methods including payment rates.

Methods: We used individual health records from national-level insurance claims data between 2015-2020 to explore variations in coronary revascularisation and mortality in 98,142 ST elevation myocardial infarction (STEMI) patients; caesarean section (CS) in 1,670,828 singleton deliveries; 147,697 women undergoing benign hysterectomy; and 39,198 older patients with primary osteoarthritis undergoing total knee arthroplasty (TKA) across different insurance schemes. Poisson regression models estimate procedure rates in the population, and generalised

linear models estimate absolute differences by insurance scheme.

Results: After adjusting for demographics, comorbidities, admission year, and health regions, significant differences in service utilisation across schemes were found. CSMBS-insured patients generally exhibited higher utilisation rates, followed by their counterparts in SHI and UCS. The variations were more pronounced in elective procedures compared to emergency and life-threatening services. Additionally, STEMI patients insured through CSMBS showed higher survival rates, followed by those insured through SHI, and then UCS.

Conclusion: Despite being insured, diverse health insurance arrangements, notably provider payment methods and rates, access rules, provider choices, and socioeconomic status contribute to variation in health care utilisation and outcome. CSMBS beneficiaries benefit from higher DRG payment rates, direct access to specialists and greater opportunity to bypass public hospital waiting lists, may also influence their higher utilisation rates. Policy recommendations include unification of public insurance schemes or harmonisation of specific insurance features. Our empirical evidence highlights the need to recognise the right to access quality health care regardless of socioeconomic status, and to advance policy discussions about health financing governance for a just health system.

abs-os274 Initiation of Buprenorphine Following an Emergency Department Visit for Medicaid Enrollees with Opioid Use Disorder

PRESENTER: **Ms. Ellen Meara**
AUTHORS: David Fiellin, Arno Cai, Brianna Hardy, Jeremy Cygler

Despite recent reductions, over 100,000 U.S. residents died of drug overdose in 2023, and three quarters of these deaths involve opioids. Individuals participating in public insurance programs like Medicaid, which insures low-income and disabled populations, have higher rates of opioid use disorder (OUD) than the average adult. Randomized trial evidence supports the initiation of buprenorphine in the emergency department (ED) for people with diagnosed OUD. Initiation of buprenorphine in an ED increases retention in OUD treatment and reduces the quantity of illicit opioids used in the 30 days after an ED visit. Some hospitals have explicit programs or protocols to initiate buprenorphine or to make rapid referrals to treatment with buprenorphine, but receipt of buprenorphine remains rare. Furthermore, we understand little about the characteristics of hospitals doing more of this evidence-based care. The goal of this paper is to identify characteristics associated with induction of buprenorphine within 7 days of an ED visit for OUD or an opioid-involved overdose. We do three things: 1) characterize the variation in buprenorphine induction within 7 days of an emergency department visit for OUD across hospitals, 2) estimate how buprenorphine induction changes with characteristics of the index hospital (ownership, patient mix, participation in alternative payment models), market characteristics (distance to opioid treatment program, local buprenorphine prescribers per population), and Medicaid policies (i.e. expansion state, participation in a Medicaid Accountable Care Organization contract).

To study the characteristics of hospitals where patients visit the ED for OUD, we examine 111,257 ED visits among 100,443 unique Medicaid enrollees aged 18 years and older, without evidence of medication for OUD in the prior 30 days treated at 550 hospitals reimbursed by Medicaid programs in seven U.S. states (Connecticut, Kentucky, Massachusetts, Michigan, Ohio, South Carolina, and Tennessee). Data on care before, during, and after ED visits come from the Medicaid Transformed Analytic Files from 2017 to 2019. States selected had relatively high rates of OUD and opioid-involved overdose and high documented data quality. The percent of patients with evidence of buprenorphine induction within 7 days of an index ED visit was low for every hospital studied, but it varied widely by hospital both across and within states (from near zero to nearly 5 percent). Across states, the lowest rate of 7-day buprenorphine induction was in Michigan (under one percent), and the highest was in Ohio (4.5 percent). In contrast, visits with a clinician were much more common (40 percent of patients discharged from one emergency department had a clinician visit within 7 days).

By linking Medicaid data to American Hospital Association survey data where these patients had an ED visit, we test the hypothesis that organizational characteristics of hospitals (participation in alternative payment models like Medicaid Accountable Care Organization contracts, and programs that integrate behavioral and physical health) and market characteristics (per population number of active buprenorphine prescribers) are correlated with higher rates of buprenorphine initiation within 7 days of an emergency department visit. These findings will identify features of high performing facilities treating patients with OUD.

abs-os607 Technology Regulation Reconsidered: The Effects of Certificate of Need Policies on the Quantity and Quality of Diagnostic Imaging

PRESENTER: **Ms. Carrie Colla**
AUTHORS: Austin Nichols, Anthony Yu, David Cutler, Jill Horwitz

Certificate of need (CON) laws are designed to control medical spending and improve quality of care by increasing volume per location. CON laws are in place in 35 U.S. states for some medical services. Estimates of the impact of CON laws on medical care have been inconsistent and have mainly focused on spending rather than quality, possibly because not all CON laws apply to all services. Identification of CON effects is difficult: CON implementation may be endogenous to state spending and it is impossible to control for all factors that can influence imaging trends. Using original datasets identifying imaging-related CON laws and each freestanding and hospital-based MRI and CT location in the U.S., we estimate the effects of CON on MRI and CT, using regression discontinuities to examine the variation at state borders in use, quality, and spending. We estimate the effects of state CON laws on the number of health care providers, where providers choose to locate, and the imaging care for Medicare fee-for-services beneficiaries. We use local regression with a triangle kernel, estimating facility placement with a 100 mile bandwidth and imaging receipt using 20 miles as the baseline bandwidth. Models for location of an imaging facility are estimated at the census tract level, and beneficiary receipt of imaging is estimated at the zip code level.

"Appropriate imaging" is measured as MRI or CT imaging with a diagnosis of trauma in the coincident set of billings. "Inappropriate imaging" draws on Choosing Wisely recommendations from physician specialty societies. Medicare beneficiaries in regulated states are slightly less likely to receive any image and considerably less likely to receive low-value imaging than beneficiaries in non-regulated states. We find a -1.4% reduction in the probability of MRI facility at the CON border (with approximately equal effect on hospital-based and freestanding units) and no significant difference in the probability of a CT facility at the CON border. We find a slight reduction in MRI probability at border (0.3 percentage points, 2% of mean on non-CON side) and no change in use of CT. High-value imaging is either unaffected at the border. We find 20-26% reductions in receipt at the border for six low-value imaging services. Overall, CON reduces low value care and largely leaves high value care unaffected.

abs-os267 The Effects of Tort Immunity on Nursing Home Staffing, Treatment, and Outcomes

PRESENTER: **Jill Horwitz**
AUTHORS: Liang Li-Jung, Lee Jennings, Jose Escarce, David Zingmond, Neil Wenger

A central goal of tort law in the medical context is to protect quality of care by deterring negligent treatment. Although previous research has produced mixed results, much finds no association between liability exposure and either treatment or outcomes. During the COVID-19 pandemic, many states provided immunity from tort liability for harms to nursing home residents, creating a natural experiment for examining the effects of immunity on nursing home staffing, care delivery, and outcomes among a particularly vulnerable population. We tested the association between various forms of state tort immunity on nursing home liability and nursing home staffing patterns, care processes and resident health outcomes using measures derived from CMS Nursing Home Compare, Payroll Based Journal Daily Staffing Averages, and Weekly Nursing Home COVID-19 Tracking Data.

During the pandemic (spring 2020-present), roughly eighty percent of the U.S. states implemented some form of tort immunity for nursing homes covering different periods of time ranging from temporary to indefinite immunity. Nursing homes immune from tort liability exhibited fewer staff-patient contact minutes per day than nursing homes in states that did not grant tort immunity. Nursing homes in states that granted tort immunity also had lower quality scores on process measures such as vaccine administration, antipsychotic use, dependence in daily activities, and use of restraints among residents. Emergency department visits, hospitalizations, and COVID-19 cases were greater among residents in nursing homes in states with immunity.

Introduction of immunity was associated with decreased staff-patient time and staff qualifications, inferior care patterns, and worse health outcomes for nursing home residents.

abs-os658 The Impact of Physician-Hospital Integration on Cost and Quality of Oncology Care

PRESENTER: **Pragya Kakani**
AUTHORS: Gabriel Brooks, Alexi Wright, David Cutler, Nancy Keating, Ms. Mary Elizabeth Landrum, Mr. Michael E. Chernew, Nancy Beaulieu, Stacy Gray
Abstract: There has been considerable growth vertical integration between physicians and hospitals in recent years. However, relatively little is known about whether and how physician-hospital integration impacts care delivery. Understanding the impact of this phenomenon is especially important in oncology because oncology has been especially impacted by integration activity in recent years and because patients use many hospital-based services which may be impacted by integration. **Research Aim:** We evaluate the impact of physician-hospital integration in oncology on cost and quality of care. **Methods:** We perform this analysis using Medicare Fee-for-Service and Part D claims from 2010 to 2022 and a unique Health System and Practice Dataset, developed by National Bureau of Economic Research and Harvard University researchers, that tracks practice ownership relationships over time. We use stacked event study design to track outcomes for oncologists moving from independent practices to hospital-owned practices between 2012-2019, 3 years before and after the employment change. Oncologists are compared to a control group of oncologists in their local market who remain at independent practices. Quality outcomes include receipt of timely chemotherapy following surgery and end-of-life intensity of care measures. We also evaluate heterogeneity of results by hospital 340B eligibility. **Results:** We find that total spending associated with six-month chemotherapy episodes decreased by $880 (95% CI: [$433, $1326]) following an oncologists' transition to hospital-based employment. The most significant contributors to this decrease are decreases in spending on chemotherapy, imaging, tests, and radiation. While part of these reductions are related to lower prices paid to hospitals, particularly for infused chemotherapies, other decreases are unrelated to price. There were increases in spending on chemotherapy administration and office visit, due to site of service differences in Medicare prices at facilities. There were also increases in intensity of infused chemotherapy treatment, as estimated by the average sales price, particularly at 340B hospitals. We find no positive impact of physician-hospital integration on quality of care overall or at academic medical centers. **Conclusions:** We find that physician-hospital integration in oncology results in lower costs with heterogeneous effects by cost category but no improvements in quality. Thus our results suggest that claims of quality improvements and concerns regarding overuse associated with physician-hospital integration may be overstated.

Our results also support the continued movement towards site-neutral payments.

Ind-690 Multi-Criteria Decision Analysis for National Immunization Programs: the Development of a Rating and Priority-setting Tool for Policy Makers

PRESENTER: **Chao Gong**
AUTHORS: Li Yang, Jiawei Zhang

Introduction: As the number of vaccines recommended by the World Health Organization (WHO) and the proportion of the program financed by domestic resources grow, it is increasingly important for low- and middle-income countries (LMICs) like China to set context-specific priorities through an explicit, transparent, and accountable process. Decision-making in national immunization is a complex process involving a mix of epidemiological, economic and social-ethical value judgements. The application of Multi Criteria Decision Making (MCDA) could help policy makers choose the strategy that best meets all of these conflicting interests.

Methods: Through literature review and expert consultation with 18 experts, a Multi Criteria Decision Making (MCDA) framework was constructed to evaluate different vaccines that would be included in the national immunization program. Indicator weights were obtained using the analytic hierarchy process (AHP). Haemophilus influenzae type B (Hib) vaccine, pneumococcal conjugate vaccine (PCV), human papillomavirus (HPV) vaccine and rotavirus vaccine (RV), which have been recommended by the WHO but not included in China's national immunization program, as well as influenza and varicella vaccine, which were preferred by some regional or local areas, were compared using the score and rank according to the indicators and weights of MCDA framework. The indicator values of different vaccines were obtained from the researches conducted in the Chinese population, mainly the Global Burden of Disease study in 2019.

Results: 12 of 18 experts (66.7%) finished the two round Delphi survey finally, and a MCDA framework containing 5 first-level indicators and 13 second-level indicators was established, including disease burden (incidence, mortality, disability-adjusted life years), disease cost (direct disease cost, indirect disease cost), vaccine characteristics (effectiveness, safety, persistence, doses), vaccine cost effectiveness (price, cost-effectiveness) and coverage status (equity in coverage, inclusion in national immunization programs in different countries). The weights of disease burden, disease cost, vaccine characteristics, vaccine cost effectiveness and coverage status were 0.10, 0.14, 0.23, 0.28 and 0.24. The six vaccines, ranked from best to worst, were Hib, HPV, influenza, PCV, RV and varicella vaccine, for which the scores were 4.25, 4.15, 3.26, 3.23, 3.21, and 2.85, respectively.

Conclusions: The MCDA tool developed in this study could be used in the LMICs like China to prioritize the inclusion of different vaccination programs into the national immunization program, by soliciting opinions from various stakeholders, with attention to the disease burden, vaccine characteristics and coverage status. However, the indicators could be adapted to the context of different countries and regions. Continuous application and evaluation in different areas are needed to ensure the framework improves priority management and decision-making for immunization programs.

abs-os637 Enhancing the Use of Context Informed Economic Evidence in Vaccine Policy Making in Africa Countries

PRESENTER: **Jacob Kazungu**

As countries in Africa increasing move towards self-financing of their immunisation programs, there will be a need to strengthen evidence to support prioritization of new vaccines to be introduced but also optimization of the existing vaccine portfolios. This is essential in not only sustaining gains made with donor support but also ensuring the countries are better positioned to even introduce additional vaccines or switch within current vaccines using their own resources.

However, a key data gap with regards to use of economic evidence within the African context has been the absence of context specific quality-adjusted life year (QALY) value sets that will improve the validity of cost-effectiveness analysis of vaccines. A collaborative study is being implemented in Kenya, Zambia, and Nigeria to develop and use country specific QALY value sets to generate evidence and support its uptake. This study presents the approach to development and use of economic evidence to inform vaccine decision-making leveraging the implementation process in Kenya.

abs-os598 Estimation of the Cost for Delivering Hepatitis B Birth Dose in Ethiopia Using Facility-Based and Home-Based Vaccination Strategies

PRESENTER: **Brendan Kwesiga**
AUTHORS: Nelly Mejia, Elias Asfaw

Hepatitis B vaccination at birth prevents prevent mother-to-child transmission of hepatitis B virus (HBV) that causes chronic liver disease, including cirrhosis and liver cancer in adults. To optimize efficacy, the Hepatitis B birth dose (HepB BD) must be given within 24 hours of birth posing unique programmatic and operational considerations especially in settings that may have low facility-based delivery. These challenges could affect efficiency of delivery but also effectiveness of the vaccination program. Ethiopia implemented a pilot project of delivering HepB birth dose through home delivery arm to address the challenge of low facility delivery. Building on a pilot roll-out of HepB BD implemented 3 regions of Ethiopia (Addis Ababa, Amhara and Afar), this study estimated the incremental cost from a provider's perspective on the cost of delivering HepB BD vaccine to children born at health facilities and in homes. Estimates for the 2 study arms were estimated in urban, agrarian, and pastoral settings in Ethiopia. Sensitivity analysis was undertaken around approaches taken to estimate cost of human resources involved in delivery of the vaccine as this was the main cost driver influencing the cost of delivery for both study arms.

abs-os592 How Can Economic Evidence be Used to Inform Change in Age Eligibility for Routine Catch up Vaccination? Estimation of Cost of Policy Change in Uganda

PRESENTER: **Chrispus Mayora**
AUTHORS: Kirsten Ward, Brendan Kwesiga

Timely and complete vaccination is crucial for achieving population immunity against vaccine-preventable diseases and optimizing the benefits of vaccination. . Catch-up vaccination through routine vaccine delivery platforms (fixed, outreach, mobile, school-based) is integral to a well-functioning immunization program. As countries continue to recover from disruptions due to COVID-19 pandemic, the World Health Organization (WHO) has developed guidance on planning and implementing catch-up vaccination strategies through routine immunization. One of the limitations of implementing catch-up vaccination is age eligibility/permissibility, as some vaccines are not recommended beyond a certain age in some countries due to policy, administrative or financial/logistical constraints. Uganda has updated its age eligibility guidelines as part of the processes of updating its the Immunization in Practice Uganda (IIP) and zero-dose guidelines. This study assesses the incremental vaccine and non-vaccine related costs required to to catch up children aged 24-59 months who are missing vaccines on Uganda's national immunization schedule each year over from 2025 – 2030.

abs-os635 New Vaccine Introduction in the Context of Local Production: Cost-Effectiveness Analysis of PCV-13 Introduction in the Egypt

PRESENTER: **Alex Adjagba**

Middle-income countries (MICs), such as Egypt, that have not been eligible for Gavi support are lagging in introducing critical new vaccines. It has been shown that the pace of new vaccine introduction across MICs generally not as fast as in the self-sustaining high-income countries (HIC), or Gavi-eligible mostly low-income countries. One of the key vaccines that Egypt is yet introduce the pneumococcal conjugate vaccine that would be useful in addressing targeted pneumococcal diseases such as pneumonia, meningitis, and non-pneumonia non-meningitis (NPNM) infections.

Although the Egyptian government intends to introduce PCV-13, they have a preference to manufacture the vaccine serving the regional market in line with the African region aspirations of vaccine self-sufficiency. To generate evidence relevant to Egyptian policy makers, a cost effectiveness analysis for PCV-13 introduction was undertaken with scenarios to reflect the decision to introduce without domestic manufacturing and also consideration of scenario with domestic manufacturing. The 3 scenarios concerned were: (i)Immediate Introduction considering the use of vaccines with no local production, (ii) A delayed start after 5 years, considering introduction only once vaccine production is established (5 years)- with a phased vaccine production with technology transfers (form/fill/finish) and (iii) A delayed start at Year 10 considering introduction after domestic production.

This study uses various willingness-to-pay (WTP) thresholds across these different scenarios to demonstrate the extent of cost effectiveness and highlight the tradeoffs the policy makers would have to make for each choice made across the different scenarios under consideration.

Integrating Gender Analysis and Health Economics for Equity and Health System Strengthening

SESSION CHAIR: **Afsan Bhadelia**,

CONVENER: **Beverley Essue**, University of Toronto

DISCUSSANT: **Eeshani Kandpal**, The World Bank

abs-os634 Accounting for Gender in Economic Evaluations: A Scoping Review of Gender Outcomes and Impacts

PRESENTER: **Beverley Essue**, University of Toronto
Background: Economic evaluations are commonly used by health system planners to inform policy decisions on resource allocations. While gender disparities can impact health outcomes, access and experiences in health systems, gender-relevant outcomes are not routinely or

explicitly accounted for in many economic analyses and where accounted for, there is wide variation in the approaches and methods used and mixed evidence on their impact on resource allocation decisions. This scoping review seeks to examine how gender is integrated into economic evaluations of cancer interventions and to assess the impact of such integration on value assessment outcomes. Methods: This scoping review follows the framework outlined by Arksey and O'Malley (2005). A search strategy was developed with a medical librarian to identify studies that include explicit gender outcomes in recent economic evaluations of cancer care interventions. Three databases (PubMed, Medline, Embase) were searched for studies published in English from 2023 to present. Studies that assessed the cost-effectiveness, cost-utility, or cost-benefit of interventions from both health care and societal perspectives were included and assessed using a gender analysis framework. Data on the type of economic evaluation, costs and outcomes and the impact on value outcomes (e.g., incremental cost-effectiveness ratios) were abstracted from the included studies. Thematic analysis synthesized the findings, with a focus on methods, gaps in evidence, and variations across regions and cancer types. Results: Findings highlight variation in the extent to which gender is accounted for in the costs and outcomes included in economic evaluations of cancer interventions.Even with productivity and patient-time costs included, economic models remain gender-blind by failing to value unpaid caregiving and underestimating a breadth of societal benefits. While ICERs drop modestly, many studies remain unchanged or above WTP thresholds, obscuring interventions that may be cost-effective for women and potentially obscuring gender inequities. Significance: This review contributes to advancing interdisciplinary research on the intersection of gender and health economics. By mapping how gender is currently accounted for in cancer evaluations, the findings provide insights to strengthen health systems' gender responsiveness and promote health equity.

abs-os640 Assessing the Cost-Effectiveness of Universal Supplementation for ASHAs in Promoting Institutional Births in India

PRESENTER: **Sujata Mishra**, University of Toronto
AUTHORS: Beverley Essue, David Naimark

Background: India continues to face high maternal and neonatal mortality rates, particularly among socio-economically disadvantaged groups. The Accredited Social Health Activist (ASHA) program, the world’s largest community health worker initiative, aims to address these challenges by promoting maternal health. This study evaluates whether expanding state incentives for ASHAs can cost-effectively increase institutional deliveries across India, using a societal perspective. Methods: The study uses data from the National Family Health Survey (2019-2021), United Nations Population Estimates (2022), and Global Burden of Disease Study (2021). A logistic regression model estimates the odds of institutional births among women aged 18-49 in states with and without additional ASHA incentives. These odds ratios are converted to prevalence ratios to project increases in institutional deliveries. A microsimulation model will simulate a cohort of pregnant women to assess the impact of ASHA incentives on institutional deliveries. This model will incorporate detailed individual characteristics from the National Family Health Survey, such as age, education, wealth index, religion, caste, urban/rural residence, health insurance, and proximity to healthcare facilities. The simulation will predict changes in maternal behaviors and birth outcomes if state incentives for ASHAs is scaled nationally. Cost assessments include direct medical expenses (antenatal care, delivery costs, complications), non-medical costs (transportation), and ASHA-related expenses (training and incentives). Outcomes are measured through the Incremental Cost-Effectiveness Ratio (ICER), focusing on cost per additional institutional birth and per Disability-Adjusted Life Year (DALY) averted. Finally, sensitivity analyses will explore the robustness of results by adjusting key parameters, ensuring that conclusions remain valid across various assumptions and model calibrations. The study uses a societal perspective over a 44-week horizon. Results: The analysis shows that 88% of women in India delivered in healthcare institutions, though disparities persist across socio-economic and regional lines. While 64% of women used ASHA services, 57% resided in low-performing states like Bihar and Uttar Pradesh. Although 94% attended at least one antenatal care visit, only 54% completed four or more. Institutional births were more likely among women with higher education, health insurance, and adequate antenatal care. Conversely, lower socio-economic status, minority religions, and rural residency in Empowered Action Group (EAGA) states were associated with lower institutional delivery rates. The result of the cost-effectiveness of expanding state incentives for ASHAs, using a societal perspective currently underway. Conclusion: Expanding ASHA incentives offers an effective strategy to enhance institutional deliveries, especially in underserved regions, aligning with Sustainable Development Goals (SDGs) 3 (Good Health and Well-being) and 10 (Reduced Inequalities). By adopting a societal perspective and focusing on equitable healthcare access, the findings provide critical insights for policymakers in India and other countries leveraging community health worker programs. The results from this study can inform evidence that supports collaborative efforts under SDG 17 (Partnerships for the Goals) to optimize resource allocation and strengthen maternal health strategies globally.
Keywords*:* ASHAs, institutional delivery, community health worker, cost-effectiveness, markov

abs-os625 Balancing the Scales: Towards a More Objective Measure of Sex Inequalities in Health

PRESENTER: **Angela Chang**, Danish Institute for Advanced Study
AUTHORS: Ole F Norheim, Sarah Hawkes, David Watkins, Margaret Kruk, Felicia Knaul, Kent Buse, Emily K Johnson, Omar Karlsson, Sarah Bolongaita

Background: The answer to whether females or males have better health, and which sex is the more disadvantaged varies depending on whom you ask. This study introduces a new method for analyzing and interpreting sex inequalities in health outcomes – defined as the avoidable sex differences in health outcomes – that is systematic and potentially more objective. **Methods:** We introduce the adjusted sex ratio as a measure for sex inequalities and determining sex disadvantage. First, we calculated the sex ratio of life expectancy at ages 0, 5, 15, 35, 50, and 70. We identified sex-specific frontier countries with the highest 5% of life expectancy and estimated the sex ratio of the frontier. We calculated the country- and age-specific adjusted sex ratio by dividing the original by frontier sex ratios. This assumes that theoretically, under the current risk and healthcare environments, females all over the world have the potential to live up to the life expectancy of the females in the frontier countries, and separately, all males to their male-specific frontier. An adjusted ratio of greater than one indicates male disadvantage, while below one indicates female disadvantage. To focus on adjusted ratios which are unlikely to be due to noise, we set a buffer for each measure within which we do not classify disadvantage. **Findings:** Before adjustment, males in all countries (except two) and ages had lower life expectancy than females. After adjustment, between 13% (at age 0) and 33% (at age 70) of the 237 countries shift from male to female disadvantage in life expectancy. More than half of the countries remain male disadvantaged, indicating that males are generally disadvantaged

in terms of life expectancy in most countries, even after our adjustments. India and approximately half of the countries in the Middle East and North Africa, North Atlantic, sub-Saharan Africa, and Western Pacific and Southeast Asia show female disadvantage. The number of countries with female disadvantage rise with age, especially in sub-Saharan Africa and Western Pacific and Southeastern Asia. Central and Eastern Europe show substantial male disadvantage across nearly all ages even with adjustment. **Interpretation:** This study provides a novel, potentially more objective method for assessing sex inequalities in health outcomes, and presents the trends across countries, age, and time.

abs-os641 Gender and Workforce Planning: Accounting for the Value of Discrimination in Paid and Unpaid Health Work

PRESENTER: **Michelle McIssac**

Introduction: This session explores the economic and social impacts of gender discrimination in health and care work, both paid and unpaid, and discusses how these insights can inform more equitable health workforce planning. Drawing on two recent WHOs reports “Fair Share for Health and Care: Gender and the Undervaluation of Health and Care Work,” and “The gender pay gap in the health and care sector a global analysis in the time of COVID-19” we aim to explore the economic implications of gender discrimination in both paid and unpaid health and care work. Methods: We employ a comprehensive gender analysis framework to evaluate the extent and impact of gender discrimination in health work. This includes quantitative analysis of data on paid and unpaid health work, highlighting disparities and undervaluation. Gender pay gaps are explored using the Oaxaca-Blinder Decomposition (OBD) technique across for each of the 54 countries where data are available. And disparities in unpaid care work are explored in 41 countries where data are available. Conclusion: Our findings reveal significant undervaluation of women’s contributions to health, with substantial economic and social costs. Addressing gender discrimination in health and care work is not only a matter of equity but also essential for developing effective and sustainable health workforce policies and planning. By integrating gender analyses with conventional health labour market analyses, we can better understand the true value of health and care work and develop more equitable health workforce planning strategies. This session provides actionable insights and explores the policy levers to promote gender equality in both paid and unpaid health and care work References: “Fair Share for Health and Care: Gender and the Undervaluation of Health and Care Work,” World Health Organization, 2024. “The Gender Pay Gap in the Health and Care Sector: A Global Analysis,” World Health Organization, 2022.

DISCUSSANT: **Jonathan Karnon**, Flinders University; **Angela Bate**, Northumbria University

abs-os73 Building a Robust Framework for Mental Health Investment in South Africa: Embedding Local Expertise, Feasibility, Efficiency and Stakeholder Ownership

PRESENTER: **Donela Besada**
AUTHORS: Sumaiyah Docrat, Crick Lund

Background. In South Africa, mental, neurological, and substance-use (MNS) conditions impose a substantial burden on the health system, with marked inequities in mental healthcare access. The National Health Insurance (NHI) was first proposed in 2011 as a means to promote equity in healthcare access towards universal health coverage (UHC). However, South Africa’s continued reliance on historical patterns of budget allocation maintains the status quo of sub-optimal and inequitable mental health resource use, highlighting the need for increased strategic priority setting and transparent decision-making processes. There is concern that unless mental health priorities are clearly incorporated into the policies and activities guiding NHI implementation, mental health may be overlooked. In response, the South African Mental Health Investment Case (MHIC) was commissioned by the National Department of Health and Treasury to guide resource allocation for mental health, emphasizing integrated community-based care, efficient service delivery, and a focus on both preventative and curative interventions.

Methods. The MHIC evaluated the return-on-investment (ROI) from scaling up interventions for anxiety, depression, psychosis, bipolar disorder, epilepsy, intellectual disability, child behavioural disorders, dementia, and substance-use disorders. The analysis utilized the WHO Inter-UN OneHealth Tool and an Excel-based model to project health benefits and estimate the total economic and social value over a 15-year period. The MHIC also incorporated a comprehensive stakeholder consultation process, a Delphi study for expert consensus, and considerations for programmatic enablers and infrastructural requirements.

Results. We found that the investment needed by the health department translates to 9% of the projected health budget expected by 2035. This is within international recommended norms of allocating 5-10% of the total health budget to mental health. Unaddressed MNS conditions represent an annual loss of 4% of the country’s GDP. Across all conditions, the estimated cost of mental health scale-up reflects just 11% of the economic value of lost productivity due to MNS conditions over the 15-year scale-up period. The investment case also demonstrates substantial returns on investment for several specific interventions. These include psychosocial interventions coupled with psychotropic medication for

adult depression and anxiety (RoI=4.0:1 and 1.5:1), social-emotional learning programmes for adolescents (RoI = 1.9:1), the identification and treatment of perinatal depression (RoI = 4.7:1), early prevention programmes for risky alcohol use (RoI= 1.2:1), and treatment of epilepsy through basic psychosocial support and antiepileptic medication (RoI = 1.8:1).

Conclusions. The MHIC highlights the critical need to address the growing burden of MNS conditions. It provides a robust framework for integrating mental health services into the NHI benefits package and emphasizes the economic rationale for investment. The comprehensive approach includes considerations for social determinants and cross-departmental costs, promoting collaborative planning and supporting economic recovery. The MHIC highlights best practices for ROI analysis by integrating key guiding principles. It fosters collective ownership with national and provincial health departments to enhance relevance and implementation potential, while valuing diverse local expertise to prioritize interventions across clinical, policy, and system levels. A focus on feasibility ensures realistic evaluations of programmatic and resource needs, and a commitment to data integrity leverages high-quality local evidence.

abs-os89 Health Prevention and Promotion Activities in Today's National Health Service: Further Challenges to the Cost-Effective Versus Affordable Conundrum

PRESENTER: **Ms. Rachael Hunter**, University College London
AUTHORS: Sarah Kalwarowsky, Rachael Frost, Cristina Avgerinou, Kate Walters, Claudia Cooper, Louise Marston, et al, on behalf of the HomeHealth Research Team, Pan Shengning, Andrew Clegg

Introduction. Health prevention and promotion initiatives are often promoted as being worth the investment given future cash-savings. This paper uses the findings of HomeHealth, a health promotion service for older adults with mild frailty, to examine how economic evaluation relates to local decision making.

Methods. The HomeHealth trial randomised 388 participants aged 65+ years with mild frailty to receive HomeHealth (195 participants) or treatment as usual (TAU; 193 participants). Health and social care resource use and carer time were self-completed at baseline, 6-months and 12-months. Primary and secondary health care resource use and medications were collected from patient files at 12-months post recruitment, covering the past 18-months. Stakeholders including local payers were consulted on the results of the trial and budget impact.

Results. At 12-months, participants allocated to HomeHealth had a significant reduction in emergency hospital admissions (IRR 0.65 95%CI 0.45 to 0.92) and unpaid carer hours at 6-months (-16 hours (95%CI -18 to -14 hours) or -£360 (95%CI -369 to -351) per patient). Although the HomeHealth intervention results in fewer emergency admissions, local payers struggle to identify the resources to fund it.

Discussion. This case study illustrates the problem with using standard economic evaluation methods to argue for implementation of health promotion and prevention initiatives in publicly financed healthcare systems. Although HomeHealth resulted in reduced emergency admissions and may be cost-saving to the system as a whole, it is not locally cash releasing. Health promotion initiatives are unlikely to be funded from local budgets without significant system wide changes. It is important to engage with stakeholders prior to designing and conducting an economic evaluation to ensure that the results meet their needs.

abs-os90 Is Economic Evaluation and Care Commissioning Focused on Achieving the Same Outcomes? Resource-Allocation Considerations and Challenges

PRESENTER: **Matthew Franklin**, University of Sheffield
AUTHORS: Sebastian Hinde, Ms. Rachael Hunter, Gerry Richardson, William Whittaker

Background. Commissioning describes the process of contracting appropriate care services to address pre-identified needs through pre-agreed payment structures. Outcomes-based commissioning (i.e., paying services for pre-agreed outcomes) shares a common goal with economic evaluation: achieving value for money for relevant outcomes (e.g., health) achieved from a finite budget.

Aim. We describe considerations and challenges as to the practical role of relevant outcomes for evaluation and commissioning, seeking to bridge a gap between economic evaluation evidence and care commissioning.

Methods. We describe conceptual (e.g., what are ‘relevant’ outcomes) alongside practical considerations (e.g., quantifying and using relevant endpoint or surrogate outcomes) and pertinent issues when linking outcomes to commissioning-based payment mechanisms, using England as a case study.

Key results. Economic evaluation often focuses on a single endpoint health-focused maximand, e.g., quality-adjusted life-years (QALYs), whereas commissioning often focuses on activity-based surrogate outcomes (e.g., health monitoring), as easier-to-measure key performance indicators that are more acceptable (e.g., by clinicians) and amenable to being linked with payment structures. However, payments linked to endpoint and/or surrogate outcomes can lead to market inefficiencies; for example, when surrogates do not have the intended causal effect on endpoint outcomes or when service activity focuses on only people who can achieve prespecified payment-linked outcomes.

Conclusions and implications for policy and practice. Accounting for and explaining direct links from commissioners’ payment structures to surrogate and then endpoint economic outcomes is a vital step to bridging a gap between economic evaluation approaches and commissioning. Decision-analytic models could aid this but they must be designed to account for relevant surrogate and endpoint outcomes, the payments assigned to such outcomes, and their interaction with the system commissioners purport to influence.

abs-os91 Mental Health Investment in Workplaces: A Study of Resource Allocation Practices in the UK

PRESENTER: **Mr. Hareth Al-Janabi**, University of Birmingham
AUTHORS: Yusuf Ozdemir, Yibei Qu, Luke Henstock

Background. Mental health problems are increasingly common in the workplace. Workplaces in the UK and many other countries are encouraged to invest in their employees' mental health, through interventions and cultural changes. There is a growing evidence base to support these investments, showing that many inventions are cost-effective. However, to date, little is known about how resource allocation for mental health and wellbeing works in workplaces in the real world, and, by extension, whether economic analysis might have to be adapted to inform decision-making in these settings.

Aim. To characterise decision-making processes, values, and evidence use in UK workplace settings and identify where this deviates from the rational, problem-solving, model.

Methods. In the *Wellbeing Investment in School and Employers* (WISE) study, we are using (i) process tracing with case study workplaces to study decision-making; (ii) think-aloud interviews with managers to study evidence use; and (iii) Q-methodology to understand values and attitudes to investment in workplaces. The initial findings from these empirical studies have been synthesised into a set of eight features of resource allocation practice.

Results. The features are: (i) diversity of decision-makers; (ii) conflicting objectives; (iii) workforce decisions; (iv) external search for resources; (v) contexts and constraints; (vi) practice wisdom; (vii) multiple sources of evidence; and (viii) varying evidence utilisation models.

Conclusion. The presentation will outline the 8 features and their implications for how health economics research is - and can be – best used workplace settings. The initial findings clearly point to important deviations in the real world from the implicit rational (problem solving) model underlying evidence production. To optimise the way that cost-effectiveness data and other research is used to support mental health investment, serious consideration needs to be given to tailoring and delivering analysis in different ways. This includes paying close attention to (i) identifying decision-makers and their goals and constraints prior to analysis; (ii) adapting analyses for varying contexts; (iii) engaging with different models of evidence use; and (iv) tackling decision problems related to time use.

abs-os82 Assessing Preferences for Pediatric Health States from a Family Perspective

PRESENTER: **Wendy J Ungar**, The Hospital for Sick Children Research Institute/University of Toronto, Toronto, Canada
AUTHORS: Ramesh Lamsal, Carol Oliveira

Abstract

Background:. A key challenge to conducing CUA in infants and very young children is reaching consensus on the concept of health-related quality of life (HRQoL), part of which is understanding the effects on family members when a child is ill. Early work by Basu and Meltzer (2005) indicated that a patient's health state utility was a function of the direct effects of the health condition plus the effect of the patient's ill health on a caregiver's utility plus the effect of a caregiver's HRQoL on a patient's utility. This concept can be adapted to illustrate the dynamic HRQoL impacts within a family with an ill child. The maternal-fetal paradigm also warrants attention given that many costly screening, diagnostic, medical and surgical interventions are directed at pregnant women with health consequences for both the mother and the fetus or neonate that may be lifelong.

Objectives: To consider the construct of family HRQoL and to examine the range of approaches used to measure, integrate and report preference-weighted HRQoL effects in family members for pediatric and maternal-fetal CUA.

Methods: Qualitative thematic analysis was used to create a conceptual framework of HRQoL in families with an ill infant based on data from focus groups with caregivers and providers. Two separate systematic reviews were undertaken to identify pediatric CUAs and maternal-fetal CUAs that included preference-weighted HRQoL effects in family members. Data describing how these effects were measured, analysed, incorporated in the CUA, and reported, were extracted and categorized.

Results: Infant HRQoL was perceived as a unique entity strongly influenced by caregivers, family and the home environment. It may be inversely correlated with the degree of effort required to achieve normalcy in everyday life for the neonate/infant and its family. With regard to capturing family member preference-weighted HRQoL in pediatric CUA, 35 studies were reviewed. Most considered HRQoL effects on one family member. Eight different approaches for measuring preference-weighted HRQoL in family members were observed. Most commonly, QALY losses experienced by caregivers/parents were measured using an isolated approach whereby preference-weighted HRQoL impacts due

only to a child's illness was quantified separately from other health effects. The most common approach for integrating HRQoL effects in pediatric CUA was to sum children's and parent/caregivers' QALYs and report them from a family perspective. Among 54 QALY-based maternal-perinatal CUAs, 12 included fetal health outcomes, the impact of fetal loss on mothers' HRQoL, and the impact of neonatal demise on mothers' HRQoL. Most studies measured preference-weighted HRQoL impacts separately for pregnant women and offspring. The most common integration approach was to sum QALYs for pregnant women and children.

Conclusions: Neonatal/infant HRQOL is a multidimensional concept that considers a child's needs for healthy development in the context of the caregiver's ability to meet those needs. Wide methodologic heterogeneity in incorporating family member preference-weight HRQoL in pediatric and maternal-fetal CUA reflects the need for a theoretical framework and practical guidance to promote more rigorous evidence to inform decision-makers on the cost-effectiveness of health interventions aimed at pregnant women, neonates and children.

abs-os84 Transitions in the Measurement and Valuation of Health-related Quality of Life Across Age-specific Instruments: Challenges for QALY Estimation

PRESENTER: **Nancy Devlin**, University of Melbourne

Abstract

Background: Relevant aspects of Health-related Quality of Life (HRQoL) may differ by age. This has led to developing age-appropriate HRQoL instruments. These have the potential to improve HRQoL measurement *within* the target age range, at the (potential) cost of reduced comparability *between* age groups. The availability of age-specific instruments has in turn led to the development of preference weights to accompany them. Differences between the methods used to value pediatric and adult HRQoL have the potential to generate values with different properties. Differences in description and valuation of HRQoL using age-specific instruments will compound when used to estimate QALYs.

Objectives: Evidence is presented from two studies undertaken to investigate: (a) differences between HRQoL observed using age-specific instruments and (b) the characteristics of preference weights for them. The research focuses on two conceptually related instruments: the EQ-5D-5L and the EQ-5D-Y, which share broadly the same five dimensions, with differences in wording that reflect adaptations made to the latter. Research questions are: (a) do the EQ-5D-5L and EQ-5D-Y-5L generate similar *descriptions* of HRQoL? (b) Are the characteristics of value sets for EQ-5D-5L similar or different from the values for the EQ-5D-Y-3L? (c) What are the implications of these findings for estimating and comparing QALY gains between age groups?

Methods: The Y-5L and 5L were administered to n=691 12-18 years olds. Differences between self-reported health on each were examined and psychometric performance compared in terms of acceptability, feasibility, ceiling effects, convergence, test–retest reliability, and known-group validity. Value sets for the Y-3L and 5L were compared in all countries where both exist. Comparisons focused on length of value scale, % states valued < 0 and relative importance of dimensions.

Key results: Both Y-5L and 5L had good psychometric properties; responses to the instruments were strongly correlated. Ceiling effects were lower for the Y-5L than 5L; the Y-5L identified a higher incidence of self-reported HRQoL problems than 5L both overall and particularly in mental health.

There are substantial differences between the value sets for the 5L and the Y-3L. The Y-3L value sets tend to have a higher minimum value and fewer values < 0. Dimension importance differs: Pain/Discomfort is nearly always the most important dimension in Y-3L value sets, and 'functional dimensions' (Self-Care, Usual Activities, Mobility) are less important in Y-3L value sets compared to their adult counterparts.

Conclusions and implications: 5L and Y-5L are conceptually related and produce correlated but somewhat different conclusions e.g. 'worried, sad or unhappy' (Y-5L) leads to a greater prevalence of mental health issues being reported than 'anxious/depressed' (5L). There are also substantial and systematic differences between the value sets for the 5L and the Y-3L.

Implications for economic evaluation depend on how these differences play out when combined and used to identify changes in HRQoL; differences in values may counteract or amplify differences in observed HRQoL. Given that many childhood interventions generate QALYs in both childhood and adulthood, identifying differences between age-specific tools, and finding ways to address the transition across age-specific tools, is important.

abs-os80 Valuing Health-related Quality of Life of Children Less than Five Years of Age: Challenges and Results from Think Aloud and Valuation Studies

PRESENTER: **Kim Dalziel**, The University of Melbourne
AUTHORS: Nancy Devlin, Xiuqin Xiong, Alexander van Heusden

Abstract

Background: The burden of disease within childhood is highest in children under 5 years of age. This is the age group where we see the greatest concentration of health service use and health technology assessment linked to activities such as vaccinations, newborn screening and genomic testing. Despite these patterns, this is the age group in which we have seen the least activity in measurement and valuation of child health-related quality of life (HRQoL), presumably because it is more difficult conceptually and methodologically. Recently, we have seen more options for the measurement of HRQoL through preference-weighted measures such as the adapted EQ-5D-Y for 2-4 years, EQ-TIPS, HUPS, CHU9D for children under five years, and the PedsUtil with growing psychometric evidence. Now is an ideal time to discuss, tackle and advance some of the valuation challenges that follow. Key issues include whose preferences to include in valuation tasks given many in the

general population have little insight into experiences of young children. Other issues include how to frame tasks, define child age, and anchor latent preferences.

Research Question: What are the task-related and valuation preferences of the general population and parents for health states of children under 5 years?

Methods: We conducted two studies as part of a larger research program. Firstly, we conducted 17 individual online semi-structured think-aloud valuation interviews with Australian adults (9 parents and 8 non-parents). Secondly, we conducted a valuation study among the general Australian adult population exploring the impact of age framing and parenthood on preferences for health states described by the CHU9D. We surveyed 3112 participants randomly allocated to the 2-4 year old or 10 year old child framing using a latent scale discrete choice experiment (DCE). The survey's latent values were anchored to a utility scale using visual analogue scale responses.

Key results: In think aloud tasks participants favoured the inclusion of those with experience of children. Despite asking participants to think of a 'hypothetical' child, participants tended to think of their own child or a child they knew. There was no preference for stating a specific age for a young child, but participants did feel their valuation responses would differ compared to being asked about an older child (i.e., 10 years or older). Participants showed evidence of pulling in additional considerations to valuation tasks such as caregiver spillovers, future spillovers, and whether health states would improve naturally or were treatable. Key findings from the valuation DCE were that there were no important differences in general adult population's preferences between the two age framings (2-4y vs 10y). However, there were significant differences in the preferences of parents compared to non-parents, with smaller disutilities for severe levels of pain, tired and activities.

Conclusions and implications: This research has important implications for understanding differences in preferences, and how to design valuation tasks of health states for children under 5 years. The research informs the need for age-specific value sets for HRQoL instruments for children under 5 years.

Determinants of Healthcare Utilization: From Social Factors to Knowledge Gaps

MODERATOR: **Laura Anselmi**,

abs-os261 Persistence Pays Off? More Persuasive Health Workers Increase COVID-19 Vaccine Take-Up in Ghana

PRESENTER: **Mylene Lagarde**, London School of Hygiene & Tropical Medicine (LSHTM)
AUTHORS: Marta Grabowska, Salifu Amadu

How to convince people to get vaccinated? Against the backdrop of a resurgence of vaccine hesitancy following disinformation and concerns around the COVID-19 vaccines, this question is more critical than ever. In this paper, we explore whether frontline healthcare workers can convince patients who come to receive curative care, to get vaccinated on the same occasion. Whilst integrating vaccination or other preventive care into routine consultations may be a promising and low-cost strategy, it is unclear whether (1) healthcare providers are willing to engage with patients beyond the usual consultation and (2) whether they can convince patients to take up vaccination. To answer these questions, we partnered with the Ghana Health Service to conduct a cluster-randomized control trial in 120 facilities in 4 regions with low COVID-19 vaccination rates. To test if providers can be motivated to offer vaccines to patients, 40 facilities were randomly allocated to a "light touch" intervention, where district health officials paid a visit to encourage all clinical staff to discuss COVID-19 vaccines with patients during curative consultations. To test the role of provider communication skills, 40 health facilities were randomized to receive both the "light touch" treatment and an additional day of "communication" skills training for providers, which focused on overcoming hesitancy and building patient trust. The remaining 40 facilities received no treatment. Using data collected from 5,400 patients for 8 weeks after treatment, we find that providers in both treatment groups talked to patients about COVID-19 and vaccination 6 times more than in the control group, where this occurred in only 5% of consultations. Only the facilities where providers received the additional training saw an impact on COVID-19 vaccine take-up, which increased 7.6 times (2.3%) relative to the control group (0.3%). We detect no change in patients' knowledge about COVID-19, (mis)perceptions of the vaccine, or own-risk beliefs. Using detailed data from consultations by 'mystery' patients (enumerators presenting as real patients), we show that the increase in vaccination in "communication" facilities may come from improved communication and inter-personal skills by providers, who inquire more about the patients' concerns and spend more time-sharing information about the vaccine. Finally, we find no evidence of unintended consequences of the interventions, such as reduced patient satisfaction, increased waiting times or reduced quality of care. Overall, our results demonstrate the potential for leveraging existing resources in the healthcare system to convince people to get vaccinated in low-income settings, as long as investments are made to ensure that patients are not simply "talked at" but "listened to".

Ind-1054 Value of Knowledge in Unexpected Health Shocks: Evidence From Physicians as Patients

PRESENTER: **Yajie Wang**, Peking University
AUTHORS: Junjian Yi, Mr. Ye Yuan, Kamhon Kan

Medical knowledge is crucial in disease management. However, few studies have rigorously examined and quantified its impact on the early detection and clinical outcomes of unexpected health events. This study investigates the role of medical knowledge in managing unexpected health shocks, focusing on clinical outcomes following a first-ever ischemic cerebrovascular event.

Using detailed administrative electronic medical records (EMRs) from 1996-2011 for Taiwan residents born between 1953 and 1957, we compare physician and nonphysician patients to assess differences in mortality, readmission, and acute ischemic stroke rates between 7 and 365 days after their first-ever ischemic cerebrovascular event. We use coarsened exact matching (CEM) to match nonphysician patients with comparable demographics, pre-stroke income, geographic access to care, and pre-shock health status to physician patients. Our findings reveal that physician patients have significantly lower mortality and readmission rates, as well as a reduced likelihood of recurrent strokes, after adjusting for treating physician and hospital fixed effects. These advantages stem from early detection, timely intervention, and informed treatment decisions. Specifically, physician patients have a 7.05% lower probability of hospitalization, and lower least absolute shrinkage and selection operator (LASSO) algorithm predicted hospitalization rate at their first ischemic cerebrovascular event. We also categorize ischemic cerebrovascular diseases into transient ischemic attack (TIA), intracranial artery stenosis (ICAS), and acute ischemic stroke (AIS) as proxies for disease severity. Patients initially diagnosed with TIA or ICAS generally had milder disease, while those with AIS had more severe symptoms. Physician patients were more likely to experience TIA or ICAS and less likely to experience AIS compared to nonphysician patients, suggesting earlier detection and treatment. Despite having less severe initial disease, physician patients tend to incur higher medical expenditures compared to nonphysician patients at the onset of an ischemic stroke.

Subsequently, we include initial disease severity measurements and five expenditure quartiles for medical expenditures at first-ever cerebrovascular disease in the matching process. The differences in mortality rates, readmission rates, and the probability of experiencing an acute ischemic stroke between physician and nonphysician patients become statistically insignificant. This suggests that the advantage of physician patients over nonphysician patients in initial cerebrovascular disease management may partly lie in early detection and early treatment. Once these factors are accounted for, the statistical significance of this advantage diminishes, though the underlying benefit still persists. We also test the external validity of these findings in the context of ischemic heart diseases.

We then explore how the general population can perform as well as physician patients. For general patients who achieve comparable outcomes in early detection and timely treatment, we estimate an additional annual expenditure of TWD 706 on primary and preventive care in the decade preceding their ischemic cerebrovascular disease—a cost-effective investment that enhances disease prevention and early health monitoring. The findings highlight the critical role of medical knowledge, as well as primary care, in mitigating unexpected health shocks and improving health outcomes and quality of life. Improved primary care can help bridge the gap in medical knowledge for the general population.

Ind-1025 The Long-term Hospital Costs of Women who Experience Intimate Partner Violence

PRESENTER: **Bonny Parkinson**, Macquarie University
AUTHORS: Jananie William, Deborah Loxton, Dana Hanna, Bronwyn Loong

Intimate partner violence (IPV) is a pervasive global public health problem with far-reaching consequences for affected individuals and society. This study comprehensively quantified the impact of IPV on long-term hospital utilisation and costs for a young cohort of women. We conducted fixed effects regression analysis on a unique longitudinal survey linked to hospital administrative data over 11 years, while controlling for observed and unobserved time-invariant confounders (N=5608). Women who reported experiences of IPV had a similar likelihood of being hospitalised and length of stay, but had 0.077 ($P<0.01$) additional hospital visits per annum, leading to 47.9% ($P<0.05$) additional hospitalisation costs per annum, than women without reported experiences of IPV. The impact of IPV on hospitalisation costs was not significant after controlling for whether the woman was hospitalised, suggesting that hospitalisation frequency, not the reason for hospitalisation, was the key driver of costs. We also find that younger women and women with chronic illness who experience IPV were more likely to be hospitalised, and were more likely to be hospitalised for a range of reasons, particularly relating to mental health, nervous system, respiratory system, and injuries & poisoning. The relationship between IPV and increased hospital costs was robust to omitted variables, based on a series of robustness tests, and reverse causality, based on the fixed effects approach. The results strongly support the conclusion that IPV has significant long-term health impacts that translate to increased hospital utilisation and costs that persist over time and are not confined to increased hospitalisation due to injury when experiencing IPV.

Ind-1150 Process and Outcome Evaluation of Integrating Primary Eye Care into Primary Health Care: A Quasi-Experimental Study in Rural China

PRESENTER: **Xiaochen Ma**
AUTHOR: Xiaodong Dong

Background Visual impairment represents a major public health challenge, particularly in low- and middle-income countries (LMICs), where unmet needs for eye care remain substantial. The World Health Organization's 2019 *World Report on Vision* emphasizes the integration of primary eye care (PEC) into primary healthcare (PHC) as a key strategy for addressing this gap. This study evaluates the effectiveness and implementation of a model integrating PEC into PHC (*Eye CARE Model*) in rural China. **Methods** From 2021 to 2023, the *Eye CARE Model* was implemented, focusing on Capacity building, Awareness raising, and Referral system Establishment (CARE). We employed a quasi-experimental design with a difference-in-differences (DID) methodology to assess the intervention's impact on service utilization. Data from the local health administrative information systems were used, spanning two years before and three years after the intervention (2019-2023). Key outcomes included primary and secondary eye care utilization, with covariates from the China County Statistical Yearbook. The DID model,

integrated with two-way fixed effects, evaluated the effect of the intervention, and event study methodology was used to track dynamic effects over time. A nested process evaluation explored facilitators, barriers, and implementation outcomes. Qualitative data were gathered through 15 focus group discussions with 148 participants (34 health providers and 114 rural residents). Thematic analysis, combining inductive and deductive approaches, identified key factors influencing implementation. All interviews were coded in NVivo 10.0, ensuring reliability and validity through triangulation with quantitative data. **Results** The *Eye CARE Model* significantly increased the utilization of both primary and secondary eye care services. Specifically, the intervention resulted in an average increase of 76 visits per 10,000 people for primary eye care services and 52 visits for secondary eye care services. The DID model, integrated with a multiple linear regression model, demonstrated the effectiveness of the *Eye CARE Model* in increasing service utilization. The event study methodology further illustrated the dynamic impact of the intervention over time. Additionally, the *Eye CARE Model* improved community-based eye health education and successfully established a three-tiered referral system. Process evaluation revealed high fidelity and broad reach, with local government support and the healthcare organizational structure identified as key facilitators. However, challenges were encountered in sustaining incentives and integrating PEC-related indicators into local health management and information systems. **Conclusions** The *Eye CARE Model* effectively enhanced eye care service utilization and demonstrated the potential for integrating PEC into PHC in rural China, leveraging the existing hierarchical healthcare system. Our findings underscore the importance of contextual factors in the successful implementation and sustainability of complex interventions in LMIC settings. These results have significant implications for scaling up PEC interventions in similar contexts and highlight the need for continued policy and system support to ensure long-term impact. **Keywords:** Primary eye care; Primary healthcare; Process evaluation; Outcome evaluation; Quasi-experimental study; Rural China

Ind-1579 The Impact of Thermal Home Upgrades on Healthcare Utilisation and Costs of People With Cardiovascular, Respiratory and Mental Health Conditions

PRESENTER: **Dan Liu**, University of Technology Sydney
AUTHORS: Lutfun Hossain, Katie Page, Rosalie Viney

Background: The relationship between the home environment and health outcomes has gained significant attention. Randomised controlled trials (RCTs) in the northern hemisphere and New Zealand demonstrate that improving the thermal comfort of homes has generally positive effects of health and well-being, especially for vulnerable populations and conditions like cardiovascular, respiratory and mental health. However, there is currently no evidence of health benefits in an Australian context. Results across countries may vary due to differences in climate, the quality of the housing stock and existing levels of energy efficiency.

Objectives: The Victorian Healthy Homes Program (VHHP) is Australia's first RCT examining the impact of thermal home upgrades on health outcomes in vulnerable older individuals during winter. The program aimed to provide home upgrades for 1,000 households (1,300 individuals), offering up to $3,500 per household to improve thermal comfort and energy efficiency. This paper evaluates the impact of the VHHP on total healthcare costs, hospital admissions, Medicare Benefits Schedule (MBS) and Pharmaceutical Benefits Schedule (PBS) services, focusing on cardiovascular, respiratory, and mental health conditions linked to cold temperatures.

Methods: The VHHP was implemented over three years using a staggered, parallel-group clustered RCT. Households were assigned to either an intervention group, receiving a home upgrade before winter (July – September) in 2018-2020, or a control group, receiving an upgrade after winter. Survey data were collected through interviews. Medical and pharmaceutical records were provided by Services Australia. Hospital data was tracked through the Victorian Admitted Episodes. The observation period for the datasets is from 2015 to 2021. To assess the impact of the intervention on healthcare utilisation and costs from 2015 to 2021, we first employ ordinary least squares regression. Second, using a difference-in-differences approach, we exploit the impact of the intervention on healthcare outcomes over the winter months from 2008 to 2020. Third, we apply an interrupted time series analysis to evaluate the program's impact over the two years preceding and one year following the intervention for the intervention group. All models control for age, gender, location, and year fixed effects.

Results: This study demonstrates that, in the short term, a modest investment in improving housing quality led to reductions in total healthcare costs and hospital admissions for individuals with cardiovascular, respiratory, and mental health conditions, although these results were not statistically significant. Due to limitations in data availability, the impact of the VHHP could not be assessed beyond one year following the intervention. However, given that the housing upgrades are permanent, there is potential for long-term health benefits for individuals with cardiovascular, respiratory, and mental health conditions.

Discussions: This program provides novel and rigorous evidence that modest home upgrades can positively impact healthcare costs and hospital admissions. Key strengths of this study include the randomised design and comprehensive linked health data for the same cohort. These findings contribute valuable evidence to the growing body of research on the co-benefits of housing improvements, highlighting the potential for broader public health impacts through targeted housing interventions.

Mental, Psychological and Social Health Needs

MODERATOR: **Eran Politzer**,

Ind-1623 An Updated Systematic Literature Review of the Economic Costs of Loneliness and the Cost-effectiveness of Interventions targeting loneliness

PRESENTER: **Lidia Engel**, Deakin University
AUTHORS: Muhammad Fikru Rizal, Cathy Mihalopoulos, Jan Faller, Sharon Clifford

Background: While the literature on health outcomes related to loneliness and social isolation has grown in recent years, our understanding of the economic outcomes associated with loneliness and social isolation is limited. A previous review published in 2019 by Mihalopoulos et al. identified only 12 studies of which four estimated the costs of loneliness, with the remaining studies examining the cost-effectiveness of interventions targeting loneliness and social isolation. There has been a growing interest into loneliness research, especially following the COVID-19 pandemic, emphasizing the importance of understanding its economic impact.

Aim: To update a previous review on the economic costs associated with loneliness and social isolation as well as evidence on the cost-effectiveness of interventions to prevent or address loneliness and social isolation.

Methods: Four bibliographic databases (Medline, PsycINFO, CINAHL, and Embase) were searched from 2018 onwards using a combination of keywords and subject headings, complemented by a search of grey literature. Cost-of-illness and economic evaluation studies, including return on investment studies, were included in the review that were published in English language. All studies were evaluated for quality and summarized using a narrative approach.

Results: In total, fourteen studies were included of which six were cost-of-illness studies (USA=1; Spain=1; Australia=1; Netherlands=1; Japan=1), three full economic evaluation studies (UK=1, Australia=1; Netherlands=1), and five social return on investment studies (UK=4, Australia=1). Most cost-of-illness studies focused on healthcare and productivity cost, with only a few studies considering other costs, such as informal care and wellbeing cost. All, except one study, reported excess cost associated with loneliness either at the population level or person level (i.e., costs associated with a lonely or socially isolated person). Among the three economic evaluation studies, two were modelled cost-utility and cost-effectiveness analyses focusing on older adults, while the third comprised a trial-based cost-utility analysis targeting low-income individuals with health problems. While the probabilities for the interventions being cost-effective ranged between 54% in study one to 55%-68% in study two, the third study found that any interventions that reduce levels of severe loneliness in older people are cost-effective but unlikely to be cost-saving. Further, all social return on investment studies demonstrated positive returns, ranging between £1.17 for a dementia peer support group to AUD 8.21 for an emergency animal boarding.

Conclusion: This updated review identified a number of recent studies on the economic outcomes of loneliness; however, the evidence remains limited, underscoring the need for further research. While cost-of-illness studies that extend beyond the healthcare sector (e.g., incorporating education costs) are warranted, further evaluations of the cost-effectiveness of interventions are needed, focusing not only on older adults but also on other population groups.

Ind-281 Economic Evaluation of Cognitive Behavioural Therapy for Insomnia (CBT-I) For Comorbid Insomnia and Depression in An Australian Context

PRESENTER: **Cathy Mihalopoulos**
AUTHORS: Phuong Le, Long Le, Shantha Rajaratnam

Abstract:

Background:

Recent studies have shown that conventional treatment for comorbid insomnia and depression, which primarily targets depression with the expectation that both depressive and insomnia symptoms will improve, has limited effectiveness. Cognitive behavioural therapy for insomnia (CBT-I), the first-line treatment for insomnia, has been proven to yield significant effects on both symptoms; however, evidence of its cost-effectiveness is lacking.

Research aims:

This study evaluated the cost-effectiveness of three ways to incorporate CBT-I into the management of this comorbidity compared to the conventional treatment: CBT-I adjunctive to ongoing treatment-as-usual (TAU) for depression compared to TAU alone (*Sequential treatment - depression first*); Concurrent use of CBT-I and antidepressant compared to antidepressant alone (*Concomitant treatment*); Standalone CBT-I compared to antidepressant (*Standalone*) over a twelve-month time horizon from both healthcare and societal perspectives in an Australian context.

Methods:

Both face-to-face (F2F) and digital CBT-I (self-help and guided) modalities were evaluated depending on the availability of clinical evidence for each treatment approach. Modelled cost-utility analyses were applied using a decision tree model. The health outcome of interest was quality-adjusted life years (QALYs). A commonly referenced threshold of A$50,000/QALY was applied in this study. All costs were presented as 2023-24 Australian dollars (A$).

Randomised controlled trials (RCTs) of CBT-I for comorbid insomnia and depression were selected using a meta-review approach, and an updated search was performed to identify trials not covered in published systematic reviews. Pooled relative risks for the remission of insomnia and depression were estimated using (network) meta-analyses of the RCTs. Probabilistic and deterministic sensitivity analyses were applied to

explore uncertainties in the results.

Key results:

The studies identified to evaluate the effectiveness of interventions included: one study for *standalone* was identified (F2F CBT-I: n = 1)*;* three studies for *concomitant treatment* (F2F CBT-I: n = 3)*;* five studies for *sequential treatment* (F2F CBT-I: n = 3, self-help digital CBT-I: n = 1, guided digital CBT-I: n = 1). The cost-effectiveness of standalone F2F CBT-I compared to antidepressant and digital CBT-I adjunctive to TAU for depression compared to TAU alone was uncertain. ICERs of F2F CBT-I, when used concurrently with antidepressants and when added to ongoing TAU for depression,* compared to depression treatment alone* were A$34,268 (95% CI: 6,222 – dominated) and A$7,829 (95% CI: 1,186 – 34,698) below the threshold from the healthcare perspective and dominant (less costly and more effective) from the societal perspective. However, the cost-effectiveness of the *concomitant treatment* approach was very sensitive to the effect size and intervention cost of F2F CBT-I. The probability of F2F CBT-I added to ongoing TAU being cost-effective was approximately 99% for both perspectives.

Conclusions and implications for policy:

The findings of this study suggested that among the three treatment approaches, introducing F2F CBT-I after standard treatment for depression that has been implemented is the most cost-effective strategy. Sensitivity analyses showed the robustness of this result. The uncertain effectiveness of digital CBT-I needs more studies to strengthen the current evidence. Adherence plays an important role in gaining the effectiveness of CBT-I, especially digital CBT-I.

Ind-515 Cost-Effectiveness of Multicentre Primary-Care Based Randomized Controlled Trial on PTSD Symptoms in ICU Survivals (PICTURE)

PRESENTER: **Elzbieta W. Buczak-Stec**, University Medical Center Hamburg-Eppendorf; Department of Health Economics and Health Services Research / HCHE
AUTHORS: Daniela Lindemann, Christian Brettschneider, Jochen Gensichen, Robert P. Kosilek, Linda Sanftenberg, Konrad Schmidt, Hans-Helmut König, Thomas Elbert, Bernhard Zwißler

Background The survival rate of patients admitted to intensive care units (ICU) increased markedly over recent decades. Nevertheless, approximately 20% of patients develop post-traumatic stress disorder (PTSD) following a stay in ICU. Recent studies have demonstrated that psychological interventions can effectively reduce PTSD symptoms. However, the cost-effectiveness has not been evaluated. **Aim** The aim of this study was to assess the cost-effectiveness of a novel brief multicomponent primary care-based intervention for ICU survivors suffering from PTSD over 12 months from societal perspective. **Methods** The PICTURE trial was a multi-centre, randomised controlled superiority trial that recruited adult survivors of critical illness with symptoms of PTSD who were discharged from ICU. The participants were randomly assigned to receive either an intervention comprising consultations based on Narrative Exposure Therapy (NET) with a general practitioner or to receive improved treatment as usual (iTAU). The cost-effectiveness analyses after 12 months were evaluated from a societal perspective. As *cost measures*, we used mental healthcare costs (primary outcome) and total costs (secondary outcome). Mental health costs included e.g., the cost of psychiatric/psychosomatic hospitalisation, psycholeptics and psychoanaleptics drugs, outpatient visits to psychiatrists. Total costs included intervention costs, healthcare use and work absenteeism. Healthcare use (inpatient care, outpatient care, medication, long-term care) and work absenteeism were collected using German version of the CSSRI. As the *effect measures* we used the change in PTSD symptoms from baseline to follow-up (primary outcome) and quality-adjusted life years (QALY), secondary outcome. PTSD symptoms were measured by Posttraumatic Diagnostic Scale (PDS-5; 0-80) and QALY by EQ-5D-5L questionnaire. To account for missing data we conducted MICE. The differences in the costs and effects were assessed using seemingly unrelated regression method adjusted for age, sex, and respective baseline costs, EQ-5D or PDS-score. We calculated ICER and a cost-effectiveness acceptability curve (CEAC). Nonparametric bootstrapping was used to show uncertainty around the ICER. **Results**

Between October 2018 and January 2023, 1,283 patients discharged from ICU were screened for PTSD symptoms and 319 were randomized. In total, 160 belonged to the intervention group and 159 to the control group. At baseline, the average PDS-5 score was 30.6, average age 57.6 (SD 13) and EQ-5D index value was 0.71. Preliminary results showed that, in adjusted analyses after 12 months, the NET group had significantly higher mental health care costs (+€754€ [95%CI €339–€1,245]), and non-significantly higher total costs (+€84.24€ [95%CI[€-12,743–€13,420]). In addition, compared to the iTAU group, the intervention group had a greater reduction in mean PDS-5 score (5.09 [95%CI 1.40–8.79]) and had more QALYs (0.041[95%CI 0.011–0.072]). The results of primary cost-effectiveness analysis showed that the ICER was 148.13€ per one point reduction of PDS-5. The CEAC showed that the intervention has high probability of being cost effective in reducing PTDS symptoms (WTP 2,000€).

Conclusions Our preliminary analysis revealed that even though the NET oriented intervention in comparison to iTAU was effective in reducing PTSD symptoms in ICU survival individuals, this intervention had moderate probability of being cost-effective.

Ind-1123 Costs Outcomes and ROI of Intersectoral Interventions for Mental, Neurological, Substance-use Conditions & Intellectual Disabilities in South Africa

PRESENTER: **Donela Besada**
AUTHORS: Crick Lund, Sumaiyah Docrat

Background: In South Africa, mental, neurological, and substance-use (MNS) conditions impose a substantial burden on the health system, with marked inequities in mental healthcare access. The National Health Insurance (NHI) was first proposed in 2011 as a means to promote equity in healthcare access towards universal health coverage (UHC). However, South Africa's continued reliance on historical patterns of budget allocation maintains the status quo of sub-optimal and inequitable mental health resource use, highlighting the need for increased strategic priority setting and transparent decision-making processes. There is concern that unless mental health priorities are clearly

incorporated into the policies and activities guiding NHI implementation, mental health may be overlooked. In response, the South African Mental Health Investment Case (MHIC) was commissioned by the National Department of Health and Treasury to guide resource allocation for mental health, emphasizing integrated community-based care, efficient service delivery, and a focus on both preventative and curative interventions.

Methods: The MHIC evaluated the return-on-investment (ROI) from scaling up interventions for anxiety, depression, psychosis, bipolar disorder, epilepsy, intellectual disability, child behavioural disorders, dementia, and substance-use disorders. The analysis utilized the WHO Inter-UN OneHealth Tool and an Excel-based model to project health benefits and estimate the total economic and social value over a 15-year period. The MHIC also incorporated a comprehensive stakeholder consultation process, a Delphi study for expert consensus, and considerations for programmatic enablers and infrastructural requirements.

Results: We found that the investment needed by the health department translates to 9% of the projected health budget expected by 2035. This is within international recommended norms of allocating 5-10% of the total health budget to mental health. Unaddressed MNS conditions represent an annual loss of 4% of the country's GDP. Across all conditions, the estimated cost of mental health scale-up reflects just 11% of the economic value of lost productivity due to MNS conditions over the 15-year scale-up period. The investment case also demonstrates substantial returns on investment for several specific interventions. These include psychosocial interventions coupled with psychotropic medication for adult depression and anxiety (RoI=4.0:1 and 1.5:1), social-emotional learning programmes for adolescents (RoI = 1.9:1), the identification and treatment of perinatal depression (RoI = 4.7:1), early prevention programmes for risky alcohol use (RoI= 1.2:1), and treatment of epilepsy through basic psychosocial support and antiepileptic medication (RoI = 1.8:1).

Conclusions: The MHIC highlights the critical need to address the growing burden of MNS conditions. It provides a robust framework for integrating mental health services into the NHI benefits package and emphasizes the economic rationale for investment. The comprehensive approach includes considerations for social determinants and cross-departmental costs, promoting collaborative planning and supporting economic recovery. The MHIC highlights best practices for ROI analysis by integrating key guiding principles. It fosters collective ownership with national and provincial health departments to enhance relevance and implementation potential, while valuing diverse local expertise to prioritize interventions across clinical, policy, and system levels. A focus on feasibility ensures realistic evaluations of programmatic and resource needs, and a commitment to data integrity leverages high-quality local evidence.

Ind-2236 The Impact of Short-term Psychotherapy on Sick Leave Among Individuals With Depression or Anxiety Disorders

PRESENTER: **Olli Kurkela**

AUTHORS: Heli Järnefelt, Aki Vuokko, Ari Väänänen, Sanna Selinheimo, Erkki Heinonen, Pauliina Mattila-Holappa, Kia Gluschkoff

Background: Depression and anxiety disorders are leading causes of work disability worldwide, substantially affecting working life through reduced work performance, increased absenteeism, long-term disability and early retirement. Psychotherapies are evidence-based treatments for depression and anxiety disorders and are included in clinical guidelines for managing these disorders in many countries. However, research on the effectiveness of interventions is primarily focused on mental health outcomes, while a more depth understanding of effective treatments on occupational outcomes is limited. **Study aim:** This study aimed to evaluate the impact of short-term psychotherapy (treatment) in an occupational health care setting on sick leave among individuals with depression or anxiety disorders. **Methods:** The treatment consisted of 1 to 20 short-term psychotherapy sessions with duration of 45 to 60 minutes, tailored based on the individual's needs and goals. The treatment group was identified from the occupational health care patient population of Terveystalo, Finland's largest occupational health care provider, between 2017 and 2022. Each individual that initiated psychotherapy was matched with 3 controls using propensity score matching. The model incorporated the intervention as the outcome, with predictors including gender, age, marital status, income, education, employer's size and industry, history of psychotropic drug purchases, as well as the number of other mental-health-related and comorbidity diagnoses. The study outcome was work disability,* measured by the number of sickness absence days due to depression and anxiety disorders (ICD-10 codes F32-33 and F40-F43). The outcome was assessed over four three-month periods before and after the intervention. Group-based trajectory modelling was employed to identify groups of patients with similar absence trajectories before the intervention. Association of socioeconomic and employer-related factors with trajectory memberships were investigated using multinomial logistic regression. **Results:** A total of 2656 individuals were identified as having at least one short-term psychotherapy visit to occupational health care during the study period. These were matched with individuals not receiving treatment (1:3 ratio), resulting in 7958 controls. According to the preliminary results, three distinct trajectories were identified, each demonstrating unique development of sick leave days prior to intervention and including a sufficient number of both treated and untreated individuals for further analyses. One trajectory showed only negligible number of sickness absences during the follow-up, while the two other showed an increasing trend towards the start of the psychotherapy. Out of socioeconomic factors, higher education was negatively associated with risk of belonging to the two more severe trajectories. Psychotherapy was associated with a decline in sickness absences in all trajectories. **Conclusions and implications:** The study provides evidence on the impact of short-term psychotherapy on an individual's ability to work, which can guide decision-makers within the occupational health sector. However, further evaluation of the intervention's cost-effectiveness is essential.

MODERATOR: **Lisa Cameron**,

Ind-222 Leader Identity and Cesarean Childbirths: Evidence From Random Allocations of Female Leaders in Indian Villages

PRESENTER: **Mujaheed Shaikh**, Hertie School
AUTHOR: Raf Van Gestel

Cesarean section (C-section) use for childbirth currently accounts for more than 1 in 5 of all childbirths (21%) worldwide and its use as a mode of delivery is expected to rise to 29% by 2030. In India, C-sections are increasing at an alarming rate with some states having C-section rates as high as 54%. The focus on birth by C-sections is a topic of policy interest for at least two fundamental reasons. First, it has consequences for women's health and economic outcomes, and second, it has been widely documented that birth by C-section as opposed to vaginal birth has detrimental effects on child development and long run outcomes. While C-sections may be medically necessary, not all C-sections are carried out for medical reasons. Therefore, policy makers have taken great efforts in reducing unnecessary C-sections and have introduced laws/ guidelines/regulations for controlling C-sections births. In this paper, we focus on the policy effects of electing a female leader at the local level and its impact on healthcare services (more generally) and C-section rates (more specifically). Due to the endogenous nature of election outcomes, we leverage a policy experiment in India that randomly allocated 1/3rd of all positions of chief at the village level to women. As these women leaders are randomly elected, we are able to elicit the causal effect of female leaders on C-sections and identify key mechanisms driving our results. We use data on fertility history of women from the Indian Human Development Survey (2011-12) and complement this data with data on elections from the Ministry of Panchayati Raj to exactly identify the year elections were due in each state. Using exogenous variation in leader identity due to random allocation of chief positions for women, we find that in villages where female leaders are elected, C-sections are lower by 4 percentage points. Data on complications during birth allow us to show that the reduction was primarily in unnecessary C-sections whereas medically necessary C-sections were not affected. We investigate possible mechanisms for this decline and find that female leaders invest in both supply and demand side measures. On the supply side, they improve public hospital infrastructure and the healthcare workforce, and improve access to healthcare institutions by investing in better transport. On the demand side, they incentivize women to utilize healthcare facilities and antenatal care services. We also show cumulative effects over time such that villages with female leaders for a longer duration show larger effects.

Ind-751 Assessing the Impact of Intergovernmental Transfers for Physical Infrastructure on Antenatal and Neonatal Care Utilization in Indonesia

PRESENTER: **Nuzulul Putri**, Universitas Airlangga
AUTHORS: David Hotchkiss, Muhammad Firmansyah, Azizah Ridwanah

This study investigates whether intergovernmental transfers for physical health infrastructure, specifically dedicated to reducing maternal mortality, enhance maternal health service coverage under Indonesia's National Health Insurance (JKN). Using a sample dataset from the Social Security Administration for Health (BPJS Kesehatan) and publicly available data on intergovernmental transfer allocations from 2019 to 2023, we analyze antenatal care (ANC), delivery, and postnatal care (PNC) coverage in districts that received intergovernmental transfers for health infrastructure aimed at accelerating reductions in maternal and child mortality, compared to non-recipient districts. Employing a Difference-in-Differences (DID) approach combined with event-study models, we assess both the immediate and dynamic effects of these transfers on service coverage. The findings show that physical infrastructure investments did not significantly improve ANC or delivery coverage but demonstrated positive effects on PNC visits. Affirmative transfers targeting disadvantaged districts had more immediate impacts on improving service coverage, while non-physical transfers also contributed positively. These results underscore that improving maternal and child health outcomes under JKN requires an integrated approach that aligns infrastructure investments with operational support, targeted fiscal policies for disadvantaged areas, and strengthened governance mechanisms to ensure timely and effective implementation.

Ind-2272 Understanding Health Policy Agenda Setting, Formulation and Implementation in Nigeria: The Case of Maternal and Child Health Reform Programs

PRESENTER: **Chinyere Cecilia Okeke**, University of Nigeria
AUTHOR: Benjamin Chudi UZOCHUKWU

Background: Poor maternal and child health indicators have been reported in Nigeria since the 1990s. Over the years, different interventions for improving maternal, neonatal and child health (MNCH) activities in Nigeria have been in place, yet MNCH indices remain poor. MNCH reforms adopted by the federal government to improve MNCH indices have traditionally focused on broadening access to healthcare, but they do not achieve the expected large impacts. Yet there has been little effort to understand how these decisions are made. This study aimed to explore the implementation processes through which policy actors operate in Nigeria by specifically developing an understanding of the context and the process of these reforms in repositioning MCH on the political agenda in Nigeria. **Methods:** This was an exploratory, descriptive study using qualitative method. The study population comprised policymakers at the Federal and State levels, community members, civil society organizations, health workers, media and academia who were purposively drawn due to the role they played and for proper representation of sectors in the study population. Data was collected through the review of 13 documents, 46 in-depth interviews and 5 focus group discussions. Data was analysed using Leichter's macro context framework; the Walt and Gilson Policy triangle framework and Shiffman and Smith's policy analysis framework. NVivo version 12 was used for coding and organizing data under common themes, and for interpretation. **Key findings:** Four primary themes influenced the policy-making process for MNCH reform programs in Nigeria: situational factors such as poor maternal and child health indices, recovery of funds from dept relief, having a decentralized health system; structural factors such as the top-down approach of these MNCH reforms, the weak nature of the primary health centres, lack of dissemination and understanding of program protocols at subnational level; socio-economic factors such as lack of sufficient funds, weak accountability structures, weak participation of the citizens and corruption on part of public office holders.; international factors such as role of the donor partners, setting of international health agenda and controlling the funds and location for implementation. We developed a model of complex relations between the context, actors, their power and the problem definition in setting the agenda and formulating the policies. A flowchart visually represents the flow of influence and interactions between the contextual influences, policy actors and their power dynamics, problem definition and agenda-setting processes, policy

formulation and implementation stages in MNCH initiatives. **Conclusions and implications for policy and practice** The findings highlight the complex contextual factors and interrelated nature of policymaking that influence the implementation of maternity and child health (MCH) reform programmes in Nigeria. Adopting findings principles, which include understanding power dynamics, advocating for stakeholder involvement, enhancing capabilities, ensuring transparency and accountability, prioritising evidence-based decision-making, and promoting empowerment and ownership, is crucial for developing MNCH policies that are responsive, fair, and efficient.

Ind-311 Bicycles, Empowerment, and Adolescent Health: An Experimental Assessment of Long-Term Impacts of a Gender-Transformative Intervention in Rural Zambia

PRESENTER: **Shruti Shukla**
AUTHORS: Yulia Shenderovich, Choolwe Jacobs, Janina Steinert

Abstract

In this study, we examine the long-term impact of a gender-transformative intervention on maternal and child health outcomes for adolescent girls and their children in rural Zambia five years post-implementation. The intervention, conducted in 2017, provided bicycles to adolescent girls across 91 schools in Zambia's Southern Province to address educational access barriers, including travel costs and safety concerns, to improve girls' school attendance and empowerment.

Using an experimental design with a final sample of 1,615 girls (676 treatment, 939 control), we estimate the causal impact of receiving a bicycle on several mother and child outcomes, specifically: (i) adolescent pregnancy, (ii) antenatal care visits, (iii) folic acid usage, and (iv) institutional delivery, (v) exclusive breastfeeding, and (vi) birth weight for their children. We apply intent-to-treat (ITT) estimates to assess the effect of the treatment on these outcomes. Additionally, we examine potential mediators, focusing on multiple dimensions of girls' empowerment, including decision-making, control, bargaining power, and voice.

Contrary to our hypothesis, we find that the treatment group reported significantly higher rates of adolescent pregnancy, suggesting complex dynamics in gender-transformative interventions. However, girls in the treatment group also exhibited significantly higher levels of empowerment. Mediation analyses are ongoing to clarify how empowerment may influence adolescent pregnancy outcomes in this sample. No significant changes were observed for other maternal and child health outcomes. These findings highlight the multifaceted outcomes of gender-transformative interventions in low-resource settings, where enhanced empowerment can intersect with unintended reproductive health consequences.

Ind-1556 Impact of an Accountable Care Model on the Risk of Suicide Attempts Involving Opioid Poisoning Among Perinatal Medicaid Beneficiaries

PRESENTER: **Jangho Yoon**, Uniformed Service University
AUTHORS: Linh Bui, Mandana Masoumirad, Ara Yoon, Nilam Gibson

Objective: Death by suicide remains one of the most common causes of perinatal mortality, accounting for one-fifth of postpartum deaths in the U.S. This study examined whether a unique health care system transformation, known as Coordinated Care Organizations (CCOs), prevented suicide attempts involving opioid poisoning among Medicaid-enrolled women during pregnancy and postpartum. Implemented in 2013 for Oregon Medicaid beneficiaries, CCOs represent a coordinated care delivery model that explicitly integrates physical and behavioral healthcare with global payment methodology.

Methods: We analyzed Oregon Medicaid eligibility and medical claims data for all Oregon Medicaid-enrolled women of reproductive age (15-44 years old) who became pregnant and gave live births between 2008 and 2018 (N=105,156). The main outcome measure was suicide attempts involving opioid poisoning. We used the interrupted time-series (ITS) research design and estimated segmented logistic regression models to estimate the immediate (and sustained) effects of CCOs, as well as incremental effects over time, separately for the initial system transition period (2013-2014) and post-implementation period (2015-2018). To further explore whether CCOs may reduce the extent of the previously documented link between perinatal opioid use disorder (OUD) and suicide attempts involving opioid poisoning, we analyzed the OUD outcome and estimated a regression model augmented with the OUD indicator and interaction of OUD and post-CCO period. All regression models controlled for substance use disorders, major depression, maternal age, race/ethnicity, rurality of residence, unobserved county heterogeneity, and time trends.

Results: A total of 1,858 suicide attempts involving opioid poisoning (1.8% of the sample) occurred during pregnancy and within one year postpartum. Of these, two-thirds (67%) occurred during this postpartum period. A total of 2,158 women (2.1%) received a diagnosis of OUD during pregnancy, compared to 2,432 women postpartum (2.3%). The CCO model was associated with an immediate decrease of 1.0 percentage point (pp) in the probability of suicide attempts by any means ($p < .001$) and a decrease of 0.07 pp per month in the probability of suicide attempts involving opioid poisoning ($p < .001$) during pregnancy and the one-year postpartum period over the initial system transition period. Specifically, the CCO model was associated with monthly decreases of 0.06 pp ($p < .001$) and 0.01 pp ($p = .010$) in the probability of postpartum suicide attempts involving opioid poisoning during the system transition and post-implementation periods, respectively. Additionally, it was associated with a 0.16 pp decrease per month in the probability of prenatal OUD ($p = .047$) and a 0.6 pp immediate decrease in the probability of suicide attempts by any means during pregnancy and one-year postpartum ($p = .043$).

Conclusions: The CCO model is effective in reducing the risk of suicide attempts involving opioid poisoning among pregnant and postpartum Oregon Medicaid beneficiaries. The findings also suggest that the CCO model may mitigate the previously reported association between

prenatal OUD and postpartum suicide attempts. Transforming the health care system toward a value-based, coordinated care model, such as Oregon's CCOs, may be effective in reducing suicidal behaviors among prenatal and postpartum women. #

Ind-2454 Baseline Distribution of Quality-Adjusted Life Expectancy in Australia: Socioeconomic, Ethnic, and Geographic Comparisons

PRESENTER: **Ali Furkan Kalay**, Macquarie University
AUTHORS: Shan Jiang, Yuanyuan Gu, Bonny Parkinson

Background

Distributional cost-effectiveness analysis (DCEA) is increasingly recognized as a valuable tool for healthcare policymakers analyzing the equity impacts of health interventions across population groups. In Australia, interest in equity informative economic evaluations is growing, with DCEA being a central approach. A critical input for DCEA is the baseline health distribution by population subgroups, as inaccuracies in this parameter can significantly bias conclusions regarding the distributional impacts of interventions.

Aims

This study aims to measure the distribution of quality-adjusted life expectancy (QALE) in Australia by socioeconomic, ethnic, and geographic groups to provide essential inputs for DCEA in the Australian context.

Methods

We utilized data from the Household, Income, and Labour Dynamics in Australia (HILDA) survey, a representative longitudinal dataset of the Australian population. Life expectancy (LE) was estimated using a stepwise modeling approach, starting with non-parametric Kaplan-Meier analysis, followed by Cox proportional hazards models, and culminating in Gompertz models to account for covariates such as income, gender, age, marital status, education, ethnicity, urban/rural residence, and state of residence.

The Gompertz model outputs provided LE estimates for population subgroups defined by socioeconomic status (income quintiles), ethnicity (Aboriginal and non-Aboriginal populations), and geographic location (urban vs. rural, and state-level groups). QALE was derived by applying general population EQ-5D norms stratified by age and gender to the LE estimates.

Results

QALE varied significantly across population groups. Among newborns, the QALE for males in the poorest income quintile was 66.6 years, compared to 71.7 years in the richest quintile—a gap of 5.1 QALYs. For females, the corresponding QALEs were 70.6 years and 73.9 years, with a gender gap of 4 QALYs for the poorest group narrowing to 2.8 QALYs for the richest.

The socioeconomic gap widened with age: at age 0, the QALE gap between the poorest and richest quintiles was 4.2 QALYs; it was 4.5 QALYs at age 20; at age 40, it was 5.1 QALYs; and at age 60, it increased to 5.4 QALYs. Ethnic disparities were also notable. For Aboriginal people at age 20, the QALE was 5.6 QALYs lower than for non-Aboriginal counterparts. Geographic comparisons revealed consistent disadvantages for rural residents compared to urban residents.

Policy Implications

This study provides robust evidence on QALE disparities across Australian population subgroups, offering direct insights into health inequalities by income, ethnicity, and geography. These findings support policymakers in addressing health inequities and provide critical baseline inputs for DCEA. By enabling more accurate analyses of the distributional impacts of health interventions, this evidence can guide equity-informed decision-making and improve resource allocation in Australia's healthcare system.

Ind-179 Educational Gradient in Physiological Risk Factors in a Workplace

PRESENTER: **Toshiaki Aizawa**

This study examines the relationship between educational attainment and health disparities among full-time male employees in a large Japanese manufacturing company, with a particular focus on physiological risk factors associated with chronic conditions, such as overweight status, hypertension, dyslipidemia, and diabetes. Drawing on the concept of the social gradient in health—which posits a decline in health status with decreasing socioeconomic status—this research explores educational inequalities in health within a workplace context, where data availability allows for a robust analysis of health disparities.

The study leverages comprehensive data from mandatory annual health check-ups and personnel records to objectively assess health conditions. Japan's institutional framework for workplace health assessments provides a unique opportunity to utilize anthropometric and blood-based biomarkers, thereby reducing the reporting biases commonly associated with self-reported health data. As chronic diseases are often asymptomatic in their early stages, self-reporting can lead to an underestimation of disease prevalence among less-educated groups, potentially masking the extent of health inequalities. This study's reliance on clinical data thus supports a more accurate analysis of the educational disparities in health.

To dissect these disparities, this research employs decomposition analysis to quantify the extent to which differences between the two educational groups can be attributed to observable factors, including socio-demographic characteristics, physiological measures, and behavioral patterns. The findings reveal that several factors significantly contribute to the observed health disparities, including differences in alcohol consumption, smoking habits, job position, psychological stress levels, and family structure. These factors were found to be more prevalent among employees without university education and serve as major contributors to the higher prevalence of chronic conditions in this group.

The study builds upon foundational research, such as the Whitehall studies, which demonstrated substantial differences in health outcomes by occupational rank independent of traditional risk factors. In line with previous literature, educational attainment—an important dimension of socioeconomic status—emerges as a key determinant of health outcomes. Mechanisms through which education influences health may include greater income and access to resources that support health-promoting behaviors, improved health literacy, and psychosocial advantages such as lower time discounting and enhanced decision-making skills.

The results underscore the persistence of significant health disparities between educational groups within a workplace setting. These findings highlight the importance of targeted interventions to address the needs of less-educated employees alongside universal health-promoting strategies. By identifying specific factors that contribute to educational health inequalities, this research offers valuable insights for policymakers aiming to reduce workplace health disparities. Addressing these disparities through targeted support and resources for employees without university education could be pivotal in promoting equity in health outcomes. The implications of these findings extend beyond the workplace, underscoring the broader societal need to mitigate educational inequalities in health to foster a more equitable and healthier population.

Ind-204 Regional Differences in Mental Health Status (Wellbeing, Illness and Mortality): the Impact of Inequality, Austerity and Regional Public Health

PRESENTER: **Mercedes Gumbau**
AUTHOR: Joaquin Maudos

Mental illness is nowadays one of the causes of major health problems worldwide. In parallel, there is a growing body of evidence in the literature showing that austerity policies affect general health but are specifically associated with worsening mental health and increasing mental health inequalities, particularly for those who are already vulnerable to poor health. As the problem increases, mental disorders are not only seen as an individual problem, but also as a social issue, which must be recognized and taken seriously, emerging the need for regional strategies for the prevention and management of these diseases. For this reason, this paper examines the uneven geography of Risk of poor mental health and non-specific psychological distress, Prevalence in registered mental disorders, and Mortality in mental disorders -that is wellbeing, illness and mortality-, evaluating the factors behind the regional differences in impact and disentangling whether regional inequality in income distribution and health burden influence these mental health indicators, and how the public health system mitigates these effects. Most previous studies related to mental disorders were conducted within a specific age group or geographical area but to date there are only a few studies related to mental health outcomes according to regions. However, the health level of the population group has epidemiological importance, and it is possible to be more effective at managing the cause of the differences in the distribution of health status when accessed at the community level. Therefore, the main hypothesis of the paper is that Risk of poor mental health, Prevalence in registered mental disorders, and Mortality in mental disorders can be explained by regional differences in socioeconomic and environmental factors but also that mental health inequalities are greatest in regions with more income inequality, more austerity and higher health burden. However, greater accessibility to medications, better coordination of care levels, improvements in patient care, and the effectiveness of psychiatric readmissions for instance, mitigate the negative impact of economic inequalities. To this end, the analysis is applied to 17 European regions using econometric techniques as principal component analysis, panel data, and instrumental variables. Between the main novelties of the paper, we can highlight, first, the analysis of not only diagnosed mental illnesses but also the analysis of serious psychological distress or non-specific psychological distress, second the use of Principle Component Analysis for modeling a deprivation index that measures the equity-relevant socio-economic dimension, and third, the use of a regional perspective in the study of mental illnesses, not well elucidated in the literature. The results obtained allow us to conclude that regional differences in income inequality generates a higher rate of illness but not deaths, highlighting the importance of the National Health Service respect to the access to health care for the treatment of the most severe cases. Likewise, unemployment, environmental conditions, and health burden are important factors that determine the differences in mental health among regions.

Ind-982 Disparities in Quality-Adjusted Life Expectancy Associated with Educational Attainment: Population Norms for Australia

PRESENTER: **Sheridan Rodda**
AUTHORS: Rosemary Korda, Jedidiah Morton, Zanfina Ademi, Jennifer Welsh, Melanie Lloyd

Background

Educational attainment is an individual measure of socioeconomic status that has been associated with inequalities in health outcomes. Summary measures of health, such as quality-adjusted life expectancy (QALE), have been used to monitor health inequalities as they reflect

both the quantity and quality of life. Additionally, the distribution of QALE across equity relevant groups within a population can be utilised in equity-informative studies that evaluate the equity impacts of a healthcare funding decision. The Australian distribution of QALE by educational attainment has not yet been reported.

Aim

To estimate QALE stratified by sex and year of age across levels of educational attainment for the Australian population aged 25 to 100 years.

Methods

This cross-sectional study incorporated multiple data sources to estimate mortality rates and health related quality of life in order to generate QALE. Individuals' highest level of educational attainment was allocated to one of three levels: low (did not complete secondary schooling), intermediate (completed secondary schooling and/or another non-tertiary qualification) and high (completed bachelor's degree or above).

The Person-Level Integrated Data Asset linked demographic information for Australian individuals from the Census (2016) to Deaths Registrations during 2016 to 2019. From this data, age-sex-education specific mortality rate ratios were determined and applied to the 2019 population, then mortality rates by year of age were extrapolated using Poisson regression. Unabridged life tables were constructed to determine life expectancy (LE) for each sex-education subgroup with the derived mortality rates.

Wave 22 of the Household, Income and Labour Dynamics in Australia survey collected in 2022-2023 provided a representative sample of Short Form (SF-6D version 1) health utility by educational attainment. Linear regression models for every sex-education group were employed to estimate mean health utility.

The person years lived within the life tables were multiplied by the utility index for each sex-education group to produce QALE. Uncertainty of the estimates was determined via probabilistic sensitivity analysis, and both 0% and 3% discounting applied to QALE estimates.

Results

Both life expectancy and QALE increased with increasing level of education. Males at age 25 with a high level of education had an undiscounted LE of 61.0 years and QALE of 39.9 (95% confidence interval 38.7-41.2) years compared to 53.7 years and 28.8 (27.4-30.3) years respectively for those with a low education level. This represents a difference of 11.1 quality-adjusted life years (39%). Females with high educational attainment had a LE of 63.1 years and QALE 36.9 (35.8-38.1) years (both undiscounted), compared to 59.2 years and 29.3 (27.9-30.8) years respectively for the low education group, a QALE difference of 7.6 years (26%).

Conclusion

There are large disparities in QALE, impacting both the quantity and quality of life, associated with educational achievement in Australia. Tailored policies addressing education-related inequalities in health are needed. This study provides baseline data for future equity-informative economic evaluations.

Innovative Approaches to Tackling Cancer

MODERATOR: **Ivan Prenhaca**,

Ind-642 Economic Evaluation of Early Trastuzumab Initiation for Treatment of HER2-Positive Breast Cancer in Kenya

PRESENTER: **Prashant Mandaliya**

AUTHORS: Faith Okalebo, Edwine Barasa, Dorothy Aywak

Abstract **Background** Human epidermal receptor 2 positive (HER2+) breast cancer presents a significant public health challenge both globally and in Kenya. Access to trastuzumab, the first-line treatment remains limited in Kenya due to its high cost, with the National Health Insurance Fund (NHIF) covering only 4 of the 18 cycles. Consequently, many patients are unable to complete treatment, leading to poor outcomes. **Aim** This study evaluated the cost-effectiveness and budget impact of different trastuzumab regimens for the treatment of HER2+ breast cancer in Kenya. **Methodology** A cost-utility analysis was conducted from a providers' perspective over a 5-year time horizon. Comparator regimens included 9-week, 6-month, 9-month, 12-month, 16-month, and 24-month courses of trastuzumab, each starting alongside chemotherapy and continuing with trastuzumab monotherapy with the reference group being chemotherapy alone. Direct medical costs associated with the treatment of HER2+ breast cancer were estimated using a micro-ingredient approach. Data on resources used and costs were collected from interviews, market surveys and treatment guidelines, and these costs were then converted to USD, 2022. Effectiveness data was obtained from a literature review. The costs and benefits were analysed using a Markov model with a one-month cycle length over the time horizon. A cost-effectiveness threshold of USD 919.11 was used and a probabilistic sensitivity analysis was conducted. The budget impact analysis was also done over a 5-year horizon. Data analysis was performed in R. **Results** The 9-week regimen had the lowest ICER (USD 45,596.27 per QALY gained), while the 6-month regimen had the highest ICER (USD 59,112.53 per QALY gained). ICER values for the 9-month,12-month, 16-month and 24-month regimens ranged between USD 56,200 to USD 57,000 per QALY, indicating a slight variation in cost-effectiveness depending on the regimen's duration. The 9-week regimen was the cheapest and would cost NHIF approximately USD 33

million and the Kenyatta National Hospital (KNH) just over USD 4 million for a period of 5 years. These estimates are for the projected 6,100 new patients covered by NHIF and 1,830 new patients at KNH over the study period. This would be 1.4% and 0.6% of the projected 5-year budget for NHIF and KNH respectively. In contrast, the 12-month regimen would require approximately 3% and 3.2% of the NHIF and KNH budget respectively over the same period. **Conclusion** At the current threshold, none of the regimens are cost-effective in the Kenyan context. However, given the benefits that these treatments confer, and that the majority of the patients can't afford the current treatment with the 12-month regimen, strategies that would facilitate inclusion of the cheaper 9-week regimen into the treatment guidelines should be considered. For instance, the government should consider negotiating lower prices for trastuzumab and improve access to bio-similars. Additionally, good dispensing practices and vial sharing will help minimize wastage. Lastly, routine breast cancer screening would increase early diagnosis, subsequently leading to better treatment outcomes.

Ind-763 Defining Lifetime Risk Thresholds for Breast Cancer Surgical Prevention: A Cost-Effectiveness Analysis

PRESENTER: **Xia Wei**
AUTHORS: Lea Mansour, Caitlin T. Fierheller, Li Sun, Adam Brentnall, Stephen Duffy, D Gareth Evans, Li Yang, Rosa Legood, Ranjit Manchanda

Background

Increasing awareness, access, broadening of clinical testing guidelines, decreasing costs of genetic testing and availability of validated personalised risk prediction models, are increasingly identifying women at elevated risk of breast cancer (BC) who do not carry *BRCA1*, *BRCA2*, or *PALB2* pathogenic variants (PVs). These women may wish to access risk-reducing mastectomy (RRM) for cancer prevention. RRM is currently recommended for women with a lifetime BC-risk exceeding 30% by the National Institute for Health and Care Excellence (NICE). However, its cost-effectiveness at this risk level has not been formally assessed. Importantly, the precise lifetime BC-risk thresholds at which RRM becomes cost-effective remain undetermined.

Objectives

This study aims to define the lifetime BC-risk thresholds for RRM to be cost-effective compared with non-surgical alternatives for BC prevention.

Methods

A decision-analytic Markov model compared the cost-effectiveness of RRM with risk-stratified BC screening and medical prevention (tamoxifen or anastrozole), among women aged 30 to 60 years at varying lifetime BC-risks from 17% to 50%. The analysis was conducted from the UK health-system payer perspective, with a lifetime horizon until age 80. UK-specific data were used wherever possible, taken from literature and public databases. Costs and health effects were discounted at 3.5%. Incremental cost-effectiveness ratio (ICER) was calculated as incremental cost per quality-adjusted life-year (QALY) gained and compared with the UK willingness-to-pay (WTP) threshold of £20,000-£30,000/QALY. Extensive sensitivity and scenario analyses were performed.

Results

In the simulated cohort of 30-year-old women, undergoing RRM became cost-effective at a lifetime BC-risk of 34% with an ICER of £28,861/QALY, using the £30,000/QALY WTP threshold. This increased to a 42% lifetime BC-risk with an ICER of 19,553/QALY, using the £20,000/QALY WTP threshold. The identified lifetime BC-risk thresholds for RRM to be cost-effective among 35-, 40-, 45-, 50-, 55-, and 60-year-old women were 31%, 29%, 29%, 32%, 36%, and 42%, respectively, using the £30,000/QALY WTP threshold. Overall, undergoing RRM at common ages of 30 to 55 was deemed cost-effective for women with a lifetime BC-risk over 35%, with more than 50% of simulations being cost-effective in the probabilistic sensitivity analysis (PSA). We estimate, offering RRM for women with a lifetime BC-risk over 35% could potentially prevent approximately 6500 BC-cases of the 58,756 occurring annually in UK women. The risk threshold increased to 41% for a longer (2-year) disutility from surgery. In the PSA, 55.04%, 87.36%, and 99.35% of simulations were cost-effective for women with 34%, 42%, and 50% lifetime BC-risk undergoing RRM at age 30.

Conclusions and policy implications

The identified lifetime BC-risk thresholds for RRM to be cost-effective varied by age. Undergoing RRM between the ages of 30 and 55 appears cost-effective for women with a lifetime BC-risk over 35%, which increases to 41% if they experience a longer disutility from surgery. The results could have significant clinical implications to expand access to RRM beyond *BRCA1*, *BRCA2*, and *PALB2* PV carriers, and could potentially prevent 6500 BC-cases annually. Future studies on understanding the acceptability, uptake, and long-term impact of RRM among these women are warranted.

Ind-1038 Cost-effectiveness Analysis of a Polygenic Risk Score to Tailor Colorectal Cancer Screening in Primary Care: The SCRIPT Trial

PRESENTER: **Antonio Ahumada-Canale**
AUTHORS: Adrian Laughlin, Richard De Abreu Lourenco, Jon Emery, Sibel Saya, Patty Chondros

Background: Colorectal cancer (CRC) is the fourth most commonly diagnosed cancer and the second highest cancer-related cause of death in Australia. Early detection has a critical role in improving survival, patient experience, and healthcare costs in CRC. However, 40% of CRC cases in Australia are detected at a later stage, i.e., stages 3 or 4. Currently, Australian bowel cancer screening guidelines are focused on age and family history to guide early detection, despite local and international recommendations to use more precise risk-based approaches. The SCRIPT randomised controlled trial tests adherence to tailored screening recommendations by providing individual's risk reports from

polygenic risk scores (PRS) to patients and general practitioners (GPs) over 12 months.

Aim: To assess the cost-effectiveness of the SCRIPT intervention compared to usual care from the Australian healthcare system perspective.

Methods: The primary endpoint of the economic evaluation is the cost per appropriately screened individual, which aligns with the SCRIPT trial's main outcome. The analysis has 2 components: (1) a within-trial analysis, and (2) a decision-analytic model. The within-trial analysis includes a cost analysis of professional consultations, PRS conducted, colonoscopies, immunohistochemical faecal occult blood test (iFOBT) and medical imaging sourced from the trial and linked administrative sources. Resource use will be valued using Australian public fees for already funded interventions and commercial rates, with costs analysed using generalised linear modelling to account for covariates. Sampling uncertainty will be tested by bootstrapping costs and appropriately screened individuals' percentage. The decision model will evaluate how the incremental cost per appropriately screened individual might vary given differences in the PRS cost, the ability of the PRS to identify those at increased risk, and compliance with risk-stratified screening recommendations. This will be represented by a decision tree incorporating risk profiles with model inputs sourced from the trial. Sensitivity will be explored by one-way sensitivity analyses and a probabilistic sensitivity analysis.

Results: The SCRIPT trial recruited 276 participants with questionnaire response rates higher than 75% by month 12. Data linkage to provide resource use will be completed by the end of 2024. Economic evaluation results and sensitivity analyses will be presented for both the within-trial and modelled evaluations.

Conclusions: This analysis will provide information on the SCRIPT intervention's value for money compared to usual care, providing decision-makers in Australia and internationally with evidence on the implementation and funding of PRS guided screening to improve earlier CRC detection.

Ind-1767 Addressing Diagnostic Delays in Hematological Cancers: Economic Insights from the Rapid Access Diagnostic LymphAdenopathy Clinic (RADLAC)

PRESENTER: **Lucy Cunnama**, University of Cape Town
AUTHORS: Jenna Oosthuizen, David Richardson, Estelle Verburgh, Waarisa Fareed-Brey, Karryn Brown

Background Hematological (blood) cancers, including Hodgkin lymphoma, non-Hodgkin lymphoma, multiple myeloma, and leukaemia, collectively rank fourth in global cancer mortality alongside breast and stomach cancers, with over 700,000 deaths annually. Diagnostic delays remain a critical barrier to improving outcomes, particularly in low- and middle-income countries (LMICs), where a high tuberculosis (TB) burden complicates cancer diagnosis. Fine needle aspiration (FNA), commonly used in TB-endemic settings, often fails to confirm lymphoma or exclude TB. Core needle biopsy (CNB) has become the preferred diagnostic modality, offering definitive results that streamline treatment initiation. However, the economic implications of diagnostic delays and the costs associated with early interventions like Groote Schuur Hospital's Rapid Access Diagnostic Lymphadenopathy Clinic (RADLAC) in South Africa remain underexplored. **Aim** To evaluate the RADLAC diagnostic and economic contributions to address hematological cancer diagnostic delays and compare early diagnosis costs to the financial burden of late-stage cases. **Methods** A retrospective analysis was conducted using RADLAC patient data, focusing on survival and the associated costs. The study compared the costs of CNB, FNA, and surgical excision biopsy (SEB), including direct medical costs (procedure costs and clinic setup) and indirect costs (transportation and income loss, presented elsewhere). Mortality and incidence data were analyzed to contextualize the burden of blood cancers relative to other cancers. Additional data on treatment costs at Groote Schuur Hospital (GSH) were used for comparison. Costs were collected in South African Rands and were adjusted and converted to 2025 United States dollars. **Results** RADLAC has demonstrated CNB effectiveness as the preferred diagnostic modality, particularly in TB-endemic settings, reducing diagnostic delays and enabling timely initiation of treatment. Additionally, SEB at $244 is 68% more costly than CNB at $145 for diagnosing (before staining). The cost of RADLAC's setup and operation was significantly lower than the cumulative costs of late-stage care for hematological cancer patients. Despite its wide use globally, FNA's sensitivity is lower than CNB, even when both are ultrasound-guided. Given the importance of diagnostic sensitivity in avoiding missed cases of lymphoma and haematological malignancies (avoiding false negatives), CNB's superior performance reinforces its role as the preferred modality for definitive diagnosis. **Conclusions and Implications** Blood cancers contribute significantly to global cancer mortality, with comparable death rates to breast and stomach cancers. Globally, incidence numbers are higher than liver, stomach, cervix, and thyroid cancers worldwide. The findings underscore the critical role of early diagnostic pathways in reducing the mortality and financial burden of hematological cancers. RADLAC provides a scalable, less costly model for improving diagnostic efficiency that can be implemented at different levels of care with patient outcomes in LMICs, particularly in high TB-endemic regions. Policymakers should prioritize implementing similar diagnostic approaches and integrate them into cancer care strategies to address the substantial burden of blood cancers. By reducing diagnostic delays, such interventions can improve survival rates, alleviate economic strain, contribute to universal health coverage, and contribute to achieving global health equity. **Acknowledgments:** The research reported was supported by the Cancer Association of South Africa (CANSA) and the South African Medical Research Council (SAMRC).

Ind-2751 Cost Analysis of an AI and Big Data Derived Scores for Use in Early Lung Cancer Idenfitication

PRESENTER: **Yaling Yang**, The University of Oxford

Background: Early diagnosis of lung cancer is contingent on both the detection of a small lung nodule and determining whether it is malignant. Whilst CT has proven to be a robust way of detecting lung nodules, Detection of non-malignant nodules have the unwanted consequences of unnecessary cost as they require follow-up scanning or alternative methods of investigation, cause patient anxiety, may result in increased morbidity potentially by biopsy or resection, and result in increased patient radiation exposure due to follow-up CT scans or from PET-CT scans. The Artificial Intelligence and Big Data for Early Lung Cancer Diagnosis Prospective Study (IDEAL) aims to test the use of novel CT image analysis techniques (i.e. CAP score) incorporated into a clinical risk model in the characterisation of small pulmonary nodules. This study present a cost analysis for the use of CAP score in the IDEAL study.

Methods: A total of 1293 patients were recruited into the IDEAL study in multiple NHS hospitals in the UK. Health care investigations

following the initial CT scan and the incidental detection of lung nodule(s) were observed and recorded within the 12 months follow up of IDEAL prospective observational study, followed the BTS guideline: category 1 patients are discharged without further investigation due to no concerns; category 2 patients are provided with CT surveillance at 3 months or 12 months follow up, and decisions such as discharge or further work up investigations will be suggested; category 3 patients have nodules of concerns of malignancy risk and PET-CT or/and imagine-guided biopsy will be provided and further surgical treatment or other treatment will be provided after clinical assessment of lung nodule(s).

Results: Among the 1102 patients included in the IDEAL study, 364 patient were discharged without follow up investigations on the basis of BTS guidance. On the other hand, less patients would be discharge therefore 178 more patients would be followed up with various investigation if CAP score were used to group the patients in the IDEAL study. This implies that using the CT analysis algorithm CAP score to manage incidental lung nodules will cost NHS more money than using the usual care based on the BTS guidance for the same patient sample in the IDEAL trial. Assuming only one extra CT scan would be provided to the 178 patients, this would cost NHS an extra £16,312. Based on information provided by the company, it costs £27 to £38 to generate CAP score for each nodule. Therefore an extra £50,355 to £70,870 will be required. Overall, it would cost NHS a total of £66,667 to £87,182 extra money (mean £64.5 to £79.1 each) to implement and apply the CAP score based AI system for the 1102 patients in the IDEAL trial. The figures will increase if assuming more CT scans and other follow up investigations would be provided.

Conclusion: This analysis indicate that use of the CAP score at its current cut off points will cost NHS more money than the usual care.

Technological Advances in Data, Digital and Telehealth

MODERATOR: **Louis Niessen**,

Ind-1775 Advancing Hospital Digital Maturity: Evaluating the Impact of Germany's Hospital Future Act with the DigitalRadar

PRESENTER: **Volker Amelung**, "Hannover Medical School - Institute of Epidemiology, Social Medicine, and Health Systems Research"
AUTHOR: Malte Haring

The digital transformation of healthcare is vital for improving care quality, efficiency, and system interoperability. However, empirical evidence on how large-scale policy interventions influence digital maturity over time remains sparse. The Hospital Future Act (KHZG), introduced in 2020, represents a landmark €4.3 billion investment in advancing the digital infrastructure of German hospitals. To evaluate the effectiveness of this initiative, the digital maturity level of all German hospitals was measured. This is the first full survey (>90%) on this topic in any country worldwide. For this purpose, the DigitalRadar was developed, a standardized digital maturity model with seven dimensions, including patient engagement, IT security, telemedicine and clinical processes. This model investigates changes in hospital digital maturity by comparing results from two national evaluations: the baseline assessment in 2021 and a follow-up in 2024. Participation in the DigitalRadar was mandatory for all hospitals receiving KHZG funding, with over 1,600 hospitals assessed at each stage. Employing a longitudinal design, the study combines descriptive analyses, multivariate regressions, and benchmarking against international frameworks like HIMSS EMRAM to identify key drivers of digital transformation and measure progress over time. To ensure the robustness of the results and refine the methodology, an accompanying evaluation was conducted alongside the DigitalRadar assessments. This evaluation used qualitative and quantitative methods to gather feedback from hospital stakeholders on the usability and relevance of the maturity model as well as from patients on the experience with and perception of digital applications in hospitals. The findings highlighted the practicality of the instrument, identified barriers to data collection, and informed refinements for subsequent assessments. This continuous feedback loop enhanced the validity of the DigitalRadar and provided actionable insights into the challenges faced by hospitals during digital transformation. Preliminary analyses from the 2021 baseline revealed an average DigitalRadar Score (DR-Score) of 33/100, with significant variability across dimensions. Hospitals performed relatively well in “Structures and Systems” but showed limited maturity in “Telehealth,” “Information Exchange,” and “Patient Participation,” reflecting persistent challenges in interoperability and patient engagement. Early insights from the 2024 evaluation suggest notable improvements in these areas, driven by targeted funding and strategic adoption of digital tools. However, disparities persist, with smaller and rural hospitals lagging behind their urban and larger counterparts. The longitudinal design offers unique insights into how KHZG-funded projects impact hospital digital maturity over time. By analyzing data across two time points, this study provides evidence of both progress and remaining challenges, informing policy adjustments to promote equity and effectiveness. The findings highlight the critical role of sustained investment, standardized assessments, and international benchmarking in fostering digital transformation. For policymakers, hospital administrators, and international stakeholders, this research underscores the importance of addressing systemic barriers and aligning funding strategies with broader healthcare goals.

Ind-2812 Telemedicine Trials in Indonesia's Universal Health Coverage: Challenges, Progress, and Future Directions

PRESENTER: **Atmi Roseva**
AUTHORS: Mawaddati Rahmi, Mr. Mahlil Ruby, Mr. Ali Ghufron, Donni Hendrawan

Introduction BPJS Kesehatan (BPJSK) initiated its first telemedicine pilot in 2020, involving approximately 125 utilizations over a three-month period. The primary goal was to enhance healthcare access for populations in remote areas with limited healthcare facilities. As an exploratory initiative, the trial aimed to evaluate the feasibility of telemedicine services, identify barriers to implementation, and provide insights for system improvements.

In 2022 and 2023, the program expanded with a more comprehensive trial adopting an *action research* approach. These trials were designed to address logistical challenges, ensure readiness for broader implementation, and refine the system for telemedicine services under the Jaminan Kesehatan Nasional (JKN) scheme. The research also aimed to monitor and evaluate telemedicine's potential in terms of accessibility, satisfaction, and quality of care for JKN participants.

Methods The study employed *action research* and purposive sampling to guide the telemedicine trials. This approach enabled iterative problem-solving and system refinements in response to challenges encountered during implementation. A pre-and post-intervention evaluation was conducted, focusing on service quality, patient satisfaction, and accessibility before and after telemedicine adoption.

The *action research* cycle included the following stages:

1. Identifying specific barriers, such as accessibility issues, inadequate infrastructure, and participant engagement challenges.
2. Planning interventions with input from stakeholders, including healthcare facilities, technology providers, and policymakers.
3. Implementing pilot interventions tailored to address these challenges.
4. Evaluating outcomes using both quantitative and qualitative data, including claim processing times, service uptake, and patient feedback.
5. Refining strategies based on observed results to improve service delivery and scalability.

Results The findings from the 2022–2023 telemedicine trials revealed both progress and ongoing challenges:

1. **System Development**: Out of 26 identified business requirements, 8 remain unresolved, primarily concerning drug delivery logistics and digital prescription integration.
2. **Service Utilization**: While 30.6% of primary healthcare facilities utilized telemedicine services, only 11.8% demonstrated increased adoption over time. Notably, tele-USG services showed no recorded usage.
3. **Claims Management**: Non-capitation claims for telemedicine services in 2023 amounted to IDR 37.38 million, a 22.42% decrease from 2022. The average claim approval time was 3.4 days.
4. **Implementation Challenges**: Persistent issues, including resource limitations and low engagement levels, highlight the need for extended trials and enhanced support for participating facilities.
5. **Community-Based Telemedicine**: Uptake for community-oriented telemedicine services remains minimal, underscoring the need for more targeted socialization efforts.

Conclusion The trials demonstrate telemedicine's potential to improve healthcare access and efficiency within the JKN framework. However, significant challenges remain, including unresolved system issues, limited engagement from participants and providers, and policy gaps.

Recommendations include:

1. Extending the trial period to resolve outstanding barriers and enhance system readiness.
2. Increasing socialization efforts to improve awareness and participation among patients, healthcare facilities, and BPJSK staff.
3. Conducting comprehensive trials within a specific district to more accurately assess cost-efficiency and quality improvements.

Addressing these challenges will be critical for telemedicine to fulfil its promise of transforming healthcare delivery for Indonesia's universal health coverage system.

Ind-2674 Digitalization for Health Service Performance: Challenges and Prospects for a Minimal Digital Ecosystem in Burkina Faso

PRESENTER: **Mr. Joël Arthur Kiendrébéogo**, University Joseph Ki-Zerbo
AUTHORS: Issa Kaboré, Simon Tiendrébéogo, Abib Noellie Konsebo, Yamba Kafando, Orokia Sory, Rémi Kaboré, David Zombré, Relwendé Nacanabo

Background Since July 2023, Burkina Faso has been piloting in two health districts the “Minimal Digital Ecosystem” (MDE) project within its healthcare system to enhance governance, efficiency, and the quality of primary healthcare, as well as to strengthen the nationwide user fee exemption policy known as *Gratuité*. The MDE consolidates eight previously standalone digital tools into an integrated system to create synergies and improve their collective impact. These tools include *E-flux Financier* (tracking health facility cash flow), *E-Gratuité* (monitoring the implementation of the *Gratuité* policy), *E-Qualité* (tracking healthcare quality), *e-SantéCom* (monitoring the activities of community health workers), the digital Individual Care Record for *Gratuité* (tracking prescriptions and billing), *NetSIGL2.0* (managing medicine supply chains), and two diagnostic and treatment aids – *REC-Maternity* and *REC-PCIME* – for maternal and child health. This study explores users' perceptions of these tools, highlights the challenges encountered during implementation, and identifies prospects for the future. **Methods** We conducted three repeated cross-sectional surveys in two intervention districts and two control districts in December 2023, May 2024, and October 2024. Each survey included a total of 72 health facilities and between 591 and 613 users, with the number of users per tool ranging from a minimum of 18 for *E-Qualité* to 170 for *REC-PCIME*. Descriptive quantitative data were analyzed using Excel, while qualitative data were examined through an inductive approach using NVivo software. **Results** Our findings reveal a predominantly positive perception among users of the MDE tools. On average, over 80% of respondents believe that these tools enhance the efficiency of healthcare services by streamlining administrative tasks and optimizing patient follow-up. Efforts to improve interoperability between the tools have been particularly beneficial, facilitating data management and supporting both managerial and clinical decision-making processes. However, approximately 35% of users reported that the complexity of certain tools poses significant challenges to their adoption. Additionally, some tools have experienced prolonged malfunctions, lasting up to a month in some cases, which has undermined the overall effectiveness of the ecosystem. Financial constraints further exacerbate these issues, with many health facilities struggling to afford internet subscriptions, repair costs, or replacement of digital

tools. Persistent challenges with fast and stable internet connectivity also contribute to user reluctance. Despite these obstacles, users remain generally optimistic about the long-term potential of the MDE tools. Stakeholders emphasize the need to strengthen interoperability, implement regular updates, provide continuous skill-building opportunities, and establish dedicated help desks to fully leverage the tools' capabilities. **Conclusions** The MDE holds significant potential to enhance the performance of primary healthcare and the *Gratuité* policy. However, our analysis highlights that stakeholders' engagement and sustained commitment to these tools largely depend on the availability of adequate resources and robust technical support. To maximize the adoption and impact of the MDE tools, it is essential to improve the user experience, simplify tool functionalities, and strengthen support systems.

Ind-2036 Endogenous Growth and Data Utilization in the Digital Health Sector: A General Equilibrium Analysis

PRESENTER: **Anran Li**
AUTHORS: Xuezheng Qin, Yisong Wang, Zifan Li

The digital health sector stands as a prime example of data-driven growth, with predictions indicating a global market expansion at a compound annual growth rate of 17.2% within the current decade. This paper constructs a dynamic general equilibrium model to examine the role of data as a productivity-enhancing factor in the health sector. By incorporating data into the production function and modeling its impact on innovation and resource allocation, we delve into the sectoral and individual level dynamics that result from digital transformation, particularly with regards to health level growth. Our model not only encompasses traditional medical and digital health sectors, but also integrates the interactive effects of multiple economic sectors, including research and development, and consumption. Upon defining the equilibrium, we calibrate the model using key features such as industry share from diverse major economies worldwide and simulate the growth trajectory under various policy and demographic scenarios. We also present an analytical solution under simplified assumptions. Our findings suggest that increased penetration of digital technology results in a higher marginal output in the health sector, thereby fostering the growth of the healthcare industry and enhancing health outcomes. Moreover, we conduct simulations with varying levels of digital penetration, data sharing, and population aging to offer policy implications. It is imperative that governments develop and refine relevant regulatory systems to ensure that while encouraging health data sharing, they also adequately address concerns such as cybersecurity and privacy protection. **Keywords:** digital health, big data, innovation, privacy regulation, growth

Ind-2171 Machine Learning Models For Predicting Hospital Activity: Systematic Review Of Systematic Reviews

PRESENTER: **Daliya Kaskirbayeva**
AUTHOR: Tim Ensor

Background

An increasing amount of published literature has utilized machine learning (ML) methods to predict hospital activity and the quality of hospital services. The aim of this review is to synthesize evidence from available systematic reviews comparing the predictive power of ML models to traditional regression models.

Method

A comprehensive search was conducted to identify all relevant systematic reviews in the databases PubMed, CINAHL, Medline, and Web of Science in August 2024. After removing duplicates, two reviewers independently screened 121 titles for eligibility based on inclusion and exclusion criteria and assessed the quality of the included reviews using the AMSTAR tool. Information was extracted on review characteristics, reported results, input parameters, accuracy metrics, and data sources used in the included studies. The review protocol was registered in PROSPERO (CRD42024593775).

Results

A total of 26 systematic reviews were included in the final analysis, encompassing approximately 200 different studies. According to the AMSTAR tool criteria, most of the reviews were of low quality. While most studies reported a high level of predictive power for ML models, they highlighted challenges related to external validation. The top three predictors across studies were risk scores, insurance type, and demographics. Other commonly used parameters included diagnosis (primary, secondary, and comorbidities), procedure types, physical examination results, admission characteristics (e.g., emergency vs. elective, admission source), hospital characteristics (e.g., rural/urban, teaching vs. non-teaching, public/private, autonomy level, size), healthcare professional characteristics (e.g., years of experience, surgical volume, seniority), medical/clinical notes, and medications.

Conclusion

Machine learning models demonstrate significant predictive power for hospital activity and service quality compared to traditional regression models. However, the lack of external validation remains a critical limitation in the current body of evidence.

Ind-1945 Effects of Electricity Outages on Primary Care Quality: Evidence from a Standardized Patient Audit in South Africa

PRESENTER: **Nicholas Stacey**
AUTHORS: Olukemi Babalola, Duane Blaauw, Mylene Lagarde

Over 540 million individuals in Sub-Saharan Africa use healthcare facilities without a reliable electricity supply. However, at present there is limited evidence on the impact of electricity outages on care quality. Understanding the effects of electricity outages on care provision is key to understanding the returns costly investments in infrastructure may yield. The literature on electricity outages has typically focused on their impacts on outcomes of tertiary care, ignoring primary care despite its acknowledged importance, and generally reports only observed correlations without causal attribution. Moreover, the empirical literature on the determinants of primary care quality has typically downplayed the role of structural inputs (such as electricity supply), and rather emphasized provider competence, training, and incentives. However, this focus may be in part due to challenges in finding credibly exogenous variation in structural inputs. In this paper, we contribute to these literatures by identifying the effect of electricity outages on the quality of care offered by primary care providers in urban South Africa. We use data from standardised patient (SP) visits undertaken at public and private primary care providers in Soweto (Johannesburg, South Africa) during a period of rotational load-shedding. Our empirical approach combines the exogeneity of randomly-assigned SP visits with the exogeneity of the randomly-assigned loadshedding schedule to address demand- and supply-side sources of endogeneity in the relationship between electricity supply and care provision. We find that electricity outages reduce diagnostic effort (the number of relevant questions asked by providers) and find suggestive evidence that outages reduce the likelihood of correct diagnosis and correct management. The findings suggest that the consequences of electricity outages extend beyond the disruption of facility administration and directly impact providers' care process, and patient-provider interactions in the primary care setting. Our findings suggest that electricity supply acts as a complement to provider effort and therefore benefits to investments in electricity supply and resilience may include improvements in care quality via improved provider process.

Ind-1343 Economic Evaluation of Next-Generation Sequencing Technologies in Paediatric Patient Groups With Rare Diseases: a Systematic Review

PRESENTER: **Jean-Pierre Uwitonze**, University of Bern
AUTHORS: Marianna De Stefano, Rudolf van Olden, Elnaz Arjmand, Julian Nam, Lasse de Fries Jensen, Birgit Schäfer, Janbernd Kirschner, Alessandra Ferlini, Rudolf Blankart, Rachel Cassidy

Background: It is estimated that ~72% of rare diseases have a genetic origin, with ~ 70% of these conditions having an exclusive paediatric onset. Next generation sequencing (NGS) technologies can be used for screening and early detection of rare disease, with potential to reduce subsequent morbidity with appropriate timely disease specific management and to help avoid a lengthy diagnostic odyssey for the family. As part of the assessment for adoption of new healthcare technologies, economic evaluations can help to shed light on the expected costs of implementation and benefits to healthcare organisations, payers, patients and society.

Research aim: To identify current evidence on the economic evaluation of NGS technologies for the diagnosis of rare diseases in paediatric populations.

Methods: A search strategy was developed to retrieve relevant literature from the Cochrane Library, EconLit, Embase, Global Health, Medline, Scopus, and Web of Science databases interrogated for relevant literature. Articles were retained if the study described a full economic evaluation on use of NGS technologies for detection of a rare disease in paediatrics, conducted in member states of either the Organisation for Economic Co-operation and Development or the European Union.

Results: Following the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines for conducting and reporting reviews, 24 articles were included in the study. The majority of studies were conducted in healthcare settings in Australia (n=14), with wide variation in study sample size (32 – 1,259 individuals), screened health conditions and model time horizon (3 months to lifetime). Most included studies took a healthcare sector perspective to their economic evaluation (n=16), with the most frequent strategy comparison for the detection of rare disease being whole exome sequencing vs. detection through standard care (n=10). More than half of studies found that NGS dominated the traditional diagnostic pathway (n=14), with less than a third of studies finding NGS to be a more expensive option but proving cost-effective due to a significantly higher diagnostic yield (n=7). Incremental cost-effectiveness ratios were the most reported outcome, with diagnostic yield being the most frequently reported measure of effectiveness (n=23) followed by quality-adjusted life years (n=6).

Conclusion: NGS technologies hold great promise for the early detection of rare disease in paediatric populations, with evidence to suggest that it dominates or is at least cost-effective when compared to standard procedures for detection. A critical area for future research must be to generate further evidence on the cost-effectiveness of the technology for the detection of rare disease in healthy or asymptomatic populations, such as in newborn screening programmes. Future research should also focus on expanding the measures for assessing the effectiveness of NGS (such as the use of quality-adjusted life years to compare strategies) and further adoption of a societal perspective and indirect costs to generate a more accurate picture of the costs and benefits of the new technology.

abs-os131 New Appraisals of Economic Evaluations of Digital Diabetes Health Interventions: International Lessons from Bangladesh.

PRESENTER: **Prof. Louis W Niessen, PhD**
AUTHORS: Carl Asche, Shariful Islam, Kathryn Antioch

Louis Niessen, Carl Asche, Shariful Islam, Kathryn Antioch, et al - This work supports efforts by the Professional Society for Health Economics and Outcomes Research (ISPOR) Consolidated Health Economic Evaluation Reporting Standards for Digital Health Interventions (CHEERS-DHI) Working Group and the Guidelines and Economists Network International (GENI) DHI and Artificial Intelligence (AI) Committee to establish standardized economic evaluation methods for DHI and AI interventions.

****Background**** Mobile phone use (mHealth) increases globally, especially in low- and middle-income countries (LMICs). Mobile phone subscribers in Bangladesh increased from 86.5 million in 2012 to 163.4 million in 2019, reaching all population groups. mHealth interventions

are practical, relatively low-cost approaches to treat chronic disease, including diabetes, depression, heart disease, smoking, and hypertension. A previous randomized controlled trial (RCT) found that a text messaging effectively reduced glycemia in type 2 diabetes (T2D) patients in Bangladesh. Given limited financial resources and the increase in mobile phone use, mHealth is an encouraging technology to alleviate the burden of diabetes and economic costs for health systems, society, and patients. This paper will use and test upcoming CHEERS variations, using this study as an example in LMICs.

Aim To test upcoming appraisal guidance on the cost-utility analysis of an RCT of a mobile phone text messaging program for people with T2D in urban Bangladesh.

Methods A generalised cost-effectiveness analysis of the RCT in Bangladesh. Patients with T2D were randomized (1:1) to a text messaging intervention plus standard care or standard care alone. Intervention participants received a text message daily for 6 months, encouraging EuroQol-5 Dimensions-3 Level (EQ-5D-3L) healthy lifestyles. Costs to users and the systems were measured. The EQ-5D-3L was used to measure improvements in health-related quality-adjusted life years (QALYs). Intervention costs were expressed as average cost-effectiveness ratios (cost-per 1% unit-reduction in glycated haemoglobin A1C (HbA1c) and cost per QALY gained), based on the World Health Organization cost-effectiveness (WHO-CHOICE) method. The upcoming CHEERS-DHI and CHEERS-AI extensions are presented, and their use is reported.

Results Among 236 patients, the adjusted difference in accumulated QALYs between the intervention and control groups over six-months was 0.010, with a 95% CI of 0.000 to 0.021. The intervention, a mobile phone text messaging, incurred an average additional cost of 24 international dollars (Int$) per patient. This resulted in incremental cost-effectiveness ratios (ICERS) of 38 Int$ per 1% reduction in HbA1c and 2,406 Intl. $ per QALY gained. The total cost of implementing the intervention across the cohort was 2,842 Int$. These findings were validated in a multi-country pooled data from 5 trials, including 2,600 patients. The study was compared to the CHEERS recommendations and limitations listed. CHEERS-AI was considered but was not applicable as messages were not AI-generated. CHEERS-DHI is applicable.

Conclusion In a robust evaluation, text messaging is likely a valuable and generalisable addition to standard treatment for diabetes care in LMIC settings. It is predicted to lead to overall savings in health system costs. CHEER-AI is not able to capture the peculiarities of mHealth. Therefore, the CHEERS-DHI under development could help include the most appropriate data in the model and report its results. The limitations of the CHEERS (2022) in addressing DHI interventions are informing the development of CHEERS-DHI. Comparative studies with longer follow-up and larger samples are needed to draw reliable conclusions in various settings, while AI may enhance the impact.

Improving Health Care Financing and Organization

MODERATOR: **Mark Akanko Achaw**,

Ind-924 Assessing Contracting-out of Health Care in Afghanistan: Lessons From 20 Years of Evolution Amid Turbulence

PRESENTER: **Sophie Witter**, Queen Margaret University Edinburgh
AUTHORS: Mohammad Mahdi Frough, Jonas Weinert, Marion Jane Cros

Background Since 2002, international donors have played a pivotal role in financing health services and supporting health system development in Afghanistan. The scope of the country's health services is defined by the Basic Package of Health Services (BPHS) and the Essential Package of Hospital Services (EPHS). Significant improvements have been observed in access to key maternal health services, such as antenatal care and institutional deliveries. Currently, BPHS/EPHS are offered nationwide through approximately 2,400 of the 4,200 health facilities. The expansion of service coverage and access has led to notable improvements in health outcomes. However, the contracting model has changed over time, including its approach to and design of results-based financing (RBF) of service providers, while the landscape has also changed considerably, particularly with the return of the Taliban in 2021. In this presentation, we examine the evolution of the contracting model and its approach to RBF, what it has achieved and where there may be gaps, and how it can be strengthened to support service delivery and resilience going forward. **Research question** What lessons can be learned from Afghanistan's two decades of contracting out health services, particularly the design and implementation of RBF component, for Afghanistan and other fragile and conflict-affected settings (FCAS)? **Methods** The study is adopting a retrospective longitudinal case study approach, using mixed methods. These include document review to track the programme's history and earlier evaluation of outputs and key informant interviews to understand the position of actors, the drivers of change in programme design, implementation issues, and the framing of the programme and its results in this challenging context. The quantitative component involves analysis of service delivery and survey data to establish the impact of changing design on health outputs using a controlled interrupted time series with synthetic control augmentation. We estimate a model using multi-level segmented regression techniques to capture both level and slope changes across programme phases and control groups & supplement this with difference in difference analysis. **Results** We find that the RBF model in Afghanistan expanded gradually, evolving to respond to the Afghanistan context and challenges, and that the contracting approach has responded to cycles of violence, including the 2021 Taliban takeover. Some resilience of the system has been built, largely through the role of the non-governmental organizations (NGOs) and their flexibility in using resources, delivering services and managing risks at local level. The program, approach, and RBF model has contributed to increased service coverage and improved health outcomes. However, outstanding challenges include the fragmentation of the health service delivery system in Afghanistan. **Conclusions and**

implications RBF and contracting out can be an effective option in FCAS. The case study brings out specific features of the Afghanistan story but also highlights the importance of understanding the impact on the mid-level organisations, the NGOs. The Afghanistan model and its design features also offer valuable insights on designing provider payment mechanisms within the context of the humanitarian-development nexus.

Ind-1415 The Impact of Market-Based Medicaid Reforms on Health Access and Preventive Care in the U.S.

PRESENTER: **Kevin Griffith**, Vanderbilt University
AUTHORS: Robert Skinner, Colleen Florio, Christopher Louis

Research Objective: This study examines a unique Medicaid expansion program in the U.S. state of Arkansas, which adopted distinctive policies to expand healthcare access for low-income adults. These policies included subsidies to help people buy private insurance plans, temporary work requirements, and requirements for premium payments. We analyzed changes in self-reported healthcare access and preventive service use in Arkansas following these policy changes. We also compared Arkansas' results to those in other U.S. states that expanded Medicaid using more traditional approaches.

Study Design: We assessed the effects of Arkansas' Medicaid waiver on four self-reported measures of access to care and preventive service utilization. These included whether the respondent:

- Had insurance coverage
- Had a personal healthcare provider
- Avoided care due to cost in the previous 12 months
- Received a routine checkup in the past 12-months

Study covariates included respondent age, education, sex, employment, household size, veteran status, homeownership, survey month, and whether the survey was conducted via landline or cell phone. We estimated interrupted time series and difference-in-difference models to compare changes in Arkansas and control states from the baseline period (2011-2013) through an 'early expansion' period (2014-2016) and a 'late expansion' period (2017-2021). All regressions were estimated as covariate-adjusted linear probability models using BRFSS sampling weights with standard errors clustered at the state level.

Population Studied: Our study used data from a nationwide survey, the Behavioral Risk Factor Surveillance System (BRFSS), focusing on U.S. adults aged 18–64 with low household incomes (below 138% of the federal poverty level).

Principal Findings: Medicaid expansion was associated with large increases in health insurance coverage (+26.2 percentage points, 95% CI:24.0,28.6), having a personal doctor (+8.8pp, 95% CI:-4.3,13.3), routine checkups (+20.2pp, 95% CI:15.3,25.1), and decreases in avoided care due to cost (-15.7pp, 95% CI:-20.4,- 10.9) among Arkansas residents. Most of these changes occurred during the early expansion period, with smaller improvements observed during the late expansion period. In DID models comparing Arkansas to traditional Medicaid expansions, Arkansas' waiver expansion was associated with an additional +13.1pp in insurance coverage (95% CI:5.6,20.6), +4.9pp in having a personal doctor (95% CI:0.9,8.8), and +9.6pp in receipt of a routine checkup (95% CI:3.9,15.2). Rates of avoided care due to cost were similar between the two groups. These results were robust to the removal of 2020 data due to the potential complicating effects of the COVID-19 pandemic.

Conclusions: Arkansas experienced large and durable increases in access to care and preventive service utilization in the eight years following their initial expansion in 2014. These gains were larger among Arkansas residents compared to residents in states that underwent traditional Medicaid expansion. Taken together, our results suggest that state approaches to Medicaid expansion that leverage market-driven options are a viable alternative to improve access to care. Arkansas' market-driven approach may be more attractive to conservative policymakers compared to traditional state Medicaid expansions.

Ind-1696 Healthcare Resource Allocation: Policy Failures and Corrective Measures in Japan

PRESENTER: **Haruko Noguchi**, Waseda University
AUTHORS: Shiko Maruyama, Shun Takagi, Sayaka Nakamura

1. **Background**

Extensive research has examined the impact of pricing policies on patients' incentives and behavior, frequently utilizing variations in co-payment ratios as exogenous shocks. However, limited attention has been given to how pricing policies influence the economic incentives of healthcare providers, despite their critical role in signaling resource allocation needs. Globally, this research gap stems partly from the difficulty in identifying uncontaminated causal relationships, as the universal nature of price regulations and payment system changes complicates the establishment of unaffected control groups. This challenge remains a significant barrier to fully evaluating the impact of pricing policies in the context of universal health coverage (UHC).

1. **Objective**

This study seeks to address the gap in understanding the effects of pricing policies on healthcare providers by analyzing the persistent excess supply and misallocation of acute care hospital beds in Japan. Specifically, it investigates the consequences of the 2006 revision of the fee-for-service (FFS) system and evaluates the impact of the FY 2018 FFS revision implemented in April. Due to the uniform and simultaneous application of the FFS revision nationwide, identifying control groups for comparison before and after the revision poses a methodological challenge.

1. **Methods**

The study applies a regression discontinuity design (RDD), using time as the running variable, to administrative data with a time-series structure. The dataset comprises monthly medical claims from all insured individuals and their dependent family members registered with the Japan Health Insurance Association (JHIA), commonly referred to as “Kyokai Kenpo” in Japanese. JHIA primarily enrolls employees of small- and medium-sized companies and their dependents. As of 2022, JHIA covers 40.296 million enrollees, representing 32% of Japan's total population, making it the second largest insurance association after the National Health Insurance (NHI). The analysis focuses on key indicators, including the number of facilities with acute care functions, patient volumes, total medical care costs, average length of hospital stays, and per-day medical costs.

1. **Results**

The 2018 revision led to: (1) a reduction of approximately 100 acute care facilities, including those with 7:1 beds, across Japan; (2) a decrease in the number of patients (by about 2.6 patients per facility) and total medical care costs (by 11%): (3) an increase in the average length of hospital stays (by approximately 0.3 days); (4) an increase in per-day medical costs (by approximately 6.3%). These changes suggest a shift toward more intensive care in acute-stage functions, consistent with policy objectives.

1. **Conclusion**

This study highlights how government misestimations of supply-side price elasticity contributed to the misallocation of acute care resources, a form of government failure. The 2018 FFS revision partially addressed these issues, realigning resource allocation with policy objectives by reducing excess supply and promoting care intensity. The findings emphasize the necessity for policymakers to better anticipate healthcare provider responses to pricing policy changes to mitigate future misallocations effectively.

Ind-2268 Implementation Experiences with Cuban Health Cooperation Programs in Low-and Middle-Income Countries

PRESENTER: **Faith Njiriri**

AUTHORS: Benjamin Tsofa, Moriasi Nyanchoka, Jacinta Nzinga

Background: Health systems in low-and middle-income countries (LMICs) face chronic Human Resources for Health (HRH) shortages. This is especially worse in rural and primary healthcare settings. The Cuban government since 1960s has been implementing a policy strategy for producing a health workforce for export, to boost their economy. Several LMICs have since established health cooperation programs with Cuba to import health workers to address their shortages. This review aimed to examine the emergence, design, utility, outcomes, and lessons learned from the implementation of these programs.**Methods:** We conducted a scoping review using the Joanna Briggs Institute (JBI) methodology and searched for literature across four databases. Two independent reviewers screened the articles and selected relevant articles based on pre-defined criteria. We extracted data and synthesised findings using thematic analysis. **Results:** We included 71 articles after screening 3509 articles. Cuban health cooperation programs have been implemented in many LMICs in South America, Africa, Southeast Asia, and Pacific region. These programs are formalised primarily through bilateral agreements and implemented as exchange initiatives. This involves importing Cuban healthcare workers and sending collaborating country students to study in Cuba. These programs aimed to address HRH shortages and maldistribution, inadequate training capacity, and respond to medical emergencies in the host countries. Cuban healthcare workers, primarily family physicians, within the host countries; are deployed in primary healthcare settings, increasing rural health workforce, and improving healthcare access and outcomes. These programs have faced several challenges including opposition from local medical professionals, underutilisation due to poorly coordinated recruitment, and language barrier. **Discussion:** Cuban health cooperations in LMICs have shown diverse results based on their designs and structures. Long-term comprehensive programs have proven to be more successful in boosting the healthcare workforce and enhancing health outcomes. Key factors for optimising HRH health cooperation include effective collaborative decision-making and need-based deployment.

Ind-2330 Stormborn: Evaluating The Impact of Facility-Based Delivery on Health And Economic Outcomes Using a Machine Learning Approach

PRESENTER: **Prof. Zoe McLaren, Ph.D.**, University of Maryland Baltimore County

Objective

There is broad consensus about the importance of early life investments in improving health and economic outcomes later in life. Encouraging women to give birth in health facilities rather than at home therefore remains a key policy objective in low- and middle-income countries where less than 75 percent of births occur in health facilities. Despite this focus, there is little unconfounded evidence on whether facility-based delivery improves child health and economic outcomes relative to delivering at home. This paper uses a rigorous instrumental variables approach with a machine learning component to examine the impact of facility-based delivery on child outcomes in Africa, including spillovers between siblings.

Literature Review

Only a few studies used a rigorous research design and econometric methods to identify plausibly causal estimates of the impact of facility-based delivery on child, mother and household outcomes. The conclusions are mixed, however. This suggests that an understanding of longer-run and spillover impacts of facility-based delivery is essential to determine its true impact and properly inform policy.

Data and Methods

I use rich data from the Demographic and Health Surveys from 2012 to 2019 for 18 Sub-Saharan African countries that includes women's detailed birth histories (including day of birth), household characteristics and geographic data (including GPS locations). I link births with high-

resolution, high-frequency weather data in the days preceding birth using the Copernicus Climate Data Store ERA5-Land database, which provides data for points on a grid of approximately 6.8-mile squares.

My identification strategy uses exogenous weather shocks such as rain and high temperatures in the week before birth as instrumental variables for facility-based delivery since they may hinder travel and induce women who considered delivering in a health facility to instead deliver at home. I exclude births occurring in the days following extreme weather shocks like flooding because they likely violate the exclusion restriction by influencing outcomes directly rather than via the likelihood of facility-based delivery. I use machine learning methods (lasso, ridge regression and elastic net) to select the strongest set of instruments from a large set of 400 potential instruments for facility-based delivery.

Results

Results from the elastic net instrumental variables estimation show that facility-based delivery is statistically significantly associated with a 7.8 percentage point increase in under-five survival, a 26.5 point increase in the height-for-age percentile, an 19.4 point increase in the weight-for-age percentile, and a 4.5 month shorter subsequent birth interval relative to children who were delivered at home. I found a large positive spillover effect of having an elder sibling deliver in a health facility on the likelihood of receiving at least one vaccination. There were no spillover effects on any outcomes from having a younger sibling delivered in a health facility.

Discussion

The instrumental variables approach identifies large benefits of facility-based delivery that accrue to women who are dissuaded from traveling to a health facility by relatively small, potentially surmountable barriers. There is therefore a need for better policies to encourage, incentivize and enable facility-based delivery for this group.

Ind-2658 Cost-Effective Approaches to PHC Transformation: Contextual Models for Indonesia

PRESENTER: **Ulfathea Mulyadita**

Background

Indonesia is transforming how primary health care (PHC) is delivered, integrating healthcare from the sub-district level (via PHC facilities called Puskesmas) down to the hamlet and household level. This reform, referred to as PHC Integration (or ILP), mandates that each village across Indonesia must have a model Auxiliary Puskesmas (Pustu), staffed with one nurse and one midwife. Given that Indonesia has over 80,000 villages, nationwide implementation would incur significant costs. Instead of one homogenous model, we proposed alternative models for this reform, considering village population and the distance to nearest health facility. Besides the potential cost savings, we argue that the adoption of this alternative model could facilitate the widespread implementation of ILP by subnational governments, as they can be tailored to accommodate the varying capacities and unique factors of each district.

Methodology

The study uses a mixed-method approach, first with focus-group discussions with experts to define alternative models of Pustus. Second, using the average cost of running a Pustu after ILP is implemented (from a previous study), we conducted a cost estimation analysis to determine the potential savings offered by the alternative models. A total of 79,996 villages were analyzed.

Result

The alternative ILP models encompass a range of approaches: the first model closely adheres to the GOI's existing guidelines, the second model reduces the required number of health workers to only one rather than two, the third model utilizes the availability of family doctor clinics in the area, and the fourth model is applied for villages unable to meet the operational criteria and would be integrated with the nearest Pustu. Our estimation found that employing these alternative models could yield approximately 30% in annual operational cost savings, reducing expenses from $634,680,975 to $435,052,074 at the national level. The significant savings are a result of distributing Pustu across the four proposed models as follows: the first model covers 14,876 villages (19%), the second model covers 48,623 (61%), the third model covers 7,866 (10%), and the fourth model covers 8,631 (11%).

Conclusion

Our research highlights the potential cost savings associated with implementing alternative Pustu models that better account for the unique contexts of villages across Indonesia. The results prompted the GOI to tailor ILP guidelines to accommodate local capacities, health determinants, and local health demand.

Ind-2760 Assessing Demand, Feasibility, and Development Strategies for EPI Vaccine Management and Financing for Myanmar Migrant Children along Thai Border

PRESENTER: **Wasin Laohavinij**, Chulalongkorn University

AUTHORS: Piya Hanvoravongchai, Natthawut Iangtanarat, Nyein Chan Oo

The Thai-Myanmar border, a 2,400-kilometer migration corridor and the largest in Southeast Asia, is also among the 20 largest globally, presenting significant public health challenges due to high population mobility and resource constraints. Approximately one million displaced individuals reside in Myanmar's southeastern region near Thai border. Around 1.5 million Myanmar nationals crossed into Thailand between

January 2023 and February 2024, sixty percent of whom lack documentation. Vaccination coverage among displaced Myanmar children along Thai border has been very low. A recent study on immunization coverage in an ethnic state along Thai border shows nearly 80 percent of children (median age 5 years old) never had a single dose of vaccine. Vaccination coverage for migrant children in Thailand is also very low compared to Thai children, estimated to be below 30%. Initial consultations with Thai and Myanmar stakeholders identified immunization as a public health priority. Lack of vaccination is a deprivation of the right of children to be protected from infectious diseases that can save their lives. It also poses risks to national and regional health security. This study evaluates the demand, feasibility, and strategies for financing equitable Expanded Program on Immunization (EPI) coverage for children aged 0–18 years in five Thai-Myanar border provinces. The research integrates literature reviews, stakeholder consultations, and field data collection. Given the dynamic, mobile and undocumented nature of significant number of Myanmar migrant workers in Thailand, estimating the population size and distribution of children eligible for EPI is not a simple task. Quantitative analyses will estimate vaccine demand using secondary data for demand modelling taking into consideration migrant population distribution, documented and undocumented migratory practice, fertility rate, and dynamic cross-border movements. Qualitative interviews and stakeholder workshops will explore logistical, financial, and systemic barriers. Comparisons with global examples, including conflict-affected settings like Syria and Yemen, provide valuable insights into sustainable immunization approaches. Preliminary findings highlight the need for robust financial mechanisms to support vaccine access for stateless and migrant children. Barriers include resource limitations, administrative hurdles, and inadequate infrastructure. Transient populations and cultural diversity further exacerbate inequities. Thailand's universal health coverage policy does not adequately address non-Thai populations, leaving critical gaps in health equity and security. The project is expected to complete by September-2025, with the aim to generate actionable policy recommendations to improve immunization coverage, mitigate transboundary health risks, and strengthen health systems.

Ind-2810 The Impact of the Medicare Shared Savings Program on Fall Prevention and Fall-Related Injuries Among Older Adults

PRESENTER: **Courtney Baird**, Brown University
AUTHORS: Elizabeth Goldberg, Pedro Gozalo, Andrew Ryan, Sarah Berry

Background:

To address perverse incentives within the U.S. fee-for-service payment system, the 2010 Affordable Care Act (ACA) established a wide range of alternative payment models in which providers are reimbursed or penalized based on cost-efficiency, process quality, and health outcomes. One of the largest alternative payment models that was created by the ACA is the Accountable Care Organization (ACO), launched through the Medicare Shared Savings Program (MSSP) in 2012. Existing evaluations of MSSP ACOs provide early evidence that the program may be effective at improving processes of care and clinical outcomes for a few conditions. However, no research studies have evaluated the impact of MSSP ACOs on the quality of care for older adults who are at risk of falls.

Research Question:

The purpose of this study is to evaluate whether Medicare patients who receive care from MSSP ACOs have a higher rate of fall prevention screenings and lower rates of falls as compared to Medicare patients who are not treated by MSSP ACOs.

Methods:

The study population included all traditional Medicare patients aged 65 years and older. We used a 20% random sample of national Medicare claims from 2010-2020 and the appropriate diagnosis and procedure codes to construct the following outcome variables: (1) screening for osteoporosis; (2) screening for future fall risk; and (3) fall-related inpatient/hospital admissions. Attribution to an MSSP ACO was based on the Tax Identification Number that provided the plurality of allowed charges for CMS-qualified primary care services, according to the attribution methodology published by CMS. We employed a difference-in-differences research design with year and Hospital Referral Region fixed effects and robust standard errors. Subgroup analyses were conducted to evaluate whether the observed treatment effects varied by age, sex, and the patient's predicted baseline level of fall risk.

Results:

Among the full sample, the change in the mean percentage of beneficiaries screened for fall risk in the ACO group was 4.43 percentage points higher than the corresponding change in the non-ACO group ($p=0.000$), representing a 42% increase from the average screening rate. These results were statistically significant among all subgroups. The change in the mean percentage of beneficiaries screened for osteoporosis in the ACO group was 0.57 percentage points higher than the corresponding change in the non-ACO group ($p=0.000$), representing a 5% increase from the average screening rate. These results were statistically significant among all subgroups except for males and were of the greatest magnitude among females ($q=1.07pp;p=0.000$). The change in the fall-related inpatient admission rate in the ACO group was 0.09 percentage points lower than the corresponding change in the non-ACO group ($p=0.023$), representing a 5% decrease from the average admission rate. These results were statistically significant among all subgroups and were of the greatest magnitude among the high fall risk group ($q=0.303pp;p=0.000$).

Conclusions:

The results of this study suggest that the MSSP may be an effective policy for incentivizing providers to comply with clinical guidelines for the prevention of falls, as reflected by higher screening rates and lower fall-related admission rates among MSSP-attributed beneficiaries.

Ind-1518 Value Based Health Care (VBHC) for the Elderly: Addressing Challenges during the Pandemic Using Multi-Criteria Decision Analysis

PRESENTER: **Kathryn Antioch**, Monash University
AUTHORS: John Pilla, Angeline Kuek, Rick Marshall

BACKGROUND

This is Stage-2 of a larger study mitigating global pandemic impacts on Value-Based-Health-Care by prioritizing economic policies using Multi-Criteria-Decision-Analysis (MCDA).

AIM

To investigate global challenges in VBHC for the elderly in aged-care, community and hospitals during the pandemic and identify remedial public-health and economic-policies.

METHODS

Preferred Reporting Items for Systematic reviews and Meta Analyses extension for Scoping-Reviews (PRISMA-ScR), PUBMED, Medline, google-scholar (1991 to 2024) analysed pandemic impacts on VBHC. MCDA prioritized economic-policies, utilizing the value-measurement model with additive-weighted scores. The criteria-weighting-method used direct-rating and ranking to priority rank economic policies for each VBHC domain.

RESULTS

All VBHC domains were impacted by the pandemic, including VBR; cost/outcome data; information-technology and artificial-intelligence; VBHC enabling policy/institutions; Regional-Systems-Integration; Geography-of -Care, and Integrated-Care.

Value-Based-Reimbursement, VBHC enabling policy/institutions, Regional-System-Integration

There is inequity across USA Medicare value-based payment programs. Affordable-Care Act (2010) and Medicare-Access and CHIP-Reauthorization Act (2015) inaugurated a Medicare value-based-payment-programs era. However, five mandatory pay-for-performance programs are inequitable and financially penalize systems with safety-net and ethnic-minority patients. Payments from penalized systems are often redistributed to better financed holders of higher performance-scores treating less vulnerable patients, creating "Reverse-Robin-Hood" effects. Payment-adjustments for social-risk factors and unmet needs could mitigate inequity by peer-grouping to stratify healthcare systems by proportion of dual-eligible Medicare/Medicaid patients served, performance evaluation and payment-adjustments within strata. Census-based, area-level indices could identify neighbourhood-level social-risk using socioeconomic data, and Social-risk best-practice, health-equity measures, and policies integrating healthcare and social services (Chen et al 2022). Liao (2020) found negative impacts on health care disparities for Medicare's Alternative-Payment-Models for population-based and episode-based payment-models.

Other VBR studies concerned healthcare-performance and/or payments for dementia, rhinology, otolaryngology, arthroplasty, sepsis, pneumonia, ophthalmology, neurosurgery.

Outcome/cost data

Self-reported elderly health parameters and quality-indicators of primary-care provider engagement in nursing homes. Home-based palliative-care program costs were analysed to improve value for frail elderly.

Frailty Indexes: A frailty-index based on Australian-Aged-Care-Assessment-Program-data; Canadian elderly frailty and QoL measures to predict death, nursing-home transfer, and hospitalisation; and baseline-frailty as a predictor of survival post-critical elderly care receiving Canadian home-care. Frailty-Screening-Questionnaire (FSQ) predicted 8-year mortality in Chinese elderly. Hospital frailty risk-scores were validated in a Swiss tertiary-hospital. Frailty-based prognostic criteria in heart-failure patients (FLAGSHIP) were developed. Frailty instruments in noncardiac surgery were compared. Frailty/comorbidity impacts on dementia institutionalization/mortality and a tool for early elderly frailty-identification in primary-care were assessed.

Integrated-care and Geography-of-Care

MCDA evaluated value-based person-centred integrated care for frail-elderly at home in Europe and an integrated care-pathway for frail elderly patients in Norway. The Danish frailty and aging health-care system holds global lessons. Evidence-base of integrated-care for multi-morbidity patients in Europe was strengthened using MCDA.

Information-Technology and AI

Online-resources for carers of frail-elderly were identified in Europe. Optimized-Geriatric-Pharmacotherapy-through-Pharmacoepidemiology-Network (OPPEN) involves frail-elderly medication, clinical-practice/research consensus principles. Frailty-assessment in primary-care compared electronic frailty-index versus frailty-coding. Elderly hospital-frailty-risk scores in acute-care use electronic-hospital-records. Heart-failure outcomes were assessed using claims-based Frailty-Index. Telemedicine in inflammatory-bowel-disease through telephone/videoconferencing is promising.

CONCLUSION

MCDA prioritized economic-policy involving economic-sustainability, healthcare-system performance, determinants-of-health, risk-adjusted costs/health data, planning and market mechanisms, demand/supply of healthcare, economic-evaluation of healthcare.

Risky Health Behaviors and Interventions

MODERATOR: **Ana Correa Ossa**,

Ind-444 The Impacts of Cigarette Prices on Adult Smoking Cessation in Indonesia

PRESENTER: **Fariza Zahra Kamilah**, Center for Indonesia's Strategic Development Initiatives
AUTHOR: Muhammad Zulfiqar Firdaus

Background: The cigarette excise tax rate in Indonesia remains among the lowest in the world, and the country faces significant challenges and complexities in its tobacco control efforts. Studies have shown that an increase in cigarette prices can reduce smoking prevalence through behavioral changes such as cessation. Nevertheless, the evidence on how the increase in cigarette prices can affect smoking cessation in Indonesia is very limited. **Objective:** This study seeks to understand the impact of cigarette price increases resulting from tax increases during 1998-2021 in influencing smoking cessation behavior among adult smokers in Indonesia. **Method:** In estimating the impact of cigarette prices on smoking cessation, this study uses duration analysis by constructing a pseudo-panel data set using Indonesia's Global Adult Tobacco Survey (GATS) 2021 and cigarette price data obtained from the National Consumer Price of Selected Goods and Services released by Statistics Indonesia (*Badan Pusat Statistik*). **Findings:** The cigarette price increases are associated with a higher probability of cessation among adult smokers (with a price elasticity of cessation of 0.017 among males and 0.013 among both genders). Comparing the results with other upper-middle-income countries, the impact of price on cessation in Indonesia is lower considering the affordability factor and the availability of alternatives for switching when a particular type or brand of cigarette price increases as a result of a higher tax **Conclusion and study implication:** This study adds to the global evidence on the impact of higher cigarette prices on smoking cessation behavior, as well as country-specific context (Indonesia), where the impact of cigarette price increases on cessation has not been evaluated. This study highlights the need for a more effective tobacco control policy, particularly increasing the cigarette tax by a higher margin, minimizing the availability of cheaper cigarettes, banning the sale of single-stick cigarettes, and combating the illicit cigarette trade. .

Ind-912 Spillover Effects of Work Fatigue on Unsafe Driving During Commutes Among Healthcare Workers: Behavioral and Policy Insights from a Multi-Method Study

PRESENTER: **Khairil Idham Ismail**
AUTHORS: Hanizah Mohd Yusoff, Rosnah Ismail, Nor Kamaliana Khamis

Background and Aim: Commuting accidents (CAs) among healthcare workers (HCWs) disrupt healthcare delivery, strain workforce sustainability, and impose economic burdens on health systems through productivity losses and service inefficiencies. Work fatigue, a critical factor in unsafe driving behaviors, often spills over from work and off-work demands, extending its impact beyond the workplace. Despite this, the mechanisms driving these spillover effects remain insufficiently explored. This study aimed to develop a validated tool for assessing unsafe driving behaviors and examine the spillover effects of work fatigue on commuting safety, focusing on mitigating factors like sleep and detachment and implications for health system efficiency and policy. **Methods:** The study was conducted in two phases. Phase 1 involved the development of the *MyUDWC* scale incorporating expert input via a nominal group technique (NGT) with 15 experts, cognitive debriefing with 6 HCWs, exploratory factor analysis (EFA) with 135 HCWs to examine the scale's structure, and confirmatory factor analysis (CFA) with 307 HCWs to evaluate model fit and psychometric properties. Phase 2 consisted of two field studies. **Phase 2a** utilized a *shortitudinal* study design to explore relationships between work demands, off-work demands, persistent fatigue, and daily unsafe driving during commutes. Over 5–7 consecutive days, 172 participants provided 976 diary entries across three daily points (T1–T3). Multilevel modeling through Hierarchical Linear Modeling (HLM) and Monte-Carlo simulations assessed mediation (2–1–1) and moderated mediation effects, controlling for factors like age, gender, number of children, commuting impedance, and within-person demand variations. **Phase 2b** employed a driving simulator study involving 30 HCWs, a cohort from the shortitudinal study, assessed across three waves (baseline, post-shift, pre-shift). Driving performance metrics were analyzed using a Generalized Linear Mixed Model (GLMM) to identify predictors of performance changes. **Results:** The *MyUDWC* scale was validated as a 20-item instrument with six domains, demonstrating strong psychometric properties ($CR > 0.8$; $AVE > 0.5$; $\chi 2/df = 2.47$; $RMSEA = 0.06$; $CFI = 0.95$; $TLI = 0.94$; $HTMT \leq 0.9$). The shortitudinal study revealed that persistent work fatigue mediated the spillover effects of work demands → daily unsafe driving (*95% CI = 0.0001, 0.011*) and off-work demands → daily unsafe driving (*95% CI = 0.0001, 0.012*), while sleep duration moderated these effects, reducing their impact (*95% CI = -0.075, -0.001; -0.074, -0.008*). The driving simulator study identified speed variability as the best-fit predictor of unsafe driving through the GLMM (*AIC = 1786.26; BIC = 1790.80; -2loglikelihood = 1784.25*), with significant predictors including unsafe driving behavior ($F(1,699) = 3.822$, $p = 0.04$), persistent fatigue ($F(1,699) = 5.949$, $p = 0.015$), and lack of detachment ($F(1,699) = 14.00$, $p < 0.001$). Persistent fatigue consistently influenced changes in driving performance across all tested models. **Conclusions and Implications**: This study highlights the spillover effects of work fatigue on commuting safety, with implications for workforce sustainability and health system efficiency. Findings support policy interventions like fatigue management programs and shift schedule adjustments to mitigate commuting risks. Addressing unsafe driving behaviors enhances worker safety, lowers economic costs, and promotes sustainable healthcare policies.

Ind-942 15 Years of TV-Advertising for Unhealthy Foods Aimed at Children in Germany

PRESENTER: **Tobias Effertz**, Universitaet Hamburg

Abstract

Introduction: Approximately 15% of German children are either overweight or obese. Still being an essential part of the industry´s media mix in Germany the TV advertising of unhealthy foods remains as a contributing factor to the obesogenic environment. Research suggests that children react towards adverts for unhealthy foods by impulsive purchases, overeating, worse nutritional knowledge and preferences formation in favor of unhealthy food choices.

Method: This analysis aims to show the extent of unhealthy food ads children in Germany are exposed to over a larger time span from 2007 to 2023. Especially trends in the design, placement and frequency of advertisements for unhealthy foods are examined. For the analysis German TV channels were recorded and their content documented over a time period from December 2007 to April 2023 with a total of 57,678 recorded and documented advertisements. Advertised foods were classified as either unhealthy or healthy and hence unsuitable or suitable for being aimed at children according to the WHO Nutrient Profile Model for Europe. Additionally, the advertised foods were categorized as being a high-palatable-, energy-dense- or ultra-processed food whenever the food either contained certain ingredients like stabilizers, emulsifiers or preservatives or thresholds of macronutrients were exceeded. The three chosen food categories are under ongoing examination as potentially causal factors for ad libitum overeating and obesity development. Furthermore, the marketing techniques of celebrity endorsements, cartoon characters and premiums within the advertisements, which likely attract children, were also documented. The data was further merged with information on children´s viewing times in Germany to identify children´s peak viewing times, i.e. time slots during the day in which children most likely watch TV. Descriptive statistics and test were done to demonstrate developments and identify significant trends.

Results: The results show a robust pattern of children´s exposure of unhealthy food advertising over time. Within the study period from 2007 to 2023 the relative amount of unhealthy food advertisements varied from 17.23 % to 20.1 % of all advertisements. Among all food ads the proportion of unhealthy food according to the WHO Nutrient Profile Model rose from 87% in 2007 up to 97% in 2023. Children watching TV saw on average 10.1 advertisements for unhealthy foods per day with a slight increase over time from 9.5 ads in 2007 to 10.3 in 2023 despite a decreasing time of watching TV over the years. A Chi2-Test revealed that unhealthy food as well as all three food categories were more likely to be advertised using a celebrity, a cartoon character and a premium. The usage of these techniques among the food categories significantly increased over time.

Discussion: The analysis shows that besides the internet and social media, TV advertising for unhealthy foods aimed at children is still a risk factor for public health in Germany.

Ind-1554 Initial Winning of Tobacco Taxation as a Tool for Reducing Smoking: Lessons from Indonesia

PRESENTER: **Nina Samidi**
AUTHORS: Hasbullah Thabrany, Risky Kusuma Hartono

Introduction Indonesia has one of the highest smoking prevalence rates globally, with over 70% of adult men being regular smokers. One major contributor to this high rate is the affordability of cigarettes. Over the past decade, the government has raised tobacco excise taxes by an average of 10-12% annually, yet smoking prevalence has barely decreased. In 2010, Indonesia applied up to 19 tobacco tax tiers, which allowed smokers to shift to cheaper products. Efforts to simplify these tiers reduced them to eight by 2024, but smoking prevalence has remained relatively unchanged. This study examines the effectiveness of Indonesia's tobacco tax policies in reducing cigarette consumption from 2013 to 2023. **Methods** The study utilized secondary data from the 2023 Indonesian Health Survey, which covered 1.2 million respondents of 315.646 households, to assess smoking prevalence. Fiscal data on tobacco tax monitoring from the Ministry of Finance was also analyzed. Econometric analysis was employed to compare trends of smoking, taxes, and affordability from 2013 to 2023. **Results** Between 2013 and 2023, government revenues from tobacco excise grew by an average of 6.5% annually, except in 2023, when revenues declined by 2.3% due to stricter consumption controls. A notable excise increase of 23.2% in 2020 reduced cigarette production by 9.7%, demonstrating the effectiveness of price measures. Conversely, in 2019, when no tax increase was enforced, cigarette production surged by 7.4%, reaching 356.54 billion sticks. Affordability indices for tobacco products fluctuated between 10% and 11% from 2010 to 2015 and averaged 14% from 2016 to 2024. Significant increases in affordability indices occurred in 2016 and 2023, coinciding with excise hikes of 15.7% and 23%, respectively. While tobacco tax policies have reduced smoking prevalence among certain groups, the overall impact has been limited. Child smoking prevalence declined from 9.1% in 2018 to 7.4% in 2023, but adult smoking prevalence remained high and stagnant at 31% of the total population in 2023. While consistent excise revenue growth reflects the dual potential of reducing cigarette consumption and increasing fiscal contributions, the current excise hikes have not significantly altered adult smoking behavior. Higher and more significant annual excise increases, alongside complementary fiscal policies such as setting a minimum retail price, narrowing the gap between excise rates and retail prices, and further simplifying tax tiers, are needed to prevent more children from starting to smoke. **Conclusion** Indonesia's tobacco tax policies are working with modest impacts on cigarette consumption. Although excises increased annually, the growths of income have maintained high affordability resulting in slow progress in tobacco control. We recommend more progressive excise policies to effectively reduce cigarette consumption across all groups. Consistent, measurable tax increases, complemented by supporting regulations, are essential to further lower smoking prevalence, particularly among vulnerable groups.

Ind-443 The Health and Economic Impacts of Sugar-sweetened Beverages Tax on Type 2 Diabetes Mellitus Burden in Indonesia

PRESENTER: **Muhammad Zulfiqar Firdaus**

Background: Studies have shown that excise taxes on SSBs increase the price and, when effective, decrease SSB consumption potentially

reducing the future burden of NCDs in a country. Indonesia's high consumption of SSBs, as well as a growing obesity and diabetes rate, have raised concern that the country's economy and health system are at risk of being substantially burdened in the next couple of years. This indicates that taxing SSBs could potentially benefit the country. **Objective:** As the SSS tax has not been implemented in Indonesia and the evidence on the potential impacts of SSB tax in the country has not been widely studied, this study aims to estimate the health and economic impacts of a 20% increase in SSB prices (a proxy for an SSB tax) on the future burden of type 2 diabetes mellitus (T2DM) in Indonesia **Method:** This study uses a modeling approach to estimate the impact of a 20% increase in the price of SSBs, on average, on the changes in T2DM incidence and premature mortality among adults (age ≥ 20 years old) over the period of 2024 to 2033, assuming tax implementation in 2024. The model's main inputs were Indonesia's Basic Research (RISKESDAS) survey data from 2018 and SSB price elasticity computed for Indonesia **Findings:** SSB taxes equivalent to a 20% increase in price could prevent 756,103 cases of overweight and obesity within one year, could avert 3,095,643 cases of T2DM, and could prevent 455,310 deaths over 10 years. Furthermore, over the same period, the tax could avert 268,080 Disability-Adjusted Life Years (DALYs) and could help the country save up to IDR 40.6 trillion (or approximately US$ 2.5 billion) due to a reduction in direct and indirect economic losses associated with T2DM. **Conclusion and study implication:** SSB taxes can contribute significantly to reduce the national burden of T2DM in Indonesia. It can also help the country to achieve its national long-term goals of "The Golden Indonesia 2045 Vision" set by the government, and support the realization of good health and well-being as articulated in the Sustainable Development Goals (SDGs).

Ind-1561 Priority-setting Alcohol Harm Reduction Policies: A Participatory Approach to Assess the Cost-effectiveness of Prioritised Policy Options

PRESENTER: **Ms. Jaithri Ananthapavan**, Deakin University
AUTHORS: Mary Rose Angeles, Mishel Shahid, Leopold Aminde, Amila Suranga Malawige, Mary Wanjau, Mr. Lennert Veerman, Moosa Al Subhi, Linda Cobiac, Phuong Nguyen

Background: Alcohol is a harmful substance that is causally linked to 29 acute and chronic conditions. Economic evidence for policy action to reduce alcohol-related harms at the population level has been identified as a key priority to support Australian government decision-making. There are varied policies that can be implemented by Australian state and Federal governments depending on their jurisdictional powers and political context. The aim of this study was to assess the cost-effectiveness of 5 prioritised alcohol harm reduction interventions in Australia that are most relevant to state and Federal governments. **Methods:** The Assessing Cost-Effectiveness (ACE) priority setting approach was used to engage state and Federal government policymakers, non-government organisations (NGOs) and academic experts (project advisory group). The study included the following steps: 1. Review of national and international alcohol harm reduction policy documents to develop a list of potential policy options for the Australian context 1. Desk review to assess effectiveness, cost-effectiveness, equity impact and population reach of all interventions 1. Workshop 1 with project advisory group to present desk review findings. During this session participants ranked interventions to identify the top 5 priority interventions for cost-effectiveness analyses 1. Develop a of a state-of-the-art Markov model to assess the long-term health and economic impact of population level alcohol-harm reduction interventions 1. Develop policy briefs for each of the 5 prioritised interventions and circulate to workshop participants via email to define the 5 policies for economic analysis 1. Undertake cost-effectiveness analyses of prioritised policies 1. Workshop 2 with project advisory group to present preliminary findings and refine evaluation assumptions. 1. Complete economic analysis and disseminate findings **Results:** Eighteen advisory group members (11 policy makers across five Australian health departments, five NGOs, and two academics) attended the two workshops. Of the 12 policy interventions presented at Workshop 1 across the alcohol policy domains of Availability, Pricing, Promotion and Healthier communities, the following were prioritised for full economic evaluation (from highest to lowest priority): 1. Regulation of alcohol advertising; 2. Restricting the concentration of licensed premises; 3. Introduction of a minimum unit price for alcoholic products; 4. Options to increase taxation; and 5. Reducing hours of sales/ lockout laws/retail restrictions. There was limited support for the following policies: 1. Changing the minimum purchase age/legal drinking age; 2. Selling through Government monopolies; and 3. Incentivising the purchase of non-alcoholic drinks, demonstrating that these interventions had a low policy relevance. The cost-effectiveness analyses showed that all interventions were highly cost-effective, ranging from AUD17 per health-adjusted life year gained (uniform volumetric tax) to AUD3,880 per HALY gained (comprehensive advertising bans). *Note: these are preliminary results, the final results of all interventions will be presented at the conference. **Conclusions**: This study demonstrates the feasibility of conducting a priority-setting process with busy decision-makers to produce policy-relevant economic evidence to assist decision-making. The results can be used to inform alcohol policy implementation at Australian state and Federal government levels.

Ind-462 High Speed Internet and the Widening Gender Gap in Adolescent Mental Health: Evidence from Spanish Hospital Records

PRESENTER: **Daniel Fernandez-Kranz**
AUTHORS: Natalia Nollenberger, Esther Arenas-Arroyo

We exploit exogenous variations in fiber optic (FTTH) deployment in Spain between 2007-2019 to assess the impact of high-speed internet access on adolescent mental health. Combining publicly available administrative data on FTTH rollout, hospital records of behavior and mental health (BMH) cases and large survey data on patterns of Internet use, we find that FTTH access increases addictive Internet usage and reduces time allocated to sleep, homework, as well as social interactions with family and friends with most of these results driven by girls. We also find that access to FTTH increases mental health diagnoses in hospitals and contributes to a notable rise in adolescent suicide rates. A one standard deviation (SD) increase in fiber penetration increases BMH cases by 4.2%. Girls entirely drive this effect. When we analyze older individuals (20 to 24 years old), we do not find statistically significant results. Instead, we do find negative effects of Internet exposure for younger girls (ages 10-14) but, again, no effect for boys of that age. When we look at BMH cases by condition type, we find that fiber penetration increases the incidence of anxiety, mood disorders (depression), drug abuse, self-harm, and suicide attempts, with most effects again due to girls. We document a large effect on cases of self-harm and suicide attempts among girls aged 15 to 19 years (+13.3%) but no significant effect for boys. These results are robust to a series of sensitivity tests, including dynamic estimates that account for treatment effect heterogeneity following the approach of Chaisemartin and D'Haultfœuille (2024), the use of an alternative instrumental variable (IV), and alternative specifications to rule out the influence of changes in ICD coding implemented in 2016.

Ind-2136 Investing In Appropriate Feeding Practices In Early Childhood (24 Months): Socioeconomic And Regional Disparities In Kenya.

PRESENTER: **Susan Arum-Jobando**
AUTHORS: James Odhiambo Oguta, Vincent Were

BACKGROUND Proper nutrition during the first two years of life promotes linear growth, physical and cognitive development that shapes future productivity and human capital. Despite Kenya having child feeding policies, growth faltering peaks at 6-23 months due to inadequate dietary intake. Investing in quality diets during the early years guarantees solid returns by reducing healthcare costs, boosting education outcomes, and breaking cycles of intergenerational poverty. This study aims to understand the factors that contribute to appropriate feeding practices in the early years to guide programming priorities. It also unpacks the socioeconomic and regional disparities to give policy recommendations. **METHODOLOGY** We used a sample size of 3,199 children aged 6-23 months from the Kenya Demographic Health Survey (2022). WHO/UNICEF guidelines were used to define appropriate feeding among children 6-23 months. This were children receiving minimum acceptable diet, minimum dietary diversity and feeding frequency. We used probit regression models to analyze factors that influence appropriate feeding practices across Kenya's diverse regions and socioeconomic settings. Marginal effects were used to estimate the probability of identified factors through coefficients which are interpreted for significance levels using z-scores and confidence intervals. Variance Inflation Facto and Breusch-pagan test were used to check for potential bias. **RESULTS** Our analysis reveals that only 17.26% adhere to appropriate feeding practices. Across the country the most consumed food is milk by 70% (sd 1.49) and food from grains, roots, tubers, and plantains by 33% (sd 0.47) of children. The probability of appropriate feeding practices shows a consistent decline with child age, decreasing by 24.3% ($p<0.001$) for children aged 6-8 months, with similar significant decreases observed through 23 months. Maternal employment and age positively influence appropriate feeding practices, increasing probabilities by 4.85% ($p=0.002$) and 0.38% ($p=0.022$) respectively. Geographic and economic disparities significantly impact feeding practices, with children in more economically developed counties (Embu, Kirinyaga, and Kiambu) showing 12-14% higher probabilities of appropriate feeding, while those in less developed regions like Mandera show decreased probabilities (-8.94%, $p=0.035$). Household wealth quintiles demonstrate a clear gradient, with children from rich households having a 9.22% ($p<0.001$) higher probability of appropriate feeding practices compared to 4.11% ($p=0.015$) for middle-income households. **CONCLUSION** The results suggest that targeted interventions that prioritize regional disparities, maternal income and increasing household economic resources can improve early years feeding practices. There is need to make animal source foods more accessible to children as they are the least consumed among children 6-23 months. The positive association of maternal employment and child feeding outcomes indicates that current human capital and productivity can contribute positively to the development of future human capital. Investing in children's diets during the early years has the potential to break intergenerational poverty. Keywords**: Appropriate feeding, Early childhood, Human capital development, Regional disparities.

Ind-481 Health, Wealth, or Equity? Trade-offs From Households Allocative Decisions in Bangladesh

PRESENTER: **Helen Harris-Fry**
AUTHOR: Mario Cortina-Borja

Introduction: The co-prevalence of underweight, overweight, and micronutrient deficiencies is a growing global challenge. This phenomenon, termed the `triple burden' of malnutrition, is driven by imbalances in dietary quantity and quality that create overlapping health risks across and within populations. Today, South Asia faces approximately equal burdens of underweight and overweight alongside high micronutrient deficiencies. Meanwhile, in the rest of the world, overweight has surpassed underweight as the dominant problem. Even amongst some of the poorest countries, undernutrition and overweight are spread across the wealth distribution, and up to half of within-country inequality in body-mass occurs within households. This provides suggestive evidence that households' budgets are not always the binding constraint, and that priorities other than health may drive households' dietary decisions.

Methods: This paper tests these suggestive claims using the Bangladesh Integrated Household Survey 2018-19 that contains dietary data on 21,808 members in 5,376 multi-person households. We first describe nutritional adequacy -- the extent to which individuals meet their clinical needs of multiple nutrients -- using nonlinear functions that account for diminishing and sometimes negative health returns to food consumption. We then estimate the gains that households can afford through changes in food choices and by reallocating foods within families, which we find by entering each person's adequacy function into a program that maximizes household nutritional adequacy. Seeking to understand the mismatch between observed and potential nutritional adequacy, we unpack the corresponding trade-offs that households face in income and equity. We quantify health-income trade-offs by estimating gender-specific wage production functions and entering them into a nonlinear program. We analyse health-equity trade-offs with a utility maximizing framework that allows decisions to be influenced by families' concerns for both equity and nutritional adequacy.

Results: Our results show that few individuals consume adequate levels of energy or micronutrients. However, food budgets are rarely the binding constraint. Households can afford to meet energy needs of nearly all people, and almost all micronutrient needs. Health-optimised solutions increase mean adequacy of 11 micronutrients from 68% to 95% (an increase of 3.1 SDs). For energy, gains primarily come from reallocation among members, while micronutrient improvements mainly require changes in household-level food choices. Pregnant and breastfeeding women would particularly benefit from intra-household food redistribution.

We further show that households do not face a health–income trade–off when allocating nutrition, at least in the short–run. Nutritional adequacy does not affects wages in this context.

The greater trade-off relates to equity preferences. We find a degree of inequality aversion (for energy) and inequality preference (for micronutrients) that leads to intra–household allocations that are not fully efficient from the perspective of the production of health. Households allocate men more food in general, but fail to adjust the composition of the diet according to needs. As a result, households insufficiently compensate men for their elevated caloric needs, women for their higher iron needs, or pregnant/ breastfeeding women for their additional needs for multiple micronutrients.

Conclusion: Bangladeshi households can afford to meet most of their nutritional needs with their current food budgets. Behavioral interventions should place particular emphasis on the importance of achieving energy balance, highlighting the risks of both deficiency and excess. Interventions should also not assume that women are disadvantaged in the allocation of food.

abs-os110 Consumer Tobacco Product Choices in China: The Impact of a Ban on Flavored E-cigarettes

PRESENTER: **Yuhan Deng**
AUTHORS: Mr. Donald Kenkel, Hua Wang, Alan Mathios

Effective October 2022, the State Tobacco Bureau of China banned the sales of flavored e-cigarettes. Previous research in health economics has explored the impact of e-cigarette flavor bans in the U.S. However, less is known about the impact of flavor bans and other e-cigarette regulations in China, the world's largest tobacco market; according to the China CDC, there are 300 million smokers and over 16 million vapers in China. Bans on flavored e-cigarettes are intended to discourage vaping among teens. Because adult smokers use flavored e-cigarettes as a way to cut down or quit smoking, flavor bans might also have the unintended consequence of discouraging smoking cessation and increasing adult smoking. This study explores the impact of China's ban on flavored e-cigarettes on the tobacco product choices of adult smokers. We conducted two online surveys of smokers in China. The first survey was conducted in 2021 when flavored e-cigarettes were legally available; the second survey was conducted in 2023 after flavored e-cigarettes were banned. The sample size of each survey was about 600 smokers. Each survey included a set of background questions about the respondents' current use of cigarettes and e-cigarettes, followed by a discrete choice experiment. The background surveys provide rich data on consumer attitudes and observational revealed-preference data on consumer choices before-and-after the ban on flavored e-cigarettes. Descriptive analyses of the frequency of the extent of the of flavored e-cigarettes across the surveys provide suggestive evidence of the impact of the flavor ban. We also describe consumer smoking- and vaping related attitudes, including their perceptions of the absolute and relative risks of e-cigarettes and explore the extent to which risk perceptions changed between 2021 and 2023. The descriptive analyses also control for demographics to address potential sampling differences across the surveys. The discrete choice experiments (DCEs) help us to understand smokers' choices between cigarettes, e-cigarettes, and quitting the use of both products. The DCEs experimentally varied policy-manipulable product attributes including prices, health warnings, and the availability of e-cigarette flavors and nicotine levels. We use the stated preference data from the DCEs to estimate linear probability models and conditional logit models of the effects of product attributes on consumer tobacco product choices. To shed light on the models' predictions, in each sample we compare the model predictions of choices under current (2021 or 2023) status quo conditions to the observational data collected in the background surveys. Our econometric analyses yield three estimates of the impact of the ban on flavored e-cigarettes: the difference between consumers' revealed preferences before-and-after the ban; the predicted impact from the choice model estimated using the 2021 stated preference data; and the predicted impact from the choice model estimated using the 2023 stated preference data. The study contributes to economic research on tobacco regulation and provides a case study of China's ban on flavored e-cigarettes.

abs-os111 Understanding Consumer Choices: A Study of Tobacco Product Choices in Indonesia and Malaysia

PRESENTER: **Puguh Prasetyoputra**
AUTHORS: Alan Farandy, Agus Syarip Hidayat, Alan Mathios, Lazuradi Imran, Felix Wisnu Handoyo, Mr. Donald Kenkel, Harris Siagian

In the most recent Global Adult Tobacco Survey data, 33.5% of Indonesian adults and 19% of Malaysian adults are current cigarette smokers. A very large body of health economics research in low-, middle-, and high-income countries estimates the responsiveness of cigarette demand to cigarette excise taxes and other regulations. An emerging body of research explores the determinants of demand for e-cigarettes, but mostly in the U.S. and other high-income countries; much less is known about e-cigarette demand in low- and middle-income countries. This study investigates the determinants of Indonesian and Malaysian smokers' choices between cigarettes, e-cigarettes, and quitting all tobacco product use. We use data from two online discrete choice experiments (DCEs) conducted in 2021 and 2024 with Indonesian subjects and a DCE conducted with Malaysian subjects in 2023. The DCEs experimentally varied policy-manipulable product attributes including prices, health warnings, and e-cigarette flavors and nicotine levels.

We use the DCE data to estimate linear probability models, logistic regression models, and McFadden's conditional logit choice model of consumer choice. The estimates suggest that price is a critical determinant of consumer choices, with higher cigarette prices significantly reducing smoking and encouraging a shift toward e-cigarettes. The results also revealed that younger consumers were more inclined to adopt e-cigarettes as a perceived less harmful alternative, whereas older consumers tended to quit smoking altogether in response to price increases. Our model provides further insights, showing that consumer preferences evolve over time, with younger users exhibiting sustained loyalty to e-cigarettes despite fluctuations in traditional cigarette prices. We further explore the differences in Indonesian consumer choices at two points in time, and we compare-and-contrast the results for Indonesia and Malaysia. In particular, we use our estimated models to simulate the choices Indonesian smokers would make if they faced the tobacco control policies in Malaysia, and vice versa.

This study highlights the necessity for targeted and multifaceted tobacco control policies that should include price interventions, support for alternative lower-risk nicotine products, and continuous monitoring to respond to market and regulatory dynamics. This study contributes to the existing literature by offering a detailed analysis of e-cigarettes in a developing-country setting, emphasizing the interaction between economic, demographic, and product-related factors. The dynamic analysis provided by the CMC Logit model sheds light on the long-term effects of tobacco control policies, particularly in emerging markets, and underscores the need for interventions that address the diverse needs of different consumer segments to enhance the efficacy of tobacco harm reduction strategies.

Ind-1739 Determinants of PBPU Membership Activeness in Indonesia and Its Clustering for Subsidy Allocation: A Multi-Year Analysis

PRESENTER: **Samuel Sormin**
AUTHORS: Mr. Mahlil Ruby, Mr. Agus Setiawan, Mr. Muhammad Ikhsan Kalla, Mr. Benjamin Saut Parulian Simanjuntak, Mr. M. Mizmara Alan Falihin

BPJS Kesehatan membership in the PBPU segment is heavily influenced by participants' ability and willingness to pay premiums, which determines the active status of membership cards (PBPU_AKTIF). Understanding the determinants of PBPU_AKTIF is critical for public policy, especially in developing countries with similar social security systems.

This study examines the impact of human development metrics, such as the Human Development Index (HDI), Life Expectancy (LE), Mean Years of Schooling (MYS), and Poverty Rate (PR) on PBPU_AKTIF. Using secondary data from 2021–2023 across various provinces in Indonesia, multiple linear regression analysis and classical assumption tests were applied. Additionally, clustering methods—K-Means, Hierarchical, and DBSCAN—were used to group provinces based on PBPU membership activeness and subsidy needs.

K-Means and Hierarchical Clustering identified 4 clusters, while DBSCAN revealed 2 clusters with significant noise in several provinces. Regression results showed that HDI (coefficient 0.0082) and PR (coefficient 0.0022) significantly influenced PBPU_AKTIF, with an adjusted R-squared of 0.479.

These findings indicate that improving HDI and reducing poverty directly impact PBPU activeness. Consequently, need-based subsidy policies can serve as strategic measures to enhance PBPU_AKTIF. The clustering results provide a foundation for targeted subsidy approaches, such as increased allocations for provinces with high noise levels in DBSCAN.

This study contributes to global literature on the efficiency of social security systems in developing countries, with practical implications for subsidy distribution and evidence-based policymaking.

Keywords: PBPU_AKTIF, health insurance activation, Human Development Index, Poverty Rate, clustering, multiple linear regression, social welfare, public policy.

Ind-1837 Medical Debt, Self-Insurance, and the Value of Health Insurance for the Non-Elderly

PRESENTER: **Katsuhiko Nishiyama**

About 60% of non-elderly workers are insured through employer-sponsored health insurance (ESHI). However, ESHI is not the only option. Workers frequently resort to two alternative forms of insurance: (1) self-insurance through saving and borrowing and (2) delaying medical bill payments, with 41% of working-age adults in some form of debt caused by medical bills (Lopes et al. 2022). This paper studies how the two alternative insurance channels affect the value of ESHI, which in turn affect job search decisions. Specifically, I address two questions: (1) How does the value of ESHI vary based on one's net liquid assets and medical debt? (2) How do job-to-job transition rates change with different net liquid assets and medical debt? These questions stem from well-documented criticism of ESHI that bundling health insurance and employment could lead to inefficient matches of employers and workers through job push and job lock. Job push occurs when uninsured workers move to less productive jobs that offer health insurance, while job lock happens when insured workers avoid more productive jobs that lack insurance. By answering these questions, I aim to identify which types of workers are more likely to make such distorted decisions in job mobility. My main contribution is to consider the role of self-insurance and medical debt, unexplored channels in the literature on ESHI and labor market dynamics (Dey and Flinn 2005; Dey and Flinn 2008; Aizawa 2019; Aizawa and Fang 2020; Fang and Shepard 2019). To that end, I develop a job search model augmented with four features: (1) a stochastic process of health status, (2) enrollment in ESHI through job search decisions, (3) saving and borrowing decisions to capture self-insurance, and (4) accumulation and repayment decisions of medical debt. I estimate the model using the Survey of Income and Program Participation (SIPP) and the Medical Expenditure Panel Survey (MEPS), covering 2017-2019. The structural parameters are estimated with Simulated Method of Moments to match data moments from the joint distribution and evolution of state variables: health insurance status, net liquid assets, medical debt, employment status, wage, health status, and flow medical expenditure. After obtaining the estimates, I quantify the value of ESHI and find non-negligible variations. For instance, for workers with the median level of wage and good health condition, the willingness to pay ranges from 23% of their wage to 36%, depending on their assets and medical debt. Moreover, the results highlight two specific profiles of workers valuing ESHI more: (i) workers with a limited to moderate net liquid assets but not near the borrowing limit and (ii) workers with more medical debt. For workers with medical debt, the valuation for ESHI peaks when their debt reaches about $40,000, beyond which there is little change. Lastly, I also confirm that uninsured (insured) employees with a higher valuation for ESHI exhibit higher (lower) rates of transition to jobs with (without) ESHI.

Ind-1658 Socioeconomic Inequalities in Financial Risk Protection in China: an Evaluation of Universal Coverage of Social Health Insurance

PRESENTER: **Yaping Deng**
AUTHORS: Jingxian Wu, Cong Li

Background Financial risk protection and equity are fundamental components of Universal Health Coverage (UHC), ensuring equitable access to health services without imposing undue financial hardship. Since the implementation of the New Medical Reform in 2009, China has made significant progress in achieving universal coverage of social health insurance (SHI), with the aim to provide equitable, accessible, and affordable basic healthcare for all its citizens. This study evaluates China's progress in financial risk protection by examining the socioeconomic inequalities in catastrophic health expenditure (CHE) and the role of SHI coverage in addressing these inequalities. **Methods** Data were obtained from seven waves of the China Family Panel Studies (CFPS), a nationally representative household survey conducted biennially from 2010 to 2022. CHE was defined as out-of-pocket (OOP) healthcare payments exceeding 10% of total household expenditures or 40% of non-food expenditures. SHI coverage was measured as a binary variable indicating whether all household members were insured. Socioeconomic inequalities in CHE were assessed using the Erreygers concentration index (ECI), with per capita household income as the ranking variable. Decomposition analysis based on the recentered influence function (RIF) regression was conducted to evaluate the contributions of SHI coverage and other covariates to CHE inequalities. All analyses were weighted using cross-sectional weights to ensure representativeness. **Results** The estimated ECI for CHE, based on the 40% non-food expenditure threshold, remained consistently negative throughout the study period, indicating a pro-poor distribution. Its absolute value decreased from 0.204 ($p<0.001$) in 2010 to 0.106 ($p<0.001$) in 2022, reflecting reduced inequality over time. The contributions of household SHI coverage to the CHE inequalities were -0.863% ($p<0.05$) in 2010, 0.622% ($p>0.1$) in 2012, -0.033% ($p>0.1$) in 2014, -4.824% ($p<0.05$) in 2016, -13.925% ($p<0.05$) in 2018, -1.203% ($p>0.1$) in 2020, and -1.110% ($p>0.1$) in 2022. Additional factors, such as higher education levels (particularly university degrees of higher) and stable employment of household heads and larger household sizes (five or more members) were more consistently associated with reduced inequalities. In contrast, utilization of inpatient and outpatient services and the prevalence of chronic diseases significantly increased the observed inequalities. Similar results were observed using the 10% threshold for CHE. **Conclusion** Despite progress in reducing socioeconomic inequalities in CHE, substantial pro-poor disparities remain. SHI coverage has played a positive role in mitigating financial risk disparities, particularly after 2016, but its impact has been limited. Socioeconomic factors, such as education and employment stability, and household composition have demonstrated stronger and more consistent effects on reducing disparities. These findings highlight the need for integrated policy strategies that strengthen financial risk protection while addressing broader socioeconomic determinants of health equity to achieve UHC.

This study is funded by the National Natural Science Foundation of China (No. 72104196).

Ind-2044 Designing and Implementing Capitation for Primary Healthcare in Rwanda: Insights from the Nationwide Rollout

PRESENTER: **Regis Hitimana**
AUTHORS: Eniola Olaleye, Juan Francisco Garamendi, Babaniyi Olaniyi, Enric Jané, Ina R. Kalisa, Jean Marie Vianney Hakizayezu

Background: Capitation, as a healthcare payment mechanism, presents a promising avenue for sustainable financing of universal health care (UHC). It shifts the emphasis from volume-based care to a model that contains costs while enhancing value-based care. Although capitation has been explored in various contexts, its design and application in primary healthcare within low-income settings, particularly in sub-Saharan Africa, remains relatively nascent. **Research Aim**: This study investigates Rwanda's approach to designing and implementing a capitation model for primary healthcare providers. By leveraging facility-level historical data, incorporating utilization heterogeneity across regions, and introducing continuous performance-based adjustments, Rwanda's capitation model is designed to chart a sustainable path toward UHC. This presentation will provide detailed insights into the innovative strategies employed to improve the cash flow and predictability of funds for healthcare facilities, incentivize efficient delivery of PHC services, and increase the predictability of expenditure for primary care services. **Methods**: The capitation formula was developed using historical healthcare utilization and cost data at the patient level, providing a robust foundation for analyzing facility-level demand patterns and costs. Facilities were stratified according to past performance metrics, ensuring that payments were aligned with variations in health demand and provider capacity. Moreover, Rwanda instituted an adjustment mechanism, enabling capitation amounts to be refined based on real-time monitoring of facility utilization rates and health trends. A set of indicators was used to track health facility performance and identify unintended consequences due to the capitation model (such as a decrease in service availability), and forecasting models were used to flag facilities with abnormal behaviors. Quantitative assessments of the implementation of the capitation model during the initial months of implementation include analyzing utilization rates, cost patterns, and the effectiveness of capitation adjustments using longitudinal data analysis. Real-time monitoring data will be used to track trends in healthcare access and the financial performance of facilities, providing insights into the adaptability of the capitation payments. **Key Results**: With capitation set to launch in January 2025, the presentation will cover findings from the first six months of implementation. Key areas of focus include the performance of the capitation formula across health facilities, the effectiveness of the quarterly adjustment strategy, the utility of indicators in monitoring progress and identifying unintended consequences, and observations on the data collection quality. **Conclusion and Implications**: This presentation aims to share experiences from Rwanda's nationwide implementation of a capitation model in primary healthcare, offering practical insights for other countries considering similar pathways. Specifically, it will highlight lessons on designing risk-adjusted, dynamically monitored capitation models suitable for resource-constrained environments, providing valuable guidance for the strategic implementation of UHC initiatives.

Ind-1098 Awareness of Strategic Purchasing Systems for Health Among Key Implementers in Ethiopia: The Case of Case-Based-Providers Payment Design in Ethiopia.

PRESENTER: **AYALNEH ASMAMAW ATNAFU**

Introduction: Many low-and middle-income countries prioritize generating enough revenue to achieve Universal Health Coverage (UHC).

However, simply increasing spending is not enough to meet a country's health goal. The funds need to be strategically allocated to priority populations, programs, and services to enhance access, improve care quality, and promote equity and financial protection. Moving away from "passive purchasing" toward more "active" or 'strategic purchasing" methods, such as Case-Based Payment (CBP), is crucial for optimizing health system performance and ensuring value for money. Additionally, designing, piloting, and implementing CBP, along with providing targeted capacity-building for implementers, is essential for effective strategic purchasing. Ethiopia has been implementing Community-Based Health Insurance since 2011, and used Fee-For-services as a provider payment modality, with all its limitations. Thus, Designing and piloting case-based payment provider payment system is crucial. This survey seeks to assess the awareness of implementers in Ethiopia regarding strategic purchasing, with a particular focus on CBP. **Methods:** An exploratory qualitative survey design was used to "to assess the awareness/ knowledge of implementers on strategic purchasing and (to) identify the training priority areas on strategic purchasing. Twenty-Six key informant interviews from the purposively selected three regions (Sidama, Oromia, Afar), and one city administration (Addis Ababa City Administration) were conducted. A semi-structured guiding tool with a structured checklist captured the qualitative and quantitative data. The qualitative and quantitative findings were analyzed thematically and descriptively, respectively. **Findings:** In this survey, we explored informants' knowledge of the selected strategic purchasing components (payment modalities, benefits packages and claim auditing), and the potential training gaps. Regarding, strategic purchasing, the understanding of the informants was found to be better at benefit packages and claim auditing. Among the explored payment modalities, the participants have relatively better awareness of Fee for Service and capitation. However, the understanding of most informants about case-based payment were low. The quantitative result also showed that only two (7.7%) from 26 respondents have a better understanding of the case-based payment. It was also explored that the respondents tried to explain benefit packages and claim auditing by relating it with their experiences even if they didn't explain them with their basic principles and assumptions. The knowledge of strategic purchasing of respondents in the hospital was lower than the purchaser. In addition, the participants recommended that short-term and long-term training should be provided on HCF, strategic purchasing, claim management, and payment modalities, **Conclusion and recommendation:** The survey explored that the knowledge of strategic purchasing is low and tailored, and focused capacity-building trainings should be provided. Besides, special attention should be given to the hospital/facility-level implementers whose understanding of strategic purchasing is relatively low.

Ind-2551 Examining the Budget Impact of Malaria Treatment at a Public Healthcare Facility in Nigeria: Evidence from a University Medical Center

PRESENTER: **Charles C Ezenduka**

Background

Malaria remains a leading cause of death and disability in Nigeria, as in most LMICs constituting huge economic burden on the population. Current evidence on the facility costs of treatment remains essential to inform the efficiency of resource utilization and planning for improved malaria control and elimination. This study estimated the financial and economic costs (for budget implication) of treating uncomplicated malaria through a public healthcare facility in Nigeria.

Methods

A cost-of-illness study approach was adopted to estimate the cost of treating uncomplicated malaria at a secondary health facility setting. Prospective and retrospective data were collected within 3 months of between September and November 2021. From a provider perspective, hospital costs were estimated from a standard and comprehensive costing procedure. Capital and recurrent items were identified, measured and valued using the ingredient approach, combined with step-down methodology. The costs of capital items were annualized according to their useful life years. Costs attributable to malaria treatment were calculated on the basis of the proportion of treated malaria cases to the total outpatient visits. The costs were broadly divided into financial and economic costs. Financial costs mostly accounted for the budget impact. Costs were calculated in local currency [Naira] and converted to US dollars at 2021 foreign exchange rate [US$1=N448].

Results

The total annual cost of N84.548 million (US$188, 723.51) was spent on the treatment of uncomplicated malaria, at US$32.48 per case, representing about 25% of the hospital's total expenditure in the study year. Personnel accounted for 77% of total expenditure, followed by antimalarial medicines at 8.7%. The financial cost of treatment amounted to US$216,869.50 per annum, at US$37.33 per case. More than 45% of outpatients' visits were treated for uncomplicated malaria. Changes in personnel costs, drug prices and malaria prevalence significantly impacted the study results, underscoring the need for improved efficiency in the use of hospital resources in the management of malaria cases in the facility.

Conclusion

Findings suggest that malaria treatment at the facility consumes a substantial amount of facility resources representing up to a quarter of the hospital budget. The costs were driven mainly by personnel and high proportion of malaria cases, highlighting the scope for enhanced efficiency of resource allocation and utilization to prevent wastages and reduce costs to the provider and ultimately the patient. Findings will contribute information for planning to enhance the efficiency of malaria control towards elimination. High budget implication underscores the need for continued funding support for malaria control and elimination in Nigeria.

***Keywords**: Malaria treatment, healthcare facility, resource utilization, financial costs, economic costs, budget impact, Nigeria.*

Ind-2121 Assessing the Efficiency of Public Health Expenditure in South Africa: A District-Level Analysis Using Data Envelopment Analysis

PRESENTER: **Anja Smith**
AUTHORS: Fouché Venter, Calumet Links

Background

Since the global financial crisis, South Africa's fiscal position has deteriorated significantly. Revenue growth slowed to a lower permanent trajectory post-2010, while government spending continued its pre-crisis path, resulting in a steady increase in public debt as a percentage of GDP—from 31.5% in 2009 to 57.2% in 2019.

The Covid-19 pandemic put further strain on the economy and fiscus, leading to debt reaching 74.1% of GDP by 2024. By 2026, the South African government will spend 17% of its budget on servicing debt, up from 6.5% om 2009 and 1.5 times more than it does on healthcare.

The rapid increase in debt over the last 15 years has brought debt consolidation to the centre of fiscal policy. While the government has made substantial effort to protect the social wage budget (health, education and social protection), even in the presence of other austerity measures, this has become increasingly more difficult. Over the next three years, the health budget is expected to grow at only 4.7%, far below expected inflation in per capita terms and definitlely below typical health inflation levels. In this context, it is a matter of urgency that healthcare expenditure efficiency, achieving maximum outcomes within a given resource envelope, is prioritised.

Research aim

This study aims to assess the efficiency of South African public healthcare expenditure at the district level. While prior studies have assessed efficiency at the provincial and facility levels, this analysis focuses on the district level.

Methodology

We use Data Evlopment Analysis (DEA) to generate district efficiency scores using a self-constructed dataset at the district-level from the District Health Barometer for 2016 to 2022. The dataset spans both primary and secondary health expenditure and outcomes with separate DEA analyses by level of care. Apart from healthcare expenditure, we utlise input variables such as health personnel, hospital beds, and outcome variables such as infant, maternal, and neonatal mortality rates. Stochastic Frontier Analysis to adjust input slacks will also be used to produce additional estimates.

Results

Using longitudinal data from 2016 to 2022, the DEA model reveals an increase in average district efficiency scores from 46.4% in 2016 to 50.3% in 2019, followed by a decline to 42.7% in 2022. This suggests that, in 2022, health resources could be reduced by 57.3%, without deteriorating outcomes if all districts achieved the efficiency level of the most efficient district. However, this initial analysis and finding do not account for exogenous factors influencing efficiency, necessitating a second-stage analysis.

In the second stage, panel regression techniques (e.g., Tobit regression) analyse how socioeconomic conditions, institutional characteristics, and district-level variables impact efficiency scores. The adjusted scores highlight the extent of resource inefficiency relative to the best-performing districts.

Conclusions and policy implications

By identifying districts with significant expenditure inefficiencies, the study will help inform targeted interventions, with high-performing districts serving as models for best practices. Ultimately, the findings aim to guide policy reforms and advance discussions on achieving universal health coverage under South Africa's proposed National Health Insurance (NHI) framework.

Ind-2676 Have we Gotten it All Wrong? A Critical Look at Prioritizing, Financing and Tracking Primary Care Through the Government Budget

PRESENTER: **Jacopo Gabani**, University of York
AUTHOR: Moritz Piatti-Fuenfkirchen

Background: Primary health care (PHC) serves as the main entry point for patients into the healthcare system. Weaknesses in the availability and quality of PHC could have a negative impact on health outcomes. In most low and lower middle-income countries PHC is financed from the government budget. Yet, problems in managing these finances abound which has detrimental consequences on the delivery of primary care and consequently health outcomes. **Research question:** In this paper we identify the most pressing public financial management challenges in the delivery of primary care and examine whether the available literature and ongoing academic discourse in PHC financing is well positioned to respond to country needs. **Methods:** The paper draws on an in-depth review of PFM systems that cater for primary care across 50 low income countries to identify how primary care is positioned within the budget, how it can be prioritized, and how expenditures can be tracked. Findings from the review are compared to an analysis of the PHC financing literature to assess how relevant and actionable this body of work is for the most dominant PFM constraints these countries are facing. The literature review was conducted, analyzing peer-reviewed articles, policy reports, and case studies published between 2000 and 2023. Databases searched included PubMed, Scopus, and the World Health Organization's Global Health Observatory. **Results and conclusions:** In this paper we find that many PFM systems don't accommodate for PHC appropriately. This does not allow for prioritization of PHC, legislative discourse, facilitating the necessary fund flows, or tracking and evidence-based

decision making. Yet, the PHC financing literature and most technical assistance work in low and lower middle income countries does not appear to cater to this urgent need. The paper concludes that an emphasis should be placed on appropriately structuring PFM systems such that an evidence based decision making process can take place such that countries can prioritize PHC, track spending and hold actors accountable for their decisions.

Ind-1379 Where is(n't) Digital Health R&D Happening? Focal Areas and Gaps in Digital Therapeutics Research Based on the Global Burden of Disease

PRESENTER: **Linea Schmidt**
AUTHORS: Lars Masanneck, Ariel Dora Stern

Introduction: In recent years, Digital Health Technologies (DHTs) have emerged as a promising opportunity for addressing (often unmet) health challenges in a scalable and decentralized manner. “Digital Therapeutics” (DTx) represent a specific subgroup of DHTs; DTx treat or alleviate health conditions by leveraging software components. This study aims to evaluate the alignment between the focal research and development (R&D) activities within DTx and national-level health trends described by the Global Burden of Disease (GBD) study. In other words, we consider where and when DTx R&D activities in digital health align with disease-driven demand for therapies.

Methods: We analyzed all DTx-related clinical trials from ClinicalTrials.gov between 2005 and 2023 (n=7,303, US studies: n=2,468) and compared their target indications with trends described by the GBD study, encompassing worldwide health data through the end of 2021. Disability-adjusted life years (DALY) from the GBD were used as the key measure of unmet medical needs throughout the analysis.

Results: We show that the areas of DTx R&D broadly follow the trends described by the GBD—i.e., R&D activity can be predicted by expected demand to a large extent—although the ranking of individual condition categories differs in key disease areas. While cardiovascular diseases and neoplasms represent the highest disease burden in the US, the largest numbers of DTx trials focus on mental and neurological disorders. Independent of the study location, the majority of DTx trial sponsors (institutions responsible for the trial, but not necessarily providing funding) are research institutions. Based on the analyzed trials we find that DTx R&D better aligns with GBD trends for countries with a high Socio-Demographic Index (SDI), as compared to those with a middle or lower SDI. The top ten DTx R&D fields in the US align closely with the US GBD for females under 70. This echoes findings from the German market, the first country globally to regulate and reimburse DTx. In general, changes in policy and reimbursement appear to influence clinical trial activity: US DTx R&D increased following the Digital Health Innovation Action Plan (2017) and the establishment of the Digital Health Center of Excellence (2020). Similarly, Germany saw growth in DTx trials registered at ClinicalTrials.gov after introducing the “DiGA” (digital health application) reimbursement pathway in 2019. Among indication fields, mental health has dominated US DTx R&D, paralleling the recent focus of digital health venture funding that has been documented. While most US funding institutions prioritize mental and neurological disorders, the US NIH uniquely emphasizes neoplasms—an area under-served by digital offerings relative to its global burden.

Conclusion: Our findings suggest that observed trends in both R&D and patient use may originate from both the demand and the supply sides. Future work will focus on understanding the economic drivers of DTx R&D, disparities in addressing under-served populations—in particular outside of wealthy regions—and how DTx are utilized across trials.

Ind-857 Marketing Authorization and Strategic Patenting: Evidence from Pharmaceuticals

PRESENTER: **Lucy Xiaolu Wang**
AUTHOR: Dennis Byrski

Patents can incentivize innovation, but pharmaceutical firms often extend market exclusivity by patenting minor modifications to existing drugs, raising concerns about low-novelty patents that add little therapeutic value. This study examines how patenting behavior changes after marketing authorization, a regulatory milestone that makes clinical trial data public and thereby creates ``prior art'' that limits future patent claims. Using a novel European patent-drug dataset and event study methods, we exploit plausibly exogenous variation in the time from patent priority filing to marketing authorization. We find a significant decline in strategic patenting after authorization, particularly in secondary patents and those covering the same disease areas. In contrast, follow-on product patents and patents for new disease areas remain stable, suggesting that authorization selectively curbs low-novelty filings. Both originators and other firms respond similarly, though at different speeds. The absence of similar responses after earlier milestones indicates increased difficulty in obtaining or enforcing low-value patents as the likely mechanism. Robustness checks---including alternative difference-in-differences estimators, constant exclusivity samples, and analyses accounting for non-European market incentives, firm characteristics, and instrumental variable approaches---support our conclusions. Our findings show how regulatory data transparency can indirectly improve patent quality.

(recently accepted into Journal of Public Economics, July 2025 issue: https://doi.org/10.1016/j.jpubeco.2025.105415; full MPI discussion paper available at: https://dx.doi.org/10.2139/ssrn.4638115)

Ind-1260 Who is More Capable? Evaluation of Diagnostic Quality between Large Language Models and Primary Care Physicians

PRESENTER: **Dr. Zhang Zhang, PhD**, Johns Hopkins University
AUTHORS: Dong (Roman) Xu, Tianqi Zhou, Wenjun He, Qianfang Cao

Introduction: Primary care physicians (PCPs) are the important gatekeepers in China's healthcare system, but challenges persist due to limited education, skillsets, and resources. To address these issues, the Chinese government has introduced various policies and interventions to strengthen PCP capacity. The rapid development of technologies such as Artificial Intelligence and large language models (LLMs) presents a promising opportunity to assist PCPs and strengthen the primary care system. However, little is known about the diagnostic quality of LLMs in primary care settings, particularly in emerging markets like China. The objective of our study is to compare the diagnostic capabilities of LLMs and PCPs** in China across nine common diseases using a standardized patients (USP) approach.

Method: We conducted a national representative sampling in 1226 primary care clinics in 7 provinces. The observation period of our study is from 2021-2024. We included 2200 USP visits, including nine disease conditions: common cold, Type 2 diabetes, gastritis, child diarrhea, low back pain, depression, angina, headache, and asthma. The LLM platforms include ChatGPT3.5, GPT4 (including GPT4o and Bing Chat), Claude, and Gemini, evaluated across four diagnostic dimensions: consultation, examination, diagnosis, and treatment. A total of 900 interactions were conducted, with 100 cases per condition and 20 interactions per LLM for each case.. LLMs' performance was measured through recall, precision, and F1 scores. Recall indicates the percentage of suggested items by LLMs or PCPs followed clinical guidelines over the total number of suggested items by clinical guidelines. Precision refers to the rate at which suggested items by LLMs or PCP followed clinical guidelines over the total suggested items by LLMs or PCPs. F1 scores are the weighted average value of precision and recall.

Results: First, for the performance of recall, on average, compared to PCPs, LLMs have a higher median value regarding consultation (LLM: 0.300 [95%CI: 0.290-0.310] vs PCP: 0.167 [0.161-0.182]), examination (LLM:0.286 [95%CI:0.273-0.300] vs PCP:0.091 [95%CI: 0.083-0.1]), diagnosis (LLM:0.167 [95%CI:0.167-0.167] vs PCP:0.001 [95%CI:0.001-0.077]), and treatment (LLM:0.429 [95%CI:0.400-0.462] vs PCP:0.167 [95%CI:0.167-0.182]). Second, in terms of precision, LLMs and PCPs demonstrate the same median value (LLM:1.00 [95%CI:1.00,1.00] vs PCP:1.00 [95%CI:1.00,1.00]) across consultation, diagnosis, and treatment, indicating comparable performance. However, LLMs have a relatively lower mean value in examination than PCPs (LLM:0.800 [95%CI:0.750-0.833] vs PCP:1.00 [95%CI:1.00-1.00]). The average F1 scores of LLMs are higher than PCPs in consultation (LLM:0.444 [95%CI:0.429-0.462] vs PCP:0.3080 [95%CI:0.296-0.313]), examination (LLM:0.417 [95%CI:0.400-0.429] vs PCP:0.286 [95%CI:0.270-0.286]), and treatment (LLM:0.545 [95%CI:0.500-0.571] vs PCP:0.400 [95%CI:364-0.400]), and similar F1 scores in diagnosis (LLM:0.286 [95%CI:0.286-0.333] vs PCP:0.286 [95%CI:0.286-0.333]).

Conclusion: LLMs demonstrated higher recall across consultation, examination, diagnosis, and treatment than PCPs. Although LLMs showed comprehensiveness in diagnosis, they were less precise in examination tasks, highlighting an area for improvement. The overall findings indicate that LLMs could enhance guideline adherence and care consistency. It suggests that LLMs have the potential to be supportive tools in primary care with resource-limited settings. Further refinement is needed to optimize their use in clinical environments to improve the precision.

Ind-2246 The Launch and Price of Patented Medicines in Canada and its Reference Countries: A Retrospective Cohort Study

PRESENTER: **Wei Zhang**, University of British Columbia
AUTHORS: Daphne Guh, Nathaniel Dyrkton, Alexander Tam, Paul Grootendorst, Aidan Hollis, Aslam Anis

Background Recent studies have criticized that a large proportion of new medicines approved for marketing in the United States (US) and European countries only add minor or no therapeutic benefit. However, limited analyses have been conducted to assess the launch (i.e., sales) and price of new medicines over time by their therapeutic value. **Objective** To examine the launch and price of new medicines by therapeutic value among Canada and its 13 previous and current price reference countries (Australia, Belgium, France, Germany, Italy, Japan, the Netherlands, Norway, Spain, Sweden, Switzerland, the United Kingdom, US). **Methods** We used the IQVIA MIDAS Sales quarterly data in Q3 2012-Q4 2023, which provide sales values and volumes of drug products for the 14 countries. We included a cohort of molecules that were sold in the 14 countries in 2013-2021 and categorized as "new active substances" and "innovative branded products" in IQVIA MIDAS Sales data. Each molecule was followed up by a minimum of 2 years. The global first launch date for each molecule was the first sale date in the 14 countries. The outcomes for each country included the cumulative probability of launching since the global first launch and median time-to-launch using Kaplan-Meier method, and list prices up to 5 years after domestic launch. Therapeutic value information was obtained from Canada's Patented Medicine Prices Review Board, the German Institute for Quality and Efficiency in Health Care, the independent French medicine bulletin, Prescrire International, and the US Food and Drug Administration. Each organization's ratings were categorized into major, minor, little to no, or missing benefit. **Results** Our cohort included 422 new molecules (13.5% major, 14.2% moderate, 38.4% little to no, and 33.9% missing). The probability of launching new molecules reached a plateau or close to a plateau within 5 years since global first launch in all countries with several exceptions. In effect, if these molecules had not been launched within 5 years, they were unlikely launched up to 11 years. Variation between countries in the speed and probability of launching molecules was the highest for molecules with major benefit. The median time-to-launch (the time by when 50% of the molecules with major benefit had been launched) ranged from 0 for the US to 10 years for Canada except for the Netherlands where the median time-to-launch could not be estimated because the cumulative probability of launching plateaued at 0.17. The launch of molecules with moderate benefit was the fastest/highest in all countries except the US and the Netherlands. The median list price of molecules with major benefit was substantially higher in the first year after domestic launch than that of molecules with moderate or little to no benefit in all countries. **Conclusions** Our preliminary analysis results indicate that medicines with major therapeutic benefit have higher list prices and slower (and more variable) launch speed. Our study will inform policy decisions regarding the review and consideration of therapeutic value for drug market approval and reimbursement.

Ind-361 Exploiting Partial Knowledge of Drug Dffects Using Optimal Fractional Treatment Rules Revealing Hidden Welfare in Zero-Effect Studies

PRESENTER: **Johannes Cordier**, University of St. Gallen
AUTHORS: Owen O'donnell, Raf Van Gestel

Introduction The high failure rates in Phase III clinical trials often stem from statistically insignificant average treat- ment effects. However, such conclusions overlook the potential benefits for specific subgroups within the study population. Traditional trial designs and stratification lack the flexibility to address this hetero- geneity, leading to missed opportunities for effective patient-targeted interventions. Our study addresses this limitation by integrating causal machine learning techniques with fractional treatment rules, offering a probabilistic, personalized approach to treatment assignment that reflects the treatment heterogeneity across patient subgroups and the confidence in the estimated effects. This methodology aims to capture hidden welfare by identifying and capitalizing on positive effects within subsets of patients.

Methodology We exploit the ACCORD dataset, including 10,251 patients with type 2 diabetes randomized into inten- sive and standard glucose-lowering therapy groups. This dataset provides a rich source of demographic, clinical, and outcome data, allowing detailed exploration of subgroup responses to treatment. We identify and quantify treatment heterogeneity through causal forests, an efficient method for estimating subgroup- specific treatment effects. Building on the insights from causal forests, we employ fractional treatment rules, grounded in the minimax-regret criterion, to guide treatment assignment. Fractional treatment rules allow for a more nuanced policy, assigning treatment with a probability based on the subgroup's estimated benefit, rather than a rigid, binary allocation. This methodological approach not only enhances decision-making flexibility in precision medicine but also enables adaptive trial designs.

Expected Results Preliminary analyses suggest that our combined approach will reveal beneficial treatment effects within certain subgroups that would otherwise be lost in estimates of average treatment effects. Specifically, we anticipate identifying patient subpopulations who experience improved cardiovascular outcomes with intensive glucose lowering, despite average results suggesting no significant benefit. Fractional treatment rules are expected to yield higher welfare by tailoring treatment probabilities to the estimated effect within each subgroup, offering a viable alternative to all-or-nothing trial designs. This framework could further inform adaptive trial designs by identifying patient segments worthy of targeted interventions and follow-up trials.

Conclusion This study makes a significant methodological contribution by integrating causal machine learning with fractional treatment rules, a novel approach that may reduce clinical trial failure rates through refined subgroup analysis and adaptive sampling. Our findings could transform clinical trial design and drug development by providing an evidence-based, probabilistic approach to patient stratification, ultimately enabling more efficient and targeted drug approval pathways. This probabilistic method holds promise not only for enhancing patient outcomes through precision medicine but also for reducing development costs by focusing resources on patient populations with demonstrated treatment response potential.

Ind-1092 Target Product Profiles: Opportunities and Implications for Policymaking a Scoping Review

PRESENTER: **Mr. Nitirot Phasitthanaphak**
AUTHORS: Yot Teerawattananon, Sichen Liu, Yi Wang, Teerawat Wiwatpanit, Tanainan Chuanchaiyakul, Carla Barceló, Thanakit Athibodee

Background

Target Product Profiles (TPPs) serve as tools for strategic planning in medical innovation development by facilitating communication with regulators and developing market access strategies. For technology developers, TPPs indicate the key product attributes for a particular medical innovation to meet specific public health needs. By highlighting these needs, policymakers involved in developing TPPs can help align the development of new technologies with health policy objectives and public health priorities. This study aims to review published TPPs, the extent of stakeholder involvement, their development process, and identifying the common themes. Through examining these elements, this review contributes to understanding how TPPs can be optimized to better support evidence-based, policy-aligned innovation in healthcare.

Methods

A scoping review of publicly available TPPs was conducted to understand the process that goes into these documents. Literature searching was conducted across multiple databases to identify TPPs including Pubmed, Scopus, Embase, Web of Science, and websites of WHO and FIND, with screening performed by independent reviewers. An initial search was conducted in August 2023 with an updated search conducted in June 2024.

Results

Eighty-two articles were selected for the review, containing a total of 122 TPPs. Most TPPs are targeted towards general global use settings (91%) while only a small number are specific to LMICs (4%). A majority of TPPs pertained to innovations for medical devices and diagnostic tools (61%), followed by drugs and advanced therapeutic medicinal products (14%). Health professionals were the most involved stakeholders among the 82 studies (79%), followed by academic researchers (63%) and policymakers (62%).

Most studies used Delphi-like processes for TPP development including scoping TPPs, drafting and identifying TPPs, and consensus building. Methods used to develop TPPs included review and evidence synthesis, interview and survey, focus group discussions and meetings, and modelling. The most used methods for each stage were review and evidence synthesis for scoping TPP, focus group discussion and meetings for drafting and identifying TPP, and public consultation for consensus building. Modelling techniques were infrequently used in TPP development, despite their potential to quantify attributes like cost-effectiveness and optimize product specifications, which may indicate an area for future development to enhance data-driven decision-making in TPPs.

The product attributes defined in the TPPs can be grouped into 34 categories. The most common categories were: intended use, target end-user, and intended use setting which were relevant to nearly all types of innovations. Target user was commonly considered under device, diagnostic tools and system-level tools, but was less frequently considered for medicinal products, vaccine, and digital health. Other commonly considered categories included performance measures such sensitivity, specificity, efficacy, and safety. The TPPs of device and diagnostic tools considered the greatest number of categories compared to other types of innovations.

Conclusion

TPPs can help guide medical innovation development to align with public health needs, by indicating product attributes defined through an iterative process combining stakeholder engagement, data-driven techniques, and existing precedence.

Ind-1632 Technological Progress or Waste? Evidence from Large Diagnostic Investments

PRESENTER: **Ms. Maria Wisniewska**
AUTHORS: Daniel Avdic, Anthony Scott, Johannes Kunz

Background: New technologies are one of the main drivers of increased healthcare spending. While they often contribute to improvements in health outcomes, the efficiency of utilisation and distribution of these technologies has become a critical issue for policymakers. One of these technologies is imaging, which plays a crucial role in diagnosing and managing diseases. While expanding imaging services can address gaps in underserved areas, its value potentially decreases in high-density markets.

Objective: This study investigates the impact of geographic variation in the adoption of new CT scanners in Australia between 2012 and 2022. Specifically, it examines the expansion of equipment in saturated and unsaturated markets. The study evaluates how new equipment influences local utilization, physician behaviour, financial implications, and testing quality.

Method: Using administrative data of all healthcare services provided in Australia from the Person Level Integrated Data Asset (PLIDA), we identified all new postal areas of the country that received their first equipment during our period of interest. We classified these areas as saturated or unsaturated based on their proximity to already existing equipment. We used two methods to obtain robust estimators of the effect of equipment emergence on the selected outcomes: difference-in-differences (DID) and synthetic difference-in-differences (SDID) framework compared treated areas (with new equipment) to controls (neighbouring areas without equipment during the study period). Outcomes included local scan utilisation, local physician requests, average cost per test, and site-specific testing patterns.

Results: Both DID and SDID results validated the classification into saturated and unsaturated areas, showing increased utilisation in unsaturated areas following new equipment introduction, while utilisation in saturated areas remained unchanged. Physician requests for CT scans rose in both market types, with a stronger effect in unsaturated areas. Site-specific analysis highlighted increased utilisation of overused scan types, such as spine and head scans, in unsaturated areas, while no significant changes were observed in saturated areas.

Discussion: The findings align with prior research on supply-side factors driving geographic variation in imaging utilization. In unsaturated areas, the emergence of new equipment appears to address unmet health needs, but it also raises concerns about overutilization, particularly for scans with higher potential for unnecessary use. The study contributes to understanding the diffusion of medical devices, complementing global literature on the adoption of technologies.

Ind-351 Investigating Consumer Preferences and Experiences of Allied Health Telehealth Services in Australia

PRESENTER: **Feby Savira**, Deakin University
AUTHORS: Madison Frith, Deniz Senyel, James Boyd, Richard Norman, Suzanne Robinson

Introduction: Since the COVID-19 pandemic, telehealth usage has surged, yet little is known about consumer preferences and experiences with telehealth in allied health practice. Existing studies primarily focus on general practice and broader primary care. Given the significant role of allied health professionals within the Australian healthcare system, this study aims to explore consumer preferences and experiences with telehealth in allied health.

Methods: This three-phase, mixed-methods study comprises: (1) two literature reviews on (a) allied health telehealth studies and (b) discrete choice experiments (DCEs) examining telehealth preferences; (2) focus group discussions exploring consumer attitudes and experiences; and (3) a DCE via online survey targeting the general population. Insights from Phases 1 and 2 informed the DCE, which will elicit consumer preferences for allied health services delivered through telehealth or face-to-face, using hypothetical scenarios with varied attributes.

Findings: The allied health telehealth review identified similar advantages and disadvantages across specialties, such as increased convenience but a reduction in personal connection and hands-on care. The DCE review showed a general preference for face-to-face consultations, though telehealth is valued when it reduces costs, shortens wait times, or is part of comprehensive care. Focus group findings revealed that telehealth experiences in allied health vary by health condition, technological literacy, and provider-patient relationships, with suitability differing across disciplines. Key considerations included accessibility, appointment quality, technological barriers, and specific needs of underserved groups. The DCE is scheduled for completion in January 2025.

Implications/Key Message: This study will provide insights to guide the development of allied health telehealth services that align with community needs and expectations.

Ind-916 Can Online Replace Offline? -- Study on the Substitutability of Online Consultation for Offline Diagnosis and Treatment

PRESENTER: **YuXin Liu**
AUTHORS: ZHANG YAN, ZhiYong LIU, Sixian Du

Abstract

Objective Evaluating the implementation effect of the online consultation. Exploring the mechanism of how it works in the process of diagnosis and treatment. And assessing its substitution for offline diagnosis and treatment. On this basis, discussing the optimization and promotion of this medical consultation pattern and giving corresponding policy recommendations.

Methods Inviting 36 physicians from different departments to co-construct an online consultation platform. Including 241 patients into this medical consultation pattern and randomly assigning them different offline personnel and equipment assistance conditions. Including 361 resulting medical cases as study samples for analysis. Firstly, using the stratified linear regression analysis method and the propensity score matching method separately to quantitatively explore the effects of the demand of the diagnosis and treatment tasks as well as the factors from different levels--such as the level of patients, physicians, and forms of medical treatment, on the suitability of the diagnosis and treatment tasks to the online scenario, and further on the completion of the diagnosis and treatment tasks. Then using the economic evaluation to quantitatively explore the benefits and costs for both physicians and patients participated. Finally conducting the semi-structured interviews with all parties involved to qualitatively analyze the advantages and disadvantages of their participation in this medical consultation pattern.

Results The study found that the suitability of the diagnosis and treatment tasks to the online scenario was significantly influenced by the demand of the diagnosis and treatment tasks and factors from the forms of medical treatment level, such as offline personnel and equipment assistance conditions, and further had a significant impact on the completion of the diagnosis and treatment tasks (all p-values <0.001). In addition, compared to offline diagnosis and treatment, online consultation was found to ease the financial burdens of medical treatment for patients while expose hospitals to potential losses of profit. Thus, patients were observed to be more willing to participate in this medical consultation pattern than physicians.

Conclusion Online consultation is able to achieve practical diagnostic and therapeutic effects. It demonstrates a certain degree of substitutability for offline diagnosis and treatment. The results suggest that the optimization of this medical consultation pattern can be considered in terms of the suitability of the diagnosis and treatment tasks to the online scenario. And the demand of the diagnosis and treatment tasks as well as the factors from the level of forms of medical treatment were found to be significant influencing factors of it. Therefore, measures such as accurately identifying patients suitable for online consultation, as well as equipping corresponding personnel and equipment assistance to the patient may be the key to optimize this medical consultation pattern. In addition, the inherent characteristic of online consultation that harms the benefits of the supply side while subsidizes the costs of the demand side also poses certain challenges in its future promotion process.

Keywords Online consultation; Medical consultation pattern; Performance evaluation; Policy recommendation

Ind-1113 Impact of National Volume-based Drug Procurement on Pharmaceutical Innovation in China: a Difference-in-differences Analysis

PRESENTER: **Zheng Zhu**
AUTHORS: Jiawei Zhang, Li Yang

Background In 2019, the Chinese government launched the national volume-based procurement (NVBP), a novel pooled procurement, intending to establish a market-oriented pricing mechanism. The prices of drugs have decreased significantly, and it remains unclear whether this will suppress innovation in the pharmaceutical industry. Sustained pharmaceutical innovation is crucial for addressing unmet patient needs. This study aimed to explore whether NVBP promotes innovation in the pharmaceutical industry. **Methods** Under the theory of change framework, this study provides a theoretical analysis of the mechanisms and potential effects of the NVBP. Using a multi-period difference-in-differences (DID) model and event study method, we analyze financial data from listed companies and patent data, with the research period spanning from December 31, 2014, to December 31, 2023. We examined the impact of the NVBP on the R&D investment amount, R&D intensity, number of R&D personnel, and number of invention patents of pharmaceutical listed companies. We also examined the heterogeneity in terms of the type of enterprise, firm size, and geographical location. **Results** After the implementation of NVBP, the multi-period difference-in-differences model indicated that the R&D investment amount in pharmaceutical listed companies affected by the policy rose by 86 million yuan, R&D intensity grew by 2.06%, the number of R&D personnel increased by 86, current period expensed R&D expenditure increased by 99 million yuan, capitalized R&D expenditure in the current period increased by 28 million yuan, and the number of invention patents grew by 12, with statistically significant. Subgroup analysis results show that the impact of the NVBP on R&D innovation in pharmaceutical companies is more significant in private enterprises and large companies, as well as in companies located in the western and eastern regions. **Conclusion** This study provides evidence that the NVBP policy was associated with pharmaceutical innovation. Although the NVBP has significantly reduced drug prices, it has fostered pharmaceutical innovation by intensifying market competition and creating a favorable environment that pressures pharmaceutical companies to increase investment in R&D innovation. This is of significant importance for enriching the supply of innovative drugs and meeting patients' unmet needs.

Ind-1593 Volume-based Procurement and Pharmaceutical Innovation

PRESENTER: **Lai Yi**
AUTHORS: Fu Hongqiao, Chen Fanghao

Background: Enhancing drug affordability while preserving pharmaceutical innovation often presents conflicting objectives. In recent years, competitive bidding is increasingly popular among both developed and developing countries due to its effectiveness in promoting drug affordability. The study examines the trade-off by evaluating the effects of the National Volume-Base Procurement (NVBP) on pharmaceutical innovation in China. NVBP is a procurement policy that combines competitive bidding with guaranteed large-scale purchases for off-patent drugs. Since 2018, China has carried out ten rounds of NVBP, leading to price reductions of over 50%. **Method and Data:** Utilizing a generalized difference-in-differences design and event study design, the study investigates how domestic pharmaceutical firms react to NVBP by analyzing comprehensive patent application and clinical trial data from these companies. We employ several datasets, including patent applications, clinical trials, drug sales, and ownership of pharmaceutical companies, a list of approved drugs in China market, and a list of NVBP tendering results. The time period of these data is from January 2017 to December 2023. Data of patents and clinical trials covers the whole sample of domestic pharmaceutical companies, which is from the State Intellectual Property Office and the National Medical Products Administration, respectively. **Preliminary Results:** In our early version of working paper, we utilized the data sample of patents and clinical trials from 2017 to 2021. We found that the inclusion of a drug in NVBP results in a 0.016 (16.6%) reduction in application of invention patents for the companies producing it, with winning bidders experiencing a further decline. The impact of NVBP becomes evident one year after its implementation. We find the NVBP has no significant impact on clinical trial behaviors, which might be attributed to time delay effect. Surprisingly, we also find that companies maintain their total sales revenue despite a substantial decrease in the sale value of procured drugs. This suggests that the revenue mechanism cannot fully explain the considerable decline in early pharmaceutical innovation, indicating that market structure plays a crucial role. But when we currently extend time period from 2017 to 2023, we found the number of early stages clinical trials has risen mildly. We haven't finished the cleaning of patent's dataset, yet. But in a coarse regression, we still found the NVBP reduced number of applications of invention patents in overall sample. Consistent with the new results of clinical trials, we found pharmaceutical companies with experiences of innovative drug R&D have responded to NVBP by increasing patent application. **Discussion and Implication:** Overall, our results suggest that the large price reduction on off-patent drugs brought by the procurement is associated with a large reduction in pharmaceutical innovation, which indicates a salient tradeoff between drug affordability and future innovative drugs. But the preliminary results in our current version suggest a divergence of pharmaceutical innovation, and the direction of drug procurement on pharmaceutical innovation depends on the countervailing power of escaping competition effect and the Schumpeterian effect. **Keywords**: competitive bidding, pharmaceutical innovation, drug prices

Ind-2431 Analyzing the Relationship Between IT Perception, Value Co-creation Behavior, and Medical Care Satisfaction Among Chronic Disease Patients

PRESENTER: **Jing Liu**
AUTHORS: Kuanlie Jiang, Wei Lu

Background: Patient satisfaction is one of the key outcome indicators of chronic disease healthcare service quality. However, research exploring its influencing factors from the perspectives of information technology perception and value co-creation remains limited. This study aims to explore the relationships between information technology perception, value co-creation behavior, patient trust, and patient satisfaction with medical care among chronic disease patients in Chinese communities. Additionally, it investigates the mediating role of value co-creation behavior between information technology perception and patient satisfaction, as well as the moderating role of patient trust in the relationship between value co-creation behavior and patient satisfaction.

Methods: A cross-sectional survey was conducted from September 2019 to December 2019 in Wuhan and Taiyuan, China. Participants were selected using a multistage stratified random sampling method. Data were collected via self-administered questionnaires from 722 chronic disease patients in Wuhan and Taiyuan (with a response rate of 90.36%). Patient satisfaction with medical care was measured using a four-item scale. Information technology perception was assessed using scales for perceived ease of use and perceived reliability, adapted from Deng Chaohua et al.'s measurement of mobile banking system perception. Value co-creation behavior was measured using a 21-item scale adapted from Yi and Gong's measurement of customer value co-creation behavior, and patient trust was measured using a four-item scale. Pearson correlation analysis was used to assess the relationships among perceived ease of use, perceived reliability, value co-creation behavior, patient trust, and patient satisfaction. Structural equation modeling (SEM) was employed to examine the hypothesized relationships among these variables.

Results: The proposed model demonstrated good model fit. Perceived ease of use (β=0.339, P<.001) and value co-creation behavior (β=0.459, P<.001) had direct positive effects on patient satisfaction, while perceived reliability (β=0.049, P=.520) did not have a direct effect on patient satisfaction. Perceived ease of use (β=-.746, P<.001) had a direct negative effect on value co-creation behavior, whereas perceived reliability (β=0.408, P<.001) had a direct positive effect on value co-creation behavior. The relationship between perceived ease of use (β=-0.342, P<.001), perceived reliability (β=0.187, P<.001), and patient satisfaction was indirectly influenced by value co-creation behavior. The mediating role of value co-creation behavior in the relationships between perceived ease of use (β=-0.075, P<.001), perceived reliability (β=0.034, P<.001), and patient satisfaction was negatively moderated by patient trust.

Conclusions: Our study elucidates the pathways linking perceived ease of use, perceived reliability, value co-creation behavior, patient trust, and patient satisfaction with medical care. The findings indicate that perceived ease of use and value co-creation behavior significantly influence patient satisfaction, while perceived ease of use and perceived reliability significantly impact value co-creation behavior. The influence of perceived ease of use and perceived reliability on patient satisfaction can be mediated by value co-creation behavior, and the impact of value co-creation behavior on patient satisfaction is moderated by patient trust.

Ind-346 Cost-Effectiveness and Benefit-Risk of Rotavirus Vaccination in Afghanistan: A Modelling Analysis Informed by Post-Licensure Surveillance

PRESENTER: **Palwasha Anwari**
AUTHORS: Frédéric Debellut, Clint Pecenka, Andrew Clark

Introduction Afghanistan added ROTARIX to the routine national immunization programme in 2018. We aimed to estimate the cost-effectiveness and benefit-risk of ROTARIX and compare its continued use with other rotavirus vaccines that could be used in the future. **Methods** We used a static cohort model with a finely disaggregated age structure (weeks of age <5 years) to assess the use of ROTARIX (1-dose vial) over a seven-year period (2018-2024) in Afghanistan. The primary outcome measure was the discounted cost (2022 US$) per Disability Adjusted Life Year (DALY) averted (from government and societal perspectives) compared to no vaccination. We also calculated the benefit-risk ratio i.e., the number of RVGE deaths prevented per one excess intussusception death. Model inputs were informed by pre- and post-licensure surveillance data, new analyses of household survey data, and updated estimates from the international literature. We ran a separate analysis to compare the potential cost-effectiveness and benefit-risk of ROTARIX (1-dose vial), ROTASIIL (1-dose vial), ROTASIIL (2-dose vial), and ROTAVAC (5-dose vial) over a ten-year period (2025-2034). Each product was compared to no rotavirus vaccination and each other. We ran deterministic and probabilistic uncertainty analyses and interpreted our results over a range of cost-effectiveness thresholds. **Findings** We estimated that routine use of ROTARIX between 2018 and 2024 has prevented 4,600 RVGE deaths (a 41% reduction), 86,400 hospital admissions, and 1.72 million outpatient visits. For every 1,493 RVGE deaths prevented by the vaccine, we estimated one potential excess intussusception death. With a heavily reduced vaccine dose cost (Gavi's support) the net cost to the Afghanistan government vaccine programme was estimated to be US$ 4.4 million per year. The cost per DALY averted was US$ 125 (0.25 times the national GDP per capita) when using a Gavi-subsidised vaccine cost and including household costs averted by vaccination. This increased to US$ 471 (0.94 times the national GDP per capita) when incorporating the full vaccine price without Gavi's subsidy and excluding household costs averted by vaccination. When assuming continued Gavi support over the period 2025-2034, the dominant product would be ROTARIX. Without Gavi support, ROTASIIL (2-dose vial) dominates. **Conclusion** Our study supports the sustained use of rotavirus vaccination in Afghanistan. The rotavirus vaccine is cost-effective and is health benefits greatly exceed its potential health risks. **Keywords:** Rotavirus vaccine; Cost-utility; Cost-effectiveness; Benefit-risk; Afghanistan

Ind-1558 Evaluating Payment Models for PPSV23 Vaccine Introduction in a Pediatric Sickle Cell Disease Cohort in Burkina Faso: A Budget Impact Analysis

PRESENTER: **Emmanuel Fulgence Drabo**, Johns Hopkins University
AUTHORS: Iman Nourhussein, Cynthia L. Gong

Background and Objective: Sickle cell disease (SCD) is a leading cause of morbidity and early mortality in Sub-Saharan Africa's "meningitis belt," particularly among children under five. Compromised immunity in children with SCD increases their risk of pneumococcal infections. In Burkina Faso, meningitis-related fatality in infants with SCD is about 19%, with higher risks among those unvaccinated, highlighting the need for pneumococcal vaccination. Since 2013, Burkina Faso's immunisation program has included the 13-valent pneumococcal conjugate vaccine (PCV13), covering 13 *Streptococcus pneumoniae* serotypes. However, children with SCD remain vulnerable to additional serotypes despite completing PCV13. Guidelines now recommend adding the pneumococcal polysaccharide vaccine (PPSV23) after PCV13 for high-risk individuals, but high costs and limited budgets have hindered its introduction. With countries increasingly expected to share healthcare costs, strategies to enhance affordability are crucial. This study evaluates the budget impact of adding PPSV23 for children with SCD after PCV13, comparing four payment models to assess affordability and cost savings from government and funder perspectives.

Methods: A 5-year budget impact analysis using a decision-tree model compared two scenarios — PCV13 alone versus PCV13+PPSV23 — in a cohort of 13,959 infants ≤5 years. PPSV23 uptake was calibrated to current PCV13 coverage. Four payment models were evaluated: 1) a one-time payment (OTP) model with the full cost paid upfront in year 1; 2) a "Costco" model with a 50% upfront "membership" fee in year 1 and a 10% annual per dose usage fee thereafter; 3) a mortgage-based payment (MBP) model with fixed, equal annual installments paid over 5 years plus interest based on government bond rates (~7.2%); and 4) an outcomes-based model with payments tied to vaccine effectiveness, reimbursing full vaccine costs per pneumococcal infection within the expected vaccine protection period (~4 years). Epidemiological and clinical inputs came from the literature and burden-of-disease studies, healthcare costs from cost studies and WHO databases, and vaccine costs from GAVI and the literature. SCD screening and management costs were excluded, assuming they were pre-established. Costs were adjusted to 2024 USD and discounted at 3% annually. One-way sensitivity analysis tested result robustness and identified key drivers.

Results: Over five years, adding PPSV23 to PCV13 for children with SCD saved $15.75 million under the OTP model. The Costco model achieved the highest savings ($15.80 million, or $57,308 more than OTP). The MBP and outcome-based models saved $15.73 million and $15.72 million (i.e., $20,662 and $25,929 more than OTP), respectively. Nearly all of these cost savings accrued to the government, in the form of cost offsets from avoided adverse health events. Key drivers of the budget impact included the case-fatality ratio, probabilities of invasive pneumococcal disease and non-meningitis non-pneumonia, and vaccine uptake in year 1.

Conclusion: Alternative payment models can enhance the affordability of PPSV23 introduction in high SCD and Streptococcus pneumoniae

prevalence settings, such as Burkina Faso, by distributing costs over time. Policymakers and funders of childhood immunization programs may consider these strategies to support broader vaccine implementation within limited healthcare budgets, improving health outcomes in high-risk pediatric populations.

Ind-1823 Reaching Zero-Dose Children in Angola: The Cost of Inaction

PRESENTER: **Getaendale Simesh Ayele, PhD**
AUTHORS: Renzo Efren Sotomayor Noel, Soazic Elise wang sonne

Background In 2022, Angola found itself among the top 10 countries globally with the highest number of zero-dose children, a situation that demands urgent attention. The lack of adequate government investment in vaccines and immunization is a key factor contributing to this alarming statistic. In 2021, the government of Angola allocated only US$ 28.7 million (KZ 18.3 billion) to routine immunization, equivalent to US$ 28.9 per surviving infant (KZ 18.4 thousand) that year. This figure falls below the WHO Sub-Saharan Africa Average spending between 2018 and 2020, estimated at US $ 41 per surviving infant, as per UNICEF's recent report. Our study is designed to assess the cost-effectiveness of a vaccination program for children in Angola from 2025 to 2029 and to urgently inform the health ministry of Angola about the need for increased resources for the immunization program. **Methods** Using the latest data from UNICEF on vaccine costs per dose and from WHO on the estimation of target groups, as well as projections from 2025 to 2029 with the National Immunization Strategy costing application (NIS.COST) and Lives Saved Tool (LiST) on vaccine costs per dose, vaccine delivery costs, and the number of lives to be saved with the vaccine intervention, we empirically quantify the economic benefits the government could reap from saving lives by devoting sufficient domestic financial resources to immunization. **Results** Our study, based on a range of assumptions and scenarios on the delivery cost of vaccines and coverage rates, reveals promising results. On average, a dollar invested in fully immunizing a child in Angola translates into a gain ranging between $1.09 to $1.34, with an annual internal rate of return ranging from 17% to 47%. The cost of inaction, on the other hand, could lead to an estimated loss of lives, around 15480 within the next five years. However, the lives saved through the immunization program from 2025 to 2029 are projected to have a net benefit worth 0.1% share of Angolan GDP, offering a beacon of hope for the future. **Conclusion** Therefore, it is not just a matter of health policy, but also a moral imperative to ensure that every child in Angola has access to routine immunization. This is a fundamental right that the government of Angola should uphold. To achieve this, the government must identify potential sources of fiscal space for immunization financing in the country, thereby saving the lives of the next generation of children and respecting their rights. **Keywords:** cost, zero-dose, immunization

Ind-2495 Exploring the Costs of In-Patient and Out-Patient Costs of Respiratory Disease and the Cost of the Influenza Immunization Program in Armenia

PRESENTER: **Stacie Gobin**
AUTHORS: Michael Kusi Appiah, Gayane Sahakyan

Background: Despite the substantial global impact of influenza, there are limited economic data to guide influenza vaccination programs investments in middle-income countries. We measured the societal costs of influenza and the costs of conducting an influenza vaccination program in Armenia.

Methods: During December 2022 through March 2023, retrospective cost data were collected from case-patients and healthcare providers through structured questionnaires at 15 healthcare facilities selected through stratified sampling using a societal perspective. In Armenia, influenza-like-illness (ILI) case-patients are treated in polyclinics (outpatient clinics offering both general and specialty medical care) daily but return to their homes nightly; severe acute respiratory illness (SARI) case-patients are admitted to hospital for treatment. Vaccination program costs from the 2021-2022 influenza season were identified using accounting records and categorized as: planning, distribution, training, social mobilization, supervision, procurement, and monitoring, and national- and facility-level administration and storage. These aggregated categories were used by default, as a consequence of the cost categories in the retrospective cost data available. While both financial and economic costs were included in the cost of illness estimate, only financial costs were included in the cost of the vaccine program.

Results: Staff enrolled 42 ILI and 873 SARI case-patients. SARI patients were admitted for a mean of 9.2 days. ILI patients were treated daily in clinic during their illnesses for a mean of 6.4 days. The mean costs per episode for SARI and ILI case-patients were $823.6 and $616.57, respectively. The societal cost per episode included direct (medical and non-medical costs) and indirect costs (productivity losses). Costs related to influenza surveillance were not included. Healthcare service costs were the largest direct expenses for ILI and SARI case-patients. In 2021, Armenia purchased 170,000 quadrivalent inactivated influenza vaccine doses in multidose vials ($7.73 per dose for procurement costs alone). Total costs of the 2021-2022 influenza vaccination program to the government were $4,353,738, with the largest costs associated with national-level administration and storage (30%) and facility-level vaccine administration and storage (65%). The total cost per dose administered was $25.61. Since the average cost of purchase per vaccine (from the manufacturer) during the 2021-2022 influenza season was $US 7.73, the marginal administration cost per dose was $US 17.88.

Conclusions: These data on the costs of seasonal influenza prevention programs and the societal and economic costs of influenza illness in Armenia may inform national vaccine policy decisions in Armenia and may be useful for other middle-income countries. Influenza vaccines, like other vaccine programs, are recognized as substantially contributing to the reduction disease burden and associated mortality and further driving economic growth. These findings suggest that the influenza vaccine, at a cost of $25.61 per dose administered could offer a substantial cost-savings over influenza treatment, at a cost of over $616.57-823.6 per episode depending on level of severity. However, a formal cost-effectiveness analysis should be performed once the burden of disease data is available.

Bali International Convention Centre – Bandung

New Methods to Measuring Health Inequalities across the Globe

MODERATOR: **Erin Strumpf**,

Ind-319 Decoding Health Disparities: Gender, Ethnicity, & Chronic Diseases in Latin Americans with Individual Data & Machine Learning

PRESENTER: **Carlos Chivardi**
AUTHORS: Ana L. Moncayo, Davide Rasella, Alejandro Zamudio Sosa, Daniella Medeiros Cavalcanti, Philipp Hessel, José Alejandro Ordoñez, Cristina Almeida

Abstract

Background. Chronic diseases, such as cardiovascular disease, diabetes, and respiratory conditions, disproportionately affect certain ethnic and gender groups, leading to substantial health disparities. In Latin America, these disparities are exacerbated by social determinants like education, employment, and access to essential services, but the extent and drivers of these disparities are not fully understood. Addressing these inequities requires insights into how specific social determinants influence chronic disease risk across diverse populations. This study aims to shed light on these drivers by exploring the impact of socioeconomic and environmental factors on chronic disease diagnoses across gender and ethnic lines in three Latin American countries: Brazil, Mexico, and Ecuador.

Methods. We conducted an analysis using data from 96,726,891 adults, obtained from national health surveys carried out in Brazil, Mexico, and Ecuador between 2018 and 2019. Our primary variables included education level, occupation, and access to essential services such as sewage, piped water, and garbage collection, as well as demographic data on ethnicity and gender. To model the complex relationships between these variables and chronic disease outcomes, we employed random forest machine learning models. This method allowed us to capture nonlinear patterns in the data and assess the predictive power of each social determinant for different gender and ethnic groups.

Results. Our models revealed substantial disparities in chronic disease risk linked to both ethnicity and gender. Notably, predictive accuracy was highest for indigenous and black individuals, underscoring the inequities these groups face in relation to chronic disease burden. Education was the most influential predictor for women, with model performance dropping by 48.2% when education data was removed. This suggests that access to education plays a crucial role in chronic disease prevention for women, likely through its impact on health literacy, health behaviors, and economic stability. In contrast, occupation was the stronger predictor for men, with a 29.7% reduction in model performance when occupation data was excluded. This finding highlights the influence of occupational factors—such as job stability, work conditions, and associated stress—on men's chronic disease risk.

Conclusion. Our results have significant implications for public health policy. They highlight the need for gender- and ethnicity-sensitive strategies in Latin America. For women, policies focused on improving access to education may help mitigate chronic disease risk, while for men, initiatives promoting stable and safe employment opportunities may be particularly beneficial. Moreover, our findings underscore the need to address basic service inequities in indigenous and black communities, where lack of access to sewage, clean water, and waste management contributes to poor health outcomes and elevates chronic disease risk.

This study provides new insights into how social determinants shape chronic disease risk in Latin America, emphasizing the need for targeted public health interventions. By addressing the unique needs of different gender and ethnic groups, policymakers can make meaningful progress toward reducing health disparities.

Ind-1177 A Distributional Regression Approach to Socioeconomic Inequalities in Infectious Diseases in the UK

PRESENTER: **Murong Yang**
AUTHORS: Julie Robotham, Nam Nguyen, A.Sarah Walker, Edwin van Leeuwen, Koen Pouwels

Background

High infection incidence causes a major burden on public health, with evidence suggesting that socioeconomically disadvantaged groups may face greater impacts. Understanding and explaining socioeconomic inequalities in healthcare utilisation for infectious diseases has important implications for health and social policy. Conventional regression models primarily capture the effect of socioeconomic factors on the mean of health outcomes, potentially overlooking critical distributional aspects across socioeconomic factors, such as variability and asymmetry. We use a distributional regression approach to examine and decompose socioeconomic inequalities in the incidence of primary care consultations for a wide range of common infections.

Methods

We analysed patient-level data from January to December 2019 using the Clinical Practice Research Datalink, a large electronic database of primary care records across the UK. We assessed the incidence of consultation for a wide range of common infections, including chronic obstructive pulmonary disease (COPD) exacerbations, asthma exacerbations, lower and upper respiratory tract infections, gastroenteritis, urinary tract infection, pyelonephritis, prostatitis, acute otitis media, otitis externa, cellulitis, and impetigo. Socioeconomic status was measured by the Index of Multiple Deprivation (IMD), a geographic area-based measure of deprivation level. We first calculated the age-

standardised incidence of infection-related primary care consultations by IMD quintile. We then used a distributional regression approach within the Generalised Additive Models for Location, Scale, and Shape (GAMLSS) framework to quantify the relationship between deprivation and incidence of consultation for infection. We specified a zero-inflated Sichel distribution in the GAMLSS model, incorporating four distributional parameters to capture the effect of deprivation on the mean, variance, skewness, and kurtosis of the incidence distribution. Subsequently, we explored the role of smoking prevalence and vaccination coverage in explaining observed socioeconomic inequalities.

Results

The analysis included 6,973,213 patients. Age-standardised incidence of consultation for infection was consistently higher for patients living in more deprived areas across most infections, except for prostatitis and impetigo. The GAMLSS model showed that higher deprivation was associated with higher mean incidence of consultation for COPD and asthma exacerbations, respiratory tract infections, otitis media, otitis externa, and cellulitis, controlling for age, sex, and ethnicity ($p<0.01$). We also found that higher deprivation was associated with lower variance of the incidence of consultation for COPD and asthma exacerbations, and upper and lower respiratory infections, indicating lower variability in the incidence of these infections in more deprived areas ($p<0.01$). Smoking prevalence and influenza vaccination coverage partially explained patterns of inequality in consultations for respiratory infections.

Conclusions

This study highlights the benefit of a GAMLSS approach in health inequality research, as it captures distributional insights that are critical for effective policy interventions. A higher incidence of infection-related consultations and lower variability among individuals in more deprived areas suggest a consistently high infection burden within these populations, especially for respiratory-related infections. Targeted policies aimed at reducing socioeconomic inequalities may reduce the burden of infectious diseases in deprived communities, particularly for respiratory infections. Efforts to prevent smoking and increase influenza vaccination coverage may help narrow these health inequalities.

Ind-2265 Assessing Cardiovascular Disease Vulnerability in India: A District-Level Index-Based Analysis

PRESENTER: **Gayathri Balachandran**
AUTHOR: Ramna Thakur

Background: Cardiovascular diseases (CVDs) have emerged as a critical public health challenge in the world, with millions being affected annually. LMICs are disproportionately affected by CVDs, as they are responsible for 80% of all cardiovascular deaths worldwide. It is also concerning in India, where in 2016, non-communicable diseases (NCDs) accounted for 63% of all fatalities, with cardiovascular diseases (CVDs) accounting for 27% of these deaths. Risk factors such as comorbidities, unhealthy eating habits, sedentary lifestyles, and environmental exposures are becoming more common, which makes some populations more vulnerable, particularly in areas with inadequate access to healthcare. ***Aim:*** The aim of this study is to develop a regional Cardiovascular Vulnerability Index (CVI) for India. This will enable focused public health interventions by identifying hotspots of vulnerability across Indian districts and offering a thorough and integrated understanding of the various factors causing CVD. ***Data & Methodology:*** The analysis integrates data from diverse sources, including the National Family Health Survey's 5th round (NFHS-5, Rural Health Statistics 2021-22, and the Census of India. Using 21 indicators across six domains such as socio-demographic, epidemiological, behavioural, dietary, healthcare and living environment, a domain-specific and overall vulnerability index was generated for 707 districts in India. Indicators were normalised using a linear maximum-minimum method, with equal weights assigned within each domain. Domain-specific scores were computed using maximum-likelihood-based factor analysis in domains with more than two indicators or arithmetic means for domains with only two indicators. These were then aggregated into an overall CVI score with equal weightage. ***Results:*** The findings reveal that districts in the eastern and northeastern regions such as Pakur, Sukma, West Khasi Hills, East Jantia Hills, West Karbi Anglong, Dumka, Mayurbhanj, West Jaintia Hills, Pashchimi Singhbhum, and South West Khasi Hills exhibit the highest vulnerability, possibly driven by limited healthcare access, socioeconomic disadvantages, unhealthy dietary patterns. Conversely, districts in western India, such as Kota, Surat, Pali, Bhopal, Jodhpur, Jaipur, Sabar Kantha, Anand, Navsari, and Gwalior, have the lowest vulnerability, benefiting from better healthcare infrastructure and greater health awareness. Notably, certain hotspots were also identified in parts of Kerala and Jammu & Kashmir as well, likely due to the prevalence of lifestyle diseases and dietary habits. ***Conclusion & Policy Implications:*** These findings emphasise the need for targeted, region-specific public health policies and interventions to reduce CVD vulnerability and its associated health burden. Strengthening healthcare infrastructure through mobile health clinics or telemedicine services and launching region-specific awareness campaigns on CVD risk factors is imperative. By addressing these challenges, the CVI serves as a critical tool for identifying and mitigating vulnerabilities at a regional level in India, facilitating the development of equitable and effective public health policies aimed at reducing the burden of CVDs in the country.

Ind-2311 Health in the Digital Economy: Unclouding Inequalities Among Online Platform Workers

PRESENTER: **Marcel Bilger**, Vienna University of Economics and Business
AUTHORS: Maddalena Josefin Lamura, Barbara Haas, Dominik Klaus, Julian Kettl

A growing number of self-employed workers are finding work through online platforms that act as intermediaries between the workers and their clients. While intermediation is readily apparent in location-based services, it is also becoming increasingly prevalent in desk work. Such online platform work, however, has little visibility and remains under-researched. This research gap is important because online platform work generates very different working conditions than more traditional, office-based employment. On the one hand, greater flexibility may allow workers to better optimize the use of their private time. On the other hand, the lack of clear boundaries between private and professional life and of contractual and social protection may also pose a significant threat to their physical and mental health and well-being.

This research contributes to the literature by analyzing inequalities in health, burnout risk, and well-being among workers from a wide range of online platforms, from high-end (macro) work to click (micro) work. In particular, this research aims to explain these inequalities using novel

measures of working conditions that we developed by adapting the Employment Precariousness Scale (EPRES) to platform work using exploratory factor analysis.

We surveyed nearly 2,000 German-speaking online platform workers by inviting them to participate in the study through the platforms where they were active, using a stratified design to ensure that a variety of platform types were observed in sufficient numbers. Our outcome measures are self-rated general health, presence of chronic physical health problems, presence of chronic mental health problems, the Burnout Assessment Tool (BAT), and the 8-item Well-Being Flourishing Scale. We then conducted multivariate regression analyzes to measure the association between the outcome variables and platform type, working conditions, and socioeconomic factors, while controlling for potential confounders using a variable indicating whether health was a motive to engage in platform work. In addition, we tested the robustness of the results to the inclusion/exclusion of potentially endogenous control variables, such as working hours and off-platform work.

While we did not find significant differences in general health and burnout risk, we found that people who work on micro-platforms are 7.4 percentage points more likely to suffer from chronic physical problems, 5.8 percentage points more likely to suffer from chronic mental health problems, and 3.2 points lower in well-being than those who work on macro-platforms. Working conditions and socioeconomic variables are key, as outcome differences between platform types are no longer statistically significant when these factors are controlled for. Lower ability to take time off and vulnerability to unfair pay and non-transparent ratings have a significant negative impact on self-reported general health and well-being. However, higher ability to take time off is also associated with a higher burnout risk that is mediated by higher emotional distress from self-time management.

We conclude that the socioeconomic gradient in health between workers from different types of online platforms is partly related to specific working conditions. Our research suggests that health inequalities could be reduced by providing workers with better protections in terms of time management, fair pay, and rating transparency.

Ind-762 Predicting Changes in U.S. County Health: What Does Machine Learning Tell Us About Multiple Determinants of Health

PRESENTER: **Di Yang**
AUTHOR: David Vanness

Background: Although a growing body of literature suggests that investing in multiple determinants of health (health care, socioeconomic and behavioral determinants) at community level is an effective approach to improving population health, few studies have investigated the relative contribution and elasticity of each health determinant at the county level, which is crucial for policymakers to prioritize investments among the multiple determinants of population health.

Methods: We used machine learning methods to investigate the temporal relationship of socioeconomic, health care, and behavioral determinants of health with premature mortality in United States counties. Using data from the County Health Rankings, we estimated a population health production function with the Extreme Gradient Boosting (XGBoost) algorithm, which allowed for a flexible functional form (interaction terms, non-linearities, polynomial orders, etc.) We used 2010-2014 change rates and baseline levels of health determinants to predict 2015-2019 changes in years of potential life lost (YPLL) at the county level. Moreover, we estimated the percent change in YPLL per percent change in each of the pre-period multiple determinants (elasticities). The examined county-level health determinants included racial economic disparities, unemployment, uninsurance, child poverty, primary care physicians per 100,000 population, obesity, physical inactivity (percentage of adults reporting no leisure-time physical activity), some-college attendance (percentage of adults aged 25-44 with some post-secondary education), and high school graduation rates.

Key findings: The 2010-2014 baseline levels of obesity, physical inactivity, and unemployment were the three strongest predictors of 2015-2019 changes in YPLL. Estimated elasticities indicated that a one percent reduction in baseline levels of obesity, physical inactivity, and unemployment predicted a 0.72, 0.37, and 0.28 percent reduction in the 2015-2019 trends in YPLL, respectively, averaged across all counties. Elasticities varied based on each county's baseline levels of health determinants.

Conclusions and implications: Policymakers seeking to maximize the impact of investments to reduce premature mortality may wish to prioritize policies targeted towards changing those determinants that predict the largest improvements per dollar spent. On a national basis, our analysis suggests those determinants are most likely obesity, physical inactivity, and unemployment. Additionally, our analysis shows that the relative elasticity of these determinants is likely to vary across U.S. counties according to their baseline levels, which suggests that different counties may wish to prioritize policies targeting different determinants.

Ind-1439 The Impact of Fiscal Policies to Promote Healthy Diets on Birth Outcomes: Evidence from the Navajo Nation

PRESENTER: **John Cawley**, Cornell University
AUTHORS: Mallory Dreyer, Kosali Simon

Many governments worldwide use fiscal policy to promote healthy diets. In most cases it is relatively narrow and takes the form of a tax on sugar-sweetened beverages (SSBs). In contrast, the Navajo Nation adopted one of the most comprehensive such policies in the world in 2014-15. The Navajo Nation is the largest Native American reservation in the U.S., consisting of roughly 27,000 square miles, making it larger than ten states. The USDA classifies much of the Navajo Nation as a food desert, and roughly three-quarters of its residents are food insecure. Motivated by a concern about poor diets and the associated chronic disease, the Navajo Nation Council enacted two policies: 1. Healthy foods and drinks (including fresh fruits and vegetables, and water) were exempted from the 5% sales tax. 1. Foods and drinks of minimal-to-no nutritional value (including SSBs, candy, baked goods, ice cream, and chips) were taxed an additional 2% on top of the existing sales tax. Together, these two policies are referred to as the Healthy Dine' Nation Act (HDNA), and they create a 7% price wedge between healthy and unhealthy foods. In this paper, we examine the impact of the HDNA on birth outcomes. Infant morbidity and mortality, and maternal conditions like gestational diabetes, are more common among American Indian / Alaska Native (AI/AN) individuals than among non-Hispanic white individuals. Healthy nutrition is seen as an important mechanism for improving such outcomes. In order to estimate the impact of the HDNA on birth outcomes, we examine CDC birth certificate data for the U.S. for 2010-2018; i.e. for more than 3 years before to 3 years after the two components of the HDNA. We estimate difference-in-difference models and event studies that estimate the effect of the two components of the HDNA on a variety of birth outcomes: very low birth weight, low birth weight, gestational diabetes, gestational hypertension, and pre-pregnancy weight of mother. The treatment group consists of mothers who live in the counties of the Navajo Nation and whose self-reported race is or includes AI/AN. The comparison group consists of mothers whose self-reported race is or includes AI/AN but who live outside the three states that include the Navajo Nation (AZ, NM, UT). (As a robustness check, we also use a second control group, which are mothers who are not AI/AN (nor are the fathers) who live in the three states that include the Navajo Nation (AZ, NM, UT) but who live in counties outside the Navajo Nation.) We hypothesize that the HDNA, given that it was designed to promote healthy diets, improved infant and maternal health outcomes. The comprehensive nature of the HDNA, as well as the prevalence of diet-related chronic disease among the Navajo Nation population, make this an important contribution to the evidence base.

Ind-2527 Impact of the Coal-to-Clean Heating Policy on Cardiometabolic Multimorbidity and Clean Fuel Adoption in Older Chinese Adults

PRESENTER: **Xian Zhang**

Impact of the Coal-to-Clean Fuel Policy on Fuel Adoption and Cardiometabolic Multimorbidity among Chinese Older Adults
Abstract **Background:** In 2015, the Chinese government introduced the Coal-to-Clean Heating Policy (CHP) to enhance air quality and public health nationwide. This initiative was expanded in 2017, prohibiting household coal burning and offering subsidies to support the transition to clean heating methods, such as electricity and gas. Studies have shown that the CHP has significant impacts on cardiovascular and cerebrovascular diseases. Building on this evidence, I aim to investigate whether the policy affects cardiometabolic multimorbidity (CMM) in affected populations. **Methods:** I included participants aged 60 and older recruited from the CHALRS (2011 to 2020). CMM was defined as the presence of at least two out of four conditions: hypertension, diabetes, heart disease, or cardiovascular disease. Cooking fuel and heating fuel were classified into three categories: coal fuel, gas, and electricity. The average treatment effect on the treated was estimated using difference-in-differences methods and instrumental variable difference-in-difference method. Logistic regression was employed to estimate odds ratios for dummy variable outcomes. The 2015 and ealier waves were regarded as the pre-treatment wave, and 2018 and 2020 were regarded as the post-treatment waves. All models were adjusted for demographic factors, socioeconomic status, and lifestyle behaviors. **Results:** Among 12,047 participants (mean age 68.7 years, female 51.7%), 761 newly diagnosed CMM patients were identified. I found that introducing the CHP was associated with a 5.95% reduction in the usage of coal fuel (95% CI: 0.71, 0.96; $p = 0.045$) and increases in the usage of gas and electricity fuel by 23.7% and 19.4% respectively, in cooking. The policy was associated with a significant 10.04% reduction in the odds of CMM (95% CI: 0.45–0.92, $p = 0.009$). **Interpretation:** The CHP significantly reduced coal fuel usage and promoted the adoption of cleaner heating methods among older adults in China. Moreover, the policy was associated with substantially reducing the odds of CMM among adults aged 65 and older, highlighting its potential to improve public health by mitigating chronic disease risks in affected populations. These findings underscore the importance of clean energy policies in addressing environmental and health challenges.

Ind-1528 Excessive Tobacco Taxes Fuel the Illicit Market and Undermine Health Benefits: Longitudinal Evidence from Australia

PRESENTER: **MohammadHossein Hadi**

AUTHORS: Maame Esi Woode, Dennis Petrie

Abstract

Excessive taxation on tobacco products aims to reduce smoking rates but may inadvertently stimulate illicit markets offering untaxed cigarettes, potentially undermining public health objectives. Illicit tobacco not only erodes tax revenues but may also pose heightened health risks due to unregulated production and content. This study provides the first empirical evidence linking these unintended consequences to smokers' health in Australia, where cigarette prices are among the highest globally.

We examine the impact of Australia's unexpected 2010 tobacco tax overhaul on smokers' engagement with the illicit tobacco market and subsequent health outcomes. Utilising a difference-in-differences event study design, we exploit spatial variation in pre-existing cigarette demand—which likely influenced the profitability and presence of illicit markets—to identify the effects of the tax increases. Our analysis employs a population-representative panel dataset that allows for individual-level estimation of cigarette purchase prices.

Our findings reveal that higher tobacco taxes are significantly associated with increased participation in the illicit tobacco market. Specifically, in SA3 regions where baseline per capita cigarette consumption was higher by one pack per week, the likelihood of smokers purchasing untaxed cigarettes increased by approximately 76%, and the quantity purchased rose by about 26% following the tax increases. Furthermore, heightened participation in the illicit market was associated with declines in smokers' physical health. The SF-6D Health State Utility Score decreased by nearly 0.01 points, and the SF-36 General Health Score declined by approximately 1.12 points (significant at the 10% level). No

significant effects were observed on mental health outcomes. These impacts are particularly pronounced among vulnerable groups, such as heavy smokers and residents of socio-economically disadvantaged areas. Our estimates also suggest that the illicit tobacco market contributes to an average annual government revenue loss of around A$3 billion.

These findings suggest that the public health benefits anticipated from higher tobacco taxes may be partially offset by unintended consequences, such as increased consumption of illicit cigarettes, which carry their own health risks and economic costs. This underscores the imperative for designing optimal tax policies that avoid becoming counterproductive by inadvertently fueling illicit markets.

Ind-1620 The Potential Impact of Taxation of Sugar-Sweetened Beverages in Mongolia

PRESENTER: **Mr. Lennert Veerman**, Griffith University
AUTHOR: Undram Mandakh

Background: The burden of obesity in Mongolia is high; more than 20% of the population has obesity. Consumption of sugar-sweetened beverages (SSB) is associated with overweight and obesity and a wide range of chronic diseases. Taxation of SSBs has been recommended as a policy to reduce sugar intake and obesity. Over 130 jurisdictions have now introduced taxes on SSBs to improve population health and/or generate revenue. To have a measurable impact, taxes that result in a consumer price increase of at least 20% are recommended. Mongolia currently applies a 10% sales tax on all non-alcoholic and sugar-sweetened carbonated drinks, but it does not have an excise tax on SSBs. In 2023, a Working Group on SSB taxation was appointed by the Parliamentary Standing Committee on Budget. Our study was conducted for the World Bank in support of this process. We modelled the potential impact of a SSB tax in Mongolia on health and health care spending. Scenarios of taxes that resulted in a 20%, 10% and 5% increases in the price of SSBs were examined. Methods: Using established proportional multi-state modelling methods, the current population of Mongolia was modelled over their remaining lifetime. Consumption data were from the Global Dietary Database (GDD), adjusted for sales volumes from Euromonitor. Euromonitor data were used to model the SSB consumption trend to 2034. Body mass estimates were from the Noncommunicable Disease Risk Factor Collaboration (NCD-RisC), with trend extrapolated to 2034. Disease epidemiology, demography and relative risks were from the Global Burden of Disease 2019. Disease costs were from the Health Insurance General Office. Economic outcomes were discounted at 3% per annum. Results: A tax on sugared drinks leads to health benefits that accrue over time. Over the first 25 years, a tax that results in a 20% increase in the consumer price is estimated to prevent >10,000 cases of obesity, >6,000 cases of type 2 diabetes mellitus, >8,500 cases of ischemic heart disease, ~3,000 cases of stroke, >300 cases of cancers and ~1.2 million tooth cavities, for an overall benefit of an additional 100,000 years of life lived in good health over the lifetime of the 2019 Mongolian population of 3.4 million. Over 25 years, reductions in health care expenditure of up to USD 0.8 million (0.1 million – 1.6 million) are projected. For a 5% tax, these results are about 64% smaller, and for a 10% tax, 44% smaller. If younger age groups continue to consume the same amount of SSBs as they get older rather than reducing their consumption as assumed, the health benefit could be about 100% larger. Conclusion: This analysis shows taxation of SSBs to have large benefits for population health and modest effects on health spending in Mongolia. These results were presented at a stakeholder meeting in Ulaanbaatar, April 2024. An SSB tax amendment in excise tax law passed the parliament in May. The law will enter into force on January 1st, 2027.

Ind-1716 Evaluating the Impact of Singapore's Nutri-Grade Beverage Labels on Prepackaged Beverage Purchases and Diet Quality: A Before and After Study

PRESENTER: **Soye Shin**, Duke-NUS Medical School

The global rise in obesity and non-communicable diseases (NCDs) presents a significant health challenge, with poor dietary intake as a major driver. In Singapore, one in nine individuals has diabetes, exacerbated by high sugar consumption, particularly from sugar-sweetened beverages. To address this, Singapore introduced the mandatory Nutri-Grade (NG) front-of-package (FOP) nutritional label for prepackaged beverages in January 2023, following a two-year grace period for manufacturers to adjust. NG grades beverages from A (healthiest) to D (least healthy) based on sugar and saturated fat content per 100 ml. Beverages are assigned a grade based on sugar content and may be downgraded (but never upgraded) based on saturated fat thresholds. The percentage of sugar in the beverage per 100ml is also displayed, with mandatory labels only for beverages graded C and D.

While prior studies suggest that FOP labels can positively influence consumer choices, most research regarding consumer's choices post-policy implementation rely on one-time controlled experiments, limiting insights into their long-term, real-world effects. Moreover, the impact of labelling policies on sugar-specific reformulation remains underexplored compared to nutrients such as sodium and fats.

This study addresses these gaps by evaluating the impact of NG on both consumer behavior and product reformulation. Using Nielsen longitudinal scanner data from 895 nationally representative Singaporean households, we analyzed beverage purchases before (April 2019-March 2020) and after (April 2023-March 2024) the policy. On the demand side, we employed a fixed-effects regression model to assess changes in household sugar consumption, comparing post-policy outcomes to a counterfactual scenario predicted from pre-policy trends (i.e., what purchases would have been expected in the post-policy period, in the absence of NG). On the supply side, we examined changes in the monthly average sugar and saturated fat content per 100 ml of the beverages purchased as well as the prevalence of artificial sweeteners, common replacements for sugar, before and after, hypothesizing that manufacturers reformulated products to avoid NG C and D classifications during the grace period.

Preliminary results show that NG label reduced household sugar consumption from beverages purchases by 3.10g [95% CI: − 4.99, − 1.23], or 17% per household per day, compared to the counterfactual. These findings align with a study on Chile's food labelling policy, which reported a 9.1 kcal per capita per day decrease [CI: –11.5 to –6.6] (13.2% decrease, equivalent to 2.28 grams of sugar reduction) relative to the counterfactual scenario. On the supply side, the average sugar content of beverages purchased decreased by 1.65g [95% CI: −1.658, −1.647], or 29%, while saturated fat content fell by 0.07g [CI: -0.071, -0.066], or 10%. Additionally, the proportion of beverages containing artificial sweeteners increased by 12.3% [CI: 12.22%, 12.37%], suggesting reformulation efforts to maintain consumer appeal.

By addressing gaps in the literature on the real-world and sugar-specific impacts of FOP labels, this study provides robust evidence of NG's dual effectiveness in driving healthier consumer choices and industry product reformulation. These findings have significant implications for policymakers globally in designing interventions to combat NCDs and promote healthier diets.

Ind-35 Do Cash Transfers Narrow Health Disparities? Evidence from Veterans with Disabilities

PRESENTER: **Johnny Huynh**

We study the effect of cash transfers on health disparities using data from the Department of Veteran Affairs' Disability Compensation program, one of the nation's largest cash transfer programs. Our instrumental variables strategy analyzes disability claims and medical records for over 800,000 veterans, leveraging the quasi-random assignment of these claims to two agents: caseworkers and physicians. Cash transfers reduce mortality on average, but there is considerable heterogeneity. Using only the caseworker instrument, we find that receiving $300 per month reduces 5-year mortality by 1.0 pp. Conversely, the physician instrument recovers a significantly smaller effect of 0.4 pp. We reconcile this discrepancy with a reverse selection-on-gains model, in which caseworkers and physicians differentially target cash transfers but sicker veterans gain the least from transfers. Our results help explain disparate findings in the literature and provide policy implications for targeting transfers to narrow disability-related health disparities. # **Long Abstract** People with disabilities generally experience worse health than those without disabilities. Health disparities based on disability reflect structural barriers like poverty, inadequate medical care, and housing precarity (WHO 2022). Governments worldwide implement cash transfers to reduce economic hardship for people with disabilities, but the effectiveness of cash transfers on improving health is mixed, with variations in methodology, settings, and transfer sizes. Additionally, differences across estimates may suggest that the effect of identical transfers varies across individuals within the same population, known as essential heterogeneity (Heckman et al. 2006). However, evidence on the health effects of cash transfers is limited, particularly for people with disabilities. This paper examines the heterogeneous effects of cash transfers for veterans with disabilities, a key group in redistributive policies in the U.S. Veterans, who have access to comprehensive health insurance, provide a useful contrast to populations for whom transfers significantly expand access to medical care. The study focuses on the VA's Disability Compensation program, which supports veterans with service-related disabilities. Using a dataset of over 800,000 veterans, we estimate the causal effect of cash transfers on health outcomes and explore heterogeneity in this relationship. The data allow us to analyze medical conditions, healthcare utilization, and migration to understand the mechanisms driving treatment effects. To isolate the causal effect of cash transfers, we use an instrumental variables (IV) strategy based on the quasi-random assignment of disability claims to caseworkers and physicians. VA policy prohibits veterans from choosing their assessors, and we validate this design by showing that veteran characteristics do not predict assignments. We also show that caseworkers and physicians vary in leniency. Veterans assigned to lenient agents receive about $300 more per month. Our IV strategy finds that receiving $300 per month reduces 5-year mortality by 0.8 percentage points, increases preventive medical care use, reduces reliance on homelessness services, and slightly lowers the incidence of metabolic diseases.

Ind-1940 Estimating the value of CEPI s 100 day mission in terms of public health, economic and educational benefits using the DAEDALUS model

PRESENTER: **Prof. Katharina Hauck, PhD**, Imperial College London
AUTHORS: Rob Johnson, Patrick Doohan, Andy Torkelson, Peter Windus, Dimitrios Gouglas, Alice Sabino

The Coalition for Epidemic Preparedness Innovations set the world the ambitious goal to put investments in place that allow the development and distribution of an effective vaccine within 100 days of a novel SARS-X virus with pandemic potential being sequenced. The health, economic and social benefits of this investment may far exceed its costs but are currently unknown.

The objective of this work is to estimate the societal value of investments that drastically decrease the time-to-market of a strain-specific vaccine (SSV) after identification of a new sarbecovirus (SARS-X) with pandemic potential, and of a broadly protective sarbecovirus vaccine (BPSV) that would be available prior to the the SSV.

Using the integrated epidemiological-economic model DAEDALUS, we simulate thousands of hypothetical SARS-X epidemic trajectories assuming different levels of investments into vaccine development, manufacturing and deployment are made. We summarise epidemic outcomes into three measures of societal welfare, measured in monetary terms: lives lost, economic losses due to business closures, and lost education due to school closures. We calculate outcomes for synthetic countries constructed by sampling from real-world demographic, societal and economic data from low-, middle and high-income countries.

The value of investing into vaccines is heavily influenced by the timing and severity of future SARS-X pandemics, which are highly uncertain. We estimate the likelihood and severity of future pandemics using data on historic pandemics, and present findings for a milder 'once-in-thirty-years' and a more severe 'once-in-one-hundred-years' pandemic.

Without advance vaccine estimates, we project that a milder pandemic would result in a counterfactual total socio-economic loss of 12.3--24.4% of global GDP and deaths of 0.9--1.6 per thousand population (all findings in interquartile ranges). A more severe pandemic is projected to result in a loss of 84.9-214.6% of GDP and deaths of 5-12.3 per thousand population. Annualised, a pandemic has a loss of 0.47-0.86% of global GDP, and deaths of 0.03-0.05 per thousand population.

An optimistic advance investment scenario reduces time to availability of a SSV to 100 days and increases the speed of vaccine administration due to investments into a 9-billion-dose reserved vaccine manufacturing capacity and a billion-dose BPSV stockpile that can be administered immediately to individuals aged 65 and over. We estimate the value of maximum advance investments to be 0.08-0.15% of global GDP per year. For a milder pandemic, the benefit would be about 3.4-6.7% of global GDP, equivalent to $3.6–7 trillion for the 2023 global GDP of $105 trillion. For a more severe pandemic, we estimate the value of maximum advance investments to be 21.4--44.2% of global GDP, or $22.5–46.4

trillion given 2023 global GDP. We consider additional scenarios to estimate the value of lower-value investments and to disentangle the contributions of the SSV and the BPSV.

Our study has many limitations but can still provide decision makers with some indicative evidence on the broader societal value of advance investments into vaccines that can protect countries around the world against a possibly devastating future SARS-X pandemic.

Ind-1764 The Social Cost of Efficiency-Seeking Plans in OECD Health Systems

PRESENTER: **Simon Combes**

AUTHORS: Bruno Ventelou, Marwan-al-Qays Bousmah, Mohammad Abu-Zaineh

Abstract

Background: Has the quest for efficiency in OECD health systems impacted the social gradient of health? We examined the cross-dynamics of the health system equity-efficiency nexus among OECD countries in the past two decades.

Methods: We used a three-step methodology based on annual macro-level data from 36 OECD countries for the period 2004-2021. First, we estimated the performance of health systems using a stochastic frontier analysis. We then assessed the equity of health systems using simple measures of income-related inequality in self-assessed health. Lastly, we estimated the dynamic relationship between health system efficiency and equity using a panel Granger causality analysis. We also stratified the analysis by type of health system: *viz*. publicly- vs. privately-dominated health service provision.

Findings: We find evidence for a bidirectional causality between health system efficiency and equity. An increase in health system efficiency leads to increasing socioeconomic inequalities in health, yet only in countries with predominantly private health service provision. Interestingly, decreases in socio-economic inequalities in health always lead to higher health system efficiency.

Interpretation: The pursuit of efficiency gains in OECD health systems has not been a precondition for socioeconomic equity in health. Adverse effects of efficiency-seeking interventions on health equity are apparent in the private provision of healthcare. However, addressing health inequalities provides a plausible route to enhance efficiency, regardless of the type of health system.

Funding: This research is part of the UNISSAHEL program, funded by the Agence Française de Développement (AFD).

Keywords: Equity-efficiency tradeoff; Health system; Stochastic frontier analysis; Granger causality; Reverse causality.

Ind-2781 Real-World Insights on Full Vaccination Effectiveness Against Covid-19: Evidence from an Instrumental Variable Approach

PRESENTER: **Mohamad Baihaqi Mohamad Basri**

Background: The Covid-19 pandemic has posed significant global challenges, with vaccination identified as a critical strategy to curb its spread. While prior studies have explored vaccination impacts at national or regional levels, little is known about localised effects, particularly in Malaysia. This study addressed the research gap by analysing the relationship between full vaccination coverage and Covid-19 case rates across 158 districts in Malaysia. It also investigated the influence of sociodemographic and economic factors such as population density and income levels on pandemic dynamics. **Aim:** The research aimed to determine the causal effect of full vaccination on Covid-19 cases at the district level. It sought to answer: *Does full vaccination coverage significantly reduce Covid-19 cases, and how do sociodemographic and economic variables interact with vaccination rates to influence case numbers?* **Methodology:** This study employed an instrumental variable (IV) approach to address endogeneity and potential reverse causality. The number of vaccination centres per district served as the instrument for full vaccination rates, assuming vaccination centres predict vaccination rates but were not directly related to case numbers. Cross-sectional data were used and sourced from the Ministry of Health and the Department of Statistics Malaysia. Variables analysed include Covid-19 case rates, full and partial vaccination rates, population density, percentage of elderly individuals, marital status, median household income and the number of schools per district. The analysis employed log-linear regression to normalise the data, which showed skewed distributions in case and vaccination rates. First-stage regressions validated the instrument's predictive power for full vaccination rates ($p < 0.01$). The second-stage regressions estimated the causal effect of full vaccination on case rates while controlling for confounders like population density and socioeconomic factors. Robustness checks were performed to confirm the validity of the instrument and ensure consistency in results. **Results:** Fully vaccinated populations were shown to significantly reduce Covid-19 case rates. IV estimates indicated that a 1% increase in full vaccination per 1,000 individuals reduced the Covid-19 cases by 2.6% to 12.1%. Partial vaccination, however, was positively associated with case rates, increasing cases by 11.2% to 12.6%, suggesting insufficient protection against highly virulent variants like Delta. Population density was a significant factor, with a 22% higher case rate observed in densely populated districts for every one-unit increase in log population density. Median household income negatively correlates with case rates, where a 1% increase in median income results in a 0.57% to 0.61% reduction in cases. Socioeconomic disparities, such as education level, also played a role, with districts having higher numbers of schools experiencing fewer cases, though this result was not statistically significant. **Conclusion:** The study highlighted the effectiveness of full vaccination in significantly reducing Covid-19 cases, emphasising its importance in densely populated and low-income areas. Policymakers should prioritise equitable vaccine distribution and remove barriers to uptake in vulnerable populations. Additionally, addressing disparities in population density and socioeconomic status was critical for managing pandemics effectively and mitigating their impact on public health.

Ind-121 Primum Non Nocere? Mortality Effects of a Physician Strike in Germany

PRESENTER: **Daniel Avdic**

AUTHORS: Lea Nassal, Martin Karlsson, Nina Schwarz

We study the consequences of a protracted physician strike in German university hospitals in 2006 on patient mortality. We compare striking and non-striking hospitals in a causal difference-in-differences design using a comprehensive dataset of all hospital admissions in Germany linked to digitised records of strike participation. Our results indicate that the strike led to a sharp decrease in hospital admissions and a significant increase in hospital mortality in striking hospitals. Applying a doubly robust LASSO algorithm to adjust for care rationing patient selection, we show that around half of the mortality effect of the strike can be attributed to quality-of-care factors. Finally, we find spillover effects on admissions to nearby non-striking hospitals but no corresponding impact on hospital mortality. We conclude that prolonged industrial action in the healthcare sector may have severe consequences for patient safety unless appropriate risk mitigation protocols are established.

Ind-1393 Efficiency Potentials of Digital Practice-Patient Communication for Outpatient Medical Practices: Results of a Mixed Methods Systematic Review

PRESENTER: **Michael Burkard**

AUTHORS: David Weber, Martin Emmert

Background: The shortage of skilled workers and demographic changes among both patients and healthcare professionals are leading to an increasing workload in outpatient medical practices. These trends are contributing to healthcare professionals burning out and the quality of outpatient medical care being at risk. Medical practice staff craves support, especially with communication-related processes. Digital solutions for practice-patient communication (PPC) have the potential to relieve the practice staff and maintain or even optimize medical quality. As the body of knowledge on digital PPC solutions is growing in terms of their impact on medical quality, research lacks knowledge on their efficiency in outpatient medical care.

Objective: This study aimed to identify and evaluate digital PPC solutions' efficiency potential for outpatient medical practices.

Method: This mixed methods systematic literature review was conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The literature search was conducted within PubMed and The Cochrane Library and included international studies that assessed digital PPC solutions' impacts on medical practice efficiency. Peer-reviewed full texts written in English and published between January 2019 and June 2024 were selected. Data were narratively summarized, categorized in time, staff, material, and cost efficiency, and evaluated regarding their impact. For synthesis of the quantitative and qualitative data, a convergent integrated approach was applied based on the JBI Manual for Evidence Synthesis. Bias assessment was performed using the AXIS (quantitative studies) and CASP (qualitative studies) checklists.

Results: The systematic screening comprised 4,237 articles. Finally, 22 studies (15 quantitative, 7 qualitative) were identified, including 2,670 physicians, 21 non-physician staff, and 301,534 patient appointments. The identified studies assessed efficiency potentials for the following PPC solutions: video consultation (10 studies), video or telephone consultation (not further specified; 8), online messaging (3), SMS (2), patient portal (1), online scheduling (1), and remote patient monitoring (1). Time was the dominant efficiency category with preparation time (15 categorizations) and process duration (17). Interestingly, staff (3) and material (1) were rarely directly mentioned and cost not at all. Summarized, video consultation was rated positively or equally (81%) and online messaging negatively (75%) compared to the standard of communication, whereas SMS, patient portal, online scheduling, and remote patient monitoring were exclusively rated positively or equally. When preparation time was mentioned, most studies (70%) reported positive impacts for all PPC solutions. In terms of process duration, however, the results were indifferent with a positive trend. Regarding staff, there was a tendency that additional non-physician staff were needed for video consultations.

Conclusions: Except online messaging, all other PPC solutions examined were associated with efficiency improvements or equivalent efficiency outcomes. However, video consultation was also associated with some negative efficiency impacts, which is why a differentiated look at individual PPC solutions is necessary. Since the literature has largely focused on video consultation and time efficiency, further research on other PPC solutions and efficiency categories is required. The results can serve as guidance for policy and practice in the further development and implementation of efficient digital PPC solutions.

Ind-126 Gendered Pathways to General Practice: A Cohort Analysis of Career Intentions Among UK Medical Graduates

PRESENTER: **Catharina Savelkoul**

Background and Aim The United Kingdom faces a critical shortage of General Practitioners (GPs), with the number of GPs per 100,000 population declining from 67 in 2009 to 60 in 2018. Despite policy initiatives to increase GP training numbers, including a 2015 government

pledge to add 5,000 GP positions by 2020, the NHS has instead lost 1,694 full-time fully qualified GPs since 2015. This shortage is exacerbated by increasing GP workload, with consultations surging to approximately 30.5 million per month as of February 2024, and the mean number of patients per GP escalating by 17% since 2015 to 2,260. These trends are further compounded by changing health needs and policies aimed at developing more primary and community-based healthcare. Given the scale of the GP shortage, it is crucial to understand the factors that shape medical graduates' intentions to pursue a career in general practice. This study investigates how gender interacts with academic performance to influence GP career intentions among UK medical graduates. While previous research has consistently shown that women are more likely than men to choose a career in general practice, fewer studies have examined how academic achievement moderates this gender difference. By exploring this interaction, we get a deeper understanding of gender-specific career decision-making patterns, which could inform more targeted interventions to boost GP recruitment and retention. **Methods** We conducted a comprehensive cohort analysis using data from the UK Medical Education Database (UKMED) and the 2018 National Training Survey (NTS). The study population comprised around 14,000 medical graduates in their Foundation Programme year 1 or 2. We employed a multi-stage data linkage process, merging NTS data with UCAS application data. The primary outcome measure was intention to pursue a GP career. We utilised a survey design-adjusted logistic regression model, incorporating sampling weights and stratification by medical school. The model included interaction terms between gender and EPM group to capture differential effects across performance levels. To account for potential confounding factors, we adjusted for socioeconomic background, ethnicity, age at entry to medical school, and medical school. **Results** Female medical students are consistently more likely to express an intention to pursue a career in General Practice (GP) than male students, regardless of academic performance and medical school. As academic performance increases, the likelihood of male medical students intending to pursue GP decreases more sharply compared to female medical students, whose GP intention remains relatively stable across performance levels. **Conclusion and Policy Implications** Our findings reveal a "GP paradox" among top-performing female medical students, who maintain a strong interest in general practice despite the overall negative correlation between academic performance and GP intention. This challenges assumptions in the literature about uniform influences of academic achievement on specialty choice across genders and highlights the importance of considering gender-specific factors in understanding career decision-making processes. There is a need to explore the underlying reasons for this gender difference, including societal expectations and perceptions of GP roles. Such insights could inform targeted interventions to enhance GP recruitment.

Ind-294 The Impact of Scale Expansion of Tertiary Hospitals on the Outflow of County-level Medical Personnel-Take Shaanxi Province as an Example

PRESENTER: **Yaxin Zhao**, Xi'an Jiaotong University

Backgrounds:

Promoting the construction of a county-level medical community is the key direction of healthcare reform in China. However, since the initiation of the new healthcare reform, the expansion of tertiary hospitals has been increasingly rampant. This potentially causes issues such as the loss of healthcare personnel in county areas and uneven distribution of medical resources. However, there is still a lack of scientific empirical support on whether the scale expansion of tertiary hospitals siphon county medical personnel.

Methods:

The data were obtained from the Database of Health Manpower Information in Shaanxi Province, Shaanxi Health Statistics Yearbook, and the Shaanxi Statistical Yearbook. The study selected 342529 medical personnel data of county-level secondary hospitals and 185474 medical personnel data of county-level primary care facilities from 2015 to 2019 as research samples. The study employed Difference-in-Differences models and mediation effect models to examine the impact of the expansion of tertiary hospitals on the outflow of county-level medical personnel and its mechanisms.

Results:

The expansion of the number, number of beds, and number of health technicians in tertiary hospitals increased the probability of medical personnel outflow from county-level secondary hospitals by 24.6% (OR=1.246, 95% *CI*: 1.058-1.478, $P<0.05$), 27.6% (OR=1.246, 95% *CI*: 1.058-1.478, $P<0.05$) and 27.9% (OR=1.246, 95% *CI*: 1.058-1.478, $P<0.05$), respectively. The probability of medical personnel from secondary hospitals flowing to tertiary hospitals increased significantly by 1.410 times, 1.270 times, and 1.367 times, respectively. The expansion of the number and the number of beds in tertiary hospitals had no statistically significant impact on medical personnel from the county-level primary care facilities. When the number of health technicians in tertiary hospitals increased by one unit, the probability of outflow from medical personnel from primary care facilities increased by 19.1% (OR=1.191, 95% *CI*: 1.045-1.357, $P<0.01$). The likelihood of flowing to secondary and tertiary hospitals increased by 1.160 times and 1.682 times, respectively. The siphon effect is not lasting on medical personnel from secondary hospitals, and is lagging on the medical personnel in county-level primary care facilities. The number of outflows from county-level secondary hospitals has a mediating effect between the effects of tertiary hospitals' expansion on the outflow of medical personnel from county-level primary care facilities. The expansion of tertiary hospitals had the most obvious siphon effect on medical technicians under 45 years old and those with junior college or above in areas with scarce medical resources.

Conclusions:

The scale expansion of tertiary hospitals has a different siphon effect on the medical personnel of county-level secondary hospitals and primary care facilities. The siphon effect on the medical personnel of county-level secondary hospitals is obvious but is limited on the personnel in primary care facilities. There is a transmission effect of expansion on the outflow of county-level medical personnel. Policymakers should pay attention to the personnel who are easily attracted by expansion, strengthen government regulatory capabilities, and clarify the functional positioning of tertiary hospitals to promote the development of county-level health talents.

Ind-1206 The Impact of Pandemic on the Quality of Future Physicians: Evidence from China

PRESENTER: **Ming Gu**

AUTHOR: Kate Bundorf

Attracting medical students with strong academic aptitudes is vital for the future quality of healthcare. This study assesses how COVID-19 pandemic, an external shock close to the time of application, affected students' career trajectory by attracting or dissuading them from entering the medical major, thereby impacting the quality of students admitted to medical majors in China. We utilized nationwide admission decisions across provinces to 49,321 bachelor's degree granting programs between 2018 and 2023. The main outcome measure is the lowest Gaokao test rank among the admitted students for each program from their home province. Students' exposure to the pandemic was measured by the daily average of the number of new cases per 100K residents and the daily average of COVID-19-specific mortality rate during the 90-day period before application submission. We find that pandemic intensity in students' home province is positively associated with the rank percentile of students admitted to the medical majors. This effect is more concentrated in less economically developed regions and programs in non-elite universities. The COVID-19 pandemic raised students' interest in medicine as well as other health-related majors. Further analysis reveals that changes in desires for job security likely played a vital role. Given the long-term predictive validity of academic aptitude for physician performance, our results indicate an improvement in the quality of future physician workforce, especially in less economically developed regions.

Ind-1446 Does Schooling Reduce Child Maltreatment? Evidence From School Entry Laws in South Australia

PRESENTER: **Adam Akmal Dzulkipli**

AUTHORS: Leonie Segal, Nicole Black, David Johnston

Background and Research Aim:

Child maltreatment victims are at high risk of suffering from adverse outcomes, including poor physical and mental health. Correspondingly, reducing children's exposure to abuse and neglect is a key policy objective. Unfortunately, rigorous evidence on policy interventions in this space remain fairly limited. In this paper, we use school entry laws in South Australia to examine whether entering school earlier in life can reduce children's exposure to maltreatment in the household at ages 4-5.

Methodology:

In South Australia, children born before 1 May are eligible to start school in the calendar year they turn 5 years old, whereas children born on or after 1 May are only eligible to start school the following year. We use this eligibility criteria in a regression discontinuity (RD) design to identify the impact of schooling on children's exposure to maltreatment in the household, by comparing the outcomes of children born just before the 1 May cut-off to children born shortly thereafter. Our analysis uses data from the Impacts of Child Abuse and Neglect (iCAN) study, which linked records from multiple government and semi-government agencies in South Australia (SA) to create a large dataset of the universe of children born in the state from 1986 to 2017.

Preliminary Results:

We find that most children comply with the school entry rules in South Australia. Children born just before the 1 May cut-off are 80.4 percentage points more likely to be enrolled in school in the calendar year of their 5th birthday. Correspondingly, we find that these children are 2.6 percentage points (or 26% relative to the control mean) less likely to be notified to CPS for suspected maltreatment and have 32% fewer CPS notifications in that corresponding year. Using data on reporters, we show that this aggregate effect is predominantly driven by a reduction in notifications from reporters outside the education sector. In comparison, we find a small increase in notifications provided by education professionals (e.g. teachers, early childhood educators, childcare employees). Disaggregating the analysis by maltreatment type suggests that the reduction in overall CPS notifications is mainly driven by a reduction in emotional abuse, instead of physical or sexual abuse. Consistent with this finding, we find no effect on emergency department visits for injuries. Heterogeneity analyses suggest larger reductions in CPS notifications among disadvantaged children and children with past maltreatment exposure. Lastly, we examine whether schooling generates spillover effects on younger siblings who are not themselves enrolled in school and find no evidence of adverse spillovers.

Conclusion:

We find that being in the school environment leads to tangible reductions in underlying exposure to maltreatment. Our findings run counter to a large body of literature which documents mostly negative impacts of starting school at an early age on child outcomes; we find that commencing school earlier may actually be beneficial for children who are at risk of maltreatment. Thus, future work should take this into consideration when discussing the overall welfare implications of delaying children's entry into school (i.e. 'redshirting').

Ind-679 The Role of Early Life Conditions on the Development of Child Adaptive Behaviour

PRESENTER: **Mario Martinez-Jimenez**
AUTHOR: Edith Aguirre

The prevalence of neurodevelopmental disabilities, including autism spectrum disorder and ADHD, has risen significantly in the past decade. This study examines the impact of early-life factors, such as infant health at birth and breastfeeding, on adaptive behaviour development by age three in the United Kingdom. Neurodevelopmental disabilities are often diagnosed using adaptive behaviour scales, which assess communication, physical skills, and social-emotional development. Using data from 4,811 children in the UK Household Longitudinal Study (2011–2023), we analyse the role of infant health at birth, breastfeeding practices and parental and household characteristics. Employing a set of robust empirical methodologies, we find that breastfed children exhibit stronger adaptive behaviour by age three. In contrast, children with poor perinatal health show slower development. These adverse effects are particularly pronounced among boys and children from non-white British maternal backgrounds. Socioeconomic status plays a key role in shaping these developmental outcomes. Our findings underscore the importance of early-life interventions to support cognitive development, especially for vulnerable populations. Addressing disparities in early childhood conditions could help mitigate long-term developmental challenges.

Ind-695 Lockdown Silver Linings: How COVID-19 Improved Parents Drinking Behaviours and Well-Being

PRESENTER: **Martina Repetto**
AUTHORS: Susan Sawyer, Julie Moschion, Ms. Susan Méndez

Background: The COVID-19 pandemic led to unprecedented lockdown measures worldwide, significantly impacting daily life. While research has explored the lockdown's broad effects on health behaviours and mental health, establishing causality remains challenging due to data limitations. Among these studies, parents have received relatively little attention, even though they make up a considerable segment of the population. In Australia, 50% of households had children under 15 in 2021, amounting to roughly 9.7 million people. Parents were particularly affected by lockdowns with the closure of schools and childcare facilities. These suddenly increased caregiving and teaching responsibilities without access to usual support networks, potentially affecting their well-being and health behaviours. **Objectives**: This study investigates the causal effects of COVID-19 lockdowns on parents' well-being and alcohol consumption in Victoria, Australia, addressing the research gap concerning the pandemic's specific effects on parents. **Methods**: We employ a quasi-natural experimental design using data from the Victorian Adolescent Health Cohort Study (VAHCS), which began in 1992 with over 2,000 participants aged 14 and includes 11 waves up to 2020. The exogenous timing of the COVID-19 lockdowns allows us to create treatment and control groups: parents interviewed after the first lockdown are the treatment group, while those interviewed just before serve as the control group. Our empirical strategy follows a difference-in-differences estimation to determine the causal effects of lockdowns. We use detailed measures of alcohol consumption over the past week and comprehensive clinical questionnaires to assess mental health. **Key Results**: Our findings indicate a negative effect of the lockdown on high-risk and binge drinking. Specifically, there is a 5.9 percentage point decrease in the likelihood of consuming five or more standard drinks in a day within the past two weeks and a 5.2 percentage point decrease in the likelihood of being a drinker or binge drinking in the previous weeks. This reduction is driven by fathers, with no significant change observed in mothers' drinking behaviours. There are no significant changes in the average units of alcohol consumed daily or weekly. Using more stringent measures of mental health than past studies and focusing on parents, we find different results. On average, we do not observe any effect of the lockdown on parents' main measures of mental health. When significant changes are observed, they indicate a positive impact: fathers exhibit a 6.5 percentage point decrease in the likelihood of being diagnosed with depression, while mothers report higher satisfaction with the relationships with their partners. **Conclusions**: The lockdown measures appear to have had a positive effect on reducing high-risk and binge drinking behaviours, especially among fathers, likely due to increased time at home and social life restrictions. Additionally, we show decreased probability of depression for fathers and improved relationship satisfaction reported by mothers. The findings suggest that lockdown-induced changes in social environments and routines can have beneficial effects on certain health behaviours and family dynamics, highlighting the complex and sometimes positive impacts of public health measures on different demographic groups.

Ind-985 Examining the Impact of Parental Separation on Children's Physical and Mental Health Outcomes

PRESENTER: **Xiaoxue Dou**
AUTHORS: Bao Nguyen, Luke Brian Connelly, Sabrina Lenzen

Background: The quality of parental relationships can have profound impacts on children's physical and mental health. There are growing concerns that parental separation may have detrimental effects on children's overall well-being and development. Many surveys and various statistical methods have been used to explore the association between parental separation on children's physical and mental health outcomes. However, the causal effects in this area are less documented, with studies so far not addressing endogeneity issues in the relationship.** **Objective/Aim:** We aim to fill the gap by providing robust estimates on the dynamic effects of parental separation on children's health outcomes using a difference-in-differences framework. **Method:** We use data from the Longitudinal Study of Australian Children (LSAC), an ongoing nationally representative study that commenced in 2003. The sample includes children from both urban and rural regions across all Australian states and territories. The study follows two cohorts, "B-cohort" (aged 0-1 years in 2003-04) and "K-cohort" (aged 4-5 years in 2003-04), tracking their development from childhood into adulthood. To estimate the impact of parental separation on children's physical and mental health outcomes, we use a dynamic difference-in-differences (DID) framework, comparing health outcomes of children who experienced parental separation compared to those who do not. Because the timing of family separation among children vary significantly in our data set, we use the estimator proposed by de Chaisemartin & D'Haultfœuille (2024). The estimator is suitable for situations where treatment timing differs and treatment lags may affect the outcome. This approach also accounts for heterogeneity in treatment intensity of trajectories. **Results:** Our analysis reveals that parental separation significantly influences children's mental health. The adverse psychological effects demonstrate the largest effect immediately after parental separation, followed by a gradual regression toward baseline levels. Our findings indicate no statistically significant impact of parental separation on children's physical health outcomes. Stratified analyses

demonstrate gender-specific variations, with girls exhibiting greater psychological vulnerability to parental separation compared to their boys counterparts. Further examination of parental educational attainment reveals that children of parents who did not complete twelve years of education or its equivalent demonstrate the most severe and persistent psychological impacts post-separation. Notably, these children fail to demonstrate the typical trajectory of returning to baseline psychological functioning observed in other groups. **Conclusion:** Our findings have significant implications for policy and practice. The results underscore the necessity for targeted mental health interventions during post-separation periods, particularly for girls and children from families with lower educational attainment.

abs-os136 Assessing Drivers of Variation in Health Care Spending Across US Counties, 2019

PRESENTER: **Joseph Dieleman**, University of Washington

AUTHORS: Maitreyi Sahu, Max Weil, Sawyer Crosby, John W Scott, Azalea Thomson, Meera Beauchamp, Kayla Taylor, Drew DeJarnatt, Marcia Weaver

Background: While the US as a whole has world leading health spending per capita, there is substantial variation in health care spending across US states and counties. The state of Utah spends close to a third as much per person as the state of Alaska. Furthermore, much of health care spending is driven by even more local factors, such as prices, underlying health, and demand. There is little research assessing variation of health care spending across US states, and even less exploring variation at the county level. Understanding drivers of health care spending across US counties could be valuable for developing policies to lower health care spending and improve outcomes. In this paper we focus on this within-country variation and estimate the contributions spending variation to of (i) population age, (ii) health conditions prevalence, (iii) service utilization, and (iv) service price and intensity to overall health care spending across US counties.

Methods: Data for four key drivers of spending per capita were extracted for 3110 US counties, 148 health conditions, 38 age-sex groups, four payers, and seven types of care for 2019 from the University of Washington's Disease Expenditure Project. Service utilization was measured as service volume per prevalent case, while price and intensity was measured as spending per visit, admission, or prescription. Linear regression and Das Gupta and Shapley decomposition methods were used to estimate the contribution of each factor.

Results: In 2019, 70.3% of cross-county health care spending variation was explained by service utilization, while population age, disease prevalence, and price and intensity of services explained 4.7%, 3.9%, and 21%, respectively. The rate at which these factors contributed to variation in spending varied by payer, type of care, and health condition. Utilization per prevalent case was most associated with insurance coverage, median income, and obesity, while service price and intensity was most associated with median household income. Differences in cross-state spending levels were also attributed to different factors. For Utah, the state with the least health care spending per capita, spending rates were lower for all types of care due to the young age profile. For Alaska, the state with the highest spending, spending rates were relatively high for ambulatory, hospital inpatient, and emergency department care. For all three types of care, high service price and intensity contributed most to the above-average spending. While service utilization was the primary driver of cross-country variation, spending increases over time were driven mostly by increases in price and intensity of care.

Conclusions: Variation in health care spending among US states and counties was largely related to variation in service utilization. Understanding the drivers of spending variation in the US can help policymakers reduce or at least maintain US health care spending in the future.

abs-os184 Estimating Health Spending on Diseases and Injury in Australia

PRESENTER: **Emily Bourke**

AUTHORS: Geoff Callaghan, Nikita Ramachandran

Background: *Health system spending on disease and injury in Australia 2022–23* analyses Australia's national health spending to provide additional detail about the people receiving care and the conditions and diseases being treated. In this analysis, 2022–23 data is presented for each of the 17 Australian Burden of Disease Study (ABDS) groups and 220 conditions within these groups.

Methods: This analysis uses a range of modelling techniques to apportion health spending to population groups based on age and sex, and to ABDS groups and to conditions within those groups. Spending for three additional groups, well care, the treatment of risk factors and examination and observation NEC are also included. Spending estimates are calculated from national datasets of hospital admissions, emergency departments, outpatient clinics, non-hospital primary care and referred medical services, prescription pharmaceuticals, and dental. Diagnostic information is based on the conditions recorded in each episode of care at a hospital, or from survey data for non-hospital services, and costs are distributed across comorbidities. This analysis also includes a time series of data between 2013–14 and 2022–23.

Results: In 2022–23 the highest spending was for cancer ($18.9 billion), followed by cardiovascular diseases ($16.2 billion), and musculoskeletal disorders ($15.9 billion). Cancer also had the highest burden, or human cost of disease in 2023. Second highest in terms of disease burden was mental health conditions and substance use disorders.

Spending on cancer more than doubled from $9.3 billion in 2013–14 to $18.9 billion in 2022–23 and has been the highest ranked disease group in terms of spending since 2014–15 accounting for around 10% of spending each year. Over the period 2013–14 to 2022–23, the largest increase in cancer spending was observed for prostate cancer, non-melanoma skin cancer, breast cancer and bowel cancer.

There was $13.3 billion spent on well care in 2022–23. The majority of this spending (82%) was for routine dental checkups and cleaning and pregnancy and postpartum care.

Conclusion: Whilst findings in this analysis are based on estimates (rather than direct observations) these data provide important insights into the nature and drivers of health spending, such as how an ageing population affects health spending.

abs-os135 Mapping Spending by Disease in Switzerland: Overcoming the Challenge of Limited Diagnostic Data in a Fragmented Health Care System

PRESENTER: **Michael Stucki**, University of Zurich
AUTHORS: Stefan Scholz, Lukas Kauer, Maria Trottmann, Mr. Simon Wieser

Background

Studies from a broad range of countries have demonstrated the usefulness of disease-specific spending estimates in assessing key health economic questions, such as identifying spending drivers and assessing overall healthcare productivity. However, in Switzerland's fragmented healthcare system, limited data on diagnoses complicates these efforts. This study breaks down total healthcare spending over a 10-year period from multiple perspectives, providing new insights into health care spending and its drivers.

Methods

We decompose total healthcare spending according to Swiss National Health Accounts (NHA) in 2012, 2017 and 2022 by 65 diseases from 20 aggregated disease groups, 19 health services, 6 payer categories, 20 age groups, and patient sex. Given the absence of a nation-wide registry of healthcare service use across services and payers, we combine a multitude of existing data sources to assign spending to diseases. These sources include a hospital inpatient registry, long-term care patient assessments, claims data from health and accident insurance, and drug sales data. In outpatient care, we identify diseases at the individual level based on diagnostic clues in claims data, such as disease-specific medication. The resulting spending estimates are scaled to align with total NHA spending.

Results

Per capita health care spending in Switzerland increased from 8'329 Swiss francs (CHF) in 2012 to 10'423 CHF in 2022 (+25.1%). Total healthcare spending increased by 37.4% over the same period. The most expensive aggregated disease group in all years were *musculoskeletal disorders*, accounting for 11.5% of total spending in 2012 and 2017 and 11.1% in 2022. They were closely followed by *mental and substance use disorders* (10.7%; 10.3%; 10.2%), and *neurological disorders* (10.4%; 10.4%; 9.7%). The single most expensive disease was *Alzheimer's and other dementia* (4.8 bn CHF in 2022; 5.2% of total spending). The largest increase in spending between 2012 and 2022 was observed for *skin and subcutaneous diseases* (+74.1%), *endocrine diseases* (+64.4%), and *neoplasms* (+47.6%). The increase was only modest for *oral disorders* (+5.4%). The spending increase was mostly driven by a substantial increase in outpatient spending, for instance accounting for 62.4% of the total spending increase in *musculoskeletal disorders*. For few disease groups, spending for medication was the most important driver, for example *digestive diseases* (54.5% of the total increase), *endocrine diseases* (66.2%), and *neoplasms* (38.0%). *Neurological disorders* dominated spending in the elderly, largely due to the high spending in long-term care.

Conclusions

Healthcare spending in Switzerland has increased substantially over recent decades. By breaking down total spending by disease, service type, payer, and patient characteristics, we build a framework to better understand the structure of healthcare spending and the drivers behind its increase. Despite the lack of diagnostic coding in many areas of the Swiss healthcare system, we successfully estimated spending across multiple perspectives over a 10-year period. Our findings provide essential inputs for more in-depth analyses of spending drivers and assessments of healthcare system productivity.

abs-os416 Do Adults and Adolescents Value EQ-5D-Y-5L Differently: A Quantitative Exploration Using DCETTO

PRESENTER: **Yiting Luo**
AUTHORS: Richard Norman, Brendan Mulhern, Deborah Street, Rosalie Viney

Objectives

An important hurdle for the development of value sets for paediatric preference-based measures such as EQ-5D-Y-5L is the largely unaddressed normative and methodological questions regarding whose preferences (adult or youth preferences) and which perspectives (self-perspective or a 10-year-old child's perspective) should be used. This study investigates similarities and differences in the valuation of EQ-5D-Y-5L health states by adult and adolescent samples and explores whether different value sets are required. This is the first study to systematically compare the impact of perspectives on preferences in adult and adolescent populations using DCE with duration (DCETTO). This work aimed to inform the development of Australian value set(s) for the EQ-5D-Y-5L.

Methods

Overall, 250 DCETTO choice sets were designed. In both samples, each respondent was presented with 20 choice sets with only one perspective. An online survey was administered to a representative sample, with respect to age, gender and region, of the Australian adult population and to a representative sample of the Australian paediatric population aged between 12-17 years old. Conditional logit models were used to estimate utility weights for the DCETTO and estimates were compared across perspectives and samples. Relative attribute importance (RAI) was estimated using the Delta method. Indicative value sets were calculated based on the DCETTO estimates. Heterogeneity was explored using latent class analysis (LCA).

Results

Overall, 2020 adults and 2151 adolescents aged between 12-17 were recruited and fully completed the survey. A number of key differences in model parameters, and therefore value sets, between the adult and adolescent samples were identified. This included significant differences in preferences for self-care. Exploration of RAI suggested for both of the perspectives, adults weighted pain/discomfort (PD) and mobility (MO) significantly differently where PD was the most important and MO was the least important while PD was the most important and SC was the least important in the youth sample for both of perspectives. Youth values from a 10-year-old perspective provided 8.4% worse-than-dead (WTD) health states and the worst health state (55555 in EQ-5D-Y-5L) valued at -0.417, a higher valuation than those from youth self-perspective or adult values with either perspective, which yielded more than 14% of WTD health states and worst health state all valued at below-0.513.

Conclusion

This study is one of the first EQ-5D-Y-5L valuation studies in both adult and adolescent samples. The evidence supports the hypothesis that adults and adolescents have different values for EQ-5D-Y-5L, influenced by the perspectives used, and the differences are more significant in certain dimensions which might drive the variation in values estimated. The results will inform the development of EQ-5D-Y-5L national value sets in Australia by informing the normative decision that needs to be made regarding which samples and perspectives to use.

abs-os426 Improving Health-Related Quality of Life Measurement for Children: Adapting the CHU9D with Visuals and Audio

PRESENTER: **Christine Mpundu-Kaambwa**
AUTHORS: Katherine Stevens, Julie Ratcliffe, Philip Powell, Donna Rowen

Background Children may find self-reporting health-related quality of life (HRQoL) using patient-reported outcome measures presented in text-based formats difficult, particularly younger children and those with developmental delays or chronic illnesses. Given the importance of inclusivity in health assessments, there is a need to explore alternative communication methods, such as visuals and audio. The Child Health Utility 9 Dimension (CHU9D) instrument, a generic utility-based paediatric HRQoL tool for children aged 7-17, currently exists only in text form. The aim of this study was to assess the feasibility of adapting the CHU9D with pictorial and audio elements to enable self-completion by children who face challenges with traditional text formats.

Methods The study followed a four-stage process. First, a systematic review was conducted to examine existing pictorial and audio-based HRQoL assessments. In Stage 2, a collaborative codesign approach was used to develop child-friendly pictorial representations for the dimensions "Worried," "Sleep," and "Daily Routine," with input from a graphic designer and clinicians, focusing on image complexity, colour, and visual appeal. Stage 3 involved the creation of pictorial response scales to complement the CHU9D's existing 5-point text response scale, along with audio recordings (using both male and female voices) for each question. Lastly, Stage 4 included semi-structured pilot interviews with children with long-term health conditions and disabilities. These interviews assessed the acceptability and comprehension of the adapted instrument.

Results The semi-structured interviews were conducted with 14 children (6 boys and 8 girls) aged 7-14 years. The children had a range of health conditions, including speech delay, autism spectrum disorder, attention-deficit/hyperactivity disorder, and physical disabilities. Among these participants, 79% understood the questions without requiring additional clarification, and 86% found the pictorial representations accurately depicted the intended emotions or states. Feedback indicated strong acceptance of the adapted instrument, with children appreciating the colourful, engaging characters. Positive responses highlighted that the audio voiceovers improved comprehension, with children expressing preferences for both visual and audio options.

Conclusion The study demonstrates that pictorial and audio adaptations of the CHU9D instrument may improve inclusivity and comprehension for children with diverse capabilities. The positive reception of the codesigned instrument suggests potential for wider use in paediatric HRQoL assessments.

abs-os508 Mapping From EQ-5D-Y-5L to EQ-5D-Y-3L: Exploration of Methods

PRESENTER: **Mina Bahrampour**
AUTHORS: Tianxin Pan, Juan Manuel Ramos-Goni, Mark Oppe, Aureliano Finch, Brendan Mulhern, Nancy Devlin, Yan Feng

Abstract

Background:

When specific utility values for health-related quality of life (HRQoL) instruments are not available, mapping algorithms, or 'crosswalks,' are often used in economic evaluations. EuroQol has developed two youth specific measures the EQ-5D-Y-3L and the EQ-5D-Y-5L. While direct estimation of preferences to establish a value set for the EQ-5D-Y-5L is still unpublished, value sets for the EQ-5D-Y-3L already exist. By applying mapping algorithms, existing Y-3L value sets can be used while preference studies for the Y-5L are still underway. This study aims to explore the different response mapping methods to map Y-5L responses to Y-3L responses.

Methods:

Various methods were explored using data from the Paediatric Multi-Instrument Comparison Study (P-MIC) within the QUOKKA project Australia. Several response mapping models, including ordered logistic regression (OLR) and multinomial logit (MNL), and nonparametric model, were employed as mapping approaches. Models were fitted with and without a latent factor to count for correlation between observations that come from the same respondent. The primary criterion for model selection was prediction accuracy (using statistical methods such as mean absolute error and mean squared error). Information criteria (AIC and BIC) were also used as predictors for selecting the best-fitting model.

Results:

The sample comprises data pooled from both baseline and follow-up questionnaires collected by PMIC. The total combined sample size was 8,920, consisting of 5,578 self-reports and 3,342 proxy-reports. Analysis indicated that the MNL without a latent factor proved a better fit among the tested methods. The method using a coefficient for self and proxy data demonstrated a better fit.

Conclusion:

Our mapping algorithms facilitates the estimation of health utilities in childhood when EQ-5D-Y-5L data is unavailable. The results of this study have been reported using Australian data set. The performance of these algorithms in childhood populations of other countries and severe condition groups, is yet to be evaluated. The statistical analysis plan and code developed from this study will inform the development of the international Y-3L Y-5L mapping algorithms.

abs-os377 Valuation of the EQ-5D-Y-5L Using Discrete Choice Experiment Methods That Account for Nonlinear Time Preferences

PRESENTER: **Brendan Mulhern**, University of Technology Sydney
AUTHORS: Bram Roudijk, Peiwen Jiang, Rosalie Viney, Nancy Devlin, Alice Yu, Deborah Street

Background

In the development of EQ-5D-5L value sets for use in cost utility analysis, Discrete Choice Experiment (DCE) methods that can account for non-linear time preferences (i.e. assume discounting of duration) are becoming more widely used, and there is emerging evidence that nonlinear time preferences do occur. However, this DCE approach is has yet to be tested for the valuation of paediatric preference based measures such as the newly approved EQ-5D-Y-5L. The aims of this study were to test the feasibility of using DCE methods which account for nonlinear time preferences in the valuation of the EQ-5D-Y-5L, and to explore the impact of valuation perspective (valuing from the self perspective, or the perspective of a 10 year old child) and parent status on the value sets produced.

Methods

A representative Australian adult general population sample completed an online survey which included the completion 15 two stage triplet choice sets. Stage 1 presents health states A and B described by EQ-5D-Y-5L for a fixed duration, and Stage 2 presents health state B and health state C which is full health for a shorter duration. Depending on arm assignment, respondents were asked to take the self or 10 year old child perspective when completing the choice sets. A Bayesian efficient design was used to construct the DCE design. This was done using a series of four design updates based on priors produced using sample sizes of 200 and resulted in a design with 600 choice sets for each perspective. Data were analysed using correlated mixed logit models.

Results

There were 955 and 947 respondents in the self and 10-year-old perspective arms, respectively. In both arms, significant nonlinear time preferences were detected in the ‘self’ (self discount rate was 17%, and ’10-year-old’ discount rate was 15%). Respondents exhibited higher

utility decrements (resulting in a utility value set with a wider range and more states valued negatively as 'worse than dead' (WTD) when valuing from a 10 year old child perspective. This resulted in value sets ranging from 1(for the best health states EQ-5D-Y-5L describes) to -1.42 (for the worst health state), with 42% WTD for the 10 year old arm, and ranging from 1 to -1.1 (26% WTD) for the self perspective. Across all arms, Pain and Discomfort had the largest overall decrement (a proxy for severity). Sensitivity analysis also revealed that being a parent or not influenced values for the self-perspective (but not the 10 year old), with parents producing value sets with a smaller range.

Conclusions

This is the first study to use a nonlinear DCE approach in the valuation of the EQ-5D-Y-5L, and in paediatric HRQoL more generally. Respondents discount future years when valuing states both for themselves and a 10-year-old. There is some evidence that DCE approaches accounting for nonlinear tine preferences are feasible for the valuation of the EQ-5D-Y-5L. However the value set ranges are wider than those produced for adults instruments using similar approaches, and the validity of this requires further investigation.

abs-os499 Economic Burden of High Temperature on Health Systems in Brazil

PRESENTER: **Huiqi Chen**

AUTHORS: Dorothea Nitsch, Josephine Borghi, Letícia Xander, Kai Wan, Shakoor Hajat, Everton Nunes da Silva, Ivan Augusto Cecilio e Silva, Zhifu Mi, Anna Foss

Background: Climate change poses a significant threat to global health, with high temperatures being among the most direct influencing factors. Current research often focuses on specific health outcomes over relatively short time spans, with limited insight into the broader economic burden, particularly within low- and middle-income countries. This gap calls for comprehensive understanding of the medium-term burden of heat on health systems including economic implications. Brazil, with its multitude of different climate zones and socio-economic disparities, provides a suitably diverse setting to explore how heat affects health systems, and the effectiveness of adaptation strategies. Therefore, this study aims to assess the impact of heat on Brazil's health system, across all causes leading to hospitalisation, in both the current and future time-periods, and projects how adaptation and mitigation efforts may alter these impacts over time and across subnational regions.

Methods: Daily non-elective hospital admissions were collected from the Brazil Hospital Information System for 5,459 municipalities, representing 98% of all Brazilian municipalities, spanning 2008 to 2019. Gridded daily maximum temperature data were obtained from European Centre for Medium-Range Weather Forecasts Reanalysis V5 (ERA5) for the historical period (2008-2023) and projected up to 2060 using six CMIP6 GCM models under three SSP emission scenarios (SSP1-2.6, SSP2-4.5, and SSP5-8.5). We used a case time-series design and distributed lag non-linear models to examine the relationship between high temperatures and the risk of hospitalisation for each state in Brazil. Then, we assessed the attributable hospitalisation burden to high temperatures from 2008 to 2060. Related economic costs were estimated using a "cost-of-illness" (COI) approach that included direct medical costs (admissions) and indirect costs (loss of production). We also modeled adaptive capacity using hypothetical scenarios with adaptation levels of 5%, 10%, and 30% to explore their effects on future burdens.

Results: High temperatures increase hospitalisation risks across Brazilian municipalities, with varied temperature thresholds by region. In the absence of adaptation, projected hospitalisations related to high temperatures are estimated to reach 134,609, 156,180, and 156,570 in the 2050s under SSP1-2.6, SSP2-4.5, and SSP5-8.5 scenarios, respectively. Corresponding subsequent annual economic costs are projected at $200.9 million, $234.7 million and $235.6 million, respectively, nearly doubling from $128 million in the 2010s. However, adaptation measures, modeled as a 10% reduction in the slope of the exposure-response curve, could reduce economic losses by $22 million in the 2050s, representing a 9.6% decrease compared to non-adaptive scenarios. Direct costs account for 79% of the total burden, with the South region disproportionately affected, bearing 22% of national costs while housing only 14% of the population. High temperature-related hospitalisation costs accounted for 0.007% of the GDP and 0.152% of domestic general government health expenditure in the 2010s.

Conclusion: This analysis highlights the substantial economic loss from high temperatures under climate and demographic change, with adaptation strategies showing strong potential to reduce these burdens. The results provide critical insights into the economic implications of heat, highlighting the need for regional adaptation and targeted healthcare investments to manage and mitigate rising health burdens.

abs-os418 From Risk Perception to Resilience: How Health and Social Factors Shape Support for Climate Adaptation

PRESENTER: **Glory Apantaku**

AUTHORS: Terre Satterfield, Mr. Mark Harrison

Background: Sustaining population health in a changing climate is critical and requires public support for adaptation initiatives. Understanding the demographic and perceptual factors driving support for climate adaptation policies is essential for creating effective, equitable, and sustainable strategies. This can enable policymakers design targeted interventions, foster broad-based support, ensure resource efficiency, and

build resilient communities capable of withstanding the impacts of climate change.

Objective: This study investigates the socio-demographic and perceptual factors driving climate adaptation behavior and preferences for future adaptation initiatives within a Canadian sample.

Methods: We conducted an online survey through a Canada-based online market research company to obtain a representative sample of Canadian adults by province, with oversampling of the three territories (Nunavut, Northwest Territories, Yukon). The survey captured participants' experiences with extreme weather, current adaptation practices, and preferences for future adaptation policies. To assess policy preferences, we used a token allocation exercise, where participants distributed a fixed number of tokens between various climate adaptation interventions to indicate their preferred allocation of resources. Descriptive statistics were used to analyze these responses, summarizing participants' perceptions and prioritization of adaptation interventions. We analyzed factors that predict an individual's engagement in adaptation actions using a logistic regression analysis. Support for future policy preferences was also analyzed using a two-part modeling approach. First, we examined the predictors of allocating tokens to one of three policy areas. In the second stage, conditional on allocating tokens to a policy area, we explored what factors predict the number of tokens allocated.

Results: 2104 respondents completed the survey. The adaptation interventions that had the highest mean number of tokens allocated to them included expanding emergency response personnel, providing heating/cooling grants for low-income households, and investing in local food production. The analysis of perceptual factors and adaptation behavior revealed distinct demographic patterns: women, non-binary individuals, and younger adults report higher concern about the health risks of extreme weather events and took more adaptation actions, especially in response to wildfire smoke and extreme heat. In contrast, men and older adults report greater self-efficacy and community attachment but engage in fewer adaptation behaviors. Higher health risk concern, perceived vulnerability to the health impacts of climate change, community attachment, and prior experience with health impacts of extreme weather events all predict taking adaptation action.

Conclusions: The emergence of concern about the health risk of extreme weather events and broader health vulnerability to climate change as an important predictor of adaptive action suggests framing climate adaptation as essential for health can boost public engagement in climate adaptation. Targeted communication with emphasis on community-specific health impacts may further increase adaptation support, fostering a more resilient and engaged public in the face of ongoing climate challenges.

abs-os484 The Burden of Climate-Related Disease in Children Under Five: Disability-Adjusted Life Years in Kenya and South Africa Across Climate Scenarios

PRESENTER: **Ziyi Lin**
AUTHORS: Olimpia Lamberti, Filiz Karakas, James Milner, Debra Jackson, Ms. Giulia Greco, PhD, Mr. Andrew Briggs

The health burden of heat-related morbidity and mortality among vulnerable populations, such as children under-five years old in Sub-Saharan Africa, remains largely unrecognized. A previous study projected the impact of future climate scenarios on three critical health outcomes for this age group in Kenya and South Africa: all-cause mortality, diarrheal disease incidence, and preterm births. Building on this, our study aims to quantify the burden of climate-related diseases in children under five in Kenya and South Africa under different climate change scenarios using Disability-Adjusted Life Years (DALYs). We used a~~ model-based approach to estimate DALYs for the 2040-2059 period by combining years of life lost (YLL) due to premature mortality and years lived with disability (YLD) from non-fatal outcomes for under-five children in Kenya and South Africa. We considered three climate scenarios: (1) a low-emission pathway, targeting net-zero CO2 emissions by 2050 with 1.5°C warming (SSP119), (2) an intermediate-emission scenario with stable emissions until 2050, resulting in 2.5-3°C warming (SSP245) , and (3) a high-emission pathway leading to a 4-5°C temperature rise by the end of the century (SSP585). YLLs were attributed to fatal cases of diarrheal disease, preterm birth complications, and other causes of under-five mortality. For each death, We calculated YLLs based on age, sex, and country-specific life expectancies. YLDs were calculated using modelling strategies, disutility weights and duration data from the Global Burden of Disease (GBD) 2019 study. Diarrheal diseases were categorised by severity (mild, moderate, severe) with corresponding disability weights and durations. Preterm birth complications were stratified by gestational age as extremely preterm (<28 weeks), very preterm (28 to <32 weeks), and moderate-to-late preterm birth (32 to <37 weeks). For each stratum, cases were further categorised by severity of symptoms (asymptomatic, mild, moderate/severe), with proportions estimated using a regression model that incorporated the Healthcare Access and Quality Index (HAQI) for each country. Lifetime durations were assumed for preterm birth complications, though without affecting life expectancy. The value of a healthy year at any age was assumed to be constant. An annual discount rate of 3% was applied to reflect the time value of health benefits. Preliminary findings show that in the high-emission scenario (SSP585), the discounted DALY estimate in 2040-2059 associated with diarrheal diseases, preterm birth complications, and any other under-five cause mortality in Kenya are 34,261 (YLL 31,598, YLD 2,678), 148,168 (YLL 106,879, YLD 41,303), and 38,073 (YLL 38,073, YLD 0), respectively. In the low-emission scenario (SSP119), the total discounted DALY dropped to 120,807, with a 39% DALY decrease for diarrheal diseases and a 45% decrease for preterm births. Complete analysis will be completed by January 2025 and results for Kenya, and South Africa will be presented. Our analysis highlights the substantial health burden on children under-five in Kenya and South Africa if future rising temperature are not effectively controlled, highlighting the urgent need for climate action to protect vulnerable populations

abs-os407 The Economic Burden of Extreme Heat on Pregnant and Postnatal Women in Zimbabwe and South Africa

PRESENTER: **Olimpia Lamberti**, London School of Hygiene and Tropical Medicine
AUTHORS: Shobna Sawry, Chuansi Gao, Celeste Madondo, Clara Heil, Jean La Roux, Tapiwa Nyakabau, Nasser Fardousi, Veronique Filippi, Stanley Luchters, Debra Jackson, Ms. Giulia Greco, PhD

The frequency and intensity of extreme temperatures have increased over the past four decades and are projected to continue rising. Pregnant and postnatal women are particularly vulnerable to adverse health outcomes from heat exposure, which can lead to increased healthcare

expenditures, income and productivity losses, as well as substantial economic burden on households. This is expected to be particularly severe for women living in low-and middle- income countries, however, this remains largely under-researched. This study aims to evaluate the economic burden of extreme heat on pregnant and post-natal women in Zimbabwe and South Africa, evaluating the differences by socio-economic status and assessing the impacts on women's wellbeing and quality of life. We hypothesise that the economic burden of extreme heat is higher among pregnant and postnatal women with lower-socio-economic status, and that women with a higher economic burden have lower levels of wellbeing and quality of life.

This study is part of the HIGH Horizons project, which investigates the economic and health impacts of heat exposure on maternal, newborn, and child health in South Africa and Zimbabwe. As part of the project, semi-structured questionnaires are administered to 100 pregnant women, 50 mothers with a live-birth in the past three months, and 50 mothers with children aged six to nine months, with assessments conducted at baseline, two-months and six-months follow-ups. Participants are recruited from communities in Gauteng Province, South Africa, and Mount Darwin district, Zimbabwe. Questionnaires asked participants about their demographics, household asset holdings, healthcare-seeking behaviours, costs associated with seeking care, out-of-pocket healthcare expenditures, lost income and productivity due to heat-related sickness, and collected data on women's quality of life and wellbeing and quality of life, all within the last month. Baseline data collection will end in January 2025 and data analysis will be completed in March 2025. Analysis will be conducted using Excel and STATA.

We will estimate self-reported direct medical and non-medical costs, productivity and income losses, and financial impacts attributed to heat exposure. The economic burden will be estimated as the sum of household direct medical and non-medical costs, and loss of income and productivity due to extreme heat. We will compare the economic burden across countries and socio-economic status determined using the Demographic and Health Survey (DHS) wealth index based on asset-ownership. We will then use a two-part regression approach to evaluate the association between heat and economic burden, stratified by socio-economic status. A logit model will assess the probability of incurring any costs versus none, while, a generalised linear logistic regression model will estimate expense intensity. The overall effect will be calculated by multiplying the probability of incurring cost by the expected mean costs, stratified by socio-economic status. In addition, we will use linear regression models to examine the association between economic burden and women's quality of life and wellbeing.

Results from this analysis will inform policies to address the financial heat exposure on vulnerable populations. This work provides foundational data to support targeted interventions to minimise heat-related health and economic burden in developing regions.

Capability Measures for Children and Young People Aged 0 to 15: Development, Validation and Valuation at the Start of the Life-Course.

MODERATOR: **Hareth Al-Janabi**, University of Birmingham

CONVENER: **Isabella Floredin**, University of Bristol

abs-os452 A Qualitative Study to Inform the Development of Capability Wellbeing Measure(s) in Economic Evaluation for Children Aged 0-5.

PRESENTER: **Isabella Floredin**, University of Bristol

AUTHORS: Philip Kinghorn, Katie Breheny, Joanna Coast, Samantha Husbands, Tim J. Peters, Sarah Byford, Paul Anand, Louise Proud, Mr. Paul Mitchell

Introduction: The capability approach offers a broad evaluative framework for funding decision making in health and care interventions, focusing on capability wellbeing outcomes. This framework can be particularly useful for the economic evaluation of interventions for children and young people (CYP), for whom health is only one aspect of their broader wellbeing. The aim of this study was to capture key capabilities for CYP aged 0 to 5 years to inform attribute development for capability wellbeing measure(s) for evaluating health and care interventions for this CYP group. The use of capability measures for CYP in economic decision making could provide a more rounded decision-making process, which captures broader wellbeing outcomes, within the context of limited resources.

Methods: Qualitative in-depth interviews were undertaken in person or online with parents or guardians of CYP aged 0 to 5 years. Purposeful maximum variation sampling aimed to capture the experiences of participants from a range of backgrounds. Initial sampling was through local authority children's centres and private nurseries but due to the COVID-19 social restrictions, participants were thereafter recruited through targeted advertisements on Facebook. Participants were asked to identify aspects of life that are important to their child's wellbeing. Data collection and analysis were undertaken iteratively, with analysis using constant comparison. Analytic accounts were developed to compare similarities and differences in important capabilities between participants and to determine whether different measures are required across CYP age groups. Data collection and analysis is ongoing.

Findings: Twenty-eight in-depth interviews have been undertaken to date with parents or guardians of thirty-two CYP aged 0-5. Three interviews were undertaken pre-COVID-19. Participants are from different areas of England (urban, rural) and from different socio-economic and ethnic backgrounds with CYP of different ages, genders and family backgrounds (one or two parent families). CYP with and without health conditions have been included. Preliminary findings suggest ten key themes important to capability wellbeing across all participants, with some

variation by CYP age: *caring and basic needs; play and enjoyment; leaning and development; communication; exploring and developing a sense of self; feeling loved; emotional security; making own choices; health; safety and protection.*

Discussion:

The qualitative work is generating important capabilities to inform the attributes of

capability measure(s) for CYP aged 0-5. Full findings from the interviews will be presented at the conference. Given that CYP aged 0 to 5 are a heterogeneous group with differing needs at different and fast evolving stages of early development, potential differences identified in important capabilities across the different ages will also be discussed. The number of measures required for this group will be driven by the data analysis. Findings may help provide an alternative approach to measuring outcomes for CYP for economic evaluation of health and care interventions which can better capture the broader outcomes of wellbeing.

abs-os488 An Assessment of the Feasibility of Completion and Construct Validity of the ICECAP Capability Measure for Children Ages 6 to 11 in the United Kingdom

PRESENTER: **Joanna Coast**, University of Bristol
AUTHORS: Tim J. Peters, Samantha Husbands, Philip Kinghorn, Sarah Byford, Mr. Paul Mitchell, Katie Breheny, Simon Leggett, Paul Anand, Isabella Floredin

Introduction: A capability wellbeing measure for children and young people (CYP) aged 6 to 11 (ICECAP-CYP:6-11) has been developed for use in economic evaluation of health and care interventions in the United Kingdom (UK). The ICECAP-CYP:6-11 measure comprises seven capability wellbeing attributes: *Fun and play; Learning and Experiencing; Attachment, stability and support; Physical protection and security; Achievement; Freedom and having choices; Well-becoming/ aspiration.* To enable the use of ICECAP-CYP:6-11 in economic evaluation, the psychometric properties of the measure need to be assessed. This paper explores the feasibility of completion and construct validity of the measure's descriptive system in a general CYP population sample; a key step in establishing the appropriateness of the measure for its specified population.

Methods: To assess feasibility and validity of the ICECAP-CYP:6-11 measure when completed by CYP themselves, a cross-sectional school-based survey was conducted with CYP aged 7 to 11 in schools across the UK, working with Childwise, a research agency that specialises in CYP. Data were collected using a computer-based survey. The sampling strategy planned to target approximately 25-30 pupils per school in each of the 12 UK regions, providing an estimated sample of 300-600 participants. Feasibility is being assessed in levels of completion amongst participants. Construct validity is being assessed by examining whether the associations between the responses to the attributes of the measure and other background factors (i.e. socio-demographic characteristics; Child Health Utility (CHU-9D) health status measure; the Good Childhood Index (subjective wellbeing)) are in the anticipated directions and of a magnitude in line with reasonable expectations. Associations between the ICECAP-CYP:6-11 descriptive system and the background variables are being investigated using chi-squared tests (for categorical variables) or one-way analysis of variance (for continuous variables), focusing on the direction and magnitude of associations as well as on p-values.

Results:

The survey was completed between May and June 2023 with respondents from 26 schools across the UK. The sample (n=672) has an approximately equal number of children by year of age except age 7 (6%), a 50/50 split of boys and girls, a mix of low (22%), middle (41%) and high (37%) school deprivation areas located in urban (38%), suburban (32%) and rural (30%) areas. The majority of responses across the capability levels of the measure suggest high levels of capability for all ICECAP-CYP:6-11 attributes, with more than half of the respondents choosing the highest or second highest capability levels. The frequency of the 'I do not want to answer' responses for the six ICECAP-CYP:6-11 attributes was low, ranging from 1% to 2% apart from the *Physical protection and security* attribute with a higher percentage of 4%. Feasibility and validation analysis of associations is ongoing.

Discussion:

Full findings from the survey will be presented at the conference. This work will provide early evidence for the feasibility and construct validity of the ICECAP-CYP:6-11 measure and can therefore provide support for its use in funding decision-making for health and care interventions. Valuation work will need to be undertaken to enable the measure's use in economic evaluation.

abs-os512 Exploring Heterogeneity in Valuing the ICECAP-CYP:11-15 Capability Wellbeing Measure Using Best Worst Scaling With Children and Young People in the UK

PRESENTER: **Mr. Paul Mitchell**, University of Bristol
AUTHORS: Philip Kinghorn, Katie Breheny, Louise Proud, Samantha Husbands, Tim J. Peters, Paul Anand, Joanna Coast, Sarah Byford, Isabella Floredin

Background

A new measure of capability wellbeing for children and young people (CYP) aged 11-15 years old has recently been developed. The ICECAP-CYP:11-15 has eight attributes: *Fun and enjoyment, Learning and experiencing, Attachment, Emotional security and support, Achievement, Identity and choice, Physical safety*, and *Aspiration*, with four levels per attribute. For the ICECAP-CYP:11-15 to be used in health and care

economic evaluations, it is important that population values are attached to the attributes and their levels so that decision makers understand their importance relative to one another.

Methods

An online panel company recruited 11-15 year olds via their parents/guardians. A best worst scaling (BWS) case 2 (profile) was used to generate population values for the ICECAP-CYP:11-15. Participants completed the ICECAP-CYP:11-15 measure first to familiarise them with eight attributes, and then 10 BWS tasks. A d-efficient design was chosen using Ngene. Surveys were blocked into four. This allowed a different ordering of attributes and their levels across blocks to address any potential order bias and level balance. Time to complete and monotonicity tests were implemented to control data quality.

To explore heterogeneity in the sample, empirical scale parameter (ESP) provides an individual summation of their best minus worst choices, with higher ESP representing higher market share (or importance) placed on that attribute level. Mean ESP were estimated across all participants. Differences in ESP between ages and gender were analysed. Scale adjusted latent class analysis and econometric modelling of the final value sets will be conducted and presented at the conference.

Results

Data were collected from October–November 2022. For the ESP analysis, 1,155 participants were included, with younger (11-12 year olds) and male participants overrepresented. The ESP was highest for *Attachment* (1.022 - 20%), followed by *Fun and enjoyment* (0.841 – 16%), *Physical safety* (0.800 – 15%), *Emotional security and support* (0.645 – 12%), *Achievement* (0.560, 11%), *Identity and choice* (0.465 -9%), *Learning and experiencing* (0.451 – 9%), and *Aspiration* (0.427 – 8%).

Males and 11-12 year olds found *Fun and Enjoyment* relatively more important, with females valuing *Physical safety* and *Attachment* as relatively more important than males. White ethnicities valued *Fun and enjoyment* and *Physical safety* more relative to other ethnicities, who valued *Learning and experiencing* relatively more. Differences were also observed for other participant characteristics, such as home ownership, home type, household income, number of children in the household, number of adults in the household, parent/guardian marriage/ civil partnership status, disability, and being religious.

Discussion

The unadjusted results suggest *Attachment* is the most valued ICECAP-CYP:11-15 attribute by CYP in that age group in the UK. However, if *Physical safety* and *Emotional security and support* were combined as a single attribute (as is the case for adult ICECAP measures), this would have a greater combined value than all other attributes. The new attributes in ICECAP-CYP compared to the adult measures (i.e. *Aspiration*; *Identity and choice*; *Learning and experiencing*) appear the least valued, although this may not be the case following reweighting the sample to be more representative of the 11-15 year old population in the UK.

DISCUSSANT: **Ama Pokuaa Fenny**, University of Ghana

abs-os477 The Impact of Ageing to the Rise of Financial Hardship: a Decomposition of Drivers Over two Decades in Mongolia

PRESENTER: **Karen Grépin**, The University of Hong Kong

Background:

Like many Asian countries, Mongolia is rapidly ageing, and like many low and middle-income countries (LMICs), its health system is ill prepared to meet the needs of the elderly. A recent systematic review found households with elderly members are much more likely than other households to incur both catastrophic (CHE) and impoverishing (IHE) health expenditures, likely due to both the higher need for health services and fewer financial resources, as they are more likely to be out of the workforce and inadequately protected from old-age security systems. Mongolia's health system has undergone significant reform and transformation following its transition from a centrally planned to a market-driven economy in the 1990s. Many of these reforms have been designed to address the rising burden of paying for health services on households, however, rates of catastrophic (CHE) and impoverishing health expenditures (IHEs) have risen sharply in the last decade. However, little research has explored how demographic shifts may have contributed to rising rates of financial hardship in Mongolia or other LMICs.

Methods:

Using nationally representative household survey data (2002-2023) from the Mongolian Household Socio-Economic Survey (HSES), we are decomposing changes in due to changes in demographic structure of households. Specifically, we used a new typology of households developed by WHO to characterise households by type, including whether or not they have elderly members over the age of 65. At the household level, we used the Oaxaca-Blinder method to decompose changes in out-of-pocket health spending, CHE, and IHEs among households with and without elderly household members to determine the determinants of changes in financial protection among elderly vs non-elderly households.

Findings:

Our preliminary analysis of almost 200,000 households over twenty years suggests that elderly households are approximately 4 times more likely to face CHE and twice as likely to face IHE than non-elderly households. The use of health services is insufficient to account for most of the changes in financial protection, suggesting that the lack of sufficient financial protection polices is placing financial burden on households.

Conclusions:

Our findings shed light on the drivers of poor financial protection among this vulnerable group in Mongolia and provide insights into the methods to develop policies to target this group to make health systems more responsive to their needs.

abs-os483 Decomposing the Rapid Increase in Catastrophic Health Expenditure in China From 1995 to 2018

PRESENTER: **Bingqing Guo**, The University of Hong Kong
AUTHOR: Karen Grépin

Background: The escalating out-of-pocket healthcare expenditures (OOPEs) and resulting financial hardship in China signal significant challenges in achieving Universal Health Coverage (UHC) goals in China by 2030. This study investigates the determinants of financial protection (FP) outcomes and analyzes the factors driving temporal changes in FP in China from 2011 to 2021.

Methods: Using household-level data from the Chinese Social Survey (N=50,866), this study employed unconditional quantile regression, logistic regression, Recentered Influence Function decomposition, and the non-linear Oaxaca-Blinder decomposition to analyze two continuous outcomes- OOPE per capita and OOPE budget share- and four binary outcomes, including any OOPE, catastrophic health expenditure (CATA), impoverishing health expenditure (IHE), and the new SDG 3.8.2 indicator-financial hardship indicator (FHI). Alongside the mean, this study also considered distributional statistics of OOPE per capita and OOPE budget share at the 30th, 50th, 70th, and 90th quantiles (Q30-Q90).

Results: From 2011 to 2019, OOPE per capita increased significantly (e.g., mean: US$202.96 to US$335.09; Q90: US$442.48 to US$746.49), primarily driven by compositional effects, including rising household income, population aging (only at mean and Q30-Q70), and increased presence of young children aged 0-5 years old. From 2019 to 2021, FP outcomes declined significantly (e.g., OOPE budget share: 13.89% to 10.30% at mean), largely due to structural effects, with many factors becoming insignificant in the 2021 wave. A sharp drop in social health insurance coverage between 2019 and 2021 (e.g., New Rural Cooperative Medical Scheme: 46.57% to 31.90%) also significantly contributed to the decline in FP outcomes (e.g., OOPE per capita: -8.39 to -0.09, $p<0.1$; OOPE budget share: -0.36 to -0.03, $p<0.05$). There was significant heterogeneity in FP determinants across distributional statistics: older adults were only linked with higher OOPE per capita at lower quantiles, but not at the Q90.

Conclusion: These findings highlight the role of demographic and socioeconomic shifts in FP changes before the COVID-19 pandemic and the role of decline in health insurance coverage during the COVID-19 pandemic. The Chinese government should prioritize policies to address population aging, the ineffectiveness of social health insurance design, and the sharp decline in social health insurance coverage following the COVID-19 pandemic.

Ind-1833 The Recent Dynamics of Catastrophic Health Expenditure (Evidence from Indonesia)

PRESENTER: **Asep Nurwanda**
AUTHOR: Anu Rammohan

Introduction

Catastrophic health expenditure (CHE) remains a significant barrier to achieving Universal Health Coverage (UHC), particularly in low- and middle-income countries (LMICs). Through its National Health Insurance program (*Jaminan Kesehatan Nasional*, JKN), Indonesia has expanded financial protection since 2014. While the overall incidence of CHE has declined in recent years, evidence on how these benefits are distributed across vulnerable populations (i.e households with elderly or disabled members) remains limited.

Objectives

This study examines the dynamics of CHE in Indonesia from 2018 to 2023, focusing on vulnerable households. It explores disparities in CHE risks for households with elderly and disabled members and assesses the mediating roles of health-seeking behaviour and premium subsidies in shaping these outcomes.

Data and Methods:

We utilise Indonesia's National Socioeconomic Survey (SUSENAS), a nationally representative dataset, from 2018 to 2023. The survey consists of more than 300.000 households annually. The primary outcome variable is a measure of CHE, where a household is considered to experience CHE if its OOP healthcare spending exceeds 10% of total household expenditure per capita. We also employ alternative CHE definitions, including indicators for OOP health expenditure exceeding 25% of total household expenditure, 40% of household capacity to pay,

and impoverishing health spending. We employ multivariate logistic regression models to assess the association between CHE incidence and household vulnerability, controlling for socioeconomic and demographic factors. Interaction terms are included to evaluate the mediating effects of health-seeking behaviour and premium subsidy receipt.

Result

The incidence of CHE in Indonesia shows a downward trend during the study period, coinciding with the JKN program expansion. However, disparities persist. Households with elderly members face a 1.2–1.5 times higher CHE risk, while households with disabled members face a substantially higher risk (ORs between 1.6–1.8).

Mediating factor analysis reveals nuanced findings. Health-seeking behaviour (HSB) is positively associated with CHE risk (OR ≈ 1.3), reflecting higher utilisation costs. HSB significantly mediates CHE risk for disabled households (Disabled×HSB OR ≈ 0.92–1.15 across thresholds), but has limited protective effects for elderly households. Interaction effects of premium subsidy and vulnerable households suggest protective roles, particularly for elderly households who significantly reduced CHE risk (Elderly×Subsidy OR ≈ 0.65–0.82), while effects for disabled households remain non-significant.

Conclusion:

Overall, Indonesia has made progress in reducing CHE incidence. However, vulnerable households continue to experience inequitable financial burdens. Premium subsidies demonstrate a protective effect for households with elderly members, but do not adequately address the needs of households with disabled members. Policies should strengthen financial protection for vulnerable households through promotive actions to improve healthcare utilisation and reform subsidy instruments to enhance inclusivity under UHC.

DISCUSSANT: **Manuel Gomes**, University College London

abs-os16 Comparing Biparametric to Multiparametric MRI in Prostate Cancer Diagnosis: Cost-Effectiveness Analysis Alongside Non-Inferiority within-Patient Trial

PRESENTER: **Jing Yi Jessica Weng**

BACKGROUND

International guidelines recommend magnetic resonance imaging (MRI) in men with suspected prostate cancer (PCa). Current UK guidelines recommend multiparametric MRI (mpMRI), comprising three sequences: T2-weighted, diffusion-weighted and dynamic contrast-enhancement (DCE). Prior studies evaluating a biparametric MRI (bpMRI) approach, omitting DCE, suggest a similar clinically significant cancer detection rate. However, a bpMRI strategy could reduce scanning time and be acceptably cost-effective vs. mpMRI.

AIM

The primary health economic objective of this analysis was to calculate incremental cost per quality-adjusted life-year (QALY) gained following bpMRI vs. mpMRI strategy based on patient-level information from PRIME, supplemented with quality-of-life (QoL), survival and resource use information from other sources for extrapolation to lifetime horizon.

METHODS

PRIME is a within-patient diagnostic yield study, therefore, the two groups for comparative economic analysis are delineated using hypothetical scenarios. Men with suspected PCa underwent full mpMRI scans. Radiologists, initially blinded to DCE, reported results from the bpMRI sequences first. DCE was then revealed, and radiologists re-reported using all three (mpMRI) sequences. Men with suspicious lesions on either report or with high prostate-specific antigen density underwent targeted (TB) or systematic biopsies (SB). Hypothetical bpMRI- and mpMRI-led treatment decisions were made separately with final treatment decision being made using all available information for ethical reasons.

The primary within-trial health economic analysis calculated mean incremental cost per additional clinically significant PCa diagnosis via bpMRI vs. mpMRI approach (TB only), over approximately 60 days from study entry to multi-disciplinary team treatment decision. Secondary analyses calculate incremental cost per significant cancer diagnosed when incorporating SB results, and incremental cost per clinically insignificant PCa diagnosis avoided using bpMRI vs. mpMRI.

Costs from health services perspective were estimated by applying standard unit costs to resource use data captured within the trial and assigned according to hypothetical routes along the pathway.

The within-trial analysis is extended using decision analytic modelling to estimate incremental cost per QALY gained over lifetime horizon. QoL information is estimated from patient-level data collected by the same group from another study (PRECISION), and literature. Bootstrapping estimates uncertainty around costs in preliminary within-study analysis, and probabilistic sensitivity analysis will be used for costs and QALYs in the decision model. Sensitivity analysis calculates the incremental cost per QALY gained using microcosted MRI unit costs.

RESULTS

Four-hundred-and-ninety patients were included in preliminary analysis. Two fewer cases of clinically significant PCa were diagnosed via bpMRI pathway vs. mpMRI (141 vs. 143), and 1 fewer insignificant cancer over-diagnosed (51 vs. 52), i.e. no indication of clear superiority of either route. Mean (SE) per-patient cost for patients diagnosed with clinically significant cancer was £1,241 (£49) in the bpMRI pathway and £1,392 (£49) in mpMRI. Further secondary analysis and decision model are in progress.

CONCLUSIONS

Removing the DCE sequence could reduce scanning time, thus alleviating some impact of health service staff shortages on MRI wait time and allow more patients to access MRI sooner, thereby improving patient outcomes. The within-trial results were inconclusive, and the lifetime model should provide clarity regarding cost-effectiveness of bpMRI vs. mpMRI.

abs-os558 A Decision Model for the Cost-Utility of Screening Technologies in Ovarian Cancer

PRESENTER: **Jiunn Wang**, University of Exeter

Background

Ovarian cancer is the sixth most common cancer among women in the UK, accounting for over 4,000 deaths annually. Computed tomography (CT) scans are the current standard of care for assessing the extent of cancer and determining surgical suitability. However, CT scans have limitations, including difficulty distinguishing between malignant and benign adnexal masses, and accurately staging cancer progression. These limitations can lead to unnecessary surgeries, including removal of the ovaries, resulting in infertility. Such procedures also impose a significant economic burden on the National Health Service (NHS). Emerging evidence suggests that multiparametric MRI (mpMRI) may offer superior accuracy in characterising adnexal masses, potentially improving diagnostic precision. However, there is limited evidence regarding its impact on clinical decision-making and cost-effectiveness compared to CT scans.

Aim

This study aims to estimate the incremental cost per quality-adjusted life-year (QALY) gained from mpMRI and the combined use of mpMRI and CT, compared to CT alone, for suspected ovarian cancer.

Methods

A total of 461 ovarian cancer suspects were included in the trial. All patients underwent both a CT scan and a mpMRI scan as soon as practically possible after enrolment. Patients were then discussed at a local multidisciplinary team (MDT) meeting to determine the most appropriate treatment pathway. Initially, treatment decisions were based on CT scan findings, but critical mpMRI findings were revealed to the MDT, prompting reassessment of the original decision for ethical reasons. Three months after enrolment, the MDT reviewed the full mpMRI report and the combined CT and mpMRI report, recording theoretical treatment plans. Nine months after enrolment, the MDT reviewed all cases again and decided what should have been the optimal treatment.

We compared the final treatment decisions to those based on CT, mpMRI, and combined CT and mpMRI results to assess whether mpMRI improves concordance with the optimal treatment. A decision tree was constructed to model treatment options following screening, as well as subsequent complications and progression. The primary outcome was the incremental cost per QALY gained, calculated using EQ-5D and applying the area-under-the-curve approach with baseline utility adjusted. Costs included those associated with intervention and treatment, derived from national reference costs, as well as healthcare utilisation costs, derived by combining national unit costs with observed individual service use. Uncertainty was explored through probabilistic sensitivity analyses.

Initial results and conclusions

The probability of concordance was 82.43% for mpMRI and 83.08% for combined mpMRI and CT, compared to the 73.75% for CT alone. Among concordance cases, mpMRI and combined mpMRI and CT identified more appropriate benign surgeries (17.63% and 17.49%) compared to CT alone (9.41%). Whilst the intervention cost of mpMRI was higher than that of CT, total NHS costs were lower for mpMRI and combined mpMRI and CT compared to CT alone. QALYs were also higher for mpMRI and combined mpMRI and CT compared to CT alone, although the differences were minimal. These findings may inform clinical practices in screening for ovarian cancer suspects, suggesting that mpMRI could improve decision-making and reduce unnecessary healthcare costs.

abs-os564 Triaging Primary Care Requested Chest X-Rays Using Artificial Intelligence: A Cost-Effectiveness Analysis of the Lungimpact Study

PRESENTER: **Siyabonga Ndwandwe**, Clinton Health Access Initiative (CHAI)

Background:

Rapid diagnosis of lung cancer is essential for improving patient outcomes. A recent randomised controlled trial showed that immediate chest X-ray (CXR) reporting significantly reduced the time to lung cancer diagnosis, from a median of 63 days with routine CXR reporting to 32 days. This suggested potential benefits in health system efficiencies, patient outcomes and cost-effectiveness. However, not all patients benefit from direct CXR triage. Integrating artificial intelligence (AI) decision support into the pathway could avoid inefficiencies by promptly identifying a CXR with suspicious findings thereby prompting CT.

The UK's National Institute for Health and Care Excellence (NICE) recognises AI's potential in supporting existing pathways and improving workforce productivity. Nonetheless, evidence on the clinical and cost-effectiveness of integrating AI into the lung cancer diagnosis pathway across UK systems remain limited. This analysis assesses the incremental cost per unit reduction in time (days) from CXR to lung cancer diagnosis when using AI, from the healthcare perspective, compared to standard care. Additionally, we address a major limitation in contemporary economic evaluation methodology for diagnostic and screening studies by using aggregate data from literature and published audits for the control arm, allowing for robust evaluation when prospective data collection in control arm is constrained. This work is part of a larger study, LungIMPACT, which also evaluates the impact of CXR AI on time to CT and diagnosis of lung cancer.

Methods:

Our analysis uses a three-way decision tree analytic model over a 60-day horizon. Our three arms are: AI triage of CXR for urgent reporting with AI assistance for interpretation (arm 1), normal reporting (no triage) timing and AI only available when reporting (arm 2), and AI not available (standard care/control). We characterise reduction in time to cancer diagnosis in the two intervention arms using information from the LungIMPACT trial, which collected data from five large healthcare networks across the UK starting July 2023. The control arm outcome uses information from the literature and national audits. Differences in short-term costs are likely to depend primarily on the cost of setting up and delivering the AI facility, estimated as the cost to implement the AI support at the time of CXR acquisition and prioritisation for immediate review of CXRs, training costs, and maintenance costs. Unit costs will come from standard national datasets. Deterministic and probabilistic sensitivity analyses will explore parameter and methodological uncertainties.

Results and conclusion:

Based on preliminary data, the intervention arm has 68,043 CXRs from 63,919 patients, with 34,946 (51.4%) CXRs from arm 1 and 33,097 (48.6%) from arm 2. Females contributed 53.8% (n=36,631) CXRs. Uneven distribution of CXRs across healthcare facility networks, the leading facility accounted for 48.8% (n=33,214) with the least accounting for 7.7% (n=5,243). The latest National Lung Cancer Audit (NLCA) has aggregate data from 37 institutions (hospitals and cancer alliances) and 39,097 patients. These findings could be key in informing policies on AI adoption within the UK, advancing patient outcomes, improving health system efficiency, and workforce productivity. The analysis will be completed before the conference.

abs-os567 Cost-Effectiveness Analysis of Whole-Body MRI Cancer Screening in Rare Genetic Illness: Decision Model Using UK Prospective and Historical Data

PRESENTER: **Ms. Caroline S Clarke**, University College London (UCL)
AUTHOR: Jing Yi Jessica Weng

Background

Li Fraumeni syndrome (LFS) is a rare genetic condition with high cancer rates; >90% of women and ~75% of men with LFS develop cancers during their lifetime. Cancer surveillance recommendations include annual breast MRI or prophylactic mastectomy in women, brain/whole-body imaging, and dermatological review. Initial evidence suggests whole-body magnetic resonance imaging (WB-MRI) is useful, but annual WB-MRI in the UK not currently recommended as is lacking evidence regarding effectiveness and cost-effectiveness, particularly regarding possible earlier cancer diagnosis.

Aim

To estimate incremental cost per quality-adjusted life-year (QALY) gained on providing two WB-MRI scans over 12 months to adult LFS patients in London, UK, versus usual care, using lifetime horizon.

Methods

Small patient population (UK prevalence ~1000) renders randomised clinical trials unfeasible. Instead we used a prospective single-arm service evaluation cohort and compared to historical control group. Information on health outcomes (EQ-5D-5L, cancer diagnosis, death) and care pathway costs (hospital care, LFS and cancer management and treatments) allow creation of lifetime decision analytic model. National reference unit costs are applied to resource use items. QALYs are calculated using standard area-under-the-curve approach, adjusting for baseline utility and demographics. Uncertainty is explored using probabilistic sensitivity analyses and scenario analysis to test robustness to assumptions around historical control and alternative scenarios. Costs and QALYs discounted at 3.5%/year.

Prospective ("intervention") group

All LFS patients at site were offered two WB-MRIs, at baseline and 12 months. EQ-5D-5L was collected at both visits. Inclusion criteria: LFS diagnosis; age >18 years; informed consent. Exclusion: TP53 variant of low penetrance or unknown significance; cancer diagnosis in last 5 years (except non-melanomatous skin cancer or in-situ cervical carcinoma); malignancy symptoms; MRI contraindication.

Retrospective (historical control) group

Anonymised records on cancer diagnoses and treatments from 57 patients diagnosed with or treated for LFS between 2000 and 2022 were obtained from the site. Inclusion criteria: study entry date is the later of patient's LFS diagnosis or 18th birthday, with 5 years elapsed since last cancer or recurrence date (except non-melanomatous skin cancer or in-situ cervical carcinoma) and provided not receiving cancer treatment. Study entry date is before death or last follow-up. Exclusion: patients with non-pathogenic (or low penetrance, according to today's rather than contemporaneous definitions) TP53 variant or variant of unknown significance.

Initial descriptive results

54 patients in prospective cohort had WB-MRI at baseline and 49 (90.7%) at 12m. 4/54 (7.4%) cancers diagnosed at baseline, 5/54 (9.3%) diagnosed between scans, and 5/49 (10.2%) diagnosed at 12m, with no deaths in this group.

45/57 (78.9%) patients identified in retrospective dataset eligible for inclusion. Main ineligibility reason was presence of cancer. Mean (SD) follow-up time 10.9 (5.8) years. In first 12 months after inclusion, 3/45 (6.7%) diagnosed with cancer, 1/45 (2.2%) died and 1/45 (2.2%) lost to follow-up.

Conclusions and implications

This will be first UK economic evaluation of annual WB-MRI screening for LFS patients. Results will be put into context regarding implementation routes of optimal screening programme and potential policy changes. Methods used showcase achievement of comparative analysis in rare disease settings.

Strategic Health Purchasing: Driving Health System Performance and Building Resilience

MODERATOR: **Mercy Mwangangi**, Amref Health Africa

CONVENER: **Frida Ngalesoni**, Amref Health Africa

DISCUSSANT: **Boniface Mbuthia**, Amref Health Africa

abs-os520 Against the Odds: A Case Study of Strategic Health Purchasing in a Fragile Health System in South Sudan

Disruptions in the delivery of quality health care in South-Sudan due to political conflict has weakened the health systems. The government capacity to finance service delivery is weak with only 2% of the public funding is committed to the health sector. The public finance management (PFM) systems are largely weak despite the passing of the PFM Act in 2011. The accountability of public funds remains low and hence majority of the budgets from donors are managed parallel to the government systems. The Health Sector Transformation Fund (HSTP) was created to pool external funding for health and hence serve to reduce fragmentation. Strategic Health Purchasing [SHP] is an important policy intervention to strengthen how the health system utilizes information on the population health needs and provider performance to effectively allocate resource to health providers even in a fragile setting like South-Sudan.

Aim:

To evaluate the progress made in the application of SHP reforms using the Strategic Purchasing Progress Tracking tool in South Sudan.

Methods:

We used the Strategic Purchasing Progress Tracking Framework created by Strategic Purchasing Africa Resource Center [SPARC] to guide data collection and analysis. We compiled descriptive information on [1] purchasing functions [benefit specification, provider contracting and payment methods [PPMs] and performance monitoring practices and their execution in the priority schemes [2] external factors and governance arrangements and how they are linked to SHP.

Results

The basic policy and legal framework established: despite a weak policy and legal framework reform MoH has developed Health Sector Strategic Plan II 2023-2027 sets the foundation through which reforms such as strategic health purchasing can be anchored on.

The MDTF is the surest way of applying SHP principles in South-Sudan: It remains largely but is the dominant source of funding for the health sector. Due to the joint nature of governance [both MoH and donors sit in the steering committee] and to ensure that it support MoH led health priorities. Currently it remains largely passive.

The state of purchasing functions: South Sudan has a Basic Health Package for Health and Nutrition that all schemes in the country are based on. The provider payment mechanisms are largely input based with providers automatically and informally engaged. The MDTF engaged both public and private [*not for profit*]. Performance monitoring exists but it is largely disconnected from purchasing decisions.

Local adaptation in the financing of the health sector applied right for the context: Through the MDTF partners can progressively grow the capacity of MoH to apply the principles of SHP in the administration of the fund. These capacities can then be passed on to the government.

Conclusion:

Layering on the existing legal and policy framework the country is still able to apply SHP reforms despite the fragility experienced to strengthen their ability to buy more health outcomes. The MDTF being the largest funding arrangement, most promising and capable of transferring skills and capacities to the MoH

abs-os515 Enabling Strategic Health Purchasing Through Resilient Primary Health Care Financing Arrangements in Malawi

Background:

In recent years, public health systems globally have experienced interruptions in the delivery of primary health care [PHC] by a range of issues, including climate change, conflicts, and emerging pandemics. These experiences highlight the importance of resilient PHC systems that can help prepare for emergencies, respond effectively, and maintain healthcare services during crises. Malawi a Low- and middle-income country [LMIC] has experienced climate change-induced extreme weather events compromising access to essential services, and increasing health risks and altering the ability to improve health outcomes for affected populations.

Aim:

We developed a PHC financing framework that provided health financing actors with a tool to analyze and gather information on opportunities for improving the resilience of PHC financing with emphasis on enabling PFM systems and processes to improve the resilient capacities of the system.

Methods:

A mixed method approach was used to include a document review of more than 57 documents to determine key elements and characteristics of a resilient health system together with key informant interviews from Ghana, Nigeria, Ethiopia, Kenya done to inform and strengthen the framework elements and benchmarks towards resilient PHC financing systems. The findings were then triangulated in two stakeholder forums held in Malawi and hosted by MoH.

Results

Applying the framework to the Malawi context revealed that:

On Resource Mobilization: The health sector heavily depends on donor funding, averaging 54.5% of total health expenditures (2016–2022), often as off-budget support. To reduce this dependency, mobilizing diverse can ensure a consistent funding flow. This approach enhances stability, supports long-term planning, and increases resources for resilient health systems

On Resource Budgeting: Rigid Public Financial Management (PFM) systems limit budget reallocation, hindering emergency responses. Advocacy for PFM reforms is needed to enable flexibility, particularly for the Department of Disaster Management Affairs. Flexible budgeting allows rapid responses to emergencies, such as disease outbreaks, supporting strategic purchasing and adaptability to shifting needs.

On Resource Allocation: Approximately half of the health sector budget is centrally managed by the Ministry of Health, limiting prioritization based on critical health needs. The ongoing pilot of Direct Facility Financing in one Malawian district of Rumphi shows promise for promoting fiscal decentralization.

On budget utilization: The Ministry of Health (MoH) consistently underspends its budget, in contrast, primary healthcare expenditures managed by Local Councils align with the Public Expenditure and Financial Accountability framework's standards for budget credibility. However, PHC facilities are not autonomous cost centers, which hampers strategic health purchasing and limits the development of a resilient health system.

On health financing governance: Strengthening governance through robust monitoring, transparency, and community engagement is crucial to prevent mismanagement, build trust, and support strategic purchasing aligned with health priorities

Conclusion:

When mobilization, allocation, and utilization align with strategic health purchasing goals, the health system becomes more adaptable, sustainable, and robust. Using the framework help actors visualize where country’s stand in the path towards resilient PHC financing identifying potential strategies to be taken to move the benchmarks towards more resilient health system

abs-os510 Strategic Health Purchasing as a Driver for Health Systems Resilience in Malawi

Background:

Only 10% of all the 54 countries have managed to allocate at-least 15% of the total government budget to health despite a firm commitment by heads of state in Abuja. While this goal remains a priority for many countries in Africa, we need to optimally use available resources for health

noting that between 20-40% of the health resources are wasted annually. Strategic Health Purchasing [SHP] is an important policy intervention to strengthen how the health system utilizes information on the population health needs and provider performance to effectively allocate resource to health providers.

Aim:

To evaluate the progress made in the application of SHP reforms using the Strategic Purchasing Progress Tracking tool in Malawi.

Methods:

In the study Amref Health Africa in collaboration with MoH used the Strategic Purchasing Progress Tracking Framework created by Strategic Purchasing Africa Resource Center [SPARC] to guide data collection and analysis. We compiled descriptive information on [1] purchasing functions [benefit specification, provider contracting and payment methods [PPMs] and performance monitoring practices and their execution in the priority schemes and [2] external factors and governance arrangements and how they are linked to SHP.

Results

Malawi's legal and policy framework provides for SHP implementation through the Health Sector Strategic Plan III and Health Financing Strategy 2023-2030 call out priority reforms on SHP. This combined with both political and technical support, the country to fast-track the needed reforms. **Progressive but consistent reforms towards SHP noted:** The third iteration of benefit specification review in the last 15 years, MoH purchasing health services from Christian Health Association Malawi [CHAM] using Service Level agreements, revision of a resource allocation criteria for district councils for the Direct Health Financing Facility [DHFF]. However, despite this most purchasing remains passive, especially those funded from health budgets.

Fragmentation of the performance monitoring practices: there are many actors, and management information systems (*both financial and health systems*) leading to fragmented practices and affecting the regular use of this information to influence purchasing decisions. **Limited capacity to sustain SHP reforms:** Malawi has a very small pool of health financing specialists to continue advocating for the implementation of strategic health purchasing, public finance management both at national and sub-national levels.

Local solutions for local problems: after the chicken gate scandal, the Joint Health Services Fund [JHSF] was established where major donors were able to pool funds. This presents a unique opportunity for donors in this program to support the government in advancing SHP principles as they allocate resources for health providers.

Conclusion:

Malawi is ready to continue applying health systems reforms to strengthen the implementation of health financing reforms. More bold steps are needed to initiate additional reforms on health financing, SHP, and Public Finance Management [PFM] especially by the District Councils. The health system has opportunities to draw lessons from the utility of SLAs with the private health sector to strengthen how MoH/District Councils engage with the public health sector facilities.

abs-os523 Strategic Health Purchasing the Surest way of Sustaining Health Systems' Performance in Zambia

Zambia has been identified as an exemplar country in the delivery of PHC cost effectively [Exemplars, 2024] In its effort to make progress towards the realization of Universal Health Coverage [UHC] goals the country has been implementing multiple reforms to strengthen its health systems both on the health budgets and developing the National Social Health Insurance Scheme as a prepaid scheme. Despite this the country faces complex health financing strains to include low fiscal space for health, high debt levels and delayed implementation of the decentralization policy in which health is one of the key services under consideration.

Aim:

To evaluate the progress made in the application of SHP reforms using the Strategic Purchasing Progress Tracking tool in Zambia.

Methods:

In the study Amref Health Africa in collaboration with MoH used the Strategic Purchasing Progress Tracking Framework created by Strategic Purchasing Africa Resource Center [SPARC] to guide data collection and analysis. We compiled descriptive information on [1] purchasing functions [benefit specification, provider contracting and payment methods [PPMs] and performance monitoring practices and their execution in the priority schemes. [2] external factors and governance arrangements and how they are linked to SHP.

Results

Legal and policy frameworks exist: The National Planning and Budget Act 2020, Public Finance Management Act 2018, Health Financing strategy 2017-27 and National Decentralization Policy 2023 provide great opportunities for further comprehensive reforms on SHP both at national and sub-national levels. There has been a delay in the implementation of the decentralization policy due to political and economic considerations

Small but sure reforms on purchasing functions have already begun: the existence of benefit specifications at MoH and NHIS, contracting arrangements for NHIS, and the use of a variety of provider payment mechanisms. **Lack of a clear way of purchasing PHC services, especially under MoH,** creates an opportunity for co-payments especially in urban areas. This creates a barrier to access to health services. Both PHC services [strategic programs and out-patient care at health facilities] are largely purchased through input-based approaches and are

largely passive.

Fragmented performance monitoring mechanisms: This limits the use of the findings in influencing the purchasing decisions. However, the recent passing of the health data governance policy provides an opportunity to strengthen data ownership and use.

Conclusion:

Continued reforms on health financing building on the existing policy and legal frameworks provides a promising opportunity to apply more SHP reforms in Zambia. This is expected to consolidate results and improve health outcomes.

Ind-394 Mobile Technology and Contraceptive Knowledge and Use: Evidence from Indonesia

PRESENTER: **Adrianna Bella**

AUTHORS: Nicole Black, Dennis Petrie, Danusha Jayawardana, Teguh Dartanto

Abstract

Insufficient knowledge of reproductive health is one of the contributors to the unmet need for family planning and unintended pregnancies. The potential for mobile phone infrastructure to enhance public health awareness and behaviours, particularly around contraceptives, is especially promising in countries like Indonesia, where rapid mobile technological advances intersect with a significant unmet need for modern contraceptives.

This study examines the role of mobile technology in influencing contraceptive knowledge and use in Indonesia. Utilising data from the Indonesia Family Life Survey (IFLS) and the Village Potential Statistics (PODES), we employ a fixed-effects regression model with cohort, sub-district, year, and province-year fixed effects to examine the role of mobile signal strength in promoting contraceptive knowledge and use among women. Using area-level mobile phone signal strength rather than individual mobile ownership or usage frames our analysis within an intention-to-treat (ITT) approach. This approach offers a key advantage by alleviating selection concerns that certain individual characteristics might simultaneously drive the choice to own or use a mobile phone and the level of health knowledge. By focusing on mobile signal strength instead of individual ownership, this method also captures the broader impact of mobile technology on knowledge sharing within the community, allowing for spillovers from those with access to mobile phones to those without.

We find that while both strong and weak mobile signals are associated with increased awareness of contraceptive methods, the role of weak signals is more pronounced. Specifically, a shift in weak mobile phone signal strength from none to full coverage is linked to a 14.7 percentage point increase in the proportion of women who have ever heard of more than six contraceptive methods; however, we did not find a significant relationship between strong signals and ever heard of more than six contraceptive methods. A plausible reason is that sub-districts with greater increases in weak signal coverage likely had a higher proportion of villages with no signal and, consequently, lower initial knowledge, making even small improvements in connectivity lead to significant gains in access to information. When we disaggregated contraceptive knowledge by method type, this increase in awareness is driven primarily by knowledge of contraceptive films, while we did not find any robust association between mobile phone signal strength and other types of contraceptive methods. However, despite gains in awareness, we do not observe a significant uptick in actual contraceptive use.

The findings highlight the pivotal role that mobile phone signal strength can play in improving women's sexual health knowledge, particularly regarding contraceptive awareness. This suggests that mobile technology, even in areas with limited connectivity, can serve as a tool for disseminating sexual health information, potentially through mobile phone usage and transferring knowledge from mobile phone owners to non-owners. However, the study also emphasises that increased awareness alone may not necessarily translate into changes in contraceptive practices. Broader societal and structural factors can significantly influence the decision to adopt contraceptive practices.

Ind-666 How Structural Homophobia is Spreading HIV-Risk Sexual Behaviors Around the World

PRESENTER: **Vincent Leo Leroy, PhD student**, Aix-Marseille University
AUTHORS: Erik Lamontagne, Bruno Spire, Sean Howell, Sylvie Boyer, Bruno Ventelou

Background: Discrimination and stigma towards LGBTI population are recognized as potential determinants of HIV-risky behaviors. Yet, data on this issue remains limited: in particular, the “channels” that generate these effects are still uncertain. In addition, there is a critical lack of data regarding developing countries. The main objective of this paper was to fill this gap by analyzing the relationships between different dimensions of homophobia, propensions to take risks and HIV-risk sexual behaviors, in a worldwide sample. Methods: We used data from UNAIDS’s Global LGBTI Happiness survey conducted among 115 000 individuals in 204 countries and territories from May 2019 to January 2020. The survey was distributed worldwide through global and national social networks, mainly dating apps, civil society organizations, and activists. Structural equation modelling was employed to identify associations between homophobia and HIV-risk sexual behaviors in participants who self- identified as cisgender, transgender and non-binary gay, bisexual and queer. The model comprised i) UNAID’s recently developed homophobic climate index, as structural measure of homophobia; ii) a measure of experienced local discrimination (latent variable indicating the experience of verbal abuse and/or physical aggression because of sexual orientation or gender identity); iii) a latent variable assessing homophobic discrimination in the workplace; iv) a measure of family homophobia (variable indicating the family's non-acceptance); v) a general propensity to take risks variable; vi) a HIV-risk sexual behavior index (composite variable measuring unprotected anal intercourse with casual partners, at risk of HIV transmission or acquisition). Results: The final sample included 69 646 participants from over 180 countries. We found that the country's homophobic climate, defined as structural homophobia, predicted local homophobia ($\beta = 0.064$, $p<0.001$), homophobia at work ($\beta = 0.025$, $p<0.001$), family homophobia ($\beta = 0.21$, $p<0.001$) and HIV-risk sexual behavior ($\beta = 0.050$, $p<0.001$). Results indicate that local and at work homophobic prejudices are directly and positively associated with HIV-risk sexual behavior ($\beta = 0.093$, $p<0.001$; $\beta = 0.014$, $p = 0.031$). Structural homophobia was also indirectly associated with general risk-taking and HIV-risk sexual behaviour, mediated by individual homophobic attitudes. Conclusion: Our findings revealed positive associations between structural and individual stigma, and then risky behaviors that have been identified as a key determinant of the transmission of HIV among sexual minorities worldwide. Homophobia is still highly prevalent in societies and its elimination is a necessary condition in a world that aims to end HIV epidemic. We encourage policymakers to prioritize policies that intend to end homophobia and promote LGBTI rights.

Ind-1797 Analysis of Women Empowerment Factors in Contraceptive Use Decisions Among Married Women in Indonesia

PRESENTER: **Annisa Dwi Noviani**
AUTHORS: Gusti Dio Faiz Mahardika, Wahyu Hidayat, Nasywa Nayifa Salsabila, Achmad Kautsar, Kheren Honey Hutabarat

The population growth in Indonesia has been declining in recent years, influenced by various factors such as education level, the role of women in households, contraceptive use, and family planning information. In Indonesia, the use of contraception among married women has increased over the past three years, accompanied by improvements in women quality of life through various aspects, including education and labor force participation. objective of this study is to measure the factors of women empowerment and the level of economic conditions in relation to contraceptive use in Indonesia. This study uses a quantitative approach with a logistic regression model, involving 36,855 women of reproductive age in Indonesia, focusing on married women aged 10-49 years. This study used the latest data from the 2017 DHS (Demographic and Health Survey), with variables including both economic and non-economic aspects, such as women's empowerment (decision-making roles), education level, and other factors, such as place of residence and partner characteristics. The results indicate that higher education levels have a significant influence, with a 2.7% lower probability of using contraception. Better knowledge has provided women with more space to consider the health impacts of contraceptive use, while women who participate in the workforce have a significantly higher likelihood 1.6% of using contraception. Improved economic status also positively influences contraceptive use, with a 1.6% higher probability in the middle-income category and a 0.5% higher probability in the high-income category compared to women in the low-income category. The role of women in decision-making within the household also has a negative and significant impact on contraceptive use, with a 5% probability value. This study highlights the role of increased women empowerment in Indonesia, both from economic and non-economic factors, in influencing contraceptive decision-making. The research also emphasizes that women decisions regarding sexual relationships are considered key determinants of family planning. Research on women empowerment in Indonesia is still very limited. This study can serve as a reference for analyzing the factors that most influence contraceptive use and can also be considered when developing regulations for the family planning program in Indonesia.

Ind-2055 From Private to Shared - Social Network Influences on Hysterectomy Decision-Making in India

PRESENTER: **Karan Babbar**, O P Jindal Global University
AUTHORS: Supriya Garikipati, Pritha Dev

This paper investigates the influence of social networks on women's decisions to undergo hysterectomies in India. We examine whether a woman's likelihood of having a hysterectomy is affected by the prevalence of the procedure among her peers, defined as other women of reproductive age residing in the same geographic cluster (neighborhood) using data from the National Family Health Survey (NFHS-5). To address the challenges of shared unobservables and simultaneity bias, we employ an instrumental variables approach with state fixed effects, comparing women in the same district but different peer groups. We instrument for peer hysterectomy rates using plausibly exogenous variation in the sex of the first child. Our results reveal a substantial positive peer effect: a 10 percentage-point increase in the peer hysterectomy rate is associated with a 5.3 percentage-point increase in a woman's own probability of undergoing the procedure. These findings, robust to falsification tests and various robustness checks, suggest that policies affecting hysterectomy rates will have spillover effects through social networks, implying that traditional analyses may underestimate their total social impact. Moreover, we find significant heterogeneity in peer

effects across public and private healthcare settings, highlighting the role of institutional context in mediating social influence. This suggests that targeted policies, such as regulations for private providers or public health campaigns promoting informed decision-making, could be particularly effective. *Keywords:* Hysterectomy, Peer Effects, Endogeneity, Instrumental Variable, NFHS-5, India.

Health and Healthcare Inequity

MODERATOR: **Beverley Essue**,

Ind-832 Effects of the Affordable Care Act on Income-Related Inequity in Health Care Delivery Among Working-Age Americans, 2008-2019

PRESENTER: **Jose Escarce**, University of California-Los Angeles (UCLA)

AUTHORS: Hao Yu, Yanlei Ma

Background: Policymakers in many countries agree that equity, achieved when use of healthcare services is based on medical need and not on any other characteristics of individuals, is an important goal for healthcare systems. Researchers have compared countries' systems on the degree of income-related inequity and found that "pro-rich" inequity, meaning that, given the same medical need, high-income persons systematically receive more care than their low-income peers, is higher in the U.S. than in other high-income countries. However, two recent policies in the U.S. would be expected to have reduced pro-rich inequity. Since 2001, the number and capacity of Federally Qualified Health Centers (FQHCs) has increased dramatically. More notably, in 2014 the Affordable Care Act (ACA) extended health insurance to millions of low-income, working-age (18-64) people. **Aim and Contribution:** Assess trends in income-related inequity among working-age persons in the U.S. between 2008 and 2019, a period encompassing six years before and six years following ACA implementation. The last U.S. study used data from 2008, and no study has examined the equity effects recent policies. **Methods:** Using 2008-2019 Medical Expenditure Panel Survey data, we analyzed income-related inequity among working-age persons for five utilization outcomes: medical care expenditures, ambulatory visits to physicians, primary care visits to physicians, internal medicine subspecialist visits, and emergency department (ED) visits. For each outcome and person, we obtained actual and predicted utilization, with predictions based on regressions using age, sex, and a wide array of health status variables to capture medical need. We used two-part models (logistic and GLM with log link) for expenditures and Poisson models with overdispersion for visits. Next, for each outcome and year, we used the convenient regression method to calculate the horizontal inequity index, which quantifies the degree to which utilization deviates from the normative standard. Finally, we regressed the inequity indexes for each outcome on a linear time trend allowing for different slopes and intercepts before and after ACA implementation in 2014. **Key Results:** We found pro-rich inequity at baseline for all outcomes except ED visits, with much higher inequity for subspecialist visits than for other visits. More strikingly, we found only very small reductions over time in pro-rich inequity for ambulatory visits to physicians and subspecialist visits, and no change in inequity for the other outcomes. Findings were unchanged in sensitivity analyses. **Conclusions:** Limitations of recent policies may explain our surprising finding of no appreciable reduction in pro-rich inequity. FQHCs are helpful but have limitations. Medicaid coverage may not lead to equitable access, especially to costly services like specialty care and advanced imaging. Additionally, low-income persons with marketplace coverage who do not qualify for the most generous cost-sharing subsidies may face affordability barriers to access. Although there is evidence that the ACA insurance provisions improved access to care for low-income persons, our analyses demonstrate the limits of health insurance in making care more equitable.

Ind-510 ADAM WAGSTAFF AWARD WINNING PAPER: Do Providers Contribute to Socioeconomic Inequalities in Health Care? An Audit Experiment in Tunisia

PRESENTER: **Rym Ghouma**

AUTHORS: Mylene Lagarde, Timothy Powell-Jackson

Background There is growing evidence that socioeconomic health disparities — differences in health outcomes between poor and richer populations — can result from variations in the quality of care patients receive. One important yet understudied cause is provider behaviour during a clinical encounter. We present novel evidence on the causal effect of a patient's socioeconomic status (SES) on doctors' provision of care in a primary care setting. Methods** We undertook an audit experiment to examine whether doctors treat patients differently according to their SES in the Grand-Tunis area of Tunisia. We sent standardised patients (SPs) with the same symptoms to 130 public and private primary care facilities for consultation varying only the SES of patients. Each facility was visited by two SPs, one was "poor" and one was "middle class". To align with the Tunisian context, the SES profiles were informed by in-depth qualitative research that went beyond just patient clothes to include aspects of language, physical appearance, and attitude to signal differences in SES. We assessed the care provided by doctors using a range of metrics on clinical quality, effort, and cost of care, as well as measures of effective communication. Findings** We found no evidence of SES differences in correct case management and clinical effort, although the rate of unnecessary treatment was greater for the poorer patients. Doctors prescribed less expensive drugs and gave significantly more free-of-charge drugs to the worse off, possibly driven by altruism towards poorer patients. In line with the literature on patient discrimination, we found significant differences in effective communication between patients: doctors were more likely to explain the diagnosis, give reasons for prescribing the drugs, and explain the treatment plan to richer patients compared to poorer ones. These results were not explained by time constraints as doctors spent comparable time with both patient profiles. Interpretation There are SES inequalities in some aspects of care, which are driven by the doctor, not the patient. Some of these differences, such as those in prescribing fewer expensive drugs and giving out more free drugs to the poorer patients, suggest concerns about higher provision of unnecessary and potentially harmful treatment to these patients. Other differences such as communicating less effectively to the poorer suggest prejudicial behaviour. To the extent that differences in communication with patients can lead to differences in patients' health decisions, our results suggest that doctors could contribute indirectly to health inequalities. Further research is needed to explain the drivers of

these inequalities and how to address them.

Ind-1959 Widening Inequalities in Cervical and Breast Cancer Screening in Kenya

PRESENTER: **Denis okova**, UNIVERSITY OF CAPETOWN
AUTHORS: Akim Tafadzwa Lukwa, Ataguba John

Background Breast and cervical cancer are the two most prevalent cancers and the leading causes of cancer deaths in both sexes in Kenya. As is the trend in many Low-and-Middle Income countries (LMICs), the incidence and mortality rates of breast and cervical cancer in Kenya are on the rise. This can be alleviated by screening to promote early diagnosis. In LMICs like Kenya, however, breast and cervical cancer screening opportunities are limited compared to High-Income Countries (HICs). Previous studies have largely examined the determinants of breast and cervical cancer screening with little efforts to assess related inequalities and decomposing the inequalities across household characteristics in Kenya. This is critical as the Kenyan government scales up screening initiatives. **Objectives** The study aims to examine trends in between-group and within-group socioeconomic related inequalities in the uptake of breast and cancer screening among eligible women. **Methods** This study used Demographic Health Survey (DHS) data sets of 2014 and 2022. Clinical breast examination (CBE) in women aged 18 and older was the indicator for breast cancer screening. Cervical cancer was indicated by “having gone for a cervical examination to check for cervical cancer” by women aged 25 and older. Normalized Errygyers concentration indices were computed to demonstrated whether cancer screening was pro-rich or pro-poor. The study then used the Theil index and decomposed the index by population subgroups (place of residence and socioeconomic status-SES) to understand within-between groups inequality. **Results** Over the two periods, the rates of cervical (15.03% versus 15.43%) and breast cancer (23% versus 24%) screening remained relatively unchanged. The Erreygyers normalised concentration indices for breast (2014; 0.15, p=0.00 & 2022; 0.13, p=0.00) and cervical screening (2014; 018, p=0.000 & 2022;0.16, p=0.000) for both periods were both positive indicating women of low SES are less likely to screen for both cancers. The Theil indices show that the socioeconomic inequalities in breast and cervical cancer screening for both periods were more dominant among women living in rural areas and those of low SES while the overall inequalities in screening of both cancers widened between 2014 and 2022. For cervical cancer screening, 96.4% to 97.1% of socioeconomic inequalities were explained by within-group household variability while 2.9% to 3.6% of the inequalities were explained the socioeconomic group which the women belongs to. A similar trend was observed with breast cancer screening. **Conclusion** Unequal distribution of household wealth as well as the rural-urban split enable the inequalities in breast and cervical cancer screening in Kenya. Thus, policies that bridge the rural-urban gap and those that address the within socioeconomic-group inequalities are vital. **Keywords:** Breast cancer screening, Cervical cancer screening, Inequalities, Socioeconomic status

Ind-2264 Unraveling Socioeconomic Inequalities in Unmet Healthcare Needs: Why Do They Persist Under Korea's Universal Health Coverage?

PRESENTER: **Inuk Hwang**, Graduate School of Public Health, Seoul National University
AUTHOR: Jongnam Hwang

Background:** Timely access to health care is of great concern to the general public, who anticipate no barriers to necessary health services regardless of an individual's socioeconomic status. However, a growing body of literature highlights that individuals with lower socioeconomic status (SES), particularly those with lower income and educational levels, have more difficulties accessing basic health care services irrespective of health status. Despite the achievement of universal health coverage through the National Health Insurance (NHI) in Korea, an inverse relationship between SES and unmet healthcare needs has been reported. This study aimed to assess socioeconomic inequalities in unmet health care needs among Korean adults over the past 13 years and to identify the major contributors to these inequalities.

Methods:** A total of 24,516 and 16,824 participants from the Korea National Health and Nutrition Examination Survey (KNHANES) in 2005 (Wave 3) and 2016–2018 (Wave 7), respectively, were included in the analyses. The analyses included respondents aged 18 and older who completed the health survey series in the KNHANES. Respondents with any missing values were excluded. To examine inequalities in unmet healthcare needs, the Concentration Index (CI), a widely used tool for measuring income-related inequality in health economics and policy research, was used. After calculating the CI, a decomposition method was applied to identify the major socio-demographic contributors to the observed inequalities between 2005 and 2016–2018. In addition to the decomposition of the CI, the horizontal inequity index (HI) was obtained to determine whether the observed inequality is a matter of inequity. For these analyses, the outcome variable was an individual's self-reported experience of unmet health care needs within the past 12 months. As the main indicator of SES, equivalized annual household income was used for the CI analyses. For the decomposition models, socio-demographic determinants were selected based on Andersen's Health Behavior Model.

Results: The CIs for unmet healthcare needs consistently showed negative values, indicating that individuals with lower income were more likely to experience unmet healthcare needs. However, the magnitude of the CIs decreased over time, from -0.241 in 2005 to -0.118 in 2016–2018. The HI, which captures the concept of equal care for equal need, also favored the poor during the given periods (2005: -0.191; 2016–2018: -0.153), suggesting that the observed inequalities in unmet healthcare needs in Korea are a matter of inequity. The decomposition of the CIs revealed that lower income and educational levels were the major contributors to the existing inequalities in unmet needs in Korea.

Conclusions: While the magnitude of inequalities in unmet health care needs has diminished over the last decade, socioeconomic inequalities under Korea’s National Health Insurance system persist. The reduction in unmet need-related inequality could be attributed to ongoing changes in services and user fees that have helped demolish financial barriers to necessary health services. To alleviate the remaining inequalities in unmet health care needs in Korea, expanding service coverage and improving accessibility to essential care at the community level should be considered as policy options.

abs-os81 Healing Gaps: The Role of General Practitioner-Patient Concordance in Health Outcomes

PRESENTER: **Elisa de Weerd**, Erasmus University Rotterdam

AUTHOR: Vahid Moghani

General practitioners (GPs) are the primary point of contact in the healthcare system and play a crucial role in patients' access to care. However, disparities in trust and communication exist, with patients indicating preferences for GPs that share similar characteristics. One proposed solution is to increase concordance between patients and provider, such as shared gender or background, to improve outcomes. This study investigates whether gender concordance between patients and GPs affects healthcare utilization and outcomes. Using Dutch administrative data (2013–2022) covering all GP practices and linked individual-level health records, we analyze variation in local access to female GPs across postal codes and over time. Focusing on areas with only one or two practices, we assess the effects of GP gender concordance on care use, including GP visits, prescriptions, and hospital care. Preliminary results suggest that female patients with access to a female GP have higher primary care utilization and higher hospital costs, with no evidence of differential sorting into areas with more female GPs. These findings can help inform strategies for reducing barriers in health care delivery.

9:00 AM –10:30 AM WEDNESDAY [Economic Evaluation Of Health And Related Care Interventions]

Bali International Convention Centre – Executive Room 1

Economics of Breast Cancer Screening

MODERATOR: **Hansoo Kim**,

Ind-1574 Cost-effectiveness of a Polygenic Risk Score-Based Breast Cancer Screening Program in Three European Countries

PRESENTER: **Filipa Sampaio**

AUTHORS: Peeter Padrik, Krista Kruuv-Käo, Katrin Koiduaru, Neeme Tõnisson, Siim Sober, Andreas Karakatsanis, Evangelos Digkas, Luis Costa, Gonçalo Nogueira da Costa, Inna Feldman

Background Mammography screening is cost-effective and reduces breast cancer mortality, yet it misses a large proportion of cases below screening age. Women under 50 with breast cancer have a 30% mortality risk. Considering genetics and other risk factors is key to reducing breast cancer burden, opening way to personalized risk-based approaches to prevention. With limited research on the cost-effectiveness of PRS-based breast cancer screening, it is unclear whether PRS-guided screening is cost-effective compared to standard mammography screening. This study evaluated the cost-effectiveness of a breast cancer screening program using the isolated effect of polygenic risk score for women aged 35 years compared with current standard biennial age-based mammography in Estonia (age 50-69), Sweden (age 40-74) and Portugal (age 50-69). **Methods** A Markov model was used to conduct a cost-utility analysis and estimate the costs and health outcomes of the current mammography screening programs compared with a polygenic risk tailored screening program, adapted to women´s risk profile. The model simulated how a cohort of 1000 women aged 35 moved between the states healthy/at risk, Ductal Carcinoma In Situ (DCIS), stage I, II, III, IV cancer, and dead, and estimated cumulative costs and health outcomes over lifetime. Costs were estimated from a health-payer perspective. Risk profiles were sourced from clinical pilots in each country collecting familial, clinical and genetic information from country-specific samples of women (the BRIGHT study). Breast cancer stage distribution, incidence, screening uptake, mortality and costs were sourced from country-level sources. Breast cancer utilities were sourced from literature and adjusted to country-specific population utilities. Costs and health outcomes were discounted at country-specific annual rates. Costs were valued in 2022 €Euro. Model outcomes were incremental cost-effectiveness ratios (ICER), calculated as the difference in costs divided by the difference in quality-adjusted life-years (QALY) between strategies. Scenario analyses, one-way and probabilistic sensitivity analyses were conducted to test model assumptions. **Results** Preliminary results indicate that PRS-guided screening led to a redistribution of discovered cancer cases, with more early stage cancers, fewer advanced stage cancers, and breast cancer deaths averted, in a cohort of 1000 women, with variations across settings. Risk-stratified screening resulted in larger net costs mainly related to polygenic test and consultation costs, more life years gained and more QALYs gained, with relatively low ICERs. Findings were sensitive to the uncertainty around risks estimates of developing breast cancer and in variations in discount rate. Probabilistic analysis showed that PRS-guided screening was likely to be cost-effectiveness at local WTP values. **Conclusions** PRS-guided screening integrated into standard breast cancer screening programs in Estonia, Sweden and Portugal may yield clinical benefits and has the potential to be cost-effective at existing local WTP thresholds. Further studies are needed to address data limitations and reduce uncertainty in model outputs.

Ind-1603 Cost-effectiveness of Artificial Intelligence in Breast Cancer Screening

PRESENTER: **Joanne Scarfe**

AUTHORS: Luke Marinovich, Alison Pearce, Nehmat Houssami

Background: Breast cancer screening in Australia involves two radiologists reviewing each mammogram with discordant results resolved by a third radiologist. The process is subjective and may lead to true positives, false positives, or missed cases due to reader error or because the cancer is not visible to the reader. Artificial intelligence (AI) algorithms for interpreting mammograms can potentially improve the effectiveness of population breast cancer screening programs if they can reduce the number of cancers 'missed' by radiologists. In addition, AI may address radiologist shortages, reduce reader workload and costs, and lower health system expenses through early detection and diagnosis, supporting screening program sustainability.

Research aim: Our objective was to investigate the cost-effectiveness of integrating AI into breast cancer screening from an Australian health care system perspective.

Methods: Using decision analytic modelling we assessed the incremental cost per additional cancer detected. We compared standard breast cancer screening practice with three AI-human screen reading strategies: AI replacing one human reader (Integrated); AI triage with human single-reading for low-risk screens (Triage Single); and AI triage with no human reading for low-risk screens (Triage Only) simulated in a retrospective cohort of 108,970 consecutive mammograms from women aged 50-74 years from 2013-2016 in an Australian breast screening service (BreastScreenWA). The two-year model incorporated cancer detection and recall rates. One-way and probabilistic sensitivity analyses explored uncertainty around costs and effects. Using prospective trial data (Lång et al., 2023), scenario analyses explored the impact of improved AI performance on cost-effectiveness.

Results: All AI-human strategies were less costly but slightly less effective than Standard. Triage Only was the most efficient with an average saving of $4 per cancer detected, but detecting 0.000521 fewer cancers per person screened compared to Standard (equivalent to 0.521 fewer cancers per 1,000 people screened). This resulted in an incremental cost-effectiveness ratio (ICER) in the south-west quadrant of the cost-effectiveness plane, with a saving of $8,206 for each cancer *not* detected. Cost savings for Triage Only were primarily driven by having no human reading for the 50% of screens triaged as low-risk for breast cancer by the AI. Sensitivity analysis indicated the ICER was most sensitive to uncertainty around the cost of human screen reading and interpretation. Scenario analyses showed that a modified version of Triage Single, where only screens classified as 'high risk' (<10%) underwent double-human reading, improved effectiveness but increased costs (ICER = $587 per additional cancer detected) compared to current practice.

Conclusions and implications for policy and practice: This study represents one of the few economic evaluations comparing AI-supported mammogram reading with human reading, and the only health economic evaluation which has used patient-level data in a real-world population breast cancer screening setting. While the AI algorithm used in this study is unlikely to be cost-effective based on our retrospective data, improved outcomes seen in prospective trial data suggest AI-human screen reading could be cost-effective in the future. Breast cancer screening programs should therefore be considering now how they might implement AI technology in the future. 2

Ind-1943 Cost-Effectiveness Analysis of BRCA1/2 Screening for Breast Cancer and Ovarian Cancer Early Detection Among Chinese Women

PRESENTER: **Yaqun Fu**, Peking University
AUTHORS: Li Yang, Xia Wei

Background In 2022, approximately 19.96 million new cancer cases were reported globally, with breast cancer (BC) emerging as the most commonly diagnosed female cancer. It accounted for 2.31 million cases, representing 15.4% of total female cancer deaths. In China, breast cancer in women accounted for 0.36 million new cases and 75,000 deaths. Although the usage of multi-cancer screening technology becomes more and more popular internationally, the cost-effectiveness results were controversial across high-income countries and low- and middle-income settings, as well as among populations with differing levels of risk. Morevoer, there is a lack of evidence specific to the Chinese context.

Objective This study aims to examine the cost-effectiveness of BRCA 1/2 genetic testing for the early detection of breast and ovarian cancer (OC) among Chinese women aged 20 and older across different risk levels.

Methods: A Markov model was developed to assess the cost-effectiveness of various screening strategies for the early detection of BC and OC from a societal perspective over a lifetime horizon. The screening methods include BRCA1/2 testing for all age eligible women, BRCA1/2 testing for high-risk women (BC patient's relatives, Gail assessment ≥1.67%, a history of chest radiotherapy, etc.) and routine screening without genetic testing (mammography and ultrasound for low-risk population, and MRI for BC high-risk population and CA125 and transvaginal ultrasound for OC high-risk population). Total costs, quality-adjusted life years (QALYs), and net monetary benefit were generated for each strategy, and incremental cost-effectiveness ratio (ICER) was calculated by comparing each strategy to routine screening. Sensitivity analyses were conducted for decision-making in providing and prioritizing BRCA testing.

Results: When the willingness-to-pay (WTP) threshold was set at 1-fold GDP per capita in China in 2023 ($12,635.22), BRCA1/2 genetic testing for the general population resulted in an incremental cost of $5,153.58 with a gain of 0.125 QALYs, yielding an ICER of $41,228.66/QALY, and was not cost-effective compared to routine non-genetic screening. In contrast, BRCA1/2 testing for high-risk groups was cost-effective, with an ICER of $1,657.01/QALY compared to routine non-genetic screening. The net monetary benefit of routine screening, BRCA1/2 testing for the general population, and BRCA1/2 testing for high-risk only were $756,572.16, $752,993.18, and $757,949.50, respectively. The results were robust through the sensitivity analyses. The three most influential factors affecting cost-effectiveness were cancer incidence for BRCA mutation carriers, BRCA mutation rate in the general population, and the utility associated with cancer status. Probabilistic sensitivity analysis indicated that at a WTP below $2262.40, routine screening strategy had a 99% probability of being cost-effective. As the WTP increased, BRCA1/2 testing for high-risk groups became more likely to be cost-effective, and at a WTP of 1-fold GDP per capita or higher, it had a 99.8% probability of being cost-effective compared to other strategies.

Conclusions Performing BRCA1/2 testing on high-risk Chinese women for the simultaneous early detection of BC and OC simultaneously is cost-effective compared to routine screening. However, genetic testing for the general population is not cost-effective in the Chinese context.

Ind-2148 Cumulative Incremental Budget Impact of Drugs For Chronic-Degenerative And Rare Diseases in The Brazilian Public Health System Between 2014 And 2024

PRESENTER: **Everton Nunes da Silva**, University of Brasilia
AUTHORS: Daniel da Silva Pereira Curado, Laís Lessa Neiva Pantuzza, Ana Carolina de Freitas Lopes, Amanda Oliveira Lyrio, Mariá Gonçalves Pereira da Silva

Background: Since 2012, all drugs dispensed in the Brazilian public health system (SUS) must be incorporated by the National Committee for Health Technology Incorporation (Conitec), which also assesses budget impact analyses (BIA). Despite health budget constraints and concerns about drug financing in Brazil, including high-cost drugs for rare diseases, the cumulative incremental budget impact (IBI) of drugs incorporated by Conitec over the years (beyond the BIA time horizon) is unknown. Thus, our aim was to estimate the per capita costs and cumulative IBI values of drugs for chronic-degenerative and rare diseases in the SUS between 2014 and 2024.

Methods: Based on the 2014-2024 public reports of the Conitec, data were collected on proposals for the incorporation of drugs for chronic-degenerative and rare diseases into the SUS. The proposals were categorized by the type of disease (rare or other chronic) and incremental budget impact (IBI) (incremental or cost-saving). Per capita costs were calculated by dividing the IBI values by the estimated population of each BIA. Then, the median and interquartile range (IQR) of per capita costs were obtained for all BIAs and for rare diseases and other chronic diseases, separately. In addition, the cumulative IBI values between 2014 and 2029 were calculated and adjusted by interpolation in the years beyond those considered in each BIA and by the Brazilian inflation rates, for 2024. The values were collected in BRL and converted to dollars, considering the World Bank's purchasing power parity (US$1 = BRL 2.44), referring to 2023 (most recent data available).

Results: Among all 106 BIA, 65.09% (n=69) resulted in incremental costs. Thus, both analyses involving rare diseases and other chronic diseases mostly represented incremental costs [70.45% (n=31) and 61.29% (n=38), respectively]. On the other hand, other chronic diseases were more cost-saving than rare diseases [38.71% (n=24) vs 29.55% (n=13), respectively]. Regarding per capita costs, the values for other chronic diseases tended to be lower than those for rare diseases [median of US$86.75 (IQR: -US$592.62 and US$832.34) vs median of US$3,914.36 (IQR: -US$496.60 and US$114,406.94), respectively]. The cumulative IBI values with interpolation were increasing, with US$9.49 million in 2014, and reaching a maximum value of US$1.85 billion in 2023, which remains relatively stable until 2029. However, when data interpolation is not considered, the cumulative IBI values were decreasing from 2024 onwards (below US$609.34 million, up to -US$140.82 million in 2029).

Conclusions: Following the global trend, the incorporation of drugs for rare diseases represented higher per capita costs and were less cost-saving than for other chronic diseases. Combined with the growing accumulated IBI, equivalent to approximately 40% of the Brazilian budget for drugs for these diseases in 2024, the next incorporations by Conitec should better consider Brazil's budget capacity, so as not to pose risks to the sustainability of the SUS. Meanwhile, Brazilian healthcare investments should prioritize health equity, not leaving specific populations unassisted, since innovative drugs, especially for rare diseases, have had increasingly higher prices due to investments in clinical research.

Ind-1730 Does the Charitable Medical Assistance Program Impact Catastrophic Medical Expenditures for Families of Children with Leukemia?

PRESENTER: **Xiaojie Sun**
AUTHORS: Jun Su, Yuqing Zhang

Background: Pediatric leukemia is the most prevalent childhood cancer in China, exerting a considerable financial impact on affected families. Despite the mandatory participation of all Chinese children in the Resident Basic Medical Insurance, out-of-pocket (OOP) expenses remain substantial for families of children with leukemia. However, charity assistance has been shown to help mitigate these financial burdens. The "Love Union Project" is a comprehensive charitable medical assistance program designed to support families of children with leukemia within China's multi-tiered healthcare security system. This study was designed to evaluate the impact of the " Love Union Project " on reducing the incidence of catastrophic health expenditure (CHE) among families of children with leukemia in China.

Methods: The study was based on a charitable medical assistance program-" Love Union Project ". The intervention group consisted of 85 children from H city who received the assistance of the program. The control group was comprised of 36 children from S and Y cities, selected to match H city in terms of comparable social and economic status. The basic demographic characteristics, medical expense expenditures, and project assistance information of pediatric leukemia patients and their caregivers were collected in this study. Non-normally distributed costs were reported as the median and interquartile range. After adjusting for other factors, multivariate logistic regression analysis was employed to examine the impact of the "Love Union Project" on the incidence of CHE.

Results: After medical insurance reimbursement, the intervention group's median OOP expenditure was CNY230,000($31,874), and the control group's median OOP was CNY217,200($30,100). However, with the program's additional reimbursement, the intervention group's median OOP expenditure was reduced to CNY 201,300 ($27,896). Thanks to the program's intervention, the CHE rate among the intervention group decreased from 75.3% to 65.9%, while the incidence of CHE in the control group was 75.0%. Compared to families with children aged 0-6

years, those aged 7-12 were more likely to incur CHE (OR 5.224; 95%CI 1.412-19.322). Families with five or more members were also at higher risk of CHE than those with four members or fewer (OR 2.847; 95%CI 1.056-7.676). Additionally, families with a monthly income of CNY8000($1,120) or more were less likely to experience CHE than those with a monthly income of CNY4000($560) or less (OR 0.257; 95%CI 0.072-0.923). Lastly, families receiving assistance from the "Love Union Project" reported significantly lower CHE rates than those who didn't receive such support (OR 0.151; 95%CI 0.044-0.524).

Conclusion: This study suggested that medical insurance offered a limited buffer against these financial strains; however, the " Love Union Project " enhanced the economic resilience of families of children with leukemia, playing a crucial role in the multi-tiered medical security system. It is essential to pay specific attention to a subgroup of pediatric patients who are younger, belong to larger households, have lower monthly incomes, and have not yet received support from charitable medical assistance.

Ind-152 Potential Impact of Immunisation on Infectious Diseases Related Out-Of-Pocket Expenditures and Catastrophic Expenditure on Indian Households

PRESENTER: **Habib Farooqui**, Qatar University
AUTHORS: Anup Karan, Giridhara Babu

Background: Immunisation remains one of the most effective and cost-effective interventions for the prevention of childhood morbidity and mortality. Recent research has reported the benefits of childhood immunization on demographic transition, schooling attainment, and earnings. However, the impact of childhood immunization on financial risk protection at the household level has not been estimated and reported for India. The core objective of this research was to answer - what is the impact of the universal immunization program (UIP) on infectious disease occurrence and related out-of-pocket expenditure and catastrophic expenditure at the household level in India? **Methods:** We analysed the 75th round of the National Sample Survey of India data (NSSO 2017-18). We employed regression models to measure the impact of UIP on infectious disease occurrence and financial risk protection measures among the households exposed to UIP vis-à-vis unexposed households. The exposure to the UIP was a binary variable: 1, if the household reported immunized children in the household and 0, otherwise. The immunisation status of the child was also binary: 1, if the child was fully immunized (has received the following UIP vaccines i.e., BCG, all doses of polio vaccine including booster dose, all doses of diphtheria-pertussis-tetanus (DTP) including booster dose, and measles) and 0, otherwise. We considered the following outcome indicators: i) percentage of households reporting any infectious disease; ii) percentage of households reporting out-of-pocket expenditure ii) per household per capita out-of-pocket expenditure per episode and iii) percentage of households reporting catastrophic expenditure. **Results:** We find that households exposed to UIP have a 10.7% (95% CI: 10.4% -10.9%) lower probability of hospitalization and a 0.5% (95% CI: 0.01% - 0.9%) and 0.7% (95% CI: 0.3% - 1.2%) lower percentage of households incurring out-of-pocket expenditure (OOPE) and catastrophic expenditure, respectively. Similarly, the probability of outpatient care was 5.4% (95% CI: 5.3% - 5.6%) lower in households exposed to UIP and the percentage of households incurring OOPE was -0.8% (95% CI: 0.00% - 0.16%) lower in households exposed to UIP compared to unexposed. However, the percentage of households reporting catastrophic out-of-pocket expenditure was only marginally lower by 0.1% (95% CI: -0.4% - 0.2%). Furthermore, there was heterogeneity in the outcomes across rural and urban areas and the magnitude of the potential impact of immunization on the reported outcomes was significantly higher in the urban areas as compared to rural areas. **Conclusions:** We recommend sustainable financial allocation to immunization programs to improve household-level health and economic outcomes.

Ind-2804 Effect of Supplemental Private Health Insurance on Suicidality Among South Korea's National Health Insurance Enrollees

PRESENTER: **Ara Yoon**
AUTHORS: Donggyo Shin, Jangho Yoon, Seungbeen Ghim, Minjeong Kim, Hyunwoung Shin

Aim: As one of the nations with the highest suicide rates, South Korea has persistently topped suicide rates for nearly two decades among OECD countries. This research examines whether supplemental health insurance coverage within a universal healthcare system may have a preventive effect on suicidality. Specifically, we examine the effect of supplemental private health insurance (PHI) on suicidal ideation among South Korea's National Health Insurance (NHI) enrollees. The NHI scheme provides controlled benefits for approximately 97% of the population; however, over 80% of NHI enrollees also have supplemental private health insurance (PHI) due to the limited coverage provided by the NHI. Our rationale is that supplemental health insurance, which covers additional out-of-pocket costs and certain non-covered treatments, may help reduce suicidality by alleviating financial strain and ensuring more stable access to mental and physical healthcare services.

Methods: We analyze data drawn from the 2011-2018 Korean Health Panel Survey, a nationally representative sample of non-institutionalized Korean citizens. The sample includes 101,349 observations on 23,644 unique individuals aged 18 and older. Suicide ideation is measured as "having suicidal thoughts or impulses in the past year." We use a probit model to assess the overall relationship between PHI coverage and suicide ideation. We also estimate effects of PHI type (fixed vs. indemnity) for those with PHI. Additionally, we construct a recursive simultaneous-equations model, consisting of two sequential equations, examining a pathway through which PHI coverage affects suicide ideation. In Stage 1, having unmet healthcare need due to cost is modeled as a function of having a PHI and other determinants of access to care. In Stage 2, suicide ideation is modeled as a function of 'unmet healthcare needs due to cost' and other determinants of suicide ideation. We utilize a bivariate probit procedure to jointly estimate the equations. Estimates are survey-weighted. We adjust standard errors for intraclass correlation and obtain average marginal effects.

Results: Over the study period,** the rate of PHI consistently increased from 76.2% in 2011 to 82.8% in 2018. In contrast, both unmet healthcare needs due to cost and suicide ideation declined gradually. The rate of unmet need decreased from 3.4% in 2011 to 1.8% in 2018, and the rate of suicide ideation similarly declined from 3.9% to 1.8%. Overall, having PHI is associated with a 0.43 percentage-point decrease in the

rate of suicide ideation (p<.001), accounting for 9.7% of the suicide ideation rate among those without PHI (4.45%). This relationship holds among non-elderly adults aged 18 to 69 but not among those aged 70 years or older. Among individuals with PHI, PHI type does not show a significant association with suicide ideation. Bivariate probit estimates support the hypothesized pathway: PHI is associated with a 0.62 percentage-point decrease in the likelihood of having unmet need (p=.001), and, subsequently, unmet need is associated with a 4.6 percentage-point increase in the likelihood of suicide ideation (p=.003).

Conclusion: Supplemental PHI coverage significantly reduces unmet healthcare needs due to cost among adult NHI enrollees in South Korea and, thereby, lowers rates of suicide ideation.

Ind-62 Reciprocal Relationship between Cognition and Depression Among Chinese Middle-Aged and Older Adults:the Mediating Role of Internet Use

PRESENTER: **ZhiChao Wang**

Objective :Prior work has identified an inverse relationship between depression and cognition in older adults, but the mechanisms underlying this association remain unclear. This study investigated whether internet use mediates this relationship in middle-aged and older adults.

Method : Data came from the 2015, 2018 and 2020 waves of the Chinese Longitudinal Healthy Longevity Survey (n = 9,610). The random intercept cross-lagged panel model (RI-CLPM) combined with mediation analysis was used to determine the relationship between cognitive function and depressive symptoms and the mediating effect of internet use on the ascertained cognition–depression relationship. Mediating effects subgroup analyses included middle-aged (45–64 years) and older (65+ years) adults.

Results: At the between-person level, a significant negative correlation was found between cognitive function and depressive symptoms. Within-person analysis revealed a bidirectional relationship: poorer cognitive function predicted increased depressive symptoms ($\beta^* = -0.080$, $p < 0.001$), and conversely, increased depressive symptoms predicted poorer cognitive function ($\beta^* = -0.019$, $p < 0.05$). Internet use partially mediated this relationship, accounting for 8.58% and 9.69% of the total effects, respectively. This mediating effect was stronger in middle-aged adults than in older adults.

Conclusions: This study notes a bidirectional association between cognitive function and depressive symptoms from a nationally representative five-year follow-up sample, and this relationship is partially explained by their impact on Internet use. These results emphasize the continued importance of exploring multidisciplinary interventions to mitigate depressive symptoms and delay cognitive decline in middle-aged and older adult populations.

Keywords: Cognitive function, Depression, Internet use, longitudinal study, mediation analysis, Random intercept cross-lagged panel model , Chinese middle-aged and older adults

Ind-765 Exploring the Impact of Broadband Access on Nutrition Assistance Benefit Utilization

PRESENTER: **Qi Zhang**, Old Dominion University

Background The Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) ranks as the third-largest nutrition assistance initiative in the United States, serving over 6 million low-income women, infants, and children under five. While WIC benefits are provided free of charge, underutilization remains a significant issue, with redemption rates as low as 5%, posing heightened nutritional risks. Technological tools like WIC shopping apps and online ordering systems have been introduced to address this, all of which rely on broadband access. However, broadband availability varies significantly across U.S. counties, potentially affecting program outcomes. **Research Objective** To investigate the relationship between broadband internet access and WIC benefit redemption rates among participating households. **Methods** As a federally funded but state-administered program, the WIC state agencies often maintain restricted access to household-level redemption data. We worked with the Oklahoma WIC agency and obtained the 2020 WIC redemption data to estimate average redemption rates. County-level broadband access was assessed using three data sources: 1. **Federal Communications Commission (FCC) Data:** Determined if at least 90% of a county had a broadband provider. 1. **American Community Survey (ACS) Data:** Measured broadband subscription rates of at least 60% among county residents. 1. **Ookla's Open Data Initiative:** Calculated average mobile network speeds (minimum 25 Mbps download and 3 Mbps upload). A fractional logit regression model was applied, accounting for socio-demographic factors at both household and county levels. The average COVID-19 incidence rate at the county level was controlled to account for the effect of the COVID-19 pandemic on the benefit redemption in 2020. **Results** The study analyzed data from 65,190 Oklahoma WIC households, revealing significant disparities in broadband access across racial and ethnic groups. For example, Hispanic households exhibited the highest broadband access rates, while non-Hispanic Black households had the lowest (P < .001). Households with children or larger household sizes demonstrated greater broadband access (P < .001). Broadband access correlated positively with redemption rates: - **FCC data:** Redemption rates of 50.3% (with access) vs. 43.0% (without access). - **ACS data:** 50.3% (with access) vs. 42.9% (without access). - **Ookla data:** 48.7% (with access) vs. 42.5% (without access). Regression analysis showed that FCC broadband availability significantly boosted redemption rates (Coefficient = .029, P < .001), as did ACS broadband (Coefficient = .012, P < .001) and Ookla mobile internet (Coefficient = .018, P < .001). **Conclusions** This pioneering study highlights the positive impact of broadband internet access on WIC benefit redemption rates. By leveraging household-level transaction data, the findings underscore how enhanced broadband infrastructure can improve program utilization and contribute to the long-term health of WIC participants. 2

Ind-1894 Women's Income And Household Nutrition And Diets

PRESENTER: **Priya Bhagowalia**
AUTHOR: Arjita Chandna

As per the Global Hunger Index 2021, 15.3% of India's population is undernourished and deficient in protein consumption (von Grebmer et al., 2021; Kolady et al., 2021). Since the Covid-19 pandemic, household nutrient consumption may have declined further due to supply and demand side factors such as lockdowns, income losses, and inaccessibility of government food safety nets (Gupta et al., 2022). Assuming that the household head and his/her spouse are the primary members who influence household nutrition, we examine the association between women's income and household nutrition using panel data. Men and women may have different consumer preferences and their ability to influence household consumption allocation depends on their relative bargaining power (Chiappori, 1992; Opata et al., 2020). Therefore, we test the association of primary woman's income (the head or the spouse of the head) as a share of the total income of the primary couple with household nutrition, using indicators that capture the quantitative as well as compositional aspects of nutrition. Second, we explore if the presence of other adult members, especially those, that may be in a hierarchical relationship with the primary woman, influences household nutrition. Using the India Human Development Survey (IHDS, 2005, 2011), we convert monthly consumption of food to household level macronutrient intakes. Food groups consumed in the last thirty days are added to get a food variety score (FVS). We also calculate Berry's index of diet diversity that indicates degree of household's diet concentration between food groups. The primary woman's income share is calculated by adding wages/ salary, government benefits, and notional farm income. OLS and LPM models, with household fixed effects test the impact of the primary woman's income on macronutrient consumption and FVS. Our results show that the primary woman's income share has a positive and significant association with household calorie intakes especially those obtained from carbohydrates; significant negative association with calories from fats; no association with calories obtained from proteins and a negative and significant association with diet diversity. Additionally, the positive association of the primary woman's income share with household calorie intake is weaker in the presence of other educated women having hierarchical relationships with the primary woman. The study underscores the importance of women's relative bargaining power in improving household nutrition. We find that a greater share of income controlled by the primary woman could improve household calorie and macronutrient intake, but may not necessarily lead to a balanced consumption of macronutrients. Additionally, an increase in the relative number of earning women within the household strengthens the impact of primary woman's income share. Our results suggest that provision of basic income to the women head of the families could improve household calorie, protein, and carbohydrate intakes. However, the effectiveness of such gendered income policies may depend on the household hierarchical structure. Our results although based on a sample from India, may be applicable to developing countries which may use universal basic income as a tool to improve malnutrition and health.

Ind-684 What to Expect WHEN You Are Expecting (War is Over)

PRESENTER: **Camilo Antonio Arias**, Universidad de los Andes (Bogotá)

This study examines the consequences of ending armed conflict on health at birth using a natural experiment in Colombia: the ceasefire between the government and FARC guerrillas. We analyze administrative records of over 5 million births (2011-2018) using a difference-in-differences approach that compares variations in birth outcomes over time between municipalities with high and low exposure to the ceasefire. We find that the end of conflict affected fetal loss rates by evaluating the probability of male births. We identify two countervailing effects on birth weight by analyzing birth weight distribution. The end of the conflict increased the number of births with very low weights, as weaker newborns could survive. Conversely, reduced maternal stress led to a higher probability of births with elevated weights. These effects were more pronounced in municipalities without the presence of other illegal armed groups. Finally, we find evidence that the end of the conflict increased the likelihood of births attended by medical personnel and the frequency of prenatal visits by mothers.

Ind-1736 Wide-Field Digital Imaging for Universal Neonatal Eye Screening: Integrating Evidence on Feasibility and Economic Implications

PRESENTER: **Khairil Idham Ismail**

AUTHORS: Izzuna Mudla Mohamed Ghazali, Che Sarida Che Ismail, Roza Sarimin

Background Childhood vision impairment poses significant challenges to public health, particularly in Malaysia, where preventable cases remain prevalent. In Malaysia, the high incidence of preventable childhood vision impairments underscores the need for its early detection through eye screening. Red Reflex Test (RRT), has been the standard method but suffers from low sensitivity and limited field view. Wide-Field Digital Imaging (WFDI) offers improved sensitivity and broader diagnostic capabilities. This study integrates a systematic review and economic evaluation to assess WFDI's feasibility, effectiveness, safety, and economic implications for universal neonatal eye screening (UNES). **Research Aim** To evaluate the effectiveness, safety, and economic feasibility of WFDI for neonatal eye screening compared to RRT, highlighting its potential role in UNES. **Methods** A systematic review following PRISMA guidelines identified relevant studies from databases including Medline and PubMed up to May 2024. Evidences were critically appraised, extracted, analysed and synthesized narratively. The economic evaluation utilized the ARIMA model (2008–2022) to project the number of newborns eligible for screening from 2026–2030. The clinical pathway for WFDI involves trained nurses performing imaging for non-ROP-risk newborns, with ophthalmologists interpreting results. Screening costs for WFDI and RRT were calculated, including human resources, consumables, and infrastructure. Sensitivity analyses examined cost variations under differing coverage scenarios. **Key Results** Following inclusion and exclusion criteria, eleven studies comprised of three cohort studies, seven cross-sectional studies and budget impact analysis finally included for this review. The review demonstrated WFDI's superior sensitivity in detecting anterior and posterior segment pathologies such as hyphema, CMV retinitis, and vitreous hemorrhage. Detection rates ranged from 4.7% to 41.2%, with an average number needed to screen (NNS) of 5.9. Between 11.1% and 59.4% of detected cases required follow-up or intervention, underscoring its clinical utility. Safety data confirmed WFDI as a USFDA-approved Class II device with no significant adverse events reported. Economically, WFDI screenings were projected to cost RM 49.48 per session compared to RM 2.62 for RRT, with a five-year implementation cost of RM 97.7 million versus RM 5.2 million for RRT. While initial costs are higher, WFDI has the potential to reduce long-term visual impairment costs. Sensitivity analyses revealed implementation costs ranging from RM 8.8 million (minimum case) to RM 36.3 million (maximum case) under 100% coverage. **Conclusions** WFDI demonstrates clear clinical advantages in neonatal eye screening, offering higher diagnostic sensitivity and safety. However, its adoption in a universal screening program is constrained by organizational barriers, such as the need for trained personnel, referral mechanisms, and high implementation costs. Policymakers should consider stratified screening focused on healthy newborns at risk as a cost-effective alternative. Phased implementation and pilot programs are

recommended to ensure scalability and feasibility, balancing clinical benefits with economic realities.

Ind-1835 Evaluating Extended Home-Visiting Programs with Advanced Econometric Methods: A Natural Experiment in Sweden

PRESENTER: **Sergio Flores**, Uppsala University

Background: In Sweden, Child Health Services (CHS) provide healthcare to all children under 18, focusing on preventive care and support for children under six through a tiered universal model. To address persistent health disparities among disadvantaged families, the government emphasized extended home-visiting programs in 2017, notably the Rinkeby model, which increased home visits from two to six and involved multidisciplinary teams. Despite investment exceeding 354 million SEK, implementation varied across regions with mixed outcomes. As these programs continue to receive government funding, there is a need to build local evidence. Our findings will inform policymaking and resource allocation.

Objective: To evaluate the effectiveness of an extended home-visiting program inspired by the Rinkeby model on child health and development outcomes among low socioeconomic status (SES) families in Sweden, using advanced difference-in-differences (DiD) econometric methods.

Methods: We conduct a natural experiment that exploits regional variations in the implementation of extended home-visiting programs between 2018 and 2020. The program involves six structured home visits by a multidisciplinary team - nurses, social workers, dental hygienists, and speech-language pathologists. Child Health Centers (CHCs) in low-SES areas are categorized into three groups:

1. **Full Treatment Group:** CHCs fully implementing the extended home-visiting program.
2. **Partial Treatment Group:** CHCs offering enhanced home-visiting services with varying intensity.
3. **General Group:** CHCs receiving resource enhancements without specific program mandates.

We utilize de-identified individual-level data from Swedish national administrative registers spanning 2012 to 2022, including demographic, socioeconomic, health, and healthcare utilization information. The study population includes all children aged 0–5 born in Sweden during this period and their parents, linked to their assigned CHCs via unique identifiers. A continuous treatment dosage variable represents the proportion of children within small geographic areas affiliated with CHCs participating in the full program. To enhance model precision and reduce confounding, we incorporate time-varying and fixed covariates—including socioeconomic status indicators (Care Need Index, household income), healthcare access variables, and demographic controls—into our advanced DiD estimators. We employ recent innovations in DiD methods suitable for staggered treatment adoption, using estimators from Sun and Abraham (2020), Callaway and Sant'Anna (2020), and Borusyak et al. (2021). These approaches adjust for group- and time-specific trends. Robustness checks include two-way fixed effects, placebo tests, and event study analyses to examine treatment effect dynamics over time.

Expected Results: Preliminary analyses suggest that the extended home-visiting program may positively impact child health outcomes among disadvantaged families. We expect to present findings on growth metrics, vaccination rates, breastfeeding prevalence, dental health status, injury diagnoses, healthcare utilization patterns, and family outcomes such as parental leave utilization. These results will inform policymakers about the program's effectiveness and guide future resource allocation.

Conclusion: The findings will directly inform a cost-benefit analysis of the program and guide policy decisions about scaling such interventions. Our results will also contribute to the broader evidence base for early childhood health services, offering relevant insights for other healthcare systems working to reduce health inequalities through targeted support within universal frameworks.

Ind-1977 Effectiveness and Cost-effectiveness of a Multifaceted Intervention to Reduce Infections and Improve Antibiotic use in European Nursing Homes.

PRESENTER: **Laura Vallejo-Torres**
AUTHORS: Beatriz G López-Valcárcel, Marina Elistratova, Anna García-Sangenís, Carl Llor

Background: The overuse and misuse of antibiotics (ATB), leading to antimicrobial resistance (AMR), is a critical issue among frail older adults in nursing homes, who are highly vulnerable to frequent and severe infections. Urinary tract infections (UTIs), some caused by resistant bacteria, are particularly common. These infections and their consequences could potentially be reduced through improved infection prevention and control (IPC) measures and enhanced antimicrobial stewardship (AMS). However, there has been a lack of substantial initiatives aimed at diminishing the prevalence of infections in nursing homes and reducing antibiotic inappropriateness. **Methods:** This three-year European project (IMAGINE, funded by the EU4H-2020-PJ2) aims to improve infection prevention—primarily UTIs—and reduce inappropriate antibiotic use for these infections through a multifaceted intervention targeting healthcare professionals in nursing homes across eight European countries (Denmark, Greece, Hungary, Lithuania, Poland, Slovenia, Slovakia, and Spain). The Audit Project Odense (APO) method is employed, involving pre- and post-intervention audit and feedback. The main part of the intervention involves a 2-day intervention program consisting of (1) presentation of the first audit results and discussion with peers; (2) AMR and IPC elements, with the participation of national experts; (3) discussion on AMS on how to improve the diagnosis of UTIs and the role of antibiotics for these infections; and (4) discussion of best practice case studies and practical issues. Patient- and facility-level indicators have been defined to assess changes in treatment appropriateness, infection reduction, and other outcomes. The effectiveness and cost-effectiveness of the interventions will be evaluated by comparing the pre- and post-intervention audit results and by estimating the cost of the interventions and potential saving associated with reduced infections and ATB-related adverse events and associated AMR. **Results:** In April 2024 the first audit was completed, involving 109 nursing homes (9,599 residents, 1,158 antibiotic prescriptions for UTIs). Overall, 12% of residents received ATB treatment for an UTI over the three-month registration period. This value varied from a 23% in Spain to 4% in Lithuania and Poland. The mean cost per ATB course was estimated in 15.4€, ranging from 4.5€ in Poland to 33.9€ in Denmark. In 49% of cases, ATB treatment for UTI was deemed potentially

unnecessary according to an algorithm developed by the project. The highest percentage of unnecessary ATBs was observed in Spain (58%), while the lowest value was seen in Greece (26%). During October and November 2024 interventions are being conducted in the nursing homes, and the second audit will take place during February to April 2025. Preliminary results on the effectiveness and cost-effectiveness of the interventions will be available in June 2025. **Conclusions:** Pre-intervention findings highlight substantial room for improvement in infection prevention and antibiotic use in European nursing homes. These results highlight the need for targeted interventions to address these critical issues.

Ind-2436 The Impact of Physician-Patient Gender Concordance on the Delivery of Medical Services in China

PRESENTER: **Shasha Yuan**
AUTHORS: Xiaojuan Sha, Kexin Xiao, Mingwei Fu

Abstract

Background The accumulating research has reported positive, neural, and negative effects of physician-patient gender concordance on health service delivery in different medical settings. However, evidence from low and middle income countries (LMIC) is scant. Our study aims to examine the effects of physician-patient gender concordance on quality of care and medical expenditure in the hospitalized acute myocardial infarctions (AMI) patients in China.

Methods This study uses personnel archive data and inpatient discharge claims data (2018- 2022) from a tertiary general hospital located in Eastern China. We focused on the patients with a primary discharge diagnosis of AMI to achieve the random matching between physicians and patients (n=1299). Multiple linear regression was used. The dependent variables were inpatient expenditure including total expenditure and specific fee categories and quality of care including treatment outcomes and readmission rate within 30 days of discharge, while key independent variable was the physician-patient gender concordance.

Results 70% of patients in the sample AMI patients were treated by surgeons of the same gender. The majority of male patients were operated on by male surgeons (69.0%), and only 1.00% of female patients were operated on by female surgeons. After controlling for confounding variables, the inpatient expenditure in the group of physician-patient gender concordance was statistically higher than those patients in gender dis-concordance group (coefficient=0.159, P<0.001), which is mainly shown in the medication and surgical expenditure, but not in diagnosis expenditure. Physician-patient gender concordance leads to an increase in the copayment rate by 4.37 percentage points (P<0.001), indicating that gender-concordant physicians do not use more reimbursable services when increasing the number of medical procedures, and may not consider cost-saving measures for patients. The gender concordance have an average of 0.07 higher treatment outcome scores, and 0.4 percentage point lower likelihood of being readmitted within 30 days of discharge. However, the latter is not statistically significant. The benchmark results are robust by two ways of robust examinations.

Conclusion

Our study revealed that gender concordance between physician and patient were related to the higher medical expenditure while it has no significant effects on quality of care for the hospitalized AMI patients in China. The findings could serve the basis of future studies to explore the underlying mechanisms regarding the difference resulted by physician-patient gender disparity during the delivery process of health care, which is important for the deep understanding of gender equity in health care.

Ind-2412 Assessing the Suitability of DALYs for Multimorbidities: Exploring Methods for Combining Disability Weights

PRESENTER: **Ewan Tomeny**, London School of Hygiene & Tropical Medicine (LSHTM)
AUTHORS: Firdaus Hafidz, Nateiya Yongolo, Felix Limbani, Phuong Bich Tran, Eve Worrall, Ben Morton

Background: Multimorbidity—the co-occurrence of multiple chronic diseases—is a growing public health challenge, particularly in low- and middle-income countries (LMICs), where Disability-Adjusted Life Years (DALYs) serve as a key metric for global health policy and resource allocation. DALYs quantify disease burden using condition-specific disability weights (DWs), but in multimorbid contexts, methods for combining DWs (e.g., additive, multiplicative) often yield divergent results, complicating burden estimations. These challenges are further amplified when addressing multimorbid states with three or more co-occurring conditions.

Aim: This study evaluates methodologies for combining disability weights to refine these approaches for improved applicability to multimorbid populations, particularly in LMICs. Specific objectives include:

1. Reviewing existing and theoretical approaches for combining DWs.
2. Examining differences in combined DW values across dyads, triads, and larger condition clusters under different methods.
3. Exploring the alignment of methodologies with patient-reported outcomes from the MULTILINK trial.

Methods: A systematic review (PubMed, Embase, Web of Science, WHO Global Health Library) identified methodologies for combining DWs, which were classified by mathematical formulation, including additive, multiplicative, non-linear dependencies, and interaction effects. Key properties (associativity, commutativity, monotonicity, boundedness, subadditivity) were tested to examine logical consistency and scalability for triads and higher-order clusters.

Hypothetical disease combinations were modelled using Global Burden of Disease (GBD) disability weights, with outputs visualised using three-dimensional heat maps (coloured surfaces) to illustrate variability across methods for common multimorbidity clusters. Real-world applicability was explored through validation using patient-reported health-related quality of life (HRQoL) outcomes from the MULTILINK trial in Malawi and Tanzania.

Results: The review identified five primary methods for combining DWs, with limited use of approaches beyond additive, simple multiplicative, and maximum-limit models. Eight distinct methodologies were modelled, revealing significant variation in combined DW values. Most methods did not satisfy all key desirable properties when applied to multimorbid states involving triads or larger condition clusters. Alternative models, such as diminishing returns and quadratic penalty approaches, offered more nuanced representations of cumulative burden but require further scrutiny. Early analyses suggest that nonlinear adjustments or penalties for overlapping impairments may align more closely with patient-reported HRQoL outcomes in the sub-Saharan African contexts studied.

Conclusion: Combining DWs for multimorbidities presents significant methodological challenges, raising questions about the accuracy of DALYs in reflecting health effects and their appropriateness for such analyses. Although all combination methods share limitations stemming from weak theoretical foundations, the alternative models tested demonstrate potential for more accurate representation of multimorbidity in DALY estimates beyond currently employed combination approaches. To ensure DALYs remain relevant for cost-effectiveness analyses of multimorbidity interventions, further empirical validation and foundational methodological development are needed. These efforts will enable more informed policymaking in LMICs, supporting better resource allocation and improved health outcomes.

Ind-978 Causal Association of Systolic Blood Pressure With Quality-Adjusted Life Years: a Mendelian Randomisation Study

PRESENTER: **Tamrat Befekadu Abebe**
AUTHORS: Jedidiah Morton, Jenni Ilomaki, Padraig Dixon, Zanfina Ademi

Background: Systolic blood pressure (SBP) is one of the main risk factors for cardiovascular disease. Studies have demonstrated the causal association of increased SBP with atherosclerotic cardiovascular disease. However, there is no robust evidence regarding the causal association between SBP and quality-adjusted life years (QALYs).

Aim: To estimate the causal association of SBP with QALYs.

Methods:

Methodological approach: Mendelian randomisation (MR) was used to estimate the causal effect of SBP on QALY. Genetic variants associated with SBP (181 single-nucleotide polymorphisms (SNPs)) were used as instrumental variables and identified from a genome-wide association study (GWAS). SBP was used as the exposure variable, and QALYs as the outcome variable.

Data source: The UK Biobank was used to source sociodemographic, clinical and genetic data. Our study included 502,151 participants, of whom 288,182 met the inclusion criteria. Participants were followed from the recruitment period (2006 – 2010) until October 31, 2022 or death, whichever came first. Health-related quality-of-life data were sourced from a previously published study.

Analytical techniques: The polygenic risk score (PRS) was constructed by summing the effects of the 181 SNPs on SBP, each weighted by its effect size derived from the GWAS meta-analysis.

Individual-level MR was performed using two-stage least squares regression (2SLS) to estimate the causal association of SBP with QALY. We regressed the exposure variable on the PRS for SBP at the first stage, followed by regressing the outcome variable on the predicted SBP from the first stage. Several sensitivity analyses were done, including inverse variance weighted regression (IVW), MR Egger, weighted median and weighted mode. The outcome of the study was presented as the annual percentage change in QALYs per 10 mmHg increase in SBP over the average year of follow-up.

Key results: The study followed participants for a median of 13.8 years (IQR: 13.1 to 14.4 years). The median age at baseline was 58.0 years (IQR: 50.0 to 63.0 years), with 53.3% (n=153,648) being female. Participants had a median SBP of 137 mmHg (IQR: 125 to 150 mmHg). The median QALYs per year was 0.76 (IQR: 0.53 to 0.89).

The 2SLS analysis demonstrated that for every 10 mmHg increase in SBP, the annual QALYs declined by 1.17% (95% CI -2.25% to -1.28%). Sensitivity analyses showed a consistent direction of effect. However, high heterogeneity (Cochran's Q = 430.3, p value <0.0001) in the genetic variant instruments was observed with I^2 = 58.2% (95% CI 50.7% to 64.5%). The MR Egger intercept showed little evidence of directional pleiotropy (MR Egger intercept -0.44% (95%CI: -0.97% to -0.09), p value 0.11).

Conclusion and implications for policy and practice: Increased SBP was observed to be associated with reduced QALYs. This finding

consolidates our previous knowledge on the effect of SBP on clinical cardiovascular outcomes. MR can be useful in health economics to estimate the impact of exposures on QALY with reduced confounding or reverse causation bias. The application of MR in health economics would facilitate the generation of unbiased evidence for decision makers.

Ind-1084 An Exploratory Study of the Appropriateness of the EQ-5D-5L and EQ-HWB for Loneliness Research

PRESENTER: **Ishani Kartik Majmudar**

Research Objectives: Loneliness, recognized as a global public health concern, severely impacts individuals' well-being and is associated with adverse health outcomes. Health-related quality of life (HRQoL), often quantified using Health State Utility Values (HSUVs), is crucial for evaluating the cost-effectiveness of interventions targeting loneliness. While generic measures like the EQ-5D(-3L/5L) are commonly used in economic evaluations, they may lack sensitivity to psycho-social aspects of loneliness. The recent development of the EQ Health and Well-Being Instrument (EQ-HWB) addresses this gap, incorporating explicitly an item on loneliness. However, head-to-head comparisons of different Multi-Attribute Utility Instruments (MAUIs) in capturing loneliness are lacking. The study aims to fill this gap by determining utility values associated with loneliness levels and assessing the performance of the EQ-5D and EQ-HWB, in capturing loneliness aspects. Methods: A secondary analysis was conducted using a nationally representative cross-sectional survey of Australian adults. The survey included the EQ-5D-5L, the experimental version of the EQ-HWB, and the 20-item revised UCLA Loneliness Scale (R-UCLA-LS), alongside sociodemographic and health-related characteristics. The study examined utility scores using the EQ-5D-5L and EQ-HWB-S, as well as the total score from the EQ-HWB, across three levels of loneliness (low/moderate/high). Significance tests were conducted using the Kruskal-Wallis test, with post-hoc analysis performed using Dunn's test. Exploratory factor analysis (EFA) was employed to explore the conceptual overlap of items from the EQ-5D-5L and EQ-HWB with the R-UCLA-LS item measure. Additionally, regression analysis was conducted to identify predictors of loneliness from the items that overlapped with the R-UCLA-LS. Results: A total of 2072 respondents completed the survey. EQ-5D-5L utility scores (Mean:0.81; SD: 0.18) were higher compared to EQ-HWB-S (Mean:0.75; SD: 0.23). Analysis revealed decrements in utility scores across loneliness levels for both EQ-5D-5L and EQ-HWB-S ($p<0.001$), particularly among respondents reporting moderate to high loneliness. In the EFA results, no items from the EQ-5D-5L overlapped with the R-UCLA-LS, which was contrary to the EQ-HWB where five items overlapped with the R-UCLA-LS (feeling lonely, feeling unsupported, feeling accepted, feeling good about myself, and able to do things), reflecting essential constructs of loneliness, perceived social isolation, and social support. Regression analysis emphasized the significant predictive value of specific EQ-HWB items, particularly those related to feelings of loneliness, being unsupported, and feeling good about oneself. Conclusion: The findings reveal a significant decline in utility values as loneliness levels escalate, emphasizing the substantial health burden associated with loneliness. While the EQ-5D-5L demonstrates moderate sensitivity to loneliness, the EQ-HWB-S and EQ-HWB exhibit stronger correlations with the R-UCLA-LS, suggesting their potential superiority in assessing loneliness-related constructs. Notably, the EQ-HWB-S emerges as a promising tool for loneliness interventions, owing to its sensitivity to loneliness and practicality in research settings.

Ind-900 Effectiveness of Direct and Indirect Time Preference Elicitation Methods Across Domains in Predicting Health Behaviors: Evidence from Rural China

PRESENTER: **Danlei Chen**, Xi'an Jiaotong University

AUTHORS: Jingxian Wu, Qiqi Liu, Cong Li

Background: Health behaviors, which involve trade-offs between immediate costs and future benefits, are closely associated with individuals' time preferences. Despite this relationship, limited attention has been paid to identifying the most effective method for eliciting time preferences to predict health behaviors, particularly using large-scale representative survey data. This study aimed to compare the effectiveness of two time preference elicitation methods—direct (self-reported) and indirect (incentivized experimental) —across both health and financial domains in predicting health behaviors among a representative sample of rural adults in China. **Methods:** The data were collected through a household paper-and-pencil questionnaire survey conducted in six counties of Shaanxi Province, China, during July and August 2023. Using a multistage stratified random sampling method, the survey included 2,878 rural individuals aged 18 to 65 from 1,377 households. Time preferences were assessed in the health and financial domains using direct methods (self-rated long-term preferences and self-reported planning horizons) and indirect methods (exponential and hyperbolic discounting) with health and monetary outcomes. Health behaviors were classified as risky behaviors (smoking and excessive alcohol consumption) and protective behaviors (active exercise and routine self-funded physical examinations). Time preference indicators were standardized with means of 0 and standard deviations of 1 to ensure comparability. Both probit and ordinary least squares (OLS) regression models were used to assess the predictive power of these indicators on dichotomous and continuous measures of health behaviors, controlling for individuals' demographic characteristics, socioeconomic status, health status, and health behavior perceptions. **Results:** Time preference elicited using direct methods, particularly self-rated long-term preferences in the health domain, significantly predicted smoking (adjusted coefficient: probit = -0.0563 [*p* < 0.10], OLS= -0.2671 [*p* < 0.10]) and active exercise (adjusted coefficient: probit = 0.1129 [*p* < 0.01], OLS = 10.3206 [*p* < 0.05]). Additionally, self-reported planning horizons in health domain (adjusted coefficient: probit = 0.0593 [*p* < 0.05], OLS = 9.9300 [*p* < 0.05]) and self-rated long-term preferences in financial domain (adjusted coefficient: probit = 0.0597 [*p* < 0.05], OLS = 10.4109 [*p* < 0.05]) significantly predicted active exercise. Conversely, time preference indicators elicited by indirect methods demonstrated limited robustness in predicting health behaviors across both

domains. **Conclusion:** Direct methods for eliciting time preferences, particularly within the health domain, were more effective in predicting health behaviors, such as smoking and active exercise, compared to indirect methods. Moreover, health-domain-specific elicitation methods exhibited greater predictive power than those centered on the financial domain. These findings provide methodological insights for accurately capturing time preferences through surveys and inform the design of targeted public health intervention. We recommend integrating questions on individuals' self-rated long-term preferences, especially within the health domain, into household surveys to better understand time preferences associated with health behaviors, which allows for the development of targeted inventions aimed at modifying inter-temporal choices to encourage better health behaviors of more impatient individuals. (This study is funded by the National Natural Science Foundation of China (No. 72104196))

Ind-990 Peer Effects on COVID-19 Vaccine Uptake

PRESENTER: **Ao Liu**
AUTHOR: Yohei Mitani

This paper investigates the role of peer effects in vaccination behavior. We use a game-theoretic framework to causally identify peer effects on COVID-19 booster uptake among 1800 adults aged 20-79 years in Japan, based on a survey experiment on vaccination behavior. To tackle the challenges of identifying peer effects and the computational complexities associated with solving Nash equilibria and conducting simulations, we develop a Bayesian model and employ the No U-Turn Sampler (NUTS) for efficient parameter estimation. Our research focuses on three key questions: Do peer effects influence COVID-19 vaccination? How are equilibria selected? What roles do economic and social preferences play in vaccination behavior? Causal identification of peer effects is notoriously complex due to the interplay of multiple effects. Manski (1993) highlighted three types of effects: endogenous effects, where behaviors are influenced by peers' behaviors; contextual effects, driven by shared exogenous characteristics; and correlated effects, arising from unobserved common shocks. Literature often assumes the absence of contextual effects, correlated effects, or both. By leveraging a Bayesian approach, we avoid these restrictive assumptions, demonstrating that weakly informative priors can offer sufficient regularization to effectively identify these effects. Even in extreme cases where certain effects remain unidentified, marginalization techniques enable consistent estimation of the remaining effects. Additionally, we incorporate Bajari et al. (2010)'s equilibrium selection framework, empirically estimating equilibrium selection mechanisms within the Bayesian model. Our findings reveal that endogenous peer effects significantly impact COVID-19 booster uptake, while contextual and correlated effects do not. The estimated average marginal effect estimate indicates that a one-peer increment among five peers increases the individual's probability of booster uptake by 12.6 percentage points. Other significant determinants of booster uptake include age, education, subjective evaluation of health, and prosociality measured in an incentivized donation experiment. These results have two important policy implications. First, policymakers could harness peer effects as non-monetary incentives, as individual uptake positively influences peers' vaccination behaviors without requiring financial incentives. Second, peer effects can operate in both directions, potentially leading to suboptimal outcomes for groups of younger, less educated individuals, who may become trapped in a low-uptake equilibrium. Targeted mass vaccination campaigns for such groups could enhance overall vaccine coverage and mitigate disparities in uptake. **References** Manski, C. F. (1993). Ind-1037 Accounting for Quality Variation in Cigarette Demand: Evidence from the Indonesian Family Life Survey

PRESENTER: **Susan Olivia**
AUTHORS: John Flood, John Gibson

Tobacco consumption kills around eight million people each year, with more than 200,000 of these in Indonesia. With two-thirds of adult males and 5% of females smoking, Indonesia faces severe health and economic burdens from tobacco use. Despite regular excise tax increases, the tobacco tax rate in Indonesia remains below the World Health Organization's recommended threshold of 75% of the retail price. Cigarette prices in Indonesia also remain among the lowest in the Asia-Pacific region. Consequently, estimating the effects of potential price increases on cigarette demand is critical for informing effective policy interventions. However, in common with most micro-econometric studies of cigarette demand, previous analyses on cigarette demand in Indonesia ignore quality variation, conflating quantity and quality adjustments in response to price increases. In general, consumers may respond to price rises by reducing the quantity consumed, but also by downgrading the quality of what they consume, with the latter response potentially undermining the effectiveness of tax policies. This issue is especially pertinent in Indonesia, where substantial price disparities exist across cigarette brands and types. In this paper, we use panel data from the Indonesian Family Life Survey (IFLS) to estimate individual demand for cigarettes. We model the quantity of cigarettes purchased and the quantity smoked, with demand depending on individual income, on a cigarette market price index formed for 320 communities, and on a vector of 25 other individual and household characteristics. Unlike previous analyses, our demand model also controls for 16 different cigarette brands (as a measure of quality choice). The longitudinal nature of the data also allows us to control for unobserved regional heterogeneity through cluster-level fixed effects. Our results show that the own price elasticity of demand for cigarettes purchased is -0.64 if quality controls are not used but just -0.40 when they are used. The brand-level effects show that people who usually purchase a cheaper type of cigarette smoke up to 40% more than those purchasing more expensive brands, conditional on prices and income. This overstatement suggests that studies of cigarette demand should use perceived quality attributes like brand. Otherwise, biased elasticities may inflate the expected reduction in cigarettes smoked after a tax-induced price increase. **JEL Codes**: D12, I10 Keywords: Cigarettes, Household Surveys, Quality, Price, Tobacco, Demand

Ind-1429 Using Technology and Behavioral Economics to Promote Development in the Early Years: The Effect of an over-the-Phone Program

PRESENTER: **Ana Balsa**
AUTHORS: Juanita Bloomfield, Alejandro Cid
Early childhood in developing countries faces a greater prevalence of risk factors and limited resources, underscoring the need for effective,

scalable support models. We develop and experimentally evaluate a multi-component approach to enhance family well-being over the phone. Our program combines scalable outreaches including calls by a teleoperator, messages, a chatbot, and an AI tool. Targeted at highly vulnerable families with children aged 0 to 3 years

in Uruguay, the intervention promotes positive parenting practices at home, fosters language development, and provides personalized assistance to help families access government benefits. The intervention was implemented with 1360 families eligible for support from the government agency Uruguay Crece Contigo over an eight-month period. We find that the program increases weekly frequency of parental engagement in stimulating activities, increases parental knowledge of language stimulation and reduces parental stress. Effects are in the order of 0.20 standard deviations. In addition, we find that the intervention significantly improves parents' linguistic interactions with their children in terms of higher average word rate of the mother and pitch range (by 0.37 standard deviations). Treated families made greater use of social benefits (by 0.30 standard deviations) including cash transfers and employment support programs. (JEL: J13, I10, I20, H43)

Ind-2761 Evaluating the Effectiveness of Financial Incentives in Promoting Influenza Vaccination Among Older Adults in China

PRESENTER: **Yuqian Lin**
AUTHORS: Fangli Geng, Yixuan Zhang, Omar Galarraga, Wangnan Cao, Refu Kaiti

Seasonal influenza imposes significant health and economic burdens globally, disproportionately affecting older adults. In China, influenza vaccination rates among individuals aged 60 and older remain alarmingly low, with uptake at just 4.16% in 2019–2023. Given the vulnerability of this population and the high associated morbidity and mortality, understanding effective strategies to increase vaccine uptake is critical. Financial incentives have shown promise in some contexts as a mechanism to improve vaccine coverage by reducing out-of-pocket costs and addressing behavioral barriers. However, limited research exists on the optimal design and impact of such incentives in low- and middle-income countries (LMICs) like China, where social determinants such as income, education, and health literacy heavily influence health behaviors. This study employed a discrete choice experiment (DCE) to evaluate preferences for financial incentives among older adults in China. A community-based survey was conducted in three diverse cities, incorporating urban and rural populations. The DCE presented participants with hypothetical vaccination scenarios featuring varying attributes: (1) subsidy amounts, (2) timing of vaccination, (3) number of co-vaccinees, and (4) form of compensation (cash, goods, or medical services). A total of 575 older adults completed the survey, and subgroup analyses were performed to assess variations in preferences by gender, income, education, health literacy, and living arrangements. Results highlight the critical role of subsidy magnitude, with higher subsidies significantly increasing vaccine uptake likelihood. Early timing of vaccination coupled with higher subsidies also demonstrated strong appeal, reflecting the urgency participants place on protecting their health during flu season. Preferences for compensation type varied: while cash incentives were broadly preferred, rural participants showed greater interest in goods or medical service vouchers. Subgroup analyses revealed significant differences: individuals with higher perceived disease risk or chronic conditions prioritized larger subsidies and earlier vaccination, while those with low vaccine literacy preferred simpler incentive structures. The study also revealed that participants often preferred to vaccinate alone rather than in groups, prioritizing convenience and reducing potential disruption to others' schedules. Interestingly, many were willing to forgo higher financial incentives to avoid the perceived inconvenience of coordinating vaccinations with others. These findings provide actionable insights for policymakers aiming to increase influenza vaccination rates among older adults in China. Financial incentives should be tailored to local needs, with a focus on addressing socioeconomic barriers and behavioral drivers. The study further suggests that integrating health education and targeted outreach into incentive programs could enhance their effectiveness and scalability. Our results contribute to the broader discourse on health-enhancing behaviors and interventions targeting vulnerable populations in LMICs, where systemic and cultural barriers to vaccination persist. By examining the interplay between financial incentives and social determinants of health, this study lays the groundwork for evidence-based policies that promote equitable access to preventive healthcare.

Ind-71 Modelling the Dynamics of Familial Hypercholesterolemia (FH) Screening and Treatment: Insights from Singapore's Emerging Genomic Testing Initiatives

PRESENTER: **Alexander Morton**
AUTHORS: Jamaica Roanne Briones, Hwee Lin Wee, Len Malczynski, Jing Lou, David Matchar

Background: Familial hypercholesterolemia (FH) is an inherited disorder characterized by high cholesterol levels, which can significantly increase the risk of cardiovascular disease if left untreated. In Singapore, an estimated 25,000 individuals have FH, though less than 10% have been diagnosed. Screening, early diagnosis, and timely intervention for FH through statin treatment can mitigate cardiovascular complications and prevent premature death. However, scaling up a nationwide FH screening program presents challenges, particularly around capacity constraints and resource allocation. This study presents a dynamic simulation model exploring strategies for screening, diagnosis, and long-term management of FH, informed by stakeholder engagement and capacity estimation.

Objective: This project aimed to develop a dynamic system model to simulate the supply-demand dynamics for FH screening and treatment in

Singapore. The objective was to identify optimal service strategies that balance the increasing demand for genetic testing with the limited capacity of healthcare providers, ensuring the program's sustainability while maximizing health outcomes.

Methods: The project leveraged a Group Model Building (GMB) approach, engaging a broad group of stakeholders including clinicians, administrators, and policymakers. The GMB sessions elicited key variables and decision points affecting FH screening, treatment capacity, and patient demand. These were integrated into a system dynamics model that reflects the complex interactions between patient referral flows, genetic screening capacity, clinical management workflows, and workforce constraints. The GMB session facilitated the development of a Causal Loop Diagram (CLD) that illustrates the feedback loops inherent in FH screening. Cascade testing, which identifies additional family members for screening, and the potential strain on primary and specialty care services were of particular concern. Capacity estimation exercises were carried out to assess the burden on both primary care providers and specialized lipid clinics. The resulting model can be used to simulate various scenarios to explore the implications of different triage strategies, workforce expansions, and potential bottlenecks in the healthcare system.

Expected Results: A concern is that while increased FH screening through genetic testing could identify more at-risk individuals, the healthcare system's current capacity would likely be overwhelmed without significant investment in both primary care and specialty services. Cascade testing in particular creates reinforcing feedback loops that could quickly escalate demand for genetic counseling and testing, further straining the system. Triaging patients based on low-density lipoprotein (LDL) levels and expanding the role of primary care providers in initial screenings could alleviate some of the pressure on specialty clinics, but additional strategies such as decentralized testing and increased genetic counselor training are crucial for program scalability.

Conclusion: This dynamic system model offers valuable insights into how FH screening and treatment programs can be optimized in the context of limited resources. The model highlights the importance of balancing screening demand with healthcare system capacity to avoid overburdening clinical services. Future research will further refine the model with additional real-world data and explore its application in other genetic conditions, making it a valuable tool for policymakers planning large-scale genomic testing initiatives.

Ind-156 Persistent Job Insecurity and Severe Mental Illness among Japanese Workers During the COVID-19 Pandemic

PRESENTER: **Narimasa Kumagai**, Seinan Gakuin University
AUTHOR: Aran Tajika

[Background] The COVID-19 pandemic reduced the standard of living of low-income households during the first two years and caused persistent job insecurity in the labor market. Prior studies have found that perceived job insecurity predicts adverse health outcomes, including worsening mental health.
[Purpose] The purpose of this study is to investigate whether job insecurity was caused by demand shocks and whether mental health deterioration persisted, taking into account the pathway from poor mental health to job insecurity.
[Methods] We used longitudinal data drawn from the Japan Household Panel Survey (JHPS) conducted by Keio University to measure the impact of job insecurity on the health of Japanese workers during the COVID-19 pandemic. Double robust estimation with inverse probability weighting was used to estimate the Average Treatment Effects on the Treated (ATET) for mental health status in the treatment group.
[Results] Low household income and experienced a layoff or bankruptcy each had a significant positive effect on job insecurity, regardless of the mental health in the past year was good or poor. Experiencing a layoff or bankruptcy had a positive impact on severe mental distress, however, was not a determinant of accumulated job insecurity. Income loss was associated with being employed in food & beverage or accommodation, transportation, construction, and manufacturing. Employed persons with debt under accumulated job insecurity were more likely to be in severe mental health condition than those with short-term job insecurity.
[Discussion] Comparing the determinants of accumulated job insecurity with that of short-term job insecurity, a greater impact of the mental distress in the past year was found in the long run. Regression analyses lacking the pathway from mental ill-health to job insecurity may overestimate the impact of income loss on job insecurity, and the impact of this pathway should be noted when considering health policies after demand shocks. In Japan during the sample period, economic policies toward the food & beverage or accommodation that suffered income losses may have been over-implemented.

Ind-740 "Reduction of Public Coverage did not Lead to Fewer Dental Visits": Fact or Fiction?

PRESENTER: **Ziade Sarroukh**
AUTHORS: Patrick Jeurissen, Stefan Listl

Background: Challenges of access have sparked political debates about dental coverage in the Netherlands. So far, policymakers have been opposing an expansion of public coverage for the adult population, arguing that previous reductions of public coverage would not have led to reduced dental attendance within the Dutch population. To this end, this study aims to evaluate the effects of public coverage reductions since 1995 on dental care utilization.

Methods: We used a population-wide dataset from Statistics Netherlands containing dental care utilization rates across insurance- and age-based subpopulations between 1981 and 2009. Drawing from an Interrupted Time Series (ITS) design with segmented regressions, the effects on dental attendance of scaling down public coverage for curative dentistry in 1995 and for preventive dentistry in 2004 were evaluated. Population groups which were not subject to the reforms (non-adult population, privately insured persons) served as control groups. Additionally, effects on the overall Dutch population were estimated through a single group ITS, controlling for economic performance indicators, including GDP per capita and household income, and cohort fixed effects.

Results: Following the 1995 reform and in comparison to privately insured persons (control group), dental attendance of publicly insured persons (intervention group) decreased by an immediate 3.5 %-points (95% CI -5.8; -1.1) and subsequently by 0.6 %-points (95% CI -0.9; -0.3)

per year. Compared to the non-adult population (control group), dental attendance by 20-40-year-olds (intervention group) immediately dropped by 4.6 %-points (95% CI -7.0; -2.1) and subsequently decreased by 1.2 %-points (95% CI -1.5; -0.8) per year. Changes following the 2004 reform were statistically insignificant. The single group ITS produced similar results. After adding cohort fixed effects, we find that dental attendance of the total Dutch population declined by 1.0 %-points (95% CI -1.8; -0.2) annually since the reform in 1995.

Conclusion: Contrary to Dutch policymakers' arguments, our findings suggest that reduced public coverage since 1995 led to fewer people visiting the dentist in the Netherlands. These findings highlight the central role of policy evaluation for evidence-informed oral health policymaking.

Ind-2444 Mining Masculinity: The Long-Term Effects of the Victorian Gold Rush on Men's Health-Seeking Behaviors

PRESENTER: **Gyeore Cha**
AUTHORS: Nicole Black, Johannes Kunz, Dennis Petrie

Objective: Resource extraction booms significantly reshape local demographics and social norms, often triggering large male-dominated migration. This study explores the long-term impact of the Victorian Gold Rush (1851-1899) on present-day mental health outcomes and healthcare utilisation. We hypothesize that masculine norms formed through intense male-male competition and demographic imbalances during the Gold Rush persist and discourage men's mental health and help-seeking behavior today.

Methods: This study employs a natural experimental design using geographic variation in historical gold mining occurrences in Victoria (1851–1899) to identify Gold Rush and non-Gold Rush areas. Adults aged 18-65 in these areas are compared using an intention-to-treat framework to assess long-term impacts on mental health outcomes and healthcare use. Historical mining data from GeoVic and demographic records from the Historical Census and Colonial Data Archive (HCCDA) are linked with individual-level administrative data from the Person Level Integrated Data Asset (PLIDA), including Medicare claims and mortality records.

Results: We find significant long-term implications of the Gold Rush on present-day mental health outcomes and mental healthcare use among men, but not among women. Men in Gold Rush regions experience, on average, 5.3 additional deaths of despair per 100,000 individuals compared to non-Gold Rush areas. However, men in Gold Rush regions have a 1.5 and 1.1 percentage point lower probability of obtaining a GP Mental Health Treatment Plan (MHTP) and visiting a psychologist, respectively. We link these results to previous studies on the formation of masculinity norms following historical shocks, showing that male-dominated environments and intense male-male competition can shape long-term patterns of behavior. Consistent with this, we find evidence of persistence dominant masculine norms in Gold Rush regions, as reflected in Victorian crime data showing higher rates of assault and sexual violence by 13.4% and 14.5%, respectively.

Conclusion: Our study demonstrates that persistent cultural barriers shaped by masculinity norms formed during intense historical male-male competition of the Victorian Gold Rush continue to influence men's mental health outcomes and mental healthcare engagement. These findings underscore how sociocultural factors shape help-seeking behaviors and highlight the need for culturally sensitive health policies and interventions tailored to men's mental health needs. Recognising and addressing these deep-rooted cultural norms is key to reducing barriers to care and improving health outcomes among men.

Ind-897 The Puzzle of Positive Drug Price Elasticity: The Role of Brand Preferences

PRESENTER: **Ran Li**
AUTHOR: Ms. Jianan Yang

The rapid rise in pharmaceutical expenditures has become a global policy challenge. While price reductions—achieved through insurance coverage, regulations, or procurement reforms—are widely believed to enhance affordability and patient welfare, these interventions may yield unexpected outcomes. For instance, price controls in India have inadvertently led to drug unavailability for vulnerable populations. Similarly, China's centralized drug procurement program, launched in 2019, has effectively lowered drug prices through competitive bidding but has paradoxically resulted in reduced utilization of chronic condition drugs among a subset of insured patients as we demonstrate in this study. We explore brand preference as a potential mechanism underlying this puzzling positive price elasticity and emphasizes the need to account for the complexity of patient preferences in policy design. China's centralized procurement program transitioned from decentralized purchasing to competitive bidding for molecules in nine provinces. Winning bidders—usually generic manufacturers—secured a guaranteed quantity at reduced prices, prompting pharmacies to prioritize prescribing these generics over branded versions. While bid-winning generics experienced substantial sales growth, analysis of 1.4 million patient records from over 300 Beijing community healthcare centers over two years reveals a surprising decline in actual purchases of price-reduced drugs among the patients with brand preferences. We define patients with brand preferences as those who exclusively purchased branded versions of specific drugs before the policy's implementation. Among pre-policy purchasers, 71.65% exhibited such preferences. Using a difference-in-differences framework, we find that patients with brand preferences significantly reduced their purchases post-policy, a shift large enough to counterbalance the anticipated utilization benefits from price reductions. This effect manifested across both extensive and intensive margins: fewer brand-preferring patients sought care post-policy, and furthermore, their visit frequency and purchase volumes per visit both declined. This pattern is in stark contrast to increased engagement and purchases by patients without brand preferences. Our findings contribute to the literature on group purchasing mechanisms and pharmaceutical policy by highlighting trade-offs between cost savings and choice distortion. Policies focused exclusively on price competition may overlook non-price attributes, such as brand loyalty, that influence patient behavior. Additionally, we shed light on the dual effects of generic drug entry on consumer welfare: while price reductions can boost affordability and access, they may simultaneously suppress utilization due to preference mismatches. These insights offer guidance for refining procurement designs, health insurance strategies, and patent policies to better balance affordability with patient-centered care.

Ind-1611 Exploring the Impact of Psychological Distress on Healthcare Utilisation: Evidence from an Australian Community Mental Health Study

PRESENTER: **Kiri Lay**, Flinders University
AUTHORS: Diana Khanna, Rachel Milte, Kate Fairweather, Jenny Cleland, Malcolm Battersby, Julie Ratcliffe

Background: Approximately 300,000 Australians with severe mental illness (SMI) face significant challenges in accessing and navigating healthcare services. Due to the complexity of their needs, further exacerbating the situation are disruptions in care caused by issues such as inefficient appointment scheduling, lengthy wait times for follow-up services, and inadequate community support systems or environments. These factors contribute to poor continuity of care, higher readmission rates, and frequent reliance on emergency services. Understanding the relationship between psychological distress and healthcare utilisation is critical for developing and refining interventions aimed at improving health outcomes in this vulnerable population.

Objective: This study examines trends in healthcare utilisation and associated costs in individuals categorised by Kessler Psychological Distress Scale (K10) scores.

Methods: A total of 120 individuals attending a community mental health service participated in an intervention which aimed to improve physical health through self-management strategies. Hospital administrative data were analysed for these participants, covering a follow-up period from baseline to 18 months. Participants were categorised into two groups based on their K10 scores: low to moderate distress (≤21) and high to very high distress (>21). Data on socio-demographic characteristics, health-related quality of life (HRQoL) using the SF6D, and healthcare utilisation were collected. Descriptive statistics were used to summarise healthcare utilisation and costs across groups, including emergency department (ED), extended emergency care unit (EECU), inpatient, and outpatient services. T-tests compared costs between the two K10 distress groups. Multilevel mixed-effects logistic regression models were employed to explore the likelihood of healthcare visits as a function of distress level, gender, intervention group assignment, and time.

Results: The overall sample had a mean age of 47 years, with 63% of participants being male. The average SF6D utility score was 0.64 (SD=0.1), with lower HRQoL in the High to Very High distress group (0.59) compared to the low to moderate group (0.68). Healthcare costs were significantly higher for individuals in the high to very high distress group ($17,181 vs $9,497; p-value=0.03), particularly for ED services ($3,344 vs $1,374; p-value=0.03). Mixed-effects logistic regression revealed that higher K10 scores were significantly associated with increased healthcare utilisation (p-value=0.017), while a non-linear interaction term suggested a diminishing effect at higher distress levels (p-value=0.017). Gender was also a significant predictor, with females more likely to utilise healthcare services than males (p-value=0.007). SF6D utilities and intervention assignment were not significant predictors of healthcare utilisation (p-value=0.866 and p-value=0.433, respectively). Temporal trends across the follow-up period showed no significant associations with healthcare utilisation (p-value>0.05).

Conclusions: This study highlights the influence of psychological distress and gender on healthcare utilisation, with higher distress levels and female gender associated with increased use of health services. Other factors, such as HRQoL and intervention assignment, demonstrated limited impact. The findings underscore the complexity of distress-related healthcare utilisation and the need for tailored interventions to address both physical and psychological health needs in individuals with SMI. Further research is necessary to explore the mechanisms underlying these associations and to evaluate the long-term efficacy of self-management interventions in this population.

Ind-1130 Narrowing Urban-Rural Disparities in Access to and Quality of Breast Cancer Care Under the National Health Insurance Program in Taiwan

PRESENTER: **Yiing-Jenq Chou**, National Yang Ming Chiao Tung University
AUTHOR: Nicole Huang

Background

Reducing rural-urban disparities in health care has been a compelling issue for decades. However, efforts in reducing urban-rural disparities may be offset by quality or payment policies such as regionalization or pay-for-performance (P4P), particularly for major morbidities such as cancer. Taiwan has implemented its National Health Insurance (NHI) program since 1995. Many people speculate that rural-urban disparities in access to care may no longer be an issue in Taiwan, a geographically small and densely populated country with a universal and comprehensive health insurance coverage. But is it true? The existing evidence in Taiwan is mostly limited to the data prior to 2010. Due to the changing morbidity patterns and technological development, it is essential to obtain an updated understanding of rural-urban disparities in Taiwan. Breast cancer serves as a good example to assess rural-urban disparities in cancer care since it is an increasingly prevalent cancer in Asia and there are well-established guidelines for breast cancer care.

Research Objectives

This study aimed to assess changes in rural-urban disparities in timely access to guideline-concordant care and patient outcomes among breast cancer patients in Taiwan over time and explore whether such disparities may be mediated through hospital characteristics.

Methods

The 2011-2016 Taiwan Cancer Registry and the 2010-2021 NHI data were used in this population-based retrospective cohort study. We identified 46,849 newly diagnosed breast cancer women with stage 1 to 3 from January 2011 to December 2016 and each patient was followed for 5 years. Timeliness in receipt of guideline-concordant treatments, recurrence and mortality were the main dependent variables. Urbanization status was categorized into two levels: remote and non-remote. Other control variables included patient characteristics (i.e. age, income, cancer stage, type of surgical treatment received) and provider characteristics (i.e. hospital level, hospital ownership, and P4P participation).

Multivariable logistic regression and Cox proportional hazard models were applied. Final models included interactions effects between urbanization level and time trend. Counterfactual event-based mediation analysis will be applied to examine potential mediation effects of hospital characteristics.

Preliminary Results:

Over the study period, the rate of delayed receipt of guideline-concordant radiotherapy from surgery decreased from 18.2% to 12.6% and five-year survival rate decreased from 9.2% to 8.4%, but the five-year recurrence rate increased from 7.6% to 9.9% over time. After adjusting for other factors, there was no significant difference in timely receipt of guideline-concordant care between people living in remote and non-remote areas. But patients living in remote areas had significantly higher hazards of 5-year recurrence (HR: 1.06) and 5-year mortality (HR: 1.30) than those living in non-remote areas. More importantly, the urban-rural gaps in 5-year recurrence and mortality hazards did not seem to narrow over time.

Conclusion

Under the NHI program in Taiwan, over time, no significant difference was observed in timeliness to guideline-concordant care between breast cancer patients living in remote and non-remote areas. But the urban-rural differences in 5-year recurrence and survival rates persisted over time. Factors other than timeliness to care such as quality of care may have contributed to the persisting gaps.

Ind-1355 The Impact of Dual Eligibility on Post-Acute Care Utilization Following Stroke

PRESENTER: **Mengyuan Cheng**
AUTHORS: Nasim Ferdows, Brady Post

Background Optimal stroke recovery relies on effective post-acute care (PAC), yet disparities persist, especially among Medicare-Medicaid dual-eligible beneficiaries. These individuals often experience greater medical complexity and financial barriers that shape their PAC choices. Medicare's 100-day skilled nursing facility (SNF) coverage limit, followed by Medicaid, creates financial incentives that may steer patients toward SNFs over inpatient rehabilitation facilities (IRFs), which generally provide better outcomes. Additionally, Centers for Medicare & Medicaid Services (CMS) eligibility criteria for IRFs can further limit access for dual-eligible patients. Understanding how dual eligibility influences PAC discharge decisions is crucial for guiding policy and optimizing healthcare resources.

Objectives To examine how dual eligibility influences discharge destinations after acute stroke care, focusing on IRFs, SNFs, and home healthcare (HH).

Methods We analyzed a nationally representative 5% sample of Medicare Standard Analytic Files linked to the Master Beneficiary Summary File for fee-for-service beneficiaries hospitalized with ischemic stroke in 2021, excluding in-hospital deaths and incomplete discharge data. Median household income and urban-rural classification were derived from publicly available datasets. The primary exposure was dual-eligibility status (full or partial Medicaid coverage at discharge). PAC discharge destinations included IRFs, SNFs, HH, and home without HH. We used propensity score matching (PSM) to balance sociodemographic (e.g., age, sex, race/ethnicity, income, and rurality), clinical (e.g., stroke severity, comorbidities, hospital length of stay), and state-level Medicaid policy factors. Matching was performed using the greedy nearest neighbor method (caliper width = 0.2; 5:1 ratio), and balance was assessed with standardized mean differences (SMD < 0.1). We then applied mixed-effects logistic regression to assess associations between dual eligibility and discharge destinations, accounting for county-level variations, stroke severity, length of stay, and their interaction. To further explore discharge patterns, we recoded the outcome variable as a multi-level categorical variable representing the four discharge destinations and fitted a multinomial logistic regression model with the propensity score-matched sample. Subgroup analyses, stratified by age, race, and stroke severity, were conducted to explore potential effect modification.

Results Prior to matching, dual-eligible patients (n = 1,438) were younger, more likely to be racial/ethnic minorities, and had higher medical complexity compared to Medicare-only patients (n = 7,506). Dual-eligible patients were less likely to be discharged to IRFs (adjusted odds ratio [aOR] = 0.49, 95% CI: 0.39–0.62) and more likely to SNFs (aOR = 2.26, 1.82–2.81) compared to Medicare-only beneficiaries. Discharges to HH were similar between groups (aOR = 1.15, 0.92–1.44). The multinomial regression model yielded consistent results. Patterns were largely stable across age and severity strata, except among younger patients (<65 years) and those with minor strokes, where differences were observed but not statistically significant.

Discussion Dual-eligible patients encounter systemic barriers to IRF access, likely due to CMS requirements and financial incentives favoring SNFs, leading to a potential mismatch between patient needs and PAC settings. This suboptimal allocation of resources may compromise recovery outcomes and healthcare spending efficiency. Future research should evaluate the cost-effectiveness of IRFs versus SNFs to inform policies that ensure equitable access to high-quality rehabilitation services.

Ind-1963 Sex Differences in Healthcare Utilisation - Evidence from Unexpected Adverse Health Shocks

PRESENTER: **Giovanni Mellace**
AUTHORS: Nadja van't Hoff, Seetha Menon

Background: The male-female health-survival paradox is a well-documented phenomenon wherein women, despite having a longer life expectancy than men, experience worse health outcomes. Previous research has highlighted gender disparities in healthcare utilization, driven by factors such as treatment access and biological differences. However, these studies often fail to establish causal relationships or quantify the magnitude of these differences. This study seeks to address this gap by examining how gender differences in healthcare utilization contribute to this paradox. **Research Question:** How do gender differences in healthcare utilization following adverse health shocks contribute to the male-

female health-survival paradox? What mechanisms drive these disparities, and to what extent can they be causally attributed to differences in treatment provision, patient behavior, or systemic factors? **Methodology:** This study applies a staggered difference-in-differences approach to examine how adverse health shocks—defined as non-fatal heart attacks or strokes—affect healthcare utilization by gender. Focusing on individuals in Denmark aged 50 to 70, the analysis compares those who experience a health shock at a given point in time (treatment group) with individuals who will experience the same type of health shock at a later point (control group). This comparison isolates the impact of the timing of the health shock while accounting for baseline similarities between groups. Importantly, this is the first study to estimate these effects separately for men and women, allowing us to uncover gender-specific differences in healthcare utilization. The method uses the estimator by Callaway and Sant'Anna (2021) to account for differences in treatment timing and includes controls for factors such as age and income. The outcomes analyzed include statin consumption, general practitioner visits, and hospital inpatient days. Using Denmark's detailed administrative healthcare data ensures high accuracy in measuring health events and utilization. Robustness checks include alternative specifications, matched samples, and validation of pre-treatment trends to confirm the reliability of the results. **Key Results:** Men consistently utilized more healthcare services than women across all measured outcomes following health shocks. For example, men's post-shock statin consumption was more than twice that of women. Similarly, men had significantly more visits to general practitioners and days hospitalized than women. These differences persisted even after accounting for baseline health conditions and other covariates. The findings challenge prior evidence suggesting greater primary care use by women and highlight potential disparities in treatment provision and uptake. **Implications:** The results reveal significant gender inequities in healthcare utilization, which may contribute to poorer health outcomes for women despite their longer life expectancy. These findings underscore the need for policy interventions that address structural and behavioral barriers to equitable healthcare access. Enhanced training for healthcare providers and targeted outreach programs could mitigate these disparities, improving health outcomes and advancing gender equity in healthcare systems.

Ind-2829 Inequalities in Healthcare Spending in Brazil: Economic Impacts for Families By Geographic Region and Income Bracket

PRESENTER: **Ivan Augusto Cecilio e Silva**

AUTHORS: HARRISON FLORIANO DO NASCIMENTO, Alessandra Gaspar Sousa, MARIANA Marzullo M PEDREIRA, Gustavo Laine Araújo de Oliveira, Luis Eduardo Maciel dos Santos Ferreira, Ivanessa Thaiane do Nascimento Cavalcanti, Ana Carolina Esteves da Silva Pereira, Ms. Erika Aragao

Introduction: Inequalities in access to and spending on healthcare in Brazil reflect economic and regional disparities. In 2017, direct out-of-pocket (OOP) expenditure accounted for 4.0% of final consumption, exceeding the OECD average of 3.3%, indicating greater financial pressure on Brazilian families, especially those on low incomes and in vulnerable regions. Despite this, there is a lack of detailed analysis on the proportion of income allocated to essential expenses by income bracket and region. **Objective:** To** compare OOP expenditure on health between income brackets and Brazilian regions, assessing the proportional commitment of income to essential expenses. **Methodology:** A quantitative analysis was carried out using data from the latest Household Budget Survey (POF) of the Brazilian Institute of Geography and Statistics (IBGE) carried out in 2017-2018, with values adjusted for October 2024 based on inflation, considering the Broad National Consumer Price Index (IPCA), calculated by the IBGE. The dependent variables were OOP spending on health (absolute values and proportional to income), while the independent variables were the Brazilian regions and income brackets based on the current minimum wage (MW) of US$ 250.45 (low income: up to MW 2; intermediate strata: over MW 2 to 25; high income: over MW 25). To ensure the validity of the model, the tests of normality (Shapiro-Wilk), homogeneity of variances (Levene), and then two-way analysis of variance (ANOVA) were applied. Tukey's post-test was used to identify specific differences between the means of the groups. Spearman's correlation test was applied to assess associations between income and health expenses. The significance level was set at 5% ($p<0.05$), and statistical analyses were performed using SPSS software. **Results:** There were statistically significant differences in OOP expenditure between regions ($F=18.25$, $p<0.05$) and between income brackets ($F=24.47$, $p<0.05$). The Southeast and South had higher absolute spending averages than the North and Northeast ($p<0.05$), showing regional inequalities. Families in the Southeast and South spend an average of US$ 91.62 and US$ 72.34 per month, while those in the North and Northeast spend US$ 35.04 and US$ 52.10, respectively. Regarding income brackets, families with a higher monthly income spend more on health on average (US$ 382.55) than low-income families (US$ 21.70). However, low-income families allocate a significantly higher proportion of their monthly income to essential expenses, such as medicines ($F=15.78$, $p<0.05$), committing an average of 4.2%, compared to 1.4% for high-income families. The post-tests showed that families in the Northeast had the highest expenditure on medicines (monthly average of 3.2%), indicating an inverse correlation between income and proportional commitment ($r=-0.61$, $p<0.05$). **Conclusions:** The economic and regional inequalities in OOP expenditure in Brazil highlight the need for public policies that prioritize the most vulnerable regions and the lower-income classes, promoting greater equity in the health system.

Ind-760 Maternal Vaccine Delivery Costs: Prospective Cost Estimates from Five Low-and Middle-Income Countries

PRESENTER: **Ranju Baral**, PATH

AUTHORS: Iracema Barros, Md. Monjurul Islam, Patience Cofie, Rose Eddah Jalang'O, Kwame Amponsa- Achiano, Jessica Fleming, Patience Dapaah, Chris Fofie, Abhiyan Gautam

Background: The maternal vaccine landscape is expanding, including the anticipated global rollout of the now licensed respiratory syncytial virus (RSV) maternal vaccine. Integrating maternal immunization (MI) into health systems in low-and middle-income countries (LMICs) is likely to require adaptation to existing immunization delivery platforms and have cost implications. Understanding this cost is critical to inform introduction decisions and ensure financial sustainability of future MI interventions. In this study, we project the cost of maternal vaccine introduction and delivery across five LMICs (Kenya, Ghana, Bangladesh, Nepal, and Mozambique). **Methods:** We used a prospective, activity-based costing approach to project maternal vaccine introduction and delivery costs for a five-year period from a health system perspective. Country stakeholders informed the potential strategies for maternal vaccine delivery in each setting through stakeholder workshops in each country. Interviews with key immunization and maternal health program representatives informed anticipated health system adaptation requirements, activities, and resource needs to support maternal vaccine introduction and delivery. Supplementary data from a sample of sub-national health administrative units, vaccine stores, and health facilities were also used to inform the costing analysis. Financial and economic costs are estimated in 2023 USD. **Results:** New maternal vaccines are expected to leverage existing systems (e.g. maternal tetanus or the antenatal care platform) in all countries. The estimated incremental costs of MI delivery (excluding commodity costs) ranged between US$0.45 and $3.42 (financial) and $2.01 and $4.49 (economic) across study countries. Excluding commodity costs, health worker training, demand generation, and program planning/coordination were primary cost drivers across countries. Cost differences between countries are influenced by population sizes, anticipated baseline coverage and baseline health system capacity gaps. **Conclusions:** Very few studies exist on the costs of delivering maternal vaccine in LMICs. This study begins to fill this gap. Per our findings, economic cost of maternal vaccine delivery is expected to fall within the range of routine vaccine delivery costs, though additional, retrospective analysis post vaccine introduction would help to validate and strengthen these prospective findings. Estimates from these five countries can serve as proxies in settings where maternal vaccine delivery cost data do not yet exist. These estimates can also be used as inputs into cost-effectiveness and budget impact analyses to help inform decision making around introduction.

Ind-2327 Determinants and Trends in Domestic Public Spending on HIV in Low- and Middle-Income Countries, 2012 2024

PRESENTER: **Deepak Mattur**

Background: This study explores the trends and determinants of domestic public spending on HIV in low-and-middle-income countries (L&MICs) from 2012 to 2023. It is set against a backdrop of plateauing international aid and increasing emphasis on domestic resource mobilization as critical to sustaining HIV responses. The study comprises two components - analyzing the determinants of domestic public spending using an econometric model and leveraging the dependent variable from the econometric model (covering 108 LMICs) along with expenditure data reported directly to UNAIDS by major domestic spenders to develop trends in domestic public spending over the past ten years. **Key results: Determinants of Domestic Public Spending** Significant positive associations were found between Domestic Public Spending and covariates - Antiretroviral Treatment (ART) coverage (15+ years), HIV Prevalence, Civil Society Index, Societal enabling environment (SEE), and the GDP per capita. Other significant predictors include non-GDP residuals of the Human Development Index (HDI) (Table 1). The regression coefficient of unfavorable SEE is negative and significant, meaning that societal enabling environment is correlated with higher level of Domestic public spending on HIV. Domestic public spending in 2023 was estimated at US$ 9.5 billion. - The trends in Domestic Public spending from the regression model indicate that domestic resources are declining for the fourth consecutive year, a trend that began during the COVID-19 pandemic. (Figure 1) - Upper-middle-income countries have seen domestic investments stagnate or decline, while low-income countries experienced sharp declines post-2019, with recovery now nearing pre-COVID-19 levels.

Conclusions and implications for policy and practice: While domestic investments accounted for a significant share of HIV financing in 2023, the observed downward trend in domestic resources underscores the urgent need for strengthened domestic resource mobilization. The econometric analysis identified key determinants such as ART coverage, societal enabling environment, GDP per capita, and civil society engagement, emphasizing the interplay of health, socio-economic, and governance factors in shaping domestic HIV financing. Policymakers must address these challenges by strengthening domestic resource mobilization, fostering supportive societal env.ironments, and prioritizing investments in HIV programs. Sustained domestic commitment is vital to reversing the downward trend in funding and achieving global HIV targets

Ind-1193 Impact of Capitation Payment on Healthcare Service Behavior in County Medical Community: Evidence from Diabetes Patients in Rural China

PRESENTER: **Jiani Zhang**

AUTHORS: Ning Zhang, Jincao Yan, Yunke Shi, Xingxing Li

Objective Amid efforts to develop primary healthcare, China has been working to establish an integrated care system through the county medical community model, incorporating capitation payment to improve chronic disease management. This study investigates the impact of capitation payment reform on healthcare service behavior related to diabetes across tiered healthcare facilities with varying service roles. **Methods** Using County F, which implemented capitation payment reform within its medical community, as the sample area, we collected outpatient treatment records of diabetic visits from six townships that began the initial reform phase in April 2015 between January 2014 and December 2019. This dataset comprises 49,326 records from primary healthcare facilities and 1,628 records from the county hospitals, including medical costs, service items, and other details. We utilized interrupted time series analysis to assess the changes in healthcare service behavior before and after the implementation of the capitation payment model. **Results** Following the implementation of the capitation payment reform, both the average medical costs per visit and proportion of examination and testing costs showed a deceleration in growth in primary healthcare facilities (-0.615, $p < 0.05$; -1.554, $p < 0.01$, respectively). The proportion of medication costs, as well as the proportion of insulin or combination therapy and the average number of medications, exhibited a significant downward trend prior to the reform, while all showed an upward trend afterward. In county hospitals, the proportion of medication costs increased by 19.115% immediately post-reform, and both the level and slope of medication varieties significantly rose (2.041, $p < 0.01$; 0.244, $p < 0.01$, respectively). Although the proportion of

examination and testing costs exhibited an upward trend before the reform, both the instantaneous level and the trend declined after implementation (-19.684, $p < 0.05$; -1.833, $p < 0.05$, respectively). **Conclusion** In the sample area, the average medical costs for diabetic outpatients were effectively controlled following the implementation of the capitation payment reform, and the standardization of medication prescriptions by physicians in township health centers improved. County hospitals provided more comprehensive examination and testing services for diabetic visits, and the intensity of medication prescriptions was greater compared to the period prior to the reform.

Ind-1077 Implementing UHC-Benefit Package in Pakistan: From National Framework to Local Realities

PRESENTER: **Obaid Arshad Khan**
AUTHORS: Mr. Sven Engels, Matt Boxshall, Dr Shabana Haider, Jeewat Rai

Background: Universal Health Coverage (UHC) implementation in decentralized health systems presents significant governance and institutional challenges, particularly in low- and middle-income countries. While Pakistan developed a national essential package of health services (EPHS) based on Disease Control Priorities 3 (DCP3) in 2020, its decentralized structure necessitates provincial-level implementation. This research examines the pilot implementation of a rationalized UHC-Benefit Package (UHC-BP) in Tando Allah Yar district of under one million people, Sindh province, addressing the gap in translating national frameworks into local realities.

Research Questions: The study aims to address three key questions:

1. What are the financial gaps between required funds for the UHC-BP and current district health financing?
2. How does the rationalization process affect the overall cost and scope of the UHC-BP?
3. How can the pilot implementation address systemic health governance challenges in Sindh?

Methods: Our approach combines quantitative financial analysis with Aga Khan University's qualitative assessment of service delivery and governance structures. We conducted a comprehensive rapid assessment of healthcare facilities and finances, analysing public accounts, estimating service-based costs using DCP3 methodologies, and consulting a wide range of stakeholders including policymakers, health officials, and service providers. The rationalization process was iterative, based on intervention availability, fiscal space, allocative efficiency, and feasible delivery models.

Results: Key findings include:

1. The initial UHC-BP of 94 interventions at community, health centre, and first-level hospital levels cost $18.09 per capita – double the current district health budget.
2. Rationalization streamlined it to 62 interventions, costing $14.47 per capita, still exceeding current allocations but more aligned with fiscal realities.
3. The process revealed significant gaps in health governance, particularly in financial management, service delivery coordination, and data-driven decision-making.
4. Innovative solutions emerged, including a high-powered steering committee, dedicated project management unit, and plans for a district health account to improve financial transparency and accountability.

Conclusion: These findings have important implications for UHC implementation in decentralized systems. While ambitious national packages are crucial for setting standards, their implementation requires careful adaptation to local fiscal and institutional realities. The rationalization process, though reducing scope, was essential for creating a feasible starting point for UHC implementation.

The pilot offers valuable lessons, underscoring the importance of:

1. Adaptive planning and iterative design in health policy implementation
2. Strong stakeholder engagement to ensure buy-in and address implementation challenges
3. Robust district-level health financing data and analysis
4. Digital health information systems for enhanced governance and service delivery

Future policy should focus on strengthening district-level capacity for health system management, improving health information systems, and enhancing resource allocation efficiency. Ongoing monitoring and evaluation will be crucial to assess the project's impact on health outcomes, financial protection, and healthcare equity.

This research contributes significantly to knowledge on pragmatic UHC implementation in resource-constrained settings. It provides a detailed roadmap for translating national policies into actionable local interventions, offering valuable insights that can inform health system strengthening efforts across similar contexts globally.

Ind-1513 The Timely Availability and Prices of Patented Medicines How Does Canada Fare Given its Price Regulations? An Analysis of 34 OECD member countries.

PRESENTER: **Wei Zhang**, University of British Columbia
AUTHORS: Nathaniel Dyrkton, Daphne Guh, Alexander Tam, Aslam Anis

Background: Canada had the second highest level of prescription drug prices in the world, after the United States (US), in 2022. Attempts to redress this situation by reforming the Patented Medicine Prices Review Board's (PMPRB's) price regulatory policies have met severe resistance from Big Pharma including court challenges and the ultimate threat by Pharma of *not launching* new drugs in Canada if the reforms are enacted. However, previous research has shown that the proposed price regulation has had little impact on the launch of new patented

medicines in Canada and that the new price regulation might or might not lower the drug list prices in Canada depending on the approaches that will be used in the PMPRB's final guidelines.

Objective: To examine both patented medicine prices and launches across the OECD to better elucidate how Canada fares compared to other countries.

Methods: IQVIA MIDAS Sales quarterly data from 2012-2023 were used. We selected molecules that were defined in the database as new active substances and innovative branded products launched after 2012. The launch date for each molecule for a given country was determined by its first local sale date and the global first launch date was the first sale date across 34 countries. The 2-year launch proportion for each country was the number of country-specific molecule-launches divided by the total global launches. Prices of all existing patented medicines in the database as of 2023 were examined at market level (i.e., the molecule, form/route of administration and strength level) using ex-manufacturer price ratios between a foreign country and Canada in 2023, weighted according to Canadian sales volume patterns. We summarized the two outcomes by country.

Results: There were 438 new molecules launched by Q4 2021 that were included in the launch proportion analysis. Out of the 34 countries, three countries launched a majority of these new molecules within 2 years of the global launch date: US (76%), Germany (55%), and the United Kingdom (UK) (51%). Canada launched 38% (9th highest proportion). In 2023, there were 1,784 markets in Canada that were included in the price ratio calculations. Bilateral foreign-to-Canadian price ratios showed US (4.35) and Mexico (1.28) had prices higher than Canada. That is, Canadians would have paid less for patented medicines in 2023 had they paid the prices from 31 other countries. Seven countries had launch proportions that were greater than Canada, yet price ratios were below 1: Italy (0.87), Germany (0.84), Austria (0.82), the UK (0.78), Sweden (0.72), Norway (0.69), and Japan (0.63).

Conclusion: This descriptive analysis of sales data suggests Canada had timely access to a moderate share of the patented medicines launched globally. However, Canadian prices remained among the highest across the OECD countries considered. Furthermore, several countries with launch proportions greater than Canada had lower prices. Further analyses will be conducted to examine the speed and cumulative probability of launching as well as the change in drug prices over time in OECD countries.

Ind-1372 Linking Drugs to Diagnoses Using Pharmaceutical Claims Data: A Method and Its Application Measuring Off-Label Prescribing

PRESENTER: **Maitreyi Sahu**, University of Washington
AUTHORS: Max Weil, Joseph Dieleman

BACKGROUND

Spending on prescribed pharmaceuticals accounted for 9% ($405.9 billion) of US healthcare spending in 2022. Off-label prescribing, meaning prescribing for uses other than what was approved by the US Food and Drug Administration, is common practice in the US and can be reimbursed by insurers. Prior research from 2001 suggests that up to 20% of commercial prescription drug claims are off-label. In this study, we develop a model to link pharmaceutical claims to the health condition for which they are prescribed, allowing us to estimate utilization and spending on off-label prescriptions by drug, health condition, and time in a commercial health insurance database for 2010 to 2018.

METHODS

For 742 commonly prescribed drugs, we estimate the fraction of retail pharmaceutical utilization and spending that is off-label in the Market Scan commercial health insurance claims data for 2010 to 2018. Because claims data contain National Drug Codes (NDCs) identifying pharmaceuticals but not the diagnoses for which they are prescribed, we probabilistically assigned health conditions to drugs in a multi-step process: (1) we linked prescription drug claims to the most recent outpatient visit occurring up to 30 days before the pharmaceutical claim, (2) we mapped diagnoses (defined by ICD-9 / ICD-10 codes) in the outpatient visit to 148 defined health conditions, (3) we restricted data to on- and off-label uses from the Thomson Micromedex pharmaceutical compendium, which we also manually mapped to our 148 conditions, and (4) we a random forest model to predict on- and off-label uses given the generic drug name, for 8 age/sex groups and leveraging drug details including dosage, package size, and route of administration. This generated a dataset of pharmaceutical spending and utilization by health condition, in which we estimated on- and off-label utilization and spending among adults over age 20. All values are reported in 2019 USD.

RESULTS

In the Market Scan commercial health insurance claims for 2010 to 2018, 742 commonly prescribed drugs accounted for an annual average of $1.38 billion total spending and 10.3 million claims. Among adults from 2010-2018, off-label prescribing accounted for 16.2% of pharmaceutical claims and 8.5% of total spending in the Market Scan claims data. While the proportion of off-label prescriptions remained stable at approximately 16% from 2010-2018, off-label spending decreased from 11.9% in 2010 to 6.1% in 2018. Across 2010-2018, health condition categories with the most off-label spending were anxiety and depressive disorders ($122.0 million), musculoskeletal disorders ($90.2 million), and respiratory conditions ($85.0 million). There was proportionally greater off-label drug use in Medicare Advantage (age ≥65) than in other private claims. Ongoing work examines off-label utilization and spending by drug, and extends this analysis to 2022.

CONCLUSIONS

Off-label prescribing accounts for a substantial proportion of retail pharmaceutical utilization and spending. From 2010-2018, spending on off-label prescriptions appears to be decreasing, while utilization has remained stable. Future work should examine the strength of evidence behind this off-label use in order to better understand its impact on quality of care.

Ind-2764 Did Intra-Province Reimbursement Reduce Patient-Requested Premature Discharge? An Impact Analysis on the Health Care Reimbursement Reform in China

PRESENTER: **Di Yang**

AUTHOR: Elias Mossialos

Background: China's health care system has been suffering from fragmentation since its restructuring in the 1980s. In addition to the varied social health insurance (SHI) programs for different segments of the population, China's health care system was geographically fragmented, and the SHI was financed and administered at the municipal level. Before the 2014 reform, patients were only able only use their SHI in the municipality of registration. Outside of the municipality of registration, SHI was essentially void, and patients would have to pay 100% out-of-pocket. Since 2014, China has implemented a series of reforms that allowed patients to receive SHI reimbursements for medical services obtained outside their municipality of SHI registration. While previous studies showed that the reform reduced catastrophic health expenditure and improved financial protection, its impact on care rationing, such as self-discharge against medical advice, remains unclear. Reduced care rationing serves as a key indicator of financial protection and a critical measure of the reform's success.

Methods: We used a Difference-in-Differences model to investigate the impact of 2014 intra-province SHI reimbursement reform on self-discharge against medical advice (defined as a patient-initiated termination of inpatient care without recovery or a physician's recommendation for discharge). We analyzed inpatient admission episodes at local hospitals from the China Health and Retirement Longitudinal Study (CHARLS 2011, 2013, and 2015). The control group comprised individuals with local SHI registration, who had continuous access to SHI-covered services at local hospitals. The treatment group included individuals with non-local SHI registration (such as internal migrants), who could only receive SHI reimbursement for inpatient care at local hospitals after the reform. We used the same Difference-in-Differences model specification for two OLS regressions. In the first regression, the outcome variable was whether the patient requested discharge against medical advice. In the second regression, the outcome variable was whether financial concern was the main reason for self-discharge.

Key findings: The likelihood of self-discharge against medical advice did not change significantly after the 2014 reform. However, individuals with non-local SHI were less likely to report financial concern as the main reason for self-discharge against medical advice. After the reform, the likelihood of reporting financial reasons for self-discharge against medical advice declined by 28 percentage points. As a robustness check, we used the same Difference-in-Differences model specification but with Logistic regressions, and the findings were consistent.

Conclusions and implications: The 2014 reform improved the financial protection of SHI but was not sufficient to reduce self-discharge against medical advice. Other factors, such as inpatient care quality and lack of long-term care facilities, would also contribute to self-discharge against medical advice. SHI reform must be complemented by supply-side reforms aimed at improving hospital care quality, as high-quality, high-tier hospitals are disproportionately concentrated in provincial capitals and major cities in China.

Cardiovascular Disease: Prevention to Rehabilitation

MODERATOR: **Jemimah Ride**, Monash University

Ind-163 Advancing Global Prevention Practices: Cost-Effectiveness of Immediate vs. 5-Year Risk Cardiovascular Strategies

PRESENTER: **Zanfina Ademi**, Monash University

AUTHOR: Jedidiah Morton

Objectives: Current Australian and global CVD prevention guidelines utilise a 5-year risk assessment, potentially overlooking individuals with low short-term but high long-term CVD risk. This study evaluates the cost-effectiveness of initiating intervention for risk factor control at age 40 years, regardless of calculated risk, compared to the conventional strategy recommended by guidelines, thereby advancing HTA to meet broader, global health demands.

Methods: We employed a causal-microsimulation model containing 108 varied risk factor profiles from the UK Biobank, each replicated 10,000 times, to project outcomes from age 40 to 85. The model evaluated the effects of early LDL-cholesterol and blood pressure management versus beginning treatment at the conventional 10% 5-year CVD risk threshold. The main side-effect in the model was an increased type 2 diabetes risk due to statin use. This trade-off was quantified in quality-adjusted life years (QALYs). Incremental cost-effectiveness ratios (ICERs) were compared to Australia's AU$28,000 per QALY willingness-to-pay threshold, with financial outcomes adjusted annually at a 3% discount rate.

Results: Early intervention was effective in preventing CVD across almost all risk profiles, resulting in increased QALYs and life expectancy for a significant portion of the population (37/54 females and 44/54 males in QALYs; 46/54 females and 47/54 males in life expectancy). Moreover, it was cost-effective in various cases (5/54 females and 17/54 males). Notably, immediate intervention showed a favourable cost-effectiveness ratio in individuals who exhibit moderate long-term risk that may not be captured by short-term assessments.

Conclusions: This study highlights the urgency of reevaluating CVD prevention strategies within HTA, demonstrating that broader, more inclusive preventive interventions are not only effective but cost-effective as well. It signals the need for a significant shift to prioritise CVD, the top cause of global morbidity and mortality.

Ind-1755 Optimizing Screening for Cardiovascular Disease Risk: Distributional Cost-Effectiveness Analysis With Stochastic Dominance

PRESENTER: **Nilmini Wijemunige**, Institute for Health Policy
AUTHORS: Pieter van Baal, Owen O'Donnell, Ravindra Rannan-Eliya

Objectives Screening for cardiovascular disease (CVD) risk is potentially cost-effective but its distributional impact by economic status likely depends on who is screened, how and with what criteria to prescribe preventive treatment. We conducted a distributional cost-effectiveness analysis to identify the CVD screening strategy for Sri Lanka with the best equity-efficiency trade-off. **Methods** Using nationally representative data on 4,745 adults, we modelled four strategies of opportunistic CVD risk screening at public outpatient clinics and the current screening program at designated clinics. We measured economic status (ES) with an assets index. For each strategy, we simulated the costs and quality-adjusted life years (QALYs), as well as the distribution of QALYs net of health opportunity costs by ES. We used stochastic dominance analysis to compare the QALY distribution of each screening strategy across ES percentiles. We also calculated inequality-penalized QALYs using a social welfare function analogous to the extended Gini family, and compared results with those from the stochastic dominance analysis. We used scenario analysis to assess the impact of different distributions of opportunity costs over the ES gradient, as well as probabilistic sensitivity analysis to test the sensitivity of the modelling to variations in the input parameters. **Results** Compared with the current program, more total QALYs were generated by opportunistic screening a) at a higher age threshold (≥ 40 vs ≥ 35), b) with statins prescribed at a lower CVD risk threshold ($\geq 10\%$ vs 20%), c) with antihypertensives prescribed at a lower blood pressure threshold (130/80 vs 140/90) to people with diabetes or at high CVD risk and d) with statins prescribed to all people with diabetes. The strategy which included the features (a)–(c), without (d), generated the highest QALYs net of health opportunity costs across ES percentiles, and dominated the other strategies. The findings were consistent with the inequality-penalized QALY analysis, where the same strategies were preferred with some degree of aversion to inequality. The results were highly sensitive to the distribution of opportunity costs over the ES gradient. # **Conclusions** Stochastic dominance analysis shows that several CVD risk screening modifications would improve health across the ES distribution but the optimal strategy was sensitive to the assumed health opportunity cost. This is one of the first times stochastic dominance analysis has been applied to analyze the distributional impact of strategies in an LMIC. This method avoids the need to specify a degree of aversion, unlike approaches that calculate inequality-adjusted QALYs, and we demonstrate that stochastic dominance analysis is a valid, non-parametric approach for comparing health distributions based on general ethical principles.

Ind-452 Cost-Effectiveness of Prehospital Extracorporeal Membrane Oxygenation in Out-of-Hospital Cardiac Arrest in Sydney Australia: PRECARE Trial Insights

PRESENTER: **Fredrick Zmudzki**, Royal Prince Alfred Hospital
AUTHORS: Mark Dennis, Paul Forrest, Emily Moylan, Hergen Buscher, Brian Burns, Changle Song, Timothy Southwood, Natalie Kruit, Hemal Vachharajani

Background: The use of extracorporeal membrane oxygenation (ECMO) in refractory cardiac arrest, termed ECMO-CPR (ECPR) has increased significantly. ECPR has demonstrated survival rates of around 30% when strict eligibility criteria are applied, for patients highly unlikely to survive without ECMO support. Prehospital ECPR (PH-ECPR) for out-of-hospital cardiac arrest (OHCA) may improve both equity of access and outcomes in this patient population by expanding service reach by up to four-fold. Cost effectiveness reflects positive survival rates, excellent neurological outcomes, and efficient use of short-duration, high-cost ECMO; resulting from characteristic ECPR survival curves where patients either do not survive or are quickly weaned off support. This study examines whether PH-ECPR is cost-effective in OHCA patients.

Methods: Using data from the current New South Wales Ambulance PH-ECPR PRECARE trial, NSW Ambulance Cardiac Arrest Registry (CAR), geospatial and time modelling, and in-hospital care pathways, a cost analysis of PH-ECPR was performed. All strategies are based on a PH-ECPR clinical team of 2 senior doctors, 1 paramedic and 1 OHCA dispatcher. The estimated cost per PH-ECPR patient combines all responses including turn backs where ECMO was not required due to return of spontaneous circulation (ROSC), or not indicated due to exclusion criteria. Immediate PH-ECPR team activation is crucial, prioritising sensitivity over specificity to ensure arrival early in the arrest phase; resulting in unavoidable turn backs potentially as high as 10:1. A Markov model combined the PH-ECPR cost analysis with reported patient outcomes across multiple mobile service strategies using innovative methods including; estimated survival probabilities weighted by ECPR eligible population to establish optimal pre hospital team location; bridging formulae from PH-ECPR survivor cerebral performance category (CPC) scores to estimate Quality Adjusted Life Years (QALYs), Incremental Cost Effectiveness Ratios (ICERs) and cost effectiveness acceptability curves (CEACs); and ECPR comparison based on low flow rates as the escalation point where conventional CPR survival probability approaches zero. Probabilistic sensitivity analysis (PSA) assessed the joint uncertainty in all model parameters.

Results: Assuming 100 PH-ECPR patients per year, the average cost per patient was $50,964, equating to an average pre-hospital cost of $12,741 assuming a conservative 25% team allocation to ECPR; and a total cost per patient of $88,656 AUD, a base case of around $44,000 per QALY. Assuming a lower 20% survival equates to $62,000 per QALY and an increased survival scenario of 40% indicates approximately $30,000 per QALY. Addition of a conservative 10% of patients' kidney organ donation from non survivors reduces the base case cost per QALY to $22,000. Survival rate and integration of the team in performing other non-ECPR clinical tasks are key aspects contributing to cost-effectiveness.

Conclusion: Building on prior research showing ECPR in carefully selected patients can efficiently utilise high cost ECMO support, the initial PH-ECPR cost analysis and modelling indicate that PH-ECPR service strategies in Sydney are likely to be cost-effective; and increase equity of access through earlier intervention to an increased OHCA population. Additional positive outcomes based on potential organ donation may further contribute to PH-ECPR cost effectiveness.

Ind-2224 A Cost-Utility Analysis of Surgical and Transcatheter Pulmonary Valve Replacement with Right Ventricular Outflow Tract Remodelling in Indonesia

PRESENTER: **Andi Nurul Annisa**
AUTHORS: Puree Anantachoti, Osot Nerapusee, Dafsah Arifa Juzar, Radityo Prakoso

Backgrounds Transcatheter Pulmonary Valve Replacement (TPVR) is better and safer than Surgical Pulmonary Valve Replacement (SPVR) for patients in right ventricular outflow tract (RVOT) who have had prior surgery. However, TPVR's price is extremely high and not covered by the current universal schemes in Indonesia. Therefore, an economic modelling approach was utilized to perform a cost-utility analysis between SPVR and TPVR. The study had two primary objectives. Firstly, to assess the cost-effectiveness of TPVR as compared to SPVR for patients with a history RVOT replacement. Secondly, this study aims to estimate an optimal price for TPVR under Indonesia's National Health Security Programme (known as Jaminan Kesehatan Nasional or JKN), by analysing threshold variations in the price of the TPVR system. **Methods** A Markov model was employed to calculate the costs over a lifetime, total quality-adjusted-life-years (QALYs) and total life-years (LYs) for a hypothetical cohort of patients with RVOT, along with total incremental cost-effective ratios (ICERs). This economic modelling considered SPVR or TPVR for patients with clinical anatomy disease. The model began with paediatric patients at 15 years of age with prior surgery (SPVR0) between the ages of 2-4 years. Patients then underwent 1st and 2nd repeated SPVR at 15-year intervals. Alternatively, patients started with an initial TPVR, followed by 1st and 2nd repeated TPVR within 10 years of intervals. The costs related to SPVR and TPVR procedures and complications were considered. After 45 years of age, all patients who underwent SPVR and TPVR had a higher mortality risk up to 10 times compared to natural death. The methodology was based on the Indonesian HTA Guideline, while clinical and cost input parameters were derived from two meta-analyses, the hospital's website, and published resources with slight modifications. The outcomes of interest were annually discounted to 3%. All prices were adjusted with the consumer price index (CPI) and expressed in 2023 USD. Deterministic and probabilistic sensitivity analyses (DSA and PSA) were conducted to validate the results. **Results** The analysis revealed that the incremental cost, QALYs, and LYs were 47,087.13 USD, 2.45, and 3.38, respectively. The threshold for cost-effectiveness was set at one-time GDP, which in Indonesia is 3900 USD. Based on this, TPVR did not prove to be a cost-effective intervention, with an ICER over a lifetime of 19,191.37 USD/QALY. Further analysis using DSA indicated that the initial TPVR utility value played a critical role in the ICER. ICER scatter plots in PSA analysis revealed that TPVR was more effective but also more expensive than SPVR. However, to be more accessible, the price of the TPVR system should be reduced by 70% of its current cost, to 10,000 USD. **Conclusions** TPVR is not cost-effective in Indonesia's real-world setting due to the high pricing of TPVR's system. This result may serve as crucial evidence for health policy makers to reach an optimal TPVR provision price while transitioning towards universal health coverage (UHC).

Ind-2560 Increasing Participation in Cardiac Rehabilitation in the United States: Cost Effectiveness of Case Management and Financial Incentives

PRESENTER: **Donald S. Shepard**
AUTHORS: Diann E. Gaalema, Philip A. Ades, Robin K. Collier, Patrick D. Savage, Jiaye Shen, Deborah E. Denkmann, Bryan R. Katz, Blair Yant

Purpose. Cardiac rehabilitation (CR) is a program of monitored exercise and instruction on diet and lifestyle for patients with heart disease. As CR is highly effective, cost-effective, and professionally recommended, policymakers seek to increase utilization. Here we applied results from a four-arm randomized trial of case management (CM) and financial incentives (FI, paid as retail gift cards), delivered separately and combined. We modeled their impact and cost-effectiveness compared to usual care (UC) in increasing quality-adjusted life years (QALYs).

Methods. The trial randomized 192 participants, all of lower socio-economic status.** Staff time logs, FI payouts and CR attendance records generated short-term data on each participant's costs and number of CR sessions. We derived the lifetime QALYs and cost-effectiveness from a 2024 cost-effectiveness study of CR calibrated from an observational cohort of 601,099 CR-eligible Medicare beneficiaries. That cohort study controlled for confounding using instrumental variables (IV) and propensity-based (PB) matching.

Results. Usual care averaged only (with 95% confidence intervals) 10.94 (6.07-15.81) CR sessions, far below the 36 sessions constituting complete CR. FI alone and CM+FI combined increased CR sessions significantly. Additional CR sessions per participant averaged 7.04 (0.93-13.15) with FI and 13.63 (7.86-19.41) with CM+FI. CM alone did not increase sessions significantly (mean 1.66, -4.23-7.56). CM+FI generated the most lifetime QALYs—0.733 (IV) and 1.100 (PB) and displayed a powerful synergy between CM and FI. Under CM+FI, financial payouts averaged $697 (range $0-$1,260) and total intervention costs averaged $2,388. The lifetime cost-effectiveness of CM+FI was 29.996 (29.636-30.296, IV) or 29.257 (28.935-29.579 PB) QALYs/$million. Both values substantially surpassed the average cost-effectiveness of the US healthcare system (10.421 QALYs/$million), published by Andres Pichon Riviere and colleagues in 2023.

Conclusions. CM+FI proved highly effective and more than twice as cost effective as the average of all health interventions in the US. The synergy appeared due to the ability of CM to show participants how to overcome barriers to CR participation and of FI to increase participants' motivation to try harder. CM+FI, combined with other effective interventions, such as automatic referral and home-based CR, merit widespread implementation and funding. The combination of coaching and incentives could likely also help control other non-communicable diseases.

Preferences for Health and Healthcare

MODERATOR: **Anne Spencer**,

Ind-187 Patient Preferences for Definitive Management of Oesophageal Cancer: a Discrete Choice Experiment.

PRESENTER: **Josipa Petric**
AUTHORS: Norma Bulamu, Gang Chen, Tim Bright, David Watson

Background: Oesophageal cancer (OC) is the eighth most common cancer and sixth leading cause of cancer-related mortality worldwide. The main treatment modalities for locally advanced disease are surgery with perioperative chemoradiotherapy, and definitive chemoradiotherapy without surgery. The aim of this study was to assess patient preferences and the trade-offs patients they are willing to make when choosing between these treatments.

Methods: A discrete choice experiment (DCE) was conducted based on four attributes: cure rate (10%, 30%, 40%, 60%), risk of death after treatment (1%, 3%, 5%), quality of life following treatment (a little worse, moderately worse, a lot worse) and follow-up schedule (standard follow-up with endoscopy every 3 months for 2 years, endoscopy every 3 months for 2 years then annually for 3 more years (total 5 years) or 8 more years (total 10 years)). Four respondent groups were recruited: patients under surveillance for OC, OC survivors, clinicians, and the general population. Data was analyzed within the framework of random utility theory.

Results:

Ninety-two surveillance patients, 80 clinicians, 35 survivors and 100 from the general population completed the DCE. All respondent groups had significant preference for a higher cure rate (40% and 60% compared to 30%) and were averse to a worse quality of life. Only clinicians were significantly averse to a 5% risk of death compared to 1%. Higher coefficients were observed for worse quality of life than cure rate for all groups except clinicians and the general population.

All respondent groups had >50% probability of choosing preoperative chemotherapy with surgery (reference: cure rate= 40%, death=3%, QoL=moderately worse, follow-up=standard) over definitive chemotherapy without surgery (reference: cure rate= 30%, death=1%, QoL=a little worse, follow-up=3 more years). Varying attribute levels for definitive chemotherapy from the reference, cancer survivors preferred preoperative chemotherapy with surgery regardless of change in attribute levels. For the other groups, the preference changed (probability >50%) to definitive treatment when preoperative treatment had a 40% cure rate. When attribute levels for preoperative chemotherapy were varied, definitive treatment was preferred if cure rate was reduced to 10% (all groups) and to 30% (except for cancer survivors), and if QoL was a lot worse (all groups).

Conclusions:

Preoperative chemotherapy with surgery was preferred by all groups to definitive chemotherapy without surgery. This could be associated with the certainty of no cancer recurrence and reduced anxiety following surgical removal. Significantly important factors when deciding treatment regime were cure rate and quality of life, and quality of life was in fact more important than cure rate for patients under surveillance and cancer survivors. These findings should be used to help guide clinicians in recommending treatment modalities.

Ind-537 Revisiting Health, Income, and Life Satisfaction: A Comparative Replication Study

PRESENTER: **Tinna Laufey Asgeirsdottir**
AUTHOR: Viktor Andri Karason

In 2018, two studies were published, placing a monetary value on health-related quality of life. In both cases the compensating income variation method was used on the same data set (Household Income and Labour Dynamics in Australia - HILDA). The differences in results across studies are difficult to reconcile, even though one paper focused on the whole Quality Adjusted Life Years (QALYs) while the other examined changes in QALYs. Specifically, the reported valuations ranged from A$42,000 to A$67,000 for a whole QALY under one approach, while the other paper found a value of A$39,000 for a 4% health decline and A$162,000 for a 10% decline. We investigate these differences and try to reconcile these seemingly irreconcilable results by (*a*) replicating each paper, using the same data and methods described in each paper, (*b*) estimating both papers using the exact same sample and waves, and (*c*) re-estimating key analyses from each paper, but using some methodological approaches from the other paper. Results show that most of the differences across these papers can be explained by the differential treatment of income in the estimations. In one of the papers, financial worsening is used to instrument household income, and the other uses financial improvement directly in the life-satisfaction equation. This showcases the sensitivity of compensating income variation estimates to the treatment of income in life-satisfaction estimations, and in turn underscores the need for methodological consistency to be developed within the compensating income variation literature. **Keywords:** Replication, Compensating Income Variation, Health, Income, QALY

Ind-755 Econometric Model Derived From Meta-Analysis to Estimate VSL and VOLY Associated to air Pollution at a Global Level

PRESENTER: **Sara Ciarlantini**
AUTHORS: Vito Frontuto, Alessandro Pezzoli, Andreas Gavros, Claudio A. Belis

Air pollution is a key determinant of health, with numerous studies linking it to a range of adverse health effects in the general population, from minor subclinical impacts to premature mortality. Exposure to air pollution is now the second leading fatal health risk worldwide, accounting for 8.1 million deaths in 2021 (Health Effects Institute, 2024). In financial terms, premature deaths due to air pollution exposure to both ambient and household sources cost the global economy about $5.11 trillion in welfare losses (World Bank/Institute for Health Metrics and Evaluation, 2016).

Addressing policy questions on the health impacts of air pollution requires methods that balance the costs of risk reduction with the expected benefits, measured in terms of prevented premature deaths. Associating a monetary value with human life is, therefore, as much challenging as important.

The benefits of prevented mortalities can be expressed in terms of a Value of a Statistical Life (VSL), an economic parameter representing individuals' willingness to exchange wealth for mortality risk reduction. In addition, the monetary Value of a Life Year (VOLY) is also an important parameter to be measured, as it considers the change in life expectancy associated with air pollution. However, obtaining reliable VSL and VOLY values is challenging, as methodologies vary widely across—and even within—countries. Furthermore, most countries have insufficient and unreliable VSL and VOLY estimates. Lack of country-specific data and of common methodology affects the comparability between countries in global assessment and makes it difficult to assess climate policy at a global scale. To address this gap, a database of 494 air pollution-related VSL estimates was compiled from the available literature, including both peer-reviewed papers and technical reports. The final database covers 186 countries across all continents. These country-specific estimates serve as inputs for the meta-analysis conducted, with the aim of integrating them into a specific econometric model assessing only the share of health costs attributable to air pollution worldwide. The model incorporates economic, socio-economic, demographic, and health proxies to tailor VSL estimates to each country's characteristics. This approach, new in air pollution analysis, enables a more specific application of VSL in policy contexts specific to each country.

Since air pollution does not directly cause death but worsens pre-existing health conditions, it is crucial also to consider the VOLY measure. VOLY is often favoured over VSL in cases involving reductions in life expectancy, such as chronic exposure to air pollution. Therefore, a corresponding VOLY database was developed, derived from VSL-based estimates. Notably, this air pollution-related country-specific VOLY database represents the first of its kind in the literature. The outcome of the present work is expected to contribute to better quantitative estimates of the economic benefits associated with air pollution abatement policies and the consequent prevented number of premature deaths worldwide.

Ind-952 How do Breast Cancer Patients Trade-Off Benefits and Risks in Treatment Decisions? A Discrete Choice Experiment (DCE).

PRESENTER: **Dr. Hui Yee Yeo, PhD**
AUTHORS: Carlo Marra, Mudassir Anwar, Gin Nie Chua, Catherine Han

Background:

Breast cancer (BC) imposes substantial burdens on healthcare system, patients, and society. While advances in treatments provide diverse options, they also complicate decision-making due to the varied benefits, risks, and costs involved. Conventionally, optimal treatment strategies have been primarily physician-driven, often with limited consideration of patients' values and preferences. Integrating patient preferences into treatment decisions can promote transitioning towards a patient-centred approach, potentially enhancing health outcomes and adherence. This study aimed to identify key attributes that influence treatment decisions and quantify patients' benefit-risk preferences for advanced BC treatment.

Methods:

Patients' preferences for BC treatments were evaluated using formative qualitative interviews followed by an online DCE. Treatment alternatives were characterized by six attributes identified during the qualitative phase: overall survival (OS), risks of hair loss (HL), risks of peripheral neuropathy (PN), waiting time to assess treatment (WT), out-of-pocket cost (OOP), and quality of life (QoL) in terms of difficulties in performing daily activities and selfcare. The survey consisted of 24 choice tasks, each featuring two unlabeled alternatives, divided into two blocks; participants were randomized to each block. The survey results from the pilot tests were used to optimize the final DCE design. Participants were recruited via NZ BC patient advocacy groups via email and social media channels. The DCE data were analyzed using mixed logit model; the estimated model results were used to compute the relative attribute importance as well as treatment trade-offs in terms of maximum acceptable risks of PN, marginal willingness to pay (mWTP) and willingness to wait (mWTW). The MXL model was also extended to include additional interaction effects between the attributes and participants characteristics to explore drivers of preference heterogeneity.

Results:

Analysis of 233 completed responses showed that OS was the most important attribute, followed by QoL. Risk of PN, WT, risk of HL, and OOP costs were relatively less important but showed significant differences across levels. Sub-group analyses revealed significant preference heterogeneity based on sociodemographic characteristics. For instance, patients solely treated within the public healthcare system placed less importance on OS compared to those in private or mixed systems. Māori respondents demonstrated a significant aversion to increased OOP costs compared to non-Māori participants. The benefit-risk trade-off analysis showed that patients were willing to tolerate a maximum 20.6% increase in PN risk for one additional year of OS and a maximum 51.6% increase for QoL improvements. Respondents were willing to pay $582 per month for a year of increased OS and $1,457 per month for QoL enhancements. Conversely, patients would pay $28 per month to avoid a 1% increase in PN risk. The mWTW analysis indicated that patients were willing to wait up to 6 months to avoid QoL reductions and up to 2 months for a year of increased OS.

Conclusion:

This study reveals strong patient preferences for OS and QoL in BC treatment, with notable heterogeneity across sociodemographic groups. Aligning these insights with clinical guidelines can enhance shared decision-making by ensuring treatment aligns with patient values, while also informing policy-making.

Ind-1748 A Fair Innings? Estimating Preferences for Prioritising the Less Healthy

PRESENTER: **Matthew Robson**
AUTHORS: Tom van Ourti, Owen O'donnell, Erik Schokkaert

The fair innings principle of health resource allocation gives priority to those who would otherwise have fewer quality-adjusted life years (QALYs). However, it leaves scope for different interpretations and intensities of this prioritisation. We conduct an experiment, with a UK general public sample (n = 230, *obs.* = 20*,*700), to test support for different interpretations and to measure the intensity of support for the principle. We specify social welfare functions (SWFs) representing alternative interpretations, estimate participant-specific parameters within each SWF and identify which SWF best fits each participant's choices. We find overwhelming support for the fair innings principle, broadly defined. *Prioritarian* SWFs - that display continuously diminishing marginal welfare from QALYs - fit the data better than *threshold* SWFs - that are linear in QALYs with weights that decrease discontinuously on reaching a 'fair innings'. We illustrate policy consequences of using the estimated SWFs in decision making, and identify welfare weights by quality-adjusted life expectancy.

Keywords: Fair Innings, Social Preferences, Inequality Aversion, Experiments.

Ind-1779 Active Transport Health Model: Valuing the Health Benefits of Active Transport

PRESENTER: **Mary Wanjau**
AUTHORS: Christopher Standen, Holger Möller, Mr. Lennert Veerman, Fiona Haigh

Background Physical inactivity is one of the contributors to the rise in non-communicable diseases worldwide. Active transport, which refers to modes of transport that involve physical activity such as walking, cycling and walking and cycling to and from public transport stops, offers a known means of raising physical activity at a population level. However, forecasting and valuing the health benefits of transport projects that increase physical activity (PA) is challenging. **Aim** To develop a best-practice method to estimate the health benefits of changes in active transport behaviour and translate these benefits to an economic value. **Methods** With oversight from the cross-agency advisory group, a previous version of the multistate lifetable model was amended to develop the A*ctive Transport Health Model*. The model is a proportional multi-state lifetable that quantifies the health impacts of changes in active transport behaviour over a population's lifetime. The Model was parameterised to New South Wales (NSW), a state in Australia, and NSW Treasury guidelines were followed. Health outcomes related to PA, air pollution and road trauma exposures are modelled. Model outputs include age- and sex-specific changes in disease incidence, prevalence, mortality, summarised as health adjusted life years (HALYs) and healthcare costs. The HALYs are then translated to monetary terms. These health benefits are valued in accordance with current *Office of Impact Analysis* recommendations. A central (reference case) scenario was modelled based on a mode-specific intervention scenario for walking, cycling and public transport. In the main analysis, a 5% discount rate was applied. Values per additional km of walking and cycling are reported. Various sensitivity analyses were conducted. **Results** Compared to car use, results from our reference case put the value the health benefits at A$5.24 (95% uncertainty interval [UI] $4.73 to $5.70) for a km walking, and A$ 2.95 (95% UI $2.71 to $3.17) an additional km cycled. The results vary systematically and substantially with age and physical activity level, with great benefits for the old and the inactive and much lower gains for the young and for the segment of the population that already achieves high levels of PA. The choice of the value for a healthy life year and the discount rates for health effects and costs impacts the results. **Conclusions and implications for policy and practice** The per-km values in our study were higher than those of previous similar studies, which is largely due to the inclusion of a direct link between PA and mortality, and the use of accelerometry-derived relative risks. The values can allow the monetised health benefits of PA to be factored into decision making on transport projects. The Model could also be used to determine the potential health benefits of other policies aimed at increasing populations' physical activity levels. Additional steps to account for non-health benefits and costs are required for full cost-benefit analyses. The Model is pending approval for adoption by relevant state and local agencies in NSW.

Ind-1996 In Search of a Preferred Time Preference Elicitation Method in the Health Domain: Testing the Consistency Between Direct and Indirect Approaches

PRESENTER: **Qiqi Liu**
AUTHORS: Cong Li, Jingxian Wu, Danlei Chen

Abstract Text:

Background:

Time preference, representing individuals' preferences over intertemporal tradeoffs, plays a crucial role in health-related decision-making. Despite extensive research on individual time preferences, no agreement has been reached on the optimal method for measuring time preferences in the health domain. Considering the importance of accurately capturing time preferences for designing effective health interventions and policies, guidelines are needed to identify the preferred elicitation methods. This study aimed to test the consistency of time preference indicators in the health domain elicited through direct (self-reported) and indirect (experimental) approaches.

Methods:

Data for this study were collected through a structured household survey conducted in six counties of Shaanxi Province, China, during July and August 2023. Using a multistage stratified random sampling method, the survey included 2,878 rural individuals aged 18 to 65 from 1,377 households. Direct (self-reported) time preferences were assessed through planning horizon (years) and self-rated long-term preference (measure on a 0-10 scale). Indirect (experimental) time preferences were elicited using iterative choices between immediate mild health losses and delayed severe health losses, with indicators calculated using exponential and hyperbolic discounting models. Consistency within self-reported approaches was tested using Spearman's rank coefficient and Kendall's tau-b correlation. For experimental methods, consistency across discounting models was assessed using the Wilcoxon signed-rank test. Ordinary least squares (OLS) and nonlinear least squares regressions were applied to evaluate the consistency between self-reported and experimental indicators.

Results:

Within direct approaches, planning horizons and self-reported long-term preferences demonstrated moderate correlation, with Spearman's rank coefficient at 0.469 ($p < 0.01$) and Kendall's tau-b correlation at 0.379 ($p < 0.01$). For indirect approaches, time preference indicators derived from exponential and hyperbolic discounting models showed significant differences ($p < 0.01$) based on the Wilcoxon signed-rank test. Comparing across direct and indirect methods, both OLS (-0.006, $p < 0.10$) and nonlinear least squares regressions (0.0008, $p < 0.10$) revealed a significant relationship between planning horizons and discount rates under the exponential discounting model. However, self-rated preferences showed no significant association in either model.

Conclusion:

Time preference indicators elicited through self-reported approaches achieved moderate consistency, whereas the consistency within experimental approaches and across the two methods was lacking. These inconsistencies highlight the limitations of relying on a single method for measuring time preferences in the health domain. Future research should employ diverse elicitation methods to capture time preferences comprehensively and explore the underlying causes for the inconsistences across approaches. Such efforts are crucial for advancing the design of effective health interventions and improving the measurement of time preferences in health-related contexts.

Ind-2084 Can Willingness-to-Pay Measure Welfare Loss Due to Cancer ? A Contingent Valuation Assessment on French Breast Cancer Patients in Remission

PRESENTER: **Hélène Huber**, Paris 1 Pantheon-Sorbonne University and Paris School of Economics
AUTHORS: Brigitte Dormont, Thomas Vermeulin, Clémence Thébaut

In this paper we present the protocol and results of a survey of more than 1,000 breast cancer patients in remission. The purpose of this survey was to elicit willingness to pay that allows us to assess in monetary units the welfare loss due to cancer. More broadly, the aim of this survey is to enable us to perform health technology assessments by using a cost-benefit analysis based on the notion of Health-Equivalent Income instead of the traditional Cost-Effectiveness approach. As stated in Fleurbaey et al, Health Economics (2013) and Samson et al., Health Economics (2017), the approach based on the Health-Equivalent Income makes it possible to build a social welfare function that allows for the preferences of individuals regarding their health and income and that considers the concern of the regulator for inequalities between individuals in these two dimensions. This approach also eliminates debates over cost-effectiveness thresholds often used to decide on the reimbursement of expensive treatments. With the rising cost of innovative treatments in cancer proposed by the pharmaceutical industry, this approach is particularly relevant.

To date, the Health-Equivalent income methodology has been applied only in evaluating hypertension treatments (Samson et al., 2017). That study demonstrated that incorporating fairness and individual preferences into cost-benefit analysis is feasible. Given the significant pain, mortality risks, and welfare loss associated with cancer, applying this methodology to cancer treatment evaluation seemed vital. This is especially true for breast cancer, the most common and deadliest cancer among French women (INCa, 2024).

The concept of Health-Equivalent Income reflects an individual's income minus their WTP to achieve perfect health. Eliciting this metric for breast cancer posed challenges due to patients' stress and the risk of relapse. Nonetheless, a partnership with a French nonprofit cancer hospital enabled us to contact cancer patients in remission, of whom 1,200 women accepted to participate, and 1,000 were eligible. Remarkably, 80% of respondents demonstrated comprehension of the survey, proving the feasibility of such research even on a sensitive topic.

The survey collected socio-demographic data and details about the timing and severity of cancer, as well as conditions related or unrelated to cancer. Respondents were presented with hypothetical scenarios comparing their current health state to an improved one (e.g., no cancer-related conditions). They were asked what portion of their income they would forgo to enjoy this improved scenario for the rest of their lives.

Preliminary analysis reveals that, on average, women were willing to give up approximately €700 per month (equivalent to €210,000 over 25 years) to avoid a relapse. This figure represents the average value women place on mitigating welfare loss due to the risk of relapse. This methodology is operational for quantifying the welfare impact of various aspects of living with cancer.

This novel approach to measuring welfare loss provides valuable insights for health policy decision-making. By monetizing welfare losses associated with cancer, the method offers a robust framework for evaluating the societal and individual value of health interventions, facilitating more informed and equitable health policy decisions.

abs-os86 Risk in Preferences for Population-Based Breast Cancer Genomic Risk Screening: A Methods Case-Study in Discrete Choice Experiment

PRESENTER: **Cun Liu**, University of Melbourne
AUTHORS: Ilias Goranitis, Mr. Dean A Regier

Background: Over the last decade, advances in genomic technologies and research have significantly enhanced our understanding of cancer susceptibility genes. In many health-care systems, clinical genetic testing for pathogenic variants associated with cancer is offered based on family history. However, most high-risk pathogenic variant carriers remain unidentified. Population-based genomic cancer risk screening provides a transformative opportunity for cancer prevention, early detection, and targeted management. Understanding patient preferences for genomic risk screening is critical for enabling high value health care. Discrete Choice Experiment (DCE) is an established approach to elicit individual preferences, values and priorities for informing the evaluation and implementation of health technologies and services. DCEs inherently assume that individuals are utility maximizers, choosing the healthcare option that provides them with the highest utility. The dominant framework underlying this utility-maximizing behavior is the linear Random Utility Maximization framework, where the respondent utility from a healthcare intervention can be modeled as a linear additive function of the intervention's key components. However, a major limitation of this linear specification is the risk-neutral and belief-neutral assumption. A growing evidence-base now highlights that cancer screening choices are conditioned on behavioral and psychological factors, primarily related to risk attitudes and perception of risk, for example based on their family cancer experiences. The objective of this study is to explore different methods to 1) demonstrate how to best incorporate risk attitudes and perceptions in preference elicitation and choice modelling using breast cancer as an exemplar; 2) investigate how individuals perceive and value information related to their breast cancer risks in a population-based genomic risk screening program, and how risks attitudes and perceptions influence cancer screening.

Methods: Seven focus groups were conducted to identify and develop the choice attributes and attribute-levels. Focus groups were recorded, transcribed, and analyzed using inductive content analysis and 6 attributes were identified. Three DCE experiments are now in progress to elicit preference and values of population genomic risk screening for individuals at different levels of breast cancer risk. Bayesian D-efficient designs with status quo alternative are used. Measures of risk attitudes and perceptions include: perceived cancer risk; cancer worry; health risk attitudes; consideration of future consequences scale; attitudes toward uncertainty. Alternative behavioral frameworks will be incorporated to accommodate risk attitudes and perceptions in choice modelling. The DCE surveys will be administrated to nationally representative samples of the Australian public. Data collection is expected to be completed by the end of 2024 and analysis will be completed by May 2025.

Results: The study will derive empirical estimates of willingness-to-pay and uptake for population-based breast cancer genomic risk screening and assess how the values vary based on individual's cancer risk and risk preferences.

Conclusions: This study will provide quantitative evidence on how risks attitudes and perceptions influence decisions to take up genomic screening programs, and how this information can be used to optimize design and outcomes of such programs.

abs-os215 Living Large or Long? Preference Estimates from Completed-Life Stories

PRESENTER: **Erzo Luttmer**
AUTHORS: Joshua Schwartzstein, Tomáš Jagelka, Amitabh Chandra
Background The value of a year of life plays a crucial role in informing policy decisions related to healthcare, the environment, innovation, and safety regulations. In healthcare, treatment costs are often measured in dollars per Quality-Adjusted Life Year, and decisions about pursuing certain treatments are sometimes guided by whether this cost falls below a specific benchmark for a life year, as is the case with the UK's National Institute for Health and Clinical Excellence (NICE). Given the significance of a life year's value for policymaking, estimates should accurately reflect people's preferences. Currently, estimates are derived from individuals' observed choices involving small risks of death and monetary compensation, such as their willingness to take riskier jobs for higher pay. However, these estimates have significant limitations: individuals may not correctly perceive small risks, may deviate from rationality for choices involving small probabilities, and those making such choices, like soldiers or firefighters, represent a non-representative sample. Furthermore, unobserved job characteristics related to risk can bias these estimates. **Methods** Our paper introduces an alternative method for estimating the value of a life year, attempting to overcome these limitations. We present a broadly representative sample of U.S. respondents with choices between pairs of "completed-life stories", asking which life they would prefer for themselves. By randomizing lifetime earnings and ages of death in each story, we estimate how the probability of choosing a particular story increases with higher lifetime earnings versus a later age of death. **Results** We find that a 7% increase in lifetime earnings increases the choice probability as much as a 1% increase in longevity, implying a Life Year Value (LYV) elasticity of 7. Consequently, a typical individual with median earnings of $80,000 annually values an additional life year at age 80 as equivalent to receiving an additional $5,700 per year for all working years, totaling approximately $225,000 over their lifetime. We validate our estimates by

demonstrating high test-retest reliability across survey waves and establishing their robustness through a series of specification checks and additional randomizations. Furthermore, we estimate markedly higher LYV elasticities for individuals whose subjective attitudes indicate that they place an above-average value on an additional life year. A key methodological advantage of our approach is that respondents engage in a natural task—assessing whether a life was desirable—which avoids triggering cultural or social norms about paying for life extension. Moreover, our method does not entail decisions under uncertainty, thereby avoiding many known behavioral biases. An important substantive advantage of our approach is that it allows us to estimate how the Life Year Value varies with respondent characteristics, age of death, and lifetime earnings in a broadly representative population. We find that the LYV increases with lifetime earnings and decreases with later life years. **Conclusions** Even when holding constant lifetime earnings and age of death, there is notable heterogeneity in the LYV across individuals. This suggests that tailoring policies to individual preferences can result in welfare improvements.

Inequality and Vulnerable Populations in Healthcare Demand and Use

MODERATOR: **Amirah Azzeri**,

Ind-1257 Healthcare Demand Response of the North Korean Refugees

PRESENTER: **Yunji Choi**
AUTHORS: Hye-Seung Wee, Sok Chul Hong

Background There are more than 30,000 North Korean (NK) refugees living in South Korea with approximately 1,000 to 3,000 newly entering each year. After spending their first 8-12 weeks in a settlement facility ("*Hanawon*"), they are automatically enrolled in a low cost-sharing public health insurance plan that charges less than US$2 out-of-pocket expenditure per visit, with the aim of helping them recover from their bad health conditions. Then, after 5 years, the income cutoff for their eligibility criteria increases rapidly, resulting in many of their health insurance plan switching to a higher cost-sharing plan with 20-30% coinsurance rate.

Objectives In this study, we investigate how NK refugees respond to an increase in cost-sharing. We first examine the responses on outpatient and inpatient care. Then, we examine the responses on low-value and overused care and high-value care discussed in the behavioral hazard literature. Lastly, we study whether any drug interruptions happened.

Methods We use the Korean National Health Insurance (NHI) administrative claims data to identify all NK refugees living in South Korea and examine their medical records. Exploiting the fact that income criteria for the NK refugees increases sharply after the first 5 years since entry, we define a staggered treatment timing: the year of switch from low cost-sharing plan to high cost-sharing plan. We estimate (1) a two-way fixed effect model among the NK refugees and (2) an event time difference-in-differences using matched South Koreans as a control group. We restrict the sample to those who switched from low to high cost-sharing plan only once and those who entered South Korea within a period between 2008 and 2018. The final sample consists of 5,934 NK refugees and 95,416 South Koreans.

Key results Our results provide three interesting findings. (1) We find that, when faced with an increase in cost-sharing, the NK refugees reduce their outpatient visits by 24 percent while the probability of hospitalization does not decrease. The magnitude of the responses is similar to those found in the existing literature, but a big level difference exists – NK refugees use 40% lower than their matched South Korean counterparts under high cost-sharing plan. (2) The use of physical therapy drops by 15.4 percent and imaging services by 7.0 percent but diabetes patients tend to adhere to their medication. (3) Most importantly, we find a sharp and persistent drop in the probability of getting a prescription on anti-psychotropic drugs.

Conclusions: We find that NK refugees have large behavioral hazard problems while showing smaller signs of moral hazard. Cutting back on anti-psychotics could be of concern given that NK refugees suffer from various mental illnesses and have 3 times higher suicide rates than the South Koreans. It is important to note that typical measures of high-value care, such as medication adherence of patients with diabetes, are not applicable to vulnerable population like NK refugees who tend to suffer from under-nutrition and where only 2% are diagnosed with diabetes. Examine whether information treatment helps mitigate behavioral hazard in the vulnerable population could be useful.

Ind-1351 Unmet Needs for Care in Europe: Are Immigrants and Native-Born Individuals Equal?

PRESENTER: **Sandy Tubeuf**, Université Catholique de Louvain
AUTHOR: Luigi Boggian

Inequalities in access to care between immigrants and native-born individuals contribute to immigrants' unhealthy assimilation, influencing their long-term health trajectories. Most existing literature focuses on measuring disparities in the actual utilization of health services, with fewer studies examining disparities in forgone care. These studies reveal substantial heterogeneity in access to healthcare and health insurance coverage across Europe, highlighting the roles of socioeconomic status, country-specific health insurance schemes, and health needs in predicting forgone care.

This study assesses disparities in forgone healthcare between native-born individuals and immigrants in 14 European countries using data from the Survey on Health Ageing and Retirement in Europe (SHARE). We contribute to the literature on healthcare access disparities across social groups by focusing on self-reported unmet care needs. Immigrant status is defined based on country of origin, identifying several groups: European and non-European first-generation immigrants, non-European second-generation immigrants, and non-citizens. Using a

comprehensive set of controls to proxy health needs and socioeconomic status, we employ linear and non-linear regression models to examine disparities in healthcare access between immigrant and native-born adults. Furthermore, we explore additional confounders identified in the literature to understand correlations with forgone care and their role in explaining group disparities. First, we account for culture-related factors, including religiosity and linguistic affinity between host and origin countries. Second, we examine social trust, financial risk aversion, and health insurance coverage.

Our results indicate that both first- and second-generation immigrants, as well as non-citizens, are more likely to forgo care, even after controlling for health needs and socioeconomic factors. These effects are predominantly driven by immigrants of non-European origin. Among the potential explanatory factors, language barriers, religiosity, and health insurance coverage partially account for the observed disparities.

Country-specific analyses confirm the pooled-sample results and provide detailed estimates of gaps in forgone care across countries. In particular, first-generation immigrants have a higher likelihood to report unmet needs for care comparatively to native-born individuals in Luxembourg (11 p.p., significant at 1% level), Estonia (5.2 p.p., significant at 10% level), Sweden (4 p.p., significant at 5% level), France (3.9 p.p., significant at 5% level), Slovenia (3 p.p., significant at 10% level), and Belgium (2.9 p.p., significant at 10% level). Second-generation immigrants are also more likely to forgo care than the native-born respondents in Estonia (6 p.p., significant at 1% level), Luxembourg (4.7 p.p., significant at 10% level), and Czech Republic (2.7 p.p., significant at 1% level).

Sensitivity checks show that our findings are robust to changes in model specifications and to the exclusion of the oldest cohorts.

Ind-368 Disparities in Emergency Department Utilisation, Wait Times, and Costs for Priority Population Children and Young People

PRESENTER: **Rezwanul Rana**
AUTHORS: Karen Zwi, Raghu Lingham, Jahid Khan, Henry Cutler

Background: The inflow of unplanned and non-urgent admissions to emergency departments (ED) presents a significant challenge to healthcare systems. These admissions often result in overcrowding, straining resources and compromising patient care. The increased patient volume for minor conditions can delay care for those needing immediate medical intervention, potentially compromising patient outcomes. **Objective**: We analysed disparities in non-urgent and unplanned ED admissions, average ED wait times, and costs between priority and non-priority populations using electronic medical record (eMR) data in Australia. Additionally, we investigated whether mean wait times and costs differed between these groups. **Method**: This study analysed prospectively collected eMR data of ED attendances for children and young people (CYP) aged 0-17 years at the Sydney Children's Hospital Network (SCHN) between January 2015 and December 2019. Four priority populations were identified from the data. Patients were categorised as Indigenous Australian, Culturally and linguistically diverse (CALD), refugee/ asylum seeker, and National Disability Insurance Scheme (NDIS) recipients. Generalised Linear Mixed Models were employed to account for the clustering of repeated observations within individuals since some patients had multiple return visits, resulting in both admission and discharge. **Results**: The study analysed 446,924 ED visits recorded in the SCHN eMR database, including 148,529 visits from people CYP in priority groups. CYP from Indigenous Australian backgrounds had a significantly higher likelihood of urgent ED admissions (55% higher) and experienced longer wait times (3% longer) and higher ED costs (3% more) compared to non-priority CYP. Additionally, CALD CYP had an 11% increase in wait times (0.11; SE: 0.15), while CYP receiving NDIS services experienced an 8% increase (0.08; SE: 0.01) relative to non-priority CYP. After adjusting for demographic, socioeconomic, and disease-specific factors, Indigenous Australian CYP had 1.55 times higher odds (OR: 1.55; SE: 0.05) of urgent admissions than non-priority CYP. Similarly, NDIS recipient CYP, had 1.63 times higher odds of non-urgent admissions (OR: 1.63; SE: 0.06) than non-priority CYP. However, CALD CYP had significantly lower odds of urgent admission (15% less likely; OR: 0.85; SE: 0.02). In terms of unplanned ED visits, refugee/asylum seeker CYP exhibited significantly higher odds (1.83 times) compared to non-priority CYP. Indigenous Australian (OR: 1.12) and CALD CYP (OR: 1.11) also had statistically significant, albeit smaller, increases in unplanned visit odds relative to non-priority CYP. Female CYP had lower (27%) odds of non-urgent ED admissions (OR: 0.73; SE: 0.01) across all priority groups. Chronic conditions significantly increased the odds of non-urgent admissions across all groups, highlighting a substantial impact (4 times higher) on ED utilisation. **Conclusion**: Our study revealed that priority population status significantly predicts disparities in ED use (urgent vs non-urgent; planned vs unplanned), wait times, and costs. The elevated odds of unplanned ED visits among refugees/asylum seekers and CALD CYP suggest gaps in access to preventive and ongoing care for these groups. Policies should consider resource reallocation within ED to accommodate the distinct needs of priority CYP groups.

Ind-2493 Inequality in Hospitalization Utilization Among Geriatric Population in India: Evidence from the 75th Round of NSSO Survey

PRESENTER: **Piyush Kumar**

Background: Health inequalities are a critical concern in developing nations, where socioeconomic disparities often limit equitable access to healthcare services. Using data from the 75th round of the National Sample Survey Office (NSSO) in India, this study examines inequality in hospitalization utilization, focusing on the concentration of service use among the geriatric population (aged 60 and above) and the key factors driving these disparities. This enquiry becomes critical in light of the Government of India's efforts to universalize health coverage for all citizens aged 70 and above. **Methods**: We conducted an inequality decomposition analysis of hospitalization data using survey-weighted logistic regression and concentration indices. The concentration index (CI) and its normalized counterparts—Erreygers' and Wagstaff's indices—were calculated to quantify inequality in hospitalization utilization. A decomposition approach was applied to identify the contributions of chronic illness, wealth quintile, education, insurance, gender, and other socioeconomic factors to the observed inequality. **Results**: The concentration index (CI) for hospitalization was found to be 0.044, indicating a mild pro-rich inequality in service utilization. The Erreygers' index (0.051) and Wagstaff's index (0.062) further confirmed this inequality. Logistic regression analysis revealed that individuals with chronic illness had 81% higher odds of hospitalization (OR = 1.81, 95% CI: 1.60–2.05, $p < 0.001$), while insurance coverage increased the odds of hospitalization by 22% (OR = 1.22, 95% CI: 1.17–1.28, $p < 0.001$). Women were significantly less likely to utilize hospitalization services (OR

= 0.73, 95% CI: 0.68–0.79, p < 0.001), highlighting potential gender disparities. Wealth quintile, insurance status, and household occupation emerged as the primary contributors to inequality, accounting for the largest shares in the decomposition analysis. **Conclusion**: Hospitalization utilization in India exhibits a mild pro-rich inequality, driven predominantly by socioeconomic factors such as wealth and insurance coverage. While chronic illness remains a critical determinant of hospitalization, the gender gap and urban-rural disparities suggest the need for targeted interventions. Expanding insurance coverage and addressing gender and wealth-based barriers could enhance equity in healthcare access.

Ind-2596 Affordability of HIV and Hypertension Treatment Among People Living with HIV in Public and Private (not-for-profit) Clinics in Uganda.

PRESENTER: **Faith Kagoya**

AUTHORS: Faith Kagoya, John Baptist Kiggundu, Rachel Nugent, Donna Spigelman, Chris Longenecker, Atousa Bonyani, Drew Cameron, Savio Mwaka, Fred Semitala, Robert Twine

Background:

Hypertension (HTN) poses a significant health challenge for people living with HIV (PLHIV), particularly in Uganda where adult HIV prevalence is 5.8% and HTN affects 21-29% of PLHIV. integrating HTN care into HIV services, as advocated by the WHO and Uganda Ministry of Health, is recommended. However, frequent medication stockouts in public health facilities often drive patients to private facilities and results in the potential for high out-of-pocket (OOP) expenditures, threatening adherence to HTN care and leading to catastrophic health expenditures (CHE).** This study aims to evaluate the affordability of HIV and HTN treatment under the standard of care to identify socio-economic predictors of CHE among PLHIV in Uganda.

Methods:

From March 2023 to September 2024, we collected baseline data from 367 randomly selected patients at 16 HIV clinics in Kampala and Wakiso districts as part of a larger trial studying the integration of HTN care in HIV clinics. Information on direct and indirect costs was gathered in a pretested questionnaire and costs were recorded in Ugandan Shillings (UGX). CHE was defined as healthcare costs exceeding 10% of household income or 40% of expenditure after deducting essential expenses such as food and rent. We performed logistic regression to examine predictors of CHE and Gaussian regression to analyze socio-economic predictors of total healthcare spending. Predictors included duration of hypertension, household size, income levels and employment status.

Results:

Patients had a mean age of 48.7 years (SD=10.7), 64% were female, and the average household size was 5.8 (SD=3.5). None of the patients had health insurance. Over 35% sold assets or obtained loans or credit to pay for medical care. Overall, 49.0% (95% CI: 43.9–54.2%) of patients experienced CHE by either definition, with 43.3% (95% CI: 38.3–48.5%) reporting direct and indirect financial costs exceeding 10% of household income, and 18.8% (95% CI: 15.1–23.1%) reporting costs exceeding 40% of household expenditure after essential expenses. Patients had significantly higher odds of CHE by time since diagnosis with ORs of 1.93 (95% CI: 1.06–3.54) for 1-2 years, 2.52 (95% CI: 1.19–5.32) for 3-5 years, and 2.32 (95% CI: 1.12–4.83) for 6+ years, compared to those diagnosed within the past year. Participants in the highest income quintile had significantly lower odds of experiencing CHE, compared to those in the lowest (OR 0.045, 95% CI: 0.02–0.11). Employment status was a significant predictor of CHE, with self-employed participants having lower odds of experiencing CHE compared to wage or salaried workers (OR 0.57, 95% CI: 0.36–0.90). Larger household sizes were not significantly associated with CHE. Gaussian results showed that each additional household member was associated with a 5.7% increase in total healthcare spending, and each additional year of living with HTN led to a 6% increase in total spending.

Conclusion:

The high prevalence of CHE highlights the need for policies that improve access to affordable HTN care for PLHIV. Strengthening public sector service delivery, implementing national health insurance schemes, and addressing the financial barriers could reduce the economic burden.

Ind-1417 Is a Trained Community Health Worker at Well-Child Care Visits Sustainable? Cost Analyses Using the United States Disease Expenditure Study Results

PRESENTER: **Marcia Weaver**, University of Washington

AUTHORS: Taylor Salaguinto, Tumaini Coker, Sarah Lowry, Esha Dwibedi

Background: Parent-focused Redesign for Encounters, Newborns to Toddlers (PARENT) is a team-based approach to care with a trained community health worker (PARENT coach) as part of the well-child care (WCC) team who provides preventive services to children ages 0-2

years. We conducted a cluster randomized controlled trial of PARENT coaches among 10 clinics from two federally qualified health centers in California and Washington. The intervention increased the anticipatory guidance as reported by the parent or caregiver, and improved WCC visit adherence, but did not decrease emergency department (ED) utilization.

Research questions: 1) Did the PARENT intervention increase non-WCC healthcare costs? and 2) Would the revenue from additional WCC visits due to improved adherence cover the direct intervention costs?

Methods: To answer question 1, we collected data on utilization and estimated cost of care using a unit cost approach. Parents were interviewed at baseline, six, and 12 months, and asked about the number of encounters and the child's diagnosis at each encounter for four services: subspecialty referral, ambulatory and urgent care visits, ED visits, and hospitalizations. Unit cost estimates for these services by health condition, and age were from the United States Disease Expenditure Study (DEX), which was the DEX estimate of 2016 spending (in 2016 United States dollars) divided by the number of 2016 encounters. We mapped each parent-reported encounter to a DEX health conditions, assigned a unit cost, and calculated total spending at baseline and during the 12-month trial. DEX provided 1,000 draws for each unit cost. We performed two-part model estimates for each of the 1,000 draws, with covariates for group, baseline spending, and child's age at enrollment.

To answer question 2, We created a revenue model based on American Academy of Pediatrics' Bright Futures Periodicity Schedule of visits by age and a cohort of children who entered at birth and progressed through visits. We calculated revenue from the improved WCC visit adherence using observed cohort sizes (minimum, mean, and maximum) and payment rates. Direct cost was the PARENT coach salary and benefits, adjusted for percentage of time devoted to the intervention.

Key results. Among 914 enrolled participants, 785 (86%) completed the 12-month interview and were included in analyses. Cost of subspecialty referrals was lower in intervention ($638, 95% uncertainty interval (UI)=365, 1403) than usual care group ($850, 95% UI=474, 1944), but the UI overlap. Total cost of ambulatory and urgent care visits, ED visits, and hospitalizations was also lower in the intervention group ($1867, 95% UI=1578, 2159) than usual care group ($1937, 95% UI=1628, 2271), but the UI overlap. Based on mean volume of newborns (5.8 per week), marginal revenue from increased WCC visits would cover the intervention costs at Washington payment rates. Based on maximum volume (13.5 per week), revenue would cover the cost at California payment rates.

Conclusions. The PARENT intervention increased WCC visits without increasing the cost of other care. Clinics may be able to recoup some or all of the costs of the PARENT coach through its effect on WCC visit adherence.

Ind-1694 Health Equity in Rare Diseases: The Diagnostic Odyssey and Cost-Effectiveness of Whole-Genome Sequencing for Indigenous Children

PRESENTER: **Mr. Dean A Regier**, BC Cancer
AUTHORS: Emanuel Krebs, Morgan Ehman, Ms. Deirdre Weymann

Introduction: Genetic and genomic sequencing diagnoses childhood rare diseases. Benefits of a diagnosis include a shorter diagnostic odyssey and the value of knowing disease cause. These benefits are not equitably distributed to Indigenous children. Indigenous ancestries are underrepresented in the background variant libraries necessary to establish etiologic diagnoses. We have found that whole genome sequencing (WGS) is not cost-effective in non-Indigenous Canadian populations, but access to research-based whole-genome sequencing (WGS) may establish additional diagnoses in Indigenous children in Canada. We estimate the diagnostic rate and cost-effectiveness of WGS for Indigenous children with developmental and/or seizure disorders. **Methods**: We obtained the diagnostic rate of WGS in Indigenous children from a single-arm Indigenous-partnered clinical trial in Canada. We abstracted real-world standard of care (SOC) outcomes data from British Columbia's Children's and Women's Hospital (C&W). Longitudinal and time-to-event analysis characterized key outcomes, including time to diagnosis and cost. We incorporated this evidence into a probabilistic state-transition Markov model examining two strategies. The first strategy is SOC, involving chromosomal microarray followed by second-tier genetic and biochemical testing, with last-tier exome sequencing. The second strategy is first-tier WGS. We calculated incremental cost per additional diagnosis over a 10-year time horizon, from the healthcare payer perspective, using a discount rate of 1.5%. **Results:** Our cohort included 63 Indigenous children who underwent WGS. For SOC, we estimated that 24.1% (95% CI: 17.1,31.2) of children would receive a diagnosis at a cost of $11,728 per patient (95% CI: 9,158,14,297). First-tier WGS diagnosed 39.0% (95% CI: 31.3,46.7) of children at a cost of $9,768 (95% CI: 6,296,13,241). Incremental costs and diagnoses were -$1.960 (95% CI: -6,308,2,389) and 14.9% (95% CI: 4.5,25.2), respectively. Mean time to diagnosis among diagnosed patients was 24 weeks for WGS, compared to 50 weeks for SOC. First-tier WGS was dominant (less costly, more effective) in 81% of simulations compared to SOC. **Conclusion:** Real-world evidence determined the impacts of research-based WGS for diagnosing genetic causes of rare diseases in Indigenous children in Canada. We find that first-tier access to WGS provides additional diagnoses to Indigenous families, sooner. Access to diagnostic WGS for Indigenous children furthers equity.

Ind-2050 Distributional Assessment of Health and Economic Impact of Population-Based Newborn Screening for Spinal Muscular Atrophy in Argentina

PRESENTER: **Natalia Espinola**
AUTHORS: Natali Soto, Constanza Silvestrini, Fernando Argento, Carla Colaci, Andrés Pichon-Riviere, Soledad Monges, Maria Jose Varco
Background Spinal muscular atrophy (SMA) is a rare, debilitating genetic disorder that greatly impacts quality of life and causes high costs for individuals and society in general. Evidence indicates that early diagnosis through newborn screening (NBS) and timely intervention with available treatments can significantly improve health outcomes and reduce costs. However, its impact on distributional equity remains unknown. **Objective** This study evaluates the distributional impact of the implementation of population-based NBS for SMA in Argentina by socioeconomic level. **Methods** We conducted a distributional cost-effectiveness analysis using a hybrid model framework combining decision tree and Markov structures. The decision tree captured the immediate outcomes of NBS, while Markov modeling projected long-term health and economic impacts across different socioeconomic levels. The model utilized the type of health coverage accessible to individuals

based on their income as a proxy for socioeconomic status. Variables such as differential access to medical care, differential delay in diagnosis and treatment, and cost differences between socioeconomic levels were included in the model. Model parameters were sourced from literature, local data (e.g., national surveys, patient registration database, unit cost database), and expert opinion. All costs were reported in US dollars 2024 (USD). **Results** The implementation of NBS for SMA in 529,794 newborns in Argentina resulted in a total gain of 402 QALYs, with 52% benefiting the lowest socioeconomic group, and generated a total saving of USD 650,000 in productivity loss and informal care costs. With the introduction of the NBS population intervention, an important impact on equity is estimated. The QALY inequality gap was reduced by 91%, from 0.82 to 0.07 per individual; and the inequality gap in social costs was reduced by around 60%, with the lowest socioeconomic group experiencing the greatest benefit. **Conclusions** Population-based NBS for SMA is not only cost-effective but also advances health equity, addressing disparities in access and outcomes. These findings offer valuable insights for policymakers seeking efficient and equitable health strategies.

Ind-2742 Cost-Effectiveness of Technologies for the Diagnosis of Attention Deficit Hyperactivity Disorder (ADHD)

PRESENTER: **Mary Ward**
AUTHORS: Nicky Welton, Josephine Walker

Background

Diagnosis of ADHD is complex and time consuming, and NHS waiting times for ADHD assessment are long. Sensor continuous performance tests (CPTs), including QbTest, are technologies for objective measurement of ADHD that use motion sensors to measure hyperactivity. This may improve the diagnostic process for ADHD. We aimed to develop a decision-analytic model to estimate the cost-effectiveness of QbTest in addition to clinical assessment ("QbTest") compared with clinical assessment alone ("Standard") for the diagnosis of ADHD in children referred with suspected ADHD. We restricted to QbTest as the only sensor CPT with sufficient data.

Methods

We did not identify any previous models evaluating cost-effectiveness of diagnostic tests for ADHD, and so we developed a *de novo* Markov model for sensor CPTs for the diagnosis of ADHD in people referred with suspected ADHD. Model parameters were sourced from our systematic review, targeted literature searches and expert opinion. Patients enter the model after referral for ADHD assessment, and join a waiting list. The time spent waiting for assessment is assumed to depend on whether a sensor CPT is used, because a potential benefit of the use of sensor CPTs is to reduce the time and resources required to reach a diagnosis, releasing clinician time and therefore reducing waiting times for assessment. Patients then undergo diagnostic assessment for ADHD which consists of a series of appointments until a diagnosis is reached or assessment is discontinued. An NHS and personal social services (PSS) perspective was taken. We conducted probabilistic sensitivity analysis (PSA) to reflect uncertainty in model inputs.

Results

Under the base case scenario, the QbTest strategy has higher costs and quality-adjusted life-years (QALYs) gained compared to Standard, with incremental costs of £238.35 and incremental QALYs of 0.0385 per person evaluated for ADHD. The resulting ICER is £6183.71 per QALY gained, and the mean incremental net benefit is £532.55 at a willingness-to-pay (WTP) threshold of £20,000/QALY. Exploring the impact of uncertainty in the input parameters, the QbTest strategy is cost-effective under 92% of model runs with a £20,000 WTP threshold. These findings were driven by reduced time waiting for assessment, reduced appointments until diagnosis, and a higher proportion receiving a diagnosis so that more patients with ADHD receive treatment benefits.

Discussion

We found that the use of QbTest in addition to clinical assessment is likely to be cost-effective in the diagnosis of children referred with suspected ADHD. Further evidence is needed to assess cost-effectiveness of alternative sensor CPTs, sensor CPTs in adults, and in medication management.

Ind-535 Inequalities in Alcohol-Related Mortality in Goi s: Analysis of Deaths and Years of Life Lost in 2022

PRESENTER: **Larissa Barbosa Cardoso**, UNIVERSIDADE FEDERAL DE GOIAS
AUTHORS: Isadora Batista Rodrigues, Tálita Silva Vilela

Background: The state of Goiás has one of the highest prevalences of alcohol abuse in Brazil, with approximately 17% of the population engaging in harmful alcohol consumption in 2013. Excessive alcohol uses not only harms health but also increases the risk of traffic and workplace accidents, along with generating losses in the labor market. Alcohol abuse disproportionately affects groups with specific sociodemographic characteristics. Although there is extensive literature on alcohol consumption in Brazil, few studies address the inequalities

associated with this issue, and most are limited to national-level analyses, overlooking regional specificities. **Objectives:** This study aims to analyze inequalities in alcohol-related mortality in Goiás in 2022, focusing on deaths directly attributed to alcohol consumption. **Methods:** We used data on deaths recorded in the Mortality Information System (SIM) for the year 2022 in the state of Goiás, along with demographic data provided by the Brazilian Institute of Geography and Statistics (IBGE). Only deaths from diseases fully attributable to alcohol, based on ICD-10 codes, were considered. Crude mortality rates were calculated by dividing the total number of deaths by the total exposed population and were expressed per 1,000 inhabitants. Additionally, years of potential life lost (YPLL) were calculated as the sum of the differences between the age at death and life expectancy for each age group. Crude mortality rates and YPLL were analyzed across different population subgroups categorized by gender, race, and age. **Results:** In 2022, a total of 927 deaths directly related to alcohol consumption were recorded in Goiás. The leading causes of death were alcoholic liver cirrhosis and mental disorders such as alcohol dependence syndrome. The results showed a crude mortality rate of 0.13 deaths per 1,000 inhabitants for the total sample, with higher rates observed among men (0.23 per 1,000 inhabitants), individuals of Asian descent (0.29 per 1,000 inhabitants), and those aged 55–59 years (0.35 per 1,000 inhabitants). Regarding years of potential life lost, the average was 22.13 years per death. The highest losses were observed among men (22.26 years/death) and individuals of mixed race (23.44 years/death). **Conclusion:** This study highlights the significant burden of alcohol-related mortality in Goiás, with disproportionate impacts on specific subgroups. Premature mortality in these groups leads to social and economic consequences that may exacerbate existing social inequalities. The findings underscore the urgent need for public policies aimed at reducing alcohol consumption and addressing inequalities.

Funding: This work was developed with support from the Research Support Foundation of the State of Goiás (FAPEG).

Ind-386 Maternal Education and Long-term Health Outcomes for the Next Generation. Causal Effects Measured using the Introduction of a School Reform in Norway.

PRESENTER: **Jostein Grytten**, Universitetet i Oslo
AUTHORS: Irene Skau Sr., Rune Sorensen

Background: The positive association between education and health is well established. Numerous studies have examined whether this association is causal. The usual outcome measure is mortality. The results differ, but in most studies, there is evidence that education leads to lower mortality for men, but not for women.

The aim of the present study was to examine intergenerational effects of maternal education on long-term health outcomes. In a few studies, intergenerational effects of maternal education on short-term health outcomes (birthweight, infant mortality) have been examined. In most of these studies a causal effect has been found. Little is known about intergenerational effects of maternal education on long-term health outcomes for the next generation. Partly, this is due to lack of data covering a long enough time span from birth to adult life for the next generation. The question is whether the short-term effects persist over time and last into adult life, or whether they fade out.

Methods: During the period 1960-1972, all municipalities in Norway were required to increase the number of compulsory years of schooling from seven to nine years. We used this reform as the instrumental variable to create exogenous variation in the individual's number of years of schooling (first stage regression). Since municipalities implemented the reform at different times, we have both cross-sectional and time-series variation in the instrumental variable. Thus, we could estimate the causal effects of mothers' number of years of schooling on our outcome variables (second stage regression) by controlling for municipality fixed effects and trend variables.

The education data were combined with population register data from the Norwegian Labour and Welfare Administration and the Norwegian Cause of Death Registry. Our sample included all mothers born during the period 1944-1960. We measured long-term health outcomes for the children when they were between the age of 20-40, both those who had died, and those who were still alive (n=529 000). We had data for our long-term outcomes up to 2020. In order to measure long-term outcomes at the age of 20-40 years, the child had to be born in 1980 or earlier.

Results: The first stage regression estimate showed that the reform led to an increase of 0.40 years of schooling (F-value=1024). The reduced form and second stage estimates showed significant negative effects for both outcomes. One year of additional education for the mothers led to a reduction in the proportion their children who died by 26%, and in the proportion of their children who received health disability allowance of about 7%. For sons, a large part of the effect on mortality was due to fewer deaths caused by traffic accidents. For daughters, the effect on mortality was due to fewer deaths caused by suicide, and alcohol and drug abuse. We carried out several robustness tests such as balancing tests and event study analyses. The results supported our main findings.

Conclusion: Rising the** level of education of the mothers, is an important mechanism through which long-term health outcomes for the next generation can be improved.

Ind-536 The Growing Divide: Income Inequities in Access to Mental Healthcare in Australia

PRESENTER: **Danusha Jayawardana**, Monash University
AUTHORS: David Johnston, Nicole Black, Trong-Anh Trinh

Rising out-of-pocket costs for psychological therapy in Australia have heightened concerns about financial barriers to mental healthcare, particularly for lower-income households, who disproportionately experience psychological distress. This study examines how income-related inequity in access to psychological therapy has evolved over the past decade. Using linked administrative data from the Australian Taxation Office and Medicare, covering almost the entire Australian population, we estimate the magnitude of inequity in psychotherapy use among individuals diagnosed with a mental health condition. Regression-based inequity estimates are provided separately for each year from 2014 to 2023 to capture potential nonlinear changes over time. We also conduct separate analyses for children (<18 years old) and adults (25-54 years old), given that differences in the willingness to pay, prices, and access to services may lead to different healthcare utilisation patterns. Our

findings show that income-related inequity is consistently higher for children than for adults throughout the study period. Furthermore, while inequity has worsened for both groups over the past decade, the increase has been particularly pronounced for children since the onset of the Covid-19 pandemic. The trends persist across demographic and geographic subgroups, and robustness checks confirm that the rising inequity is not attributable to changes in the severity or complexity of mental health disorders. These results underscore the need for policy interventions to reduce financial barriers and promote equitable access to mental health care.

Ind-1432 Socioeconomic Inequalities in Ideal Cardiovascular Health in Kenya: A Decomposition Analysis

PRESENTER: **James Odhiambo Oguta**
AUTHORS: Penny Breeze, Catherine Akoth, Elvis Wambiya, Grace Mbuthia, Peter Otieno, Gladwell Gathecha, Elizabeth Onyango, Yvette Kisaka, Peter Dodd

Background During the last three decades, Kenya has experienced a substantial rise in the burden of cardiovascular diseases (CVDs), the leading causes of non-communicable diseases (NCD) deaths. To guide the equitable scale-up of prevention interventions, it is essential to understand patterns of inequality in cardiovascular health (CVH). A useful framework for this is ideal cardiovascular health (iCVH), which is defined by four health behaviours [diet, tobacco use, physical activity (PA), and body mass index(BMI)] and three biological health factors (blood pressure [BP], fasting blood glucose [FBG], and total cholesterol). This study assessed the extent of socioeconomic inequality in iCVH in Kenya, the gender differences in the socioeconomic inequality, and decomposed the inequality to examine its drivers. **Methods** We used data from the 2015 World Health Organization (WHO) STEPwise survey on NCD risk factors. We classified an individual to have an iCVH status if they had at least five out of seven CVH metrics (tobacco exposure, fruit and vegetable intake (FV), PA, BMI, FBG, BP, and cholesterol levels) at ideal levels as defined by American Heart Association 2010. The concentration index (C) was used to assess the socioeconomic inequalities in overall iCVH. We performed Wagstaff-type decomposition analysis of the inequality to examine its drivers, and conducted sensitivity analyses to explore the gender-differences in inequalities. **Results** The study sample included 3816 adults aged 18-69 years. The overall C was positive (C= 0.08; p=0.006), indicating that iCVH was more concentrated among the rich (pro-rich). Pro-rich inequalities were observed in ideal BMI (C= 0.31; p<0.001), ideal BP (C= 0.16; p<0.001) and ideal cholesterol (C= 0.15; p=0.005) metrics, while pro-poor inequalities were observed in ideal tobacco exposure (C= -0.1; p=0.012) and FV (C= -0.09; p=0.048) metrics. There were no significant inequalities in ideal FBG (C= -0.03; p=0.534), and PA (C= 0.05; p=0.291). The gender-stratified analyses revealed significant pro-rich inequalities in iCVH among females (C= 0.11; p=0.006) but not in males (C= 0.07; p=0.128). Wealth (30.7%), urban residence (31.4%), region (16.5%), and education (8.5%) were the highest contributors to the observed pro-rich inequality in iCVH. Among females, wealth (45.2%), urban residence (24.4%) and education (12.8%) were the highest contributors to the observed inequality, whereas urban residence (27.6%), wealth (27.2%) and region of residence (24.6%) were the highest contributors among males. Ethnic disparities contributed between 5.3% and 9.9% of the observed inequality in all groups, with the Kikuyu ethnic group being the highest contributor (2.1%-5.2%). **Conclusion** This study finds pro-rich and gender differences in the inequalities in iCVH in Kenya. The study highlights the need for the design and scale up of equity and gender-focused interventions targeting the poorer and less-educated individuals especially in urban areas.

Financial Burdens of Health Care and Poverty

MODERATOR: **Stephen Jan**, The George Institute for Global Health, UNSW Sydney

Ind-339 The Relationship Between Health Costs and Poverty in Rare Genetic Diseases in Australia

PRESENTER: **Josh Kraindler**
AUTHORS: Rupendra Shrestha, Deborah Schofield

Background Rare genetic diseases present a unique challenge for health systems, with complex diagnostic and treatment pathways. In Australia, an estimated 6-8% of the population is affected by rare diseases, approximately 80% of which are genetic. The conditions lead to significant health costs for affected families. These financial pressures are compounded as the individuals affected and their families are already vulnerable to reduced income and workforce participation due to the chronic and debilitating nature of their conditions. Given the rarity of each disease, rare diseases are often neglected from research and policy due to a lack of data on each condition, including on out of pocket (OOP) costs and poverty. Using a combination of primary and linked administrative data, this study aims to estimate the financial burden in three clinical cohorts with different rare genetic diseases, focussing on how health spending contributes to poverty in households with these diseases. **Methods** Data were collected from a cohort of Australian households impacted by three rare genetic diseases; familial intellectual disability (ID), mitochondrial disorders, and inherited retinal diseases (IRD). The study utilised primary data from the three studies, which were then linked with administrative healthcare records, enabling a comprehensive account of healthcare and other disease related costs for each disease. OOP expenditures were classified into direct medical costs (such as medications, surgeries, and consultations) and societal costs (such as transportation, caregiving, and home modifications). Using income data and an established measure of income poverty in Australia – the Henderson poverty line – we estimated the proportion of patients in poverty with each of the three diseases, and the potential contribution of health costs to contribute to or exacerbate poverty. **Results** Across the three diseases, average annual OOP costs related to the disease ranged from approximately $2,800 to $7,050 AUD, with substantial differences between the diseases and within each disease. These costs are significantly higher than average annual OOP costs across the population. On average, patients and their carers had below average incomes when matched to those in the population with similar characteristics. **Conclusion** Rare genetic diseases impose a substantial financial burden on Australian families, pushing many vulnerable households into or closer to poverty. Estimates of income poverty may underestimate poverty for those with rare diseases due to the increased costs these families face. These findings highlight the need for policy action to reduce OOP costs

for families with rare diseases. Future research should examine the long-term economic impacts on affected families to guide policies promoting equitable access to healthcare and reducing poverty rates.

Ind-2776 Effect of Medicare Advantage Versus Traditional Medicare On Financial Burdens of Healthcare Among Older Adults With and Without Dementia: 2017-2021

PRESENTER: **Elham Mahmoudi**

Research Objective. Medicare pays Medicare Advantage (MA) plans based on a prospective capitated model. About 50% of older adults are enrolled in MA, incentivized to offer more efficient care than traditional Medicare (TM). We aimed to examine the effect of MA vs. TM on the financial burdens of healthcare. We hypothesized that MA enrollees would have fewer financial burdens than TM.

Study Design. In this cross-sectional case-control study, we pooled data from the 2017-2021 Medicare Current Beneficiary Survey (nationally representative of older adults in the U.S.). We used multivariable generalized linear models to examine the financial burdens of care, utilizing three outcomes (delayed care due to cost, problem paying medical bills, and dissatisfaction with out-of-pocket (OOP) costs. We examined the outcomes among (1) everyone and (2) those with less than 200% of the federal poverty level (FPL) who were not in Medicaid, with and without dementia. All models were adjusted for age, gender, race/ethnicity, chronic conditions, functional status, family income as a share of the FPL, Medicaid, education, rurality, interview language, and survey year. We applied Inverse Propensity Weighting to address the potential selection bias into MA and the Average Treatment Effect (ATE) to examine the effect of MA vs. TM on financial burdens.

Populations Studied: Community-dwelling older adults (65+) with and without dementia diagnosis who enrolled in TM or MA. [N=54,216 (MA=23,082; with-dementia=1,232); (TM=31,134; with-dementia=1,475)].

Principal Findings: Among people without dementia, a higher percentage of MA vs. TM enrollees had problems paying medical bills [MA=7.04%; TM=5.25%; diff=1.79 percentage point (PP) (95% CI:1.28, 2,31)] but lower percentage had dissatisfaction with OOP cost [MA=12.18%; TM=13.78%; diff=-1.59 PP (95% CI:-2.32, -.87)]. A higher percentage of people with dementia had financial burdens compared with those without dementia, with no significant difference between MA and TM [difficulty paying the medical bills (MA=9.54%; TM=7.41%), delaying care due to cost (MA=6.27%; TM=7.40%); and dissatisfied with OOP costs (MA=13.57%; TM=14.46%)]. Financial burdens were more pronounced among older adults with <200% FPL who did not have Medicaid. In this group, for example, among people without dementia, 13.29% in MA vs. 10.85% in TM [diff=2.43PP (95% CI:1.01, 3.86)] had problems paying medical bills; 18.15% in MA vs. 20.42% in TM [diff=-2.27PP (-4.01, -.53)] were dissatisfied with OOP costs. Among people with dementia with <200% FPL who did not have Medicaid, the financial burdens were higher compared with dementia patients with higher income levels, but the outcomes were not statistically different between MA and TM [difficulty paying the medical bills (MA=14.35%; TM=11.35%), delaying care due to cost (MA=8.40%; TM=11.98%); and dissatisfaction with OOP costs (MA=19.27%; TM=19.68%)].

Conclusions: Older adults with and without dementia whose incomes were less than 200% FPL but did not have Medicaid had the highest financial burdens. A higher percentage of MA vs. TM enrollees had problems paying medical bills or delaying care due to cost, but a higher percentage of TM vs. MA enrollees were dissatisfied with OOP costs. Financial burdens of care were higher among people with dementia, with no difference between MA and TM.

Ind-678 Did State Medicaid Policies Increase Telemedicine Use? A National Survey Analysis of U.S. Working-Age Low-Income Adults and Their Children

PRESENTER: **Lucinda B. Leung**
AUTHORS: Susan Ettner, Haiyong Xu, Jasmeen Santos, Jose Escarce

Background: Telemedicine historically existed to close access gaps in specialty, especially mental health, care services. During the COVID-19 pandemic, U.S. Medicaid insurance programs for low-income Americans adopted different policies on telemedicine services, making it possible to naturalistically examine the effect of telemedicine policy changes on care access. This study aimed to examine whether the number of pro-telemedicine Medicaid policies adopted by states predicted greater telemedicine use among low-income Americans and their children.

Methods: Our cohorts included 18- to 64-year-old U.S. adults with Medicaid insurance in all 50 U.S. states (n=107,442) and the subset of those with children under 18 (n=54,988). Responses about telemedicine use were obtained from the Household Pulse Survey (4/14/2021-8/8/2022), a repeated online cross-sectional survey administered by the U.S. Census Bureau and National Center for Health Statistics. Our two outcomes were 1) adults and 2) their children having an "appointment with a doctor, nurse, or other health professional by video or by phone" in the last 4 weeks. Using legal mapping methods, we identified whether, and the date when, states adopted Medicaid policies (e.g., audio-only reimbursement) promoting telemedicine delivery. Linear probability models predicted association of telemedicine use with the number of Medicaid state policies adopted, controlling for state fixed effects, survey week, respondent characteristics (age, sex, race-ethnicity, education, income, marital status, number of children), and time-varying state characteristics (unemployment rates, COVID-19 cases/deaths/vaccination rates, COVID-19 emergency policies). Models used multiple imputation, included survey weights and adjusted for robust standard errors. We also stratified models by whether respondents/parents reported any current psychological symptoms (Patient Health Questionnaire-2[Depression] or Generalized Anxiety Disorder-2 ≥3).

Results: 32.8% of adults with Medicaid insurance and 23.1% of their children sought health care by video or phone during the last 4 weeks. By the study period's end, states had a median of 3 Medicaid telemedicine policies (range: 0-6). In fully adjusted models, there was no significant policy effect on telemedicine use among adults. However, we observed a significant policy effect, increasing with the number of policies, on

children's telemedicine use, ranging from 3 to 7 percentage points in states with 3 policies or more. Among children with parents reporting current psychological symptoms, telemedicine use increased by 6 to 13 percentage-points in states with 3 policies or more. There was no significant policy effect on telemedicine use among children of parents without current psychological symptoms.

Conclusions: Many U.S. states adopted Medicaid policies and as intended, enabled flexible healthcare delivery to low-income populations via telemedicine. Although there was no policy effect on adults, parents reported that their children were more likely to use telemedicine when more policies were in place. Importantly, Medicaid policies most increased telemedicine use among children of parents in psychological distress. Potential explanations include correlation between children's and parents' health (e.g., parents worry about sick children), parents prioritizing their children's health needs over their own, and parental concern over children's wellbeing during the pandemic. Findings suggest policies promoting telemedicine use may overcome access barriers related to travel, time, and/or mental health stigma for disadvantaged populations.

Ind-2151 Health Effects of Universal Non-contributory Pensions: Evidence from Mexico

PRESENTER: **María-José Mendoza-Jiménez**, Erasmus University Rotterdam

AUTHORS: Bram Wouterse, Carlos Javier Riumallo Herl

Background and aim: Poverty at old-age is a growing concern for policymakers, particularly in lower and middle-income countries where many older individuals lack access to contributory pensions. Several countries, including Mexico, have implemented non-contributory pension programs aimed at ensuring a dignified and healthy old age. Existing literature highlights the positive impacts of such programs on health and wellbeing when targeted specifically at low-income groups. Less is known on the effects of programs for the entire older population. In 2019, Mexico turned its non-contributory pension program into a universal scheme known as the "*Programa Pensión para el Bienestar de las Personas Adultas Mayores" (*PBAM). The expansion of the program to all who are age-eligible has sparked support but also concerns about its efficiency. Understanding the program's effect on health and wellbeing is crucial for a comprehensive evaluation of the policy's costs and benefits. This study aims to identify the health effects of the PBAM policy among age-eligible older adults. Methods: We analyse panel data for approximately 13,500 adults aged 50 years or older from four waves of the Mexican Health and Ageing Study (MHAS), covering the period from 2012 to 2021. The pre-policy periods correspond to 2012 (wave 3), 2015 (wave 4) and 2018 (wave 5), as the PBAM policy was introduced in 2019. We employ a differences-in-differences approach to estimate the effects by comparing outcomes for individuals aged 65 and older (age-eligible) with those under 65 (non-eligible), both before and after the introduction of PBAM. The analysis focuses on variables such as financial situation, self-reported health, and broader wellbeing. All regressions include individual-level fixed effects. Results: The results reveal a significant increase in individual income, namely 1,300 Mexican pesos on average ($p<0.01$), representing a 26% increase relative to the 2018 sample mean. Statistically significant improvements were also observed for household consumption, perceived financial situation and availability of money for food, confirming that age-eligible individuals experienced better financial stability after the introduction of the PBAM. These financial improvements contributed to health benefits: age-eligible respondents showed a 3 percentage point increase in the probability of positive health changes ($p<0.01$), a 4 percentage point increase in food affordability ($p<0.05$), and a 2 percentage point reduction in stopping medication due to costs ($p<0.05$). While the positive self-reported health changes are observable for all income groups, heterogeneity analyses suggest that health gains are concentrated in the middle-assets groups, and there are no statistically significantly different effects among those who are under and above the previous income condition of the targeted scheme. Conclusions: Our study shows that the PBAM introduction resulted in significant income increases and health benefits in the short-run for age-eligible individuals in Mexico. Universal NCPs can reduce exclusion errors and deliver health benefits beyond the poorest groups, highlighting their potential role in promoting wellbeing in ageing populations.

Ind-2322 Does the Informal Carer Identification Method Matter? Evidence From Self-Declaration and Time Diary Approaches

PRESENTER: **Mr. Charles Smith, BSc**

AUTHORS: Sean Urwin, Matt Sutton

Introduction:

Informal caregiving is widespread, but there is concern that studies do not identify all the caregiving that is taking place. This may bias estimates of caregiving effects and lead to ineffective support for caregivers. There is little evidence on whether the method of carer identification uncovers different carers and whether these methods result in different conclusions on caregiving consequences.

We aim to investigate whether the use of a time diary compared to when self-declaration is used: (i) identifies more and different carers and (ii) estimates worse outcomes

Data:

We use the Innovation Panel component of the UK Household Longitudinal Study, which is an experimental set of questions asked to a panel of individuals. In wave seven, this included a time diary, which records all activities done in two 24-hour periods and has an activity code for co-

and extra-residential caregiving. Self-declaration as a co- or extra-residential caregiver is asked in all waves of the main and innovation panels.

Methods:

We compare the characteristics of carers identified by a time diary and from self-declaration using linear OLS regression. Using a doubly-robust approach of entropy balancing alongside regression adjustment, we assess whether the association of caregiving with health and wellbeing measures change depending upon the identification method.

Results:

Out of a sample of 1055 individuals, we identify 261 carers by at least one method. 16% of these are only identified through the time diary, and so would be missed if identification was based on self-declaration alone. Time diary-identified carers are more likely to have low household income and be from ethnic minorities. They experience mental health 1.35 points worse on the GHQ-12 scale than non-carers – the equivalent of the effect of being in the lowest income quintile relative to the highest. These results are larger than for self-declared carers in the innovation panel, which themselves are consistent for self-declared carers in the larger main UKHLS survey (N=28,815).

Implications:

Correlations of informal care with health and wellbeing are under-estimated when we only identify carers with self-declaration. Activity-based methods may identify carers earlier and therefore help provide more timely support to carers who may face a greater unmet need for support. Future survey design and the assessment of the scale of caregiving should consider the degree to which caregiving is under-reported. Policies that attempt to aid informal carers should consider that the consequences of caregiving on mental health are greater than currently understood.

Ind-41 Decomposition Analysis of Wage Differentials by Gender and Sexual Diversity in the Canadian Physician and Nursing Labour Markets

PRESENTER: **Neeru Gupta**
AUTHORS: Pablo Miah, Sean Waite

Background: Work is not a gender-equal opportunity for women and men within and across national healthcare labour markets, despite women representing 70% of the global health workforce. Many studies from different countries reveal that women physicians earn significantly less on average than their male counterparts due to factors that remain unexplained, widely attributed to effects of gender discrimination, including fewer opportunities for career advancement among women in the traditionally male-dominated medical profession. Gender wage gaps also persist in female-dominated professions such as nursing, associated with accelerated promotions and other workplace rewards favouring men. The research is less clear on wage disparities for gender and sexual minorities (GSMs). We systematically searched five bibliographic databases and found no empirical studies integrating experiences in the health workforce of devaluation of women's labour with GSM status.

Objective: This Canadian observational study represents, to our knowledge, the first-ever national investigation into earnings differentials among GSM practitioners in the physician and nursing labour markets.

Methods: The 2021 Canadian Population Census was the first large-scale data source (nationally or anywhere) to collect information on both sex at birth and gender identity, along with same-gender couples, thus allowing to distinguish GSM individuals. Medical and nursing professionals are categorized based on the National Occupational Classification. Our outcome of interest is annual earnings from employment or professional practice, as captured through integrated administrative income tax records. First we describe whether the active physician and nursing workforces ages 20-64 reflect the population they serve in relation to gender and sexual diversity. Second, we conduct multiple regression analyses for the roles of gender and GSM status as predictors of earnings differentials (logged), controlling for a range of confounders related to human capital (educational attainment, place of work, hours worked) and intersecting social characteristics (immigration status, racial/ethnic origin, childcare status). The analyses are implemented in Stata v18, applying bootstrapped person-level census weights to ensure population representation of the results and robust 95% confidence intervals.

Results: Among Canada's 387,900 nurses, 1.3% identified as GSM, including 0.3% as transgender or non-binary (similar to 0.33% of the general adult population). Relative to cisgender men nurses, transgender men's earnings averaged significantly less (-18.3%, 95% CI: -30.6 to -3.7) as did those of cisgender women (-11.2%, 95% CI: -12.1 to -10.3); wage differences were not found significant for trans women or non-binary nurses after adjusting for confounders. A similar proportion 1.3% of physicians (N=87,900) identified as GSM. Relative to cisgender men physicians, cisgender women earned significantly less (-12.5%, 95% CI: -14.0 to -10.9) whereas trans men earned more (56.9%, 95% CI: 24.4 to 97.9); adjusted wage differences were not significant for trans women or non-binary physicians.

Conclusions: This research builds knowledge on gender and sexual diversity-related wage gaps to help inform policy and practice for optimizing equity in healthcare labour market access, opportunities, and barriers commonly associated with social discrimination. Results highlighted heterogeneity in health labour market outcomes by gender diversity.

Ind-1768 Developing and Piloting a Life-Cycle Prioritization Framework for Oncology Product Innovation

PRESENTER: **Ms. Deirdre Weymann**, BC Cancer
AUTHORS: Morgan Ehman, Emanuel Krebs, Mr. Dean A Regier

Background: The translational pathway for emerging oncology products is time-consuming. Oncology trials last a median of 13.1 years from Phase I to Phase III, with only 3.4% of trialled products eventually receiving regulatory authorization. Considered alongside the rising costs of cancer care observed worldwide, value-based mechanisms are urgently needed to accelerate the equitable translation of safe, effective, and cost-

effective oncology products into global healthcare systems. We sought to develop and pilot a life-cycle prioritization framework to address translational inefficiencies. Our pilot study implements our framework for prioritizing innovations in targeted radiopharmaceutical development, with a focus on metastatic castration-resistant prostate cancer (mCRPC) in Canada. Targeted radiopharmaceuticals are an emerging class of cancer medicines that bind radionuclides with cell-targeting molecules to deliver radiation directly to cancer cells, without affecting normal tissue. Further research and development are necessary to expand translation of these innovative medicines.

Methods: Through a scoping literature review and multi-disciplinary expert consultations, we developed a life-cycle framework for prioritizing candidate oncology products. We engaged patient partners, clinicians, decision-makers, industry, and health researchers from across Canada to co-develop and refine framework components. We are piloting the framework for a radiopharmaceutical in early scientific development for treating patients with mCRPC. Multi-criteria decision analysis with our stakeholder committee is enabling systematized prioritization of competing products. Evidence synthesis across multiple orthogonal criteria informs total early-stage value, with committee members completing a direct ranking exercise to assess relative importance of competing value elements. Weights derived using rank-ordered probit regression analysis of survey response data allows for scoring of competing radiopharmaceutical products.

Results: Our literature review included 24 articles, which highlighted relevant decision points, value criteria, and evaluative methods for informing our prioritization framework. We then engaged n=15 pan-Canadian stakeholders to refine our framework and ensure suitability and feasibility for oncology product innovation. The final prioritization framework includes three gated stages throughout the entire product life-cycle, with sequentially planned evaluative methods that iteratively guide decision-making. Key components for each stage include: (i) needs assessment for prioritizing product innovation areas; (ii) early value assessment for go/no-go decision-making on continued development and further evidence generation; and (iii) life-cycle health technology assessment to support regulatory and reimbursement pathways. In mCRPC, we are identifying which value elements stakeholders, including patients, prioritize most highly for radiopharmaceutical product prioritization. For initial needs assessment, public health burden, equity and access, healthcare cost, level of innovation, and technology readiness, including radionuclide and ligand availability and biomanufacturing feasibility, have emerged as key criteria for deliberative decision-making. Estimated prioritization scores for mCRPC can be contrasted across products and indications, providing greater transparency in deliberations and systematizing prioritization processes.

Conclusions: Our prioritization framework enables value-based innovation for candidate oncology products, from very early stages of development to evaluation and implementation. Weighted prioritization scores measured in our proof-of-concept study can be contrasted across indications to inform future research and development investment for radiopharmaceuticals. Application of our framework throughout the oncology product life-cycle will ensure translational medicine achieves timely patient benefit and value-for-money in healthcare.

Ind-618 Priority Setting for Effective Maternity Care Models to Improve Outcomes for Women from Refugee Backgrounds in Australia: A Modified Delphi Study

PRESENTER: **Yordanos Yeshitila**

AUTHORS: Julie Abimanyi-Ochom, Ha N.D Le, Elisha Riggs, Linda Sweet, Ms. Lisa Gold

Background Women from refugee backgrounds often experience poor perinatal outcomes due to disparities in access to health and social services. Effective, culturally responsive maternity care models for these women is critical to improving perinatal outcomes. Different models of care were implemented in response to the diverse needs of women from migrant and refugee backgrounds This study seeks to establish expert consensus on prioritizing effective maternity care models and identifying key outcomes. **Methods** A two-round modified Delphi survey was conducted to establish priority models of maternity care for refugee background women, informed by a literature review and expert insights. In the first round, experts prioritised (a) 17 identified models of maternity care, also suggesting additional models through an open-response format, and (b) perinatal outcomes such as stillbirth, neonatal death, low APGAR score, small for gestational age, postpartum haemorrhage, abnormal labour, 3rd/4th-degree perineal tear, puerperal sepsis and maternal admission to intensive care. In the second round, highest-rated models from the first round were scored based on their priority levels, specifically their potential to meet the healthcare needs of refugee background women. A consensus threshold was defined as a model receiving a priority rating from at least 50% of participants. **Results** The initial survey round saw participation from 50 experts across Australia with 31 experts completing the second round. Consensus was achieved on outcomes in the first round, with a majority agreeing that adverse outcomes should be given equal priority in implementing maternity care models rather than prioritising specific outcomes. Experts recommended several additional adverse perinatal outcomes be considered related to implementing care models. Most emphasised the need for a perinatal mental health and support system. Others suggested outcomes including caesarean section, breastfeeding, access to care, satisfaction with/view on care, women's well-being post-birth, gestational diabetes, parenting skills, diet and exercise, pre-eclampsia/hypertensive conditions, fetal growth restriction, terminations and congenital anomalies, family violence, low birth weight, and preterm birth. Six models deemed most relevant in the first round were ranked in the second round, with Refugee Midwifery Group Practice, cross-cultural workers model, community-based antenatal clinic specialising in maternity care for CALD identified as the top three models among the evaluated options. **Conclusion** Health systems should consider adopting adaptable, culturally responsive models such as midwifery-led and multidisciplinary team-based care to better address the needs of refugee women. Incorporating support from cross-cultural workers and doulas may help mitigate social barriers and facilitate care navigation. Establishing standardised outcome measures for maternal quality of life and well-being would allow for better evaluation and comparison of care models. Future research is needed to evaluate the long-term impact and effectiveness of these models on maternal and infant health outcomes. Keywords Perinatal outcomes, consensus, priority setting, Delphi method, maternity care models, refugee-background women

Ind-1043 Who Is Providing Care for the Elderly in Asia? Comparing Five Countries at Different Stages of the Demographic Transition

PRESENTER: **Marie Ishida**

AUTHORS: Victoria Fan, Ajay Singh Mahal, Sumit Kane, Teralynn Ludwick

Asia comprises approximately 60 percent of world population and is experiencing rapid population ageing, with the share of elderly population

expected to rise continuously over the next several decades. The demand for caregiving is also expected to accompany rising numbers of elderly. Traditionally, family members have been the first line of support with female members typically taking the role of primary caregivers for the elderly. However, declining fertility, increases in women's labour force participation and rural-to-urban migration over time have led to fewer household members remaining at home to take up caregiving responsibilities. Despite these shifts in family structure, there is limited understanding of the current profiles of primary caregivers across countries at different stages of demographic transition in the region. We investigate the profile of primary caregivers of older adults (aged 60 years and above) that report difficulty with activities of daily living (ADLs) and factors associated with the use of non-family caregivers in five Asian countries with significant numbers of elderly (China, India, Indonesia, Japan, and South Korea).

Cross-sectional analysis based on data from nationally representative household surveys – the Chinese Longitudinal Healthy Longevity Study (2018), Comprehensive Survey of Living Conditions (2016) from Japan, Korean Longitudinal Study of Ageing (2018), Indonesian Family Life Survey (2014), and Longitudinal Aging Study of India (2017). Primary caregivers were identified from self-reports of respondents. The distribution of primary caregivers by relationship to care recipients (spouse, child, child's spouse, grandchild, other relatives, and non-family members) is described, along with hours of care provided by caregivers classified by their relationship to care recipients. Lastly, socioeconomic and demographic factors associated with the use of non-family caregivers were explored using multivariate linear probability models.

Among respondents experiencing difficulties with ADLs, the share of respondents reporting support by caregivers ranged from 47.5% in India to 90.4% in Japan. Most primary caregivers consisted of family members, with the share of non-family caregivers being 10.3% in Japan and 18.7% in South Korea (excluding institutional care), but fewer than 4.0% in China, India, and Indonesia. Among family caregivers, spouses were the major source of caregiving, but care responsibility transferred to younger generations, mostly women, as care recipient grew older. This generational transition occurred more rapidly in India and Indonesia, where younger cohorts were increasingly assigned to caregiving roles, including in some cases, grandchildren. Median weekly hours of care provided by primary caregivers ranged from 7 hours in Indonesia to 15 hours in South Korea, with caregivers who were spouses contributing the most across all the countries in the sample. Higher socioeconomic status was associated with the use of paid non-family caregivers; and rural residents were more likely to rely on unpaid non-family caregivers than urban residents in China, India, and Indonesia.

Family is the main source of elderly care in Asia, with younger members disproportionately shouldering care burdens in middle-income countries. Demographic transitions further strain family care, increasing unmet care needs where non-family care resources are limited. Strategies to support and substitute family caregivers are essential to meet growing caregiving demands.

Ind-648 From Constitutional Provisions to the Implementation of Basic Health Care Service (BHCS) Delivery in Nepal: Toward Achieving UHC

PRESENTER: **Ravi Kanta Mishra**
AUTHORS: Kjell Arne Johansson, Krishna Kumar Aryal, Shiva Raj Adhikari

Background: Delivering Basic Health Care Service (BHCS) is a commitment of the Government of Nepal to achieve progressive realization of universal health coverage (UHC). This study aims to identify availability, accessibility, quality of care, and utilization and the expenses of the BHCS entitlements in Nepal.

Methods: We analyzed data from the Nepal Demographic and Health Survey (NDHS) 2022 and Nepal Health Facility Survey (NHFS) 2021, focusing on the services included in the Nepal's BHCS package. Descriptive analysis of the key indicators of the BHCS availability, accessibility, quality of service, and utilization was conducted drawing data on 1448 public health facilities, 457 observations and 320 client interviews from the NHFS 2021 and 14,845 women aged 15-49 from the NDHS 2022. The quality-of-care index was calculated with equal weight to three domains: experience of care, standard of care, and service readiness. Secondary data were analyzed from the existing health related financial data (2018/19 to 2020/21) of Local Governments in Nepal from the sub-national treasury regulatory application. Then, the actual expenses of BHCS package were calculated. R 4.3.2 software was used for the analysis.

** **Results:**

Overall, 16 out of 41 services assessed under BHCS package were available at more than 90% of the health facilities, but all 41 services were available at less than one percentage of the health facilities. Two of three women could reach the nearest health facility within a 30-minute travel time. Child health services had low utilization, with growth monitoring (6.0%) being the least used. Care seeking fever (19.6%), diarrhea (25.4%), and acute respiratory infection care (25.5%) were also low, while antenatal care visits (80.5%) and deworming (84.1%) were highly utilized. The overall quality of care index was 69.3 out of 100. Most of the BHCS budget expenses were allocated to health programs followed by health workforce, health infrastructures and health care logistics and medicines over three years periods. Among the different categories of health programs, Maternal, newborn, child health and nutrition programs had the highest share of expenses (> 50%) followed by emergency Health. Other categories, like immunization, non-communicable diseases, and communicable diseases, hovered between 1-10% in three years period.

** **Conclusions:**

Despite constitutional mandate to provide BHCS, this study found low availability of BHCS in public health facilities of Nepal. Although accessibility was not a problem, we found low utilization of services (especially child health) and moderate quality of care. Almost 50% of the total budget of BHCS expenses focused on maternal neonatal child health and nutrition. Categories like non-communicable diseases, mental health and communicable diseases remain underfunded in terms of expenses. Early BHCS implementation showed the need for realism and service review.

Ind-2057 Overprescription of Generic Drugs and Diagnostic Tests: Insights From a Randomized Experiment With Unannounced Standardized Patients in Urban India

PRESENTER: **Mr. Nikkil Sudharsanan**, Professorship of Behavioral Science for Disease Prevention and Health Care, Technical University of Munich
AUTHORS: Vasanthi Subramonia Pillai, Caterina Favaretti, Dimple Janardhan

Background: Overprescription of medications and diagnostic tests poses a significant challenge in many low- and middle-income countries (LMICs). Inappropriate prescribing practices deplete valuable healthcare resources and have serious implications for patient health. For example, numerous studies in LMICs, such as India and Sub-Saharan Africa, highlight the tendency of primary care clinicians to overprescribe antibiotics, even for conditions that do not warrant their use. This has led to an emerging pattern of antibiotic resistance among the LMIC population. However, existing literature on overprescription largely focuses on addictive drugs and antibiotics, with limited attention given to other drug classes commonly prescribed in primary care, such as analgesics, antacids, and anti-inflammatories. Moreover, there is a lack of objective evidence on the systemic factors of clinician overprescription and overdiagnosis. While some studies suggest that overprescription is partly driven by patient demand and the perception that medications signify high-quality care, these factors remain unexamined in the context of non-infectious diseases. Hence, using data from a randomized experiment with standardized patients (SPs, actors depicted as real patients) in India - an important LMIC setting - we aim to address two key objectives. First, we examine the current levels of generic medication over-prescription and inappropriate ordering of screening tests (X-rays, blood draws) among primary care clinicians. Second, we investigate whether prescription and diagnosis patterns systematically differ by category of care requested (curative care vs. preventive care), provider type (public vs. private facilities), incentives (consultation fee), and patient demographics.

Methods: We conducted a randomized experiment using unannounced SPs in two large Indian cities, Chennai and Kolkata. We randomly sampled 600 primary healthcare facilities, evenly split between the two cities and provider type (public and private). For public facilities, we recruited the universe of facilities listed by the Ministry of Health in both cities. Due to the absence of a similar list for private facilities, we compiled one using two widely prevalent business listing services (JustDial and Practo) and then randomly sampled clinics for our study. In each sampled facility, we randomized SPs to seek care for one of two common conditions - lower back pain or preventive hypertension check. After each visit, SPs participated in an in-person exit interview, where all interaction details, including prescription information, were recorded on a tablet.

Results and Conclusion: Our preliminary findings show that among the 600 clinician visits, 355 clinicians prescribed at least one medication. On average, clinicians prescribed 2.6 medications per patient (SD = 1.1), with a mean of 2.8 (SD = 1.1) medications for the back pain group and 1.9 (SD = 1) for the hypertension group. Across all 355 patients, a total of approximately 925 medications were prescribed. We are currently analyzing the data to estimate the degree of inappropriate prescriptions and whether medication prescriptions and diagnostic testing differed by clinic and patient characteristics. A first draft of the results is expected by February 2025. These results will provide critical insights into overprescription for non-infectious diseases, highlighting opportunities to improve prescribing practices and optimize primary care delivery in LMICs.

Ind-814 Impact of Continuity of Primary Care on Hospitalizations and New Complications among Hypertensive Patients: A Longitudinal Study in China

PRESENTER: **Chunlu Yu**
AUTHORS: Wen Chen, Luying Zhang

Background: Chronic diseases pose a major challenge to healthcare systems worldwide. Better continuity of care (COC) has been shown to improve patient health outcomes in many countries. This study aimed to measure the continuity of primary care among hypertensive patients in China and analyze its impact on patients' hospitalizations and new complications. **Methods:** This is a longitudinal retrospective study of 184,299 patients with hypertension based on the medical insurance claims database from a provincial capital city in eastern China. Three indicators, Usual Provider Continuity (UPC), Bice-Boxerman Continuity of Care Index (COCI) and Sequential Continuity Index (SECON) were calculated to comprehensively measure the COC in 2016-2018. Logistic regression models and a zero-inflated poisson regression model were used to examine the impact of COC on the number of hypertension-related hospitalizations and new hypertension complications in the subsequent year (2017-2019). **Results:** In 2016, the average age of the sample population was 67.31 years old and 61.66% of patients had hypertension comorbidities. The average annual number of outpatient visits for hypertension-related conditions was 12.33. From 2016 to 2018, the continuity of primary care increased, with the mean values of UPC, COCI, SECON reaching 0.75, 0.61, 0.74, respectively in 2018. 24.38% of patients consistently visited the same community health center, achieving high COC scores. The proportion of patients with low level of UPC (<0.75), COCI (<0.60), and SECON (<0.75) were 47.87%, 48.56% and 44.34%, respectively. Age, type of medical insurance and comorbidities were associated with higher COC. Compared to the high COC group, the low COC group had a significant higher risk of hypertension-related hospitalizations (OR: UPC: 1.76, COCI: 1.73, SECON: 1.75), as similarly observed in the modest COC group (OR: UPC: 1.41, COCI: 1.38, SECON: 1.40). Additionally, both the low COC group (OR: UPC: 1.53, COCI: 1.50, SECON: 1.52) and the modest COC group (OR: UPC: 1.32, COCI: 1.30, SECON: 1.31) showed an increased risk of developing new hypertension complications. Higher COC was also significantly associated with fewer number of new hypertension complications (IRR: UPC: 0.58, COCI: 0.70, SECON: 0.61). **Conclusion:** This study indicated that** better continuity of primary care could improve health outcomes among Chinese hypertensive patients. However, the COC needs to be further improved. Strengthening the family doctor system and reinforcing the capacity of primary care providers to manage patients with multimorbidity can guide more patients to community health centers, improve the continuity of primary care and further enhance the effectiveness of chronic disease management in China.

Ind-379 Barriers Associated with Unavailable Medicines in Primary Health Care Institutions: A Mixed-Methods Study from China

PRESENTER: **ZhiXin Fan**

AUTHORS: Qing HE, Jia Yin, Qiang Sun

Background With an aging population and the increasing prevalence of chronic non-communicable diseases, medicine needs in primary health centers (PHCs) have become diversified. There is a need to comprehensively evaluate the availability of PHC medicines, as well as the characteristics and reasons for unavailability. **Methods** We used a three-stage sequential explanatory design strategy to conduct a mixed-methods study in Shandong Province, China. We conducted a medication questionnaire for PHC patients and semi-structured qualitative interviews with the pharmacy managers, physicians and patients in township hospitals. In order to validate the qualitative findings, fuzzy-set qualitative comparative analysis (fsQCA) was used to explore the interrelationship between the influencing factors of high medicine unavailability in township hospitals. **Results** We collected information from a total of 6,323 patients. The total number of the population with unavailable medicines was 945 (15.31%). The data showed high unavailability of chronic disease medicines such as Aspirin, Nifedipine, Metoprolol, and Metformin, but for different reasons. Qualitative data revealed that people's medicine needs have become more diverse and refined, and PHCs had insufficient incentive to equip more medicine varieties. Fuzzy-set QCA analysis suggested that there were three configuration paths driving the high medicine unavailability in township hospitals. **Conclusion** While the overall availability of medicines in PHCs is relatively stable, it is noteworthy that the reasons for unavailable medicines vary, and significant variations exist among different PHCs. Additionally, the "Central Pharmacy" may be a novel strategy to establish a unified medicines list, procurement processes, and pharmaceutical services in PHCs. **Keywords** Medicine need, Unavailability, Primary health centers, Mixed-methods study, Central Pharmacy, China

Ind-2296 The Efficiency of Secondary-Level Hospitals in Hard-to-Reach and Non-Hard-to-Reach Areas in Bangladesh: A Data Envelopment Analysis Approach

PRESENTER: **Sayem Ahmed**

AUTHORS: Jahangir AM Khan, Md. Zahid Hasan, Abu Noman, Mohammad Wahid Ahmed

Background: Efficiency in healthcare delivery is crucial for maximizing resource utilization and achieving broader health system objectives, particularly in resource-constrained settings like hard-to-reach (HTR) areas in Bangladesh. Despite people in these areas facing barriers in accessing health services, health facilities have not undergone comparative efficiency evaluations with facilities in non-hard-to-reach (non-HTR) areas. **Objectives:** The study's aim was to assess the association between HTR area characteristics and the technical efficiency of secondary-level hospitals. **Methods:** Data envelopment analysis was performed with output orientation to calculate the efficiency scores of 62 secondary-level hospitals using both constant and variable returns to scale assumptions. We used the number of physicians, nurses and beds available in the hospitals as the inputs for service production. The number of different types of services provided by the hospitals, namely, antenatal care, normal deliveries, postnatal care, outdoor department visits, and hospital admission, were included as the output variables. These input and output data for each hospital were extracted from the Local Health Bulletin-2022 of the Directorate General of Health Services in Bangladesh. Using the Water and Sanitation Program report published by the World Bank in 2012, geographic locations with specific characteristics, such as beel/wetland, coastal, offshore island, saline, and hilly areas, were categorized as HTR areas. We conducted descriptive analysis and performed a Mann-Whitney two-sample statistic test to test the mean difference of efficiency scores between the HTR and non-HTR areas. Finally, multiple Tobit regression models were employed to determine the association between HTR area characteristics and hospital efficiency while adjusting for bed occupancy ratio, average length of stay and administrative division. Results: The findings revealed that, on average, hospitals were 73% and 80% efficient using constant and variable returns to scale assumptions, respectively. Hospitals located in HTR areas were relatively less technically efficient (efficiency score = 0.76) than those in non-HTR areas (efficiency score = 0.84), and the differences were statistically significant (p-value = 0.08) when the variable returns to scale assumption were used. Similar significant differences in efficiency scores (p-value = 0.06) were observed between these two groups of hospitals when constant returns to scale assumptions were used. The regression analysis results showed that hospitals in HTR areas experience lower efficiency scores (coefficient = 0.258; p-value < 0.05) than hospitals in non-HTR regions. Additionally, the bed occupancy ratio and average length of stay were significantly associated with the efficiency scores of secondary-level hospitals. **Conclusion:** Hospitals in HTR regions are found to be less technically efficient than non-HTR regions in Bangladesh. Policymakers should address the underlying causes of inefficiencies and implement targeted interventions such as improving healthcare access for vulnerable HTR area populations, optimizing bed occupancy rates and length of stay with proper referral systems and discharge planning in these particular areas. This indicates that further research on health systems in climate-vulnerable areas in Bangladesh should be prioritized to address these challenges effectively. 2 | Page

Health System Reform in Latin America: The Health and Health System Impacts of Reforms Aiming to Reduce Fragmentation

MODERATOR: **Thomas Hone**, Public Health Policy Evaluation Unit, Imperial College London

CONVENER: **Diego Cerecero Garcia**, Imperial College London

abs-os412 A Mixed Methods Evaluation of Regulatory Efforts to Promote Regional Coordination of Secondary Care Services in Brazil (1998-2019)

PRESENTER: **Vinicius Pecanha**
AUTHORS: Frederica Padilha, Renílson Rehen, Thomas Hone, Christopher Millett, Letícia Nunes, Rudi Rocha, Beatriz Rache, Renato Tasca

Background: Globally, many countries have implemented decentralization reforms to strengthen their health systems, yielding varied outcomes. In Brazil's health system was highly decentralised to municipal governments in the 1990s. However, the country now faces issues of fragmentation and low access to secondary care. Re-centralizing governance and service provision into health regions is one option for improving care delivery. Since the 2000s, federal regulations have attempted to initiate health system regionalization. Based on a comprehensive empirical analysis of the patterns of expansion and reorganization of healthcare services and hospitalization flows between municipalities, this study assesses whether the health system reorganized towards a regional model and if this shift correlated with federal regulations. Additionally, it explores the challenges and possibilities to promote regional coordination in decentralized health systems.

Methods: We conducted mixed methods evaluation. In the quantitative approach we used the National Register of Health Facilities and Hospital Information System data for a descriptive analysis of the expansion of health services and applied an adapted gravity model to examine hospital admission flows, analyzing patient movements between their municipalities of residence and hospitalization locations from 1998 to 2019 and potential discontinuities in hospitalization trends around the years of the regulations. In the qualitative approach, a two-round Delphi study with 31 experts in the Brazilian health system was conducted to reach consensus on the main challenges of the regionalization model and potential improvements.

Results: The analysis revealed a broad expansion of healthcare infrastructure and services over the period. The average distance travelled for outpatient procedures, such as emergency services, fell from 10.0 km to 5.6 km, and ICU beds, from 83.5 km to 59.2 km. However, an opposite trend was observed for hospitalizations: in 1999 an average of 18.4 km was travelled for hospital admission, but this rose to 29.6 km in 2019. These changes in patient flow for hospitalizations occurred gradually without significant breaks over the regulatory years, suggesting that the federal efforts to promote regionalization did not have immediate or clear impacts. For the experts consulted in the Delphi study, it was the consensus that the federal regulations played a small role, with the states and autonomous regional bodies with dedicated resources as important enablers of regionally-coordinated care.

Conclusion: The decentralization of the Brazilian health system has created challenges for coordinated health services. This study suggests continued misalignment between the reorganization of resources and flows of patient, and the established health regions. Moreover, this reorganization does not appear related to federal regulation. Remaining challenges include further centralisation of governance, strengthening the role of states, and redefining health regions into broader, more integrated territories.

abs-os315 Does Expanding Health Benefits Improve Health? An Analysis of Colombia's Subsidised Regime Reform

PRESENTER: **Paul Rodriguez-Lesmes**
AUTHORS: Thomas Hone, Giancarlo Buitrago, Sandra Camacho, Diana Pinto

Countries aiming to achieve Universal Health Coverage often expand health benefit plans (HBPs) to include previously uncovered populations or technologies. However, such expansions can generate unintended effects when health system capacity is fixed. This paper studies the impact of Colombia's 2013 reform, which equalized the benefits of the Subsidized Regime (SR) to those of the Contributory Regime (CR), effectively extending access to a wide set of medical procedures and diagnostic services for poor adults.

Using administrative data covering 95\% of the population and a difference-in-differences design, we estimate the effects of the reform on healthcare utilization, availability, and geographic coverage of newly included procedures. We find a substantial increase in use among SR enrollees, concentrated in diagnostic services, alongside a decline in use within the CR—suggesting therapeutic substitution across regimes. The reform also expanded access across municipalities, particularly in underserved areas.

Heterogeneity analyses reveal no clear differential impacts by procedure cost or prior diffusion, highlighting the constraints of supply-side rigidity. These findings underscore that benefit expansions without parallel investments in capacity may lead to redistribution rather than net gains in access. Colombia's experience offers valuable lessons for countries pursuing entitlement reforms under resource constraints.

abs-os420 The Impact of Dismantling Seguro Popular on Diabetes Management in Mexico

PRESENTER: **Diego Cerecero Garcia**
AUTHORS: Thomas Hone, Edson Servan--Mori, Judite Gonçalves, Christopher Millett, Octavio Gómez-Dantés

Background: Mexico has made significant progress towards universal health coverage (UHC) in recent decades. One major UHC-advancing reform was the creation of Seguro Popular (SP) in 2003. By 2018, SP had covered 75% of the country's uninsured population, significantly reduced out-of-pocket expenditures, and increased service utilization. However, in 2019, a major reform replaced SP with another insurance scheme named INSABI. The reform focused on re-centralising financing and service delivery. The INSAB was replaced in 2023 by IMSS-Bienestar (IMSS-B). We assessed the impact of Mexico's SP replacement on diabetes management from 2018-2023.

Methods: We used data from Mexico's National Hospital Discharge Registry and the Registry of healthcare services for diabetes patients. We used ICD-10 codes from the OECD Healthcare Quality and Outcomes Indicators list to identify diabetes hospitalisations. We exploit the natural experiment setting of the SP elimination with 23 out of 32 states adopting the new reforms and the remaining continuing with a decentralised health system. We used event study design to validate parallel trends assumption before treatment and explore impacts over time. We also estimated difference-in-differences models to assess the effects of the reform. Several key events were tested: INSABI discussion and approval

of reform in congress (reference point), implementation of centralised procurement mechanisms, IMSS-B congress discussion and approval, and IMSS-B roll-out.

Results: We analysed data from 274,394 diabetes hospital discharges. Diabetes hospitalisation rates per 100,000 before the elimination of SP increased significantly among adopting states. We also observed a reduction in the proportion of diabetes patients with glucose control after the reforms, mainly among adopting states. Difference-in-differences analyses and event study models confirmed a sustained increase in diabetes hospitalisations after the reform implementation and a significant reduction on adequate diabetes management among adopting states.

Conclusion: This study suggests that SP elimination affected diabetes outcomes and management in Mexico. Potential explanations include disruptions in the continuity of care for chronic conditions as well as inefficiencies and inequalities in healthcare access stemming from the reform. Given the well-documented weakness of the INSABI and IMSS-B reforms, policies to recentralise services and reduce fragmentation should be considered carefully.

abs-os313 The Impact of Reorganising Bogota's Health System on Health Outcomes and Costs in Hypertensive Patients

PRESENTER: **Daniela Sánchez-Santiesteban**, Universidad Nacional de Colombia
AUTHORS: Giancarlo Buitrago, Diana Pinto, Thomas Hone, Christopher Millett

Background: In 2015, Bogotá's health system faced challenges from delays in paying providers, high administrative costs, financial instability, low quality infrastructure, service delivery inefficiencies, and poor care coordination. To address these challenges, the government in Bogotá implemented a public health sector reorganisation to improve comprehensive care, enhance health outcomes, and decrease fragmentation between actors. This study evaluates the impact of the Bogotá health reorganisation on health outcomes and costs in patients with hypertension.

Methods: Administrative data and health records were linked using a unique identifier by the Ministry of Health in Colombia and cross-referenced to generate a cohort of individuals with data points for over 10 years. We employed a difference-in-differences analysis to evaluate the impact of the reorganisation in Bogotá between 2014 and 2018, using 2017 as the intervention year. Patients with hypertension in Bogotá in the subsidised scheme (exposed group) were compared to those in the contributory scheme (control group). We constructed a closed cohort to evaluate clinical outcomes and healthcare costs using fixed effects and a dynamic cohort to assess mortality in the population. Each outcome was measured yearly and at an individual level. Clinical outcomes evaluated included organ damage from hypertension, dialysis requirement, and myocardial revascularisation (myocardial infarction). We also included the number of outpatient and hospitalisation services and mortality. Economic outcomes evaluated total healthcare costs in million COP.

Results: The reorganisation was associated with increased outpatient care services. Conversely, there were associated reductions in adverse outcomes, such as hospitalisations, myocardial revascularisation, dialysis, and mortality. Additionally, total healthcare costs in millions of COP, also reduced. There was a finding that the effects grew larger over time.

Conclusions: The Bogotá health reorganisation positively impacted clinical and economic outcomes in patients with hypertension. These findings suggest that reforms focused on decreasing healthcare fragmentation can yield benefits for chronic conditions such as hypertension in resource-constrained settings.

Can we Define a Reference Case of Methods to Cover Both Environmental and Health Economic Evaluations?

MODERATOR: **Andrew Briggs**, London School of Hygiene and Tropical Medicine

abs-os767 Guideline Development: More Than Just Another Checklist

PRESENTER: **Mireia Jofre-Bonet**, Office of Health Economics

The impacts of climate change are increasingly being felt directly around the world, with negative effects on both human health and healthcare systems already becoming evident. Demand for economic evidence on the health impacts of climate change mitigation actions (or failures to act) is growing; this growing demand is accompanied by a desire to establish robust guidelines for such evaluations.

Our recent scoping review on measuring and valuing the health co-benefits of climate change mitigation actions made a number of findings relevant to guideline development. Unsurprisingly, we found a lack of standardisation in both methods for estimating health impacts of mitigation interventions and for valuing those health impacts. We also found that most of these studies are published in environment rather than health journals. More surprisingly, we found that a large majority of studies in this literature focused on near-term health co-benefits (e.g. from reduced air pollution), and only a small minority actually estimated longer-term health benefits from mitigating climate change itself.

Yet before addressing technical issues, any discussion of guideline development in this area must start further upstream, with questions of purpose and scope. Who would use guidelines in this space: researchers, policy makers, research funders, journals etc.? Why would they use

them: to guide real-world decision-making; to improve standardisation and generalisability of research; or to tick boxes to pre-register study protocols? What kinds of climate mitigation actions are in scope, and which are not, and why? Are these guidelines for global or national use? To what extent should we seek to align economic evaluations of the health benefits of climate mitigation actions outside the health sector with those of climate change mitigation actions within healthcare systems? Given the extreme urgency of accelerating action, and the (tragically) still contentious political economy of climate action, focusing on "technical" excellence without first answering these more fundamental questions is a sure route to irrelevance.

Having done so, several critical parameters will then need to be addressed. These include time horizons and intergenerational equity; geographical scope (given that costs and benefits occur over different geographies); evidence sources and methods for (more) standardised estimates of the health impacts of climate actions; and more standardised approaches to valuing these benefits. If done well, guidelines can help to simplify and prioritise effort, coordinate more effective interdisciplinary cooperation, and even move towards better sharing of scarce skills and capabilities in this field. Effective guideline design must navigate between two extremes – ineffectual guidelines under which "anything goes", and which fail to achieve any real standardisation; or excessive standardisation which undermines innovation and promotes simplistic "monkey see, monkey do" analysis which lacks insight or flexibility. Guideline design must also be careful not to confuse the laudable desire for analytical rigour with the longstanding tendency to downplay and minimise "extreme" outcomes and risks which has dogged – some would say fatally undermined – the credibility of economic analysis of the wider societal impacts of climate change.

abs-os761 Green HTA: Redefining Value in Health Care

PRESENTER: **Sarin KC**

The health sector accounts for approximately 5–8% of global greenhouse gas emissions. This alarming finding challenges one of the core ethical principles of healthcare: nonmaleficence, as these emissions drive climate change, which negatively affects health and health systems. The production, supply-chain, use, and waste management of health technologies appear to be a significant contributor to this problem. Therefore, health technologies that are reimbursed under UHC should be both cost-effective and environmentally sustainable to ensure the likely benefits always outweigh the harm. Traditionally, HTA through economic evaluations have helped us define the value of health technologies. However, it only considers economic costs and health benefits, omitting environmental impacts as a value metric. Hence, there is a growing call from the HTA community to develop methods that can adequately incorporate the environmental impacts of health technologies into existing HTA frameworks.

Therefore, we are developing a method, "Green HTA", which involves three steps: (i) estimating the environmental impact of health technologies through product life cycle assessment (LCA) using carbon emission as a proxy; (ii) estimating the economic cost associated with those emissions; and (iii) performing traditional economic evaluation by adding the emissions cost as an additional cost parameter into economic models. We are testing this concept through a case study by comparing the environmental and economic sustainability of peritoneal dialysis and hemodialysis as treatment options for end-stage renal disease in Thailand. For step (i), we are analysing the cradle-to-grave impact of dialysis using the bottom-up approach*.* Data on emissions from the manufacturing process and supply chain are being gathered from Baxter and Fresenius. Emissions related to use of service and patient travel are being collected from dialysis centers across six Thai provinces including Bangkok, Chanthaburi, Chiang Mai, Kanchanaburi, Nakhon Ratchasima, and Nakhon Sawan. Emissions from waste management are being tracked through Bangkok Thanacom, the central agency responsible for managing medical waste. Environmental impact will be analysed using Simapro, with results including total emissions per session of dialysis, annual DALYs, annual loss of species, annual loss of natural resources, and emission hotspots for each dialysis option. For step (ii), we are using the social cost of carbon from the literature, which is the monetised value of the damage to society caused by carbon dioxide. For step (iii), we are using our previous economic evaluation study on dialysis interventions in Thailand. Final results of the study will be presented as emissions per QALY, emissions per cost, emission-adjusted ICER, and a comparison of QALYs gained from dialysis with the DALYs generated by its use.

While our proposed methodology integrates well with existing HTA framework, limited technical capacity and insufficient data for LCA can hinder adoption. Developing and maintaining a medical LCA database will prove critical. For this method to be effectively integrated into policymaking, several gaps must be addressed, including the selection of the most appropriate proxy for environmental impact, defining tolerable emissions threshold, understanding the trade-offs and preference between health gains and environmental sustainability, and potential adjustments to the willingness-to-pay (WTP) threshold.

Methodological Pathways for Valuing Health in Climate Action: Integrating Health Developmental Impacts into Applied Economic Evaluation

PRESENTER: **Dr. Bernard Moscoso, PhD**, ESPOL - Escuela Superior Politécnica del Litoral

Introduction. Climate change presents a growing threat to global health, affecting everything from disease exposure to food security and developmental outcomes. Despite this, health is often inadequately incorporated into economic evaluations of climate policy. Most cost-benefit analyses emphasize mitigation costs and emissions targets while neglecting the dynamic, long-term health effects of climate-related exposures. Recent literature suggests that integrating health, particularly health assessment within a development economics approach into applied economic evaluation, can provide a more accurate and socially solid foundation for policy-making.

Motivation. Emerging studies underscore the importance of early-life health in shaping long-term economic outcomes, yet these effects are rarely internalized in climate economics. For instance, Currie and Almond (2011) show that prenatal environmental shocks can affect lifetime earnings and education. Similarly, Deschênes (2014) and Adhvaryu et al. (2019) link childhood exposure to heat, pollution, rainfall and drought to adverse cognitive and physical development, and education outcomes. Ignoring such pathways leads to underestimating the true costs of inaction. A systematic review by Swinburn et al. (2019) also highlights how climate mitigation policies in energy, transport, and food systems can deliver immediate public health benefits, yet these are seldom valued in economic terms in the literature.

Methods. This review synthesizes recent methodological approaches from health economics, climate policy, and development economics to outline feasible pathways for integrating health into climate-related economic evaluations. Sources include peer-reviewed articles, WHO economic tools, and interdisciplinary models published between 2010 and 2024. Key methods identified include: (1) co-benefit quantification of health outcomes from mitigation policies; (2) integration of developmental health shocks into intertemporal human capital models; and (3) equity-weighted cost-benefit analysis to account for distributional effects.

Results. Across the preliminary reviewed literature, two methodological pathways emerge:

Health Co-Benefits Frameworks: Studies such as Markandya et al. (2018) and Vandyck et al. (2018) show that monetizing health gains—e.g., avoided premature deaths from reduced air pollution—can offset a significant share of mitigation costs. Tools like the WHO's HEAT and the OECD's CIRCLE tool help quantify these benefits.

Developmental Health Impact Modeling: Incorporating early-life exposure effects into economic evaluation, as demonstrated by Fishman et al. (2019), and Maccini and Yang (2009), reveals long-term productivity and educational attainment losses linked to exposure to weather variations, even at early life stages. These models allow policymakers to evaluate the economic returns of preventive health measures in climate-vulnerable regions.

Conclusion. Valuing health in climate action is not only technically feasible but ethically necessary. Integrating developmental health impacts and co-benefits into applied economic evaluations provides a fuller picture of the costs and benefits of climate policies. It also aligns economic decision-making with public health, intergenerational equity, and sustainable development. Furthermore, interdisciplinary methods that bridge climate science, health and development economics, must be scaled and institutionalized to inform robust, health-sensitive climate policies in the short and long-term.

abs-os730 Primary Healthcare Resource Tracking: Strengthening Methods and Supporting Data Use

PRESENTER: **Ms. Anne Mills**

AUTHORS: Manjiri Bhawalkar, Katie Shepard, Rajesh Jha, Cicely Thomas, Parfait Uwaliraye, Ellyana Selamat, Karsten Vrangbæk, Kara Hanson, Anne Mills

Background: Many countries have committed to increasing priority to primary health care, as the foundation for universal health coverage. To design, implement and monitor reforms to strengthen PHC delivery, countries need timely and credible data on PHC resource flows that can be linked to other health system data about services delivered and health outcomes. A range of frameworks, methods, tools and databases have been used globally to collect and analyse information about the flow of health funds. Yet little is known about how individual countries are tracking resources for PHC.

The aim of this paper is to analyse the approaches specific countries are adopting to collect information to track PHC resources, how they are using this information to strengthen the equity and efficiency of PHC delivery, and how best to support and strengthen these tracking systems.

Methods: The study used rapid appraisal case studies in nine countries (Denmark, Ethiopia, India (Bihar State), Indonesia, Malawi, Malaysia, Rwanda, South Africa, Zimbabwe) to understand these issues. Official documents were reviewed and interviews with key stakeholders conducted. Data were consolidated into country analysis tools, capturing details of each country's PHC delivery platforms, health financing arrangements, public financial management (PFM) and resource tracking systems. Cross country thematic analysis was undertaken.

Results: Routine data systems were generally unable to capture flows of resources to PHC; (mis) alignment between the degree of decentralisation of government structures and the financial management information systems was an important influence on data capture. LMICs used a variety of different methodological approaches and tools to track resources, many of which were harmonized in part with Health Accounts framework and exercises. In some countries, resource tracking exercises technically allowed for estimation of PHC spending, but this was not sufficiently prioritised for actual expenditure to be captured and used. Challenges included many that are common to routine health resource tracking, such as difficulties tracking donor-provided in-kind resources, fragmented purchasing and payment systems and flows of domestic funding, resource constraints (e.g., time, institutional capacity) and lack of alignment between the architecture of the public financial management system and health sector financing objectives. Challenges specific to PHC included the variety of operational definitions of PHC and the invisibility of the PHC service delivery level in the budget. Weak accountability structures also impeded PHC tracking and prioritisation.

Conclusion: There are many strong use cases for improved PHC resource tracking. The barriers to improving tracking vary enormously across

country contexts, so no single approach or tool will be sufficient. Where PHC is not trackable within public financial management systems, gathering comprehensive information on resources committed is challenging and impedes further prioritisation of PHC.

abs-os731 Programme-Based Budgeting for Primary Care Financing: Insights for Practitioners

PRESENTER: **Helene Barroy**, World Health Organization

Background: The traditional use of line-item budgeting has negatively impacted the financing of primary care services in low- and middle-income countries (LMICs) by fragmenting expenditures and complicating budget allocation identification, leading to underfunding and accountability issues. In response, many LMICs have adopted programme-based budgeting (PBB) to align budgets with policy priorities. PBB groups inputs around policy goals or outputs, offering greater flexibility and accountability. Health is a priority sector for this reform, with two-thirds of LMICs implementing some form of PBB. However, significant changes to public financial management (PFM) processes and systems have often delayed implementation. Despite its potential, the impact of PBB on primary care financing remains undocumented.

Methods: To address this, WHO conducted a 2023 study analyzing how 20 LMICs integrated primary care financing into their PBB structures. The study reviewed budgetary structures, disbursement rules, and performance-monitoring frameworks.

Results: The analysis revealed that countries had not fully leveraged PBB to enhance primary care financing. National-level PBBs often failed to make primary care more visible or prioritized, while inconsistent budget formulations at subnational levels hindered resource allocation and tracking. Major inputs for primary care (e.g., personnel, vaccines, therapeutics, infrastructure) were often fragmented across different budget lines, leading to inefficiencies. Additionally, rigid disbursement processes and flawed performance-monitoring frameworks limited primary care providers' access to resources and impeded the tracking of primary care outputs.

Conclusion: This paper builds on lessons from the 2023 study, additional evidence from WHO's PFM programme, and consultations with experts within the Montreux Collaborative, to offer insights on more effective approaches for formulating and implementing PBB for primary care. The guidance aims to assist countries in reorienting their health systems towards primary care and aligning their financing arrangements to support primary care more effectively. It covers five key dimensions: national budget structure, subnational budget structure, coverage of costs, disbursement policies, and performance-monitoring frameworks. Through this process, PBB can facilitate system re-orientation, making PFM and health financing reforms more interconnected and mutually reinforcing.

abs-os732 Addressing Fragmentation of Primary Health Care (PHC) Financing for More Equitable, People-Centered PHC

PRESENTER: **Ms. Agnes Gatome-Munyua**, Results for Development
AUTHORS: Prastuti Soewondo, Kara Hanson, Ms. Cheryl Cashin, Ms. Susan Sparkes

Background: Primary health care (PHC) is recognized in global declarations – Alma Ata in 1978 and Astana in 2018 – and is increasingly being prioritized in national health strategies. However, resources directed to primary care remain low, and under-resourcing has been compounded by fragmented and rigid funding flows, which are inefficient and may erode quality of PHC care.

In Indonesia, primary care facilities *Puskesmas* receive funding from three main sources of funding – Ministry of Health, District Health Office and the insurance agency *Badan Penyelenggara Jaminan Sosial Kesehatan* (BPJS-K) each managed separately by the Puskesmas. In this paper we examine the consequences of health financing fragmentation at the system level on fragmentation in the financial flows to PHC providers.

Methods: Indonesia is used as a country example to map funding flows to *Puskesmas* and undertake a bottleneck analysis to identify the obstacles to resources reaching health facilities and the entry points to reduce the fragmentation at facility level. Financial data from the Ministry of Health (including vertical disease programs), sub-national level via the District Health Office, and insurance agency is used to map and track flows to primary care level and describe financial management at the Puskesmas level.

Results: In 2014, multiple public insurance schemes (civil servants, formal sector workers' health benefits and health assistance schemes for the poor) were consolidated under a single pool through the national insurance program *Jaminan Kesehatan Nasional* (JKN) managed by a single insurer BPJS-K. Before 2014, the insurance schemes were managed independently with different benefits and provider payment systems. The move to JKN reduced fragmentation in the funding pools and harmonized the main purchasing functions, meaning that JKN funds flow to providers for services in one unified benefits package, through a single provider payment system. Despite the consolidation in public insurance pools brought about by JKN, funding still flows to PHC providers through multiple (up to five) streams to fund different sets of PHC services or inputs and with different financial management rules, which continues to undermine the coherence of the health financing system and undermine PHC delivery.

Conclusion: The merger of public health insurance schemes to create JKN, was helpful in reducing fragmentation in the insurance system but did not resolve the fragmentation from the other sources of PHC financing. This can impact financial management and service delivery if providers are not able to use funds flexibly across the different sources . This means there is more to be done to address fragmentation in the government budget flows as an unfinished agenda.

abs-os734 A Framework for Understanding and Improving the Financing of Primary Health Care (PHC) Commodities with an Application to Ethiopia

PRESENTER: **Yewedalem Tesfaye**
AUTHOR: Ms. Cheryl Cashin

Background: Access to essential medicines is an integral part of universal health coverage (UHC), and primary health care (PHC) plays a crucial role in delivering both health services and medicines. While medicines make up a large share of total spending on PHC--sometimes as high as 40–50% of all expenditure and often paid for out-of-pocket through private pharmacies—the Lancet Global Health Commission on Financing Primary Health Care found that there is very little evidence about how medicines are financed end-to-end through government systems. There is tremendous scope to leverage financing policy tools to address the many challenges related to access to medicines at the PHC level such as frequent stock-outs in public health facilities and the high level of out-of-pocket payments for medicines purchased in private pharmacies, representing a substantial barrier to the use of medically appropriate and high-quality medicines. One factor limiting the evidence on improving financing of medicines at the PHC level is a lack of understanding of the different ways PHC financing is organized at the country level from procurement and supply chain systems to PHC providers and patients, and how the financing of PHC medicines is incorporated into health financing policy levers such as revenue generation, pooling, and strategic purchasing.

Methods: Results for Development developed an analytical framework to describe systems for financing PHC commodities and how these financing systems interact with procurement and supply chain systems and broader health financing policy in the country. This framework was applied to the case of Ethiopia to describe the flow of funds and commodities directly from the government budget to the procurement agency Ethiopia Pharmaceutical Supply Service, and indirect channels to PHC facilities and patients through Community-Based Health Insurance (CBHI) and social health insurance managed by the Ethiopia Health Insurance Service (EHIS).

Results: Ethiopia is facing declining donor funding for family planning and MNCH commodities. A list of "fee-exempted services" (MCH, TB / HIV / malaria, and family planning) has historically been fully funded by the government and donors, and provided free of charge at all levels of the health system. Donors have been decreasing their support for the commodities needed to deliver these services, requiring a larger domestic role in financing and procurement. The threat of decreased funding for essential commodities prompted a discussion about sustainable financing, and an effort to prioritize the services, and associated commodities, that should continue to be provided to the population free of charge. At the same time the Community-Based Health Insurance Scheme is losing subscribers as covered individuals are unable to use their cards to obtain prescribed medicines due to stock-outs at public facilities.

Conclusion and implications for policy: The results of the mapping analysis suggests opportunities to harmonize the financing of PHC medicines through the direct and indirect channels through, for example, harmonized benefits entitlements, incorporating medicines financing into provider payments in the CBHI and EHIS systems.

9:00 AM –10:30 AM WEDNESDAY [Economic Evaluation Of Health And Related Care Interventions]

Improving the Evidence Base on the Cost-Effectiveness of Interventions to Address Neglected Tropical Diseases

MODERATOR: **Jacob Kazungu**, KEMRI Wellcome Trust Research Program

CONVENER: **Olimpia Lamberti**, London School of Hygiene and Tropical Medicine

abs-os47 A Systematic Review of Economic Evaluations for Neglected Tropical Diseases of the Skin

PRESENTER: **Iris Penny Mosweu**, London school of Hygiene & Tropical Medicine
AUTHORS: Catherine Pitt, Purity Nyaikamba, Lucas Sempe, Yohannes Hailemichael, Sandra Ndongwe, Yaw Amoako, Jacob Novignon, Michael Marks, Lucy Owusu

One-fifth of the world's population required individual or mass treatment for neglected tropical diseases (NTDs) in 2022. Affecting people across all continents, NTDs impose a substantial morbidity, mortality, and cost burdens on affected households, communities, and health systems. Many NTDs, notably those affecting the skin, are also associated with stigma and social exclusion. NTDs disproportionately affect the poorest and most marginalised people, and exacerbate health and social inequities; they are therefore considered important tracers of equity in health systems. Sustainable Development Goal 3.3 targets an "end" to the NTD "epidemic," but progress is off track. NTDs receive less funding for research and programme implementation than diseases with much smaller burdens, and NTD programme priorities have long been influenced by drug donation programmes. The World Health Organization now recommends integrated strategies to target multiple NTDs simultaneously, but evidence is needed to support intervention choices, particularly regarding the costs and efficiency of alternative approaches. Previous reviews of skin NTD economic evaluations are increasingly out of date; did not include robust critical appraisal; and did not assess skin NTDs as a group, making it difficult to draw conclusions regarding the economics of integration. We systematically reviewed economic evaluations for 11 skin NTD to inform current policy debates and guide future skin NTD economic evaluations.

We searched 13 electronic databases in July 2024 using a pre-defined strategy to identify peer-reviewed, full economic evaluations and cost analyses published since January 2000. Six reviewers working in pairs independently screened records based on pre-defined eligibility criteria and categorised all included studies. Four reviewers double-extracted detailed data from full economic evaluations to assess methodological quality and to describe methods and results. Methodological quality was assessed using both the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) and also the International Decision Support Initiative (IDSI) reference case. We report findings in accordance with PRISMA guidelines and analyse data using descriptive statistics and narrative synthesis. The protocol was registered on PROSPERO (2022 CRD42022350844).

From 3,723 records screened, we identified 151 skin NTD economic evaluations: 42 full economic evaluations, 73 (47%) intervention cost (only) studies, and 36 cost-of-illness or economic burden (only) studies. Most evaluations studied countries in Africa (n=60, 40%) Asia (n=52, 34%), or the Americas (n=29, 19%). The full economic evaluations adhered, on average to <50% of CHEERS and <15% of IDSI items, indicating overall very low quality (with some exceptions); most concluded that new, usually more expensive interventions would be cost-effective, often based on inappropriately high (or no) thresholds.

We found skin NTD economic evaluations to be of inconsistent quality and usually focused on individual diseases, which limits their usefulness for priority-setting. Nonetheless, important commonalities and differences emerged across skin NTDs. Future economic evaluations should draw on existing evidence where possible, while ensuring adherence to methodological standards, to ensure validity and usefulness of results. Full economic evaluation of integrated strategies remains an important gap.

abs-os379 Cost and Cost-Effectiveness of Home-Based Self-Sampling and Clinic-Based Sampling for Screening of Female Genital Schistosomiasis in Zambia

PRESENTER: **Olimpia Lamberti**, London School of Hygiene and Tropical Medicine
AUTHORS: Helen Ayles, Amaya Bustinduy, Helen Kelly, Nkatya Kasese, Fern Terris-Prestholt, Kwame Shanaube, Jennifer Fitzpatrick, Rhoda Ndubani, Fiammetta Bozzani

Introduction: Female genital schistosomiasis (FGS) is a neglected gynaecological disease affecting 45 million women in sub-Saharan Africa, particularly in rural areas with poor water and sanitation. FGS is associated with increased prevalence of HIV and cervical precancer. There are no organised screening programmes for FGS, and its burden is not included in the global burden of disease study. Clinic-based point-of-care colposcopy by a midwife is the standard screening for FGS, but it requires expensive equipment and specialised training, seldom available in endemic settings. Self-collected genital samples ('self-sampling') can be collected during community health workers outreach, potentially overcoming some of the health system constraints associated with colposcopy. We evaluate the cost-effectiveness of home-based self-sampling and clinic-based sampling, compared to a no-screening approach, using data from the Zipime-Weka-Schista study in Zambia.

Methods: We combined a decision tree for FGS screening strategies, with a Markov model for the natural history of cervical cancer. The decision tree simulates the accuracy of home-based self-sampling and clinic-based sampling for FGS screening. Individuals then transition to the health state corresponding to their status in the Markov model. For each strategy, we estimated the FGS screening costs per woman screened, the disability-adjusted life years (DALYs), and incremental cost-effectiveness ratios (ICERs) from a societal perspective. Model parameters were obtained from the Zipime-Weka-Schista study and the published literature. Disability weights for FGS were derived by combining weights from similar conditions in the 2019 GBD study and cervical cancer DALYs from the Markov model. We analysed different intervention scenarios, varying screening frequency and coverage across rural and peri-urban populations. Expansion paths were used to identify optimal combinations of home-based self-sampling and clinic-based screening. A lifetime time-horizon was considered, with costs and outcomes discounted at 3% annually, presented in 2021 United States dollars.

Results:FGS screening using a home-based self-sampling approach costs $7.7 per woman screened, while clinic-based sampling approach costs $11.9. Under the base-case assumption of 70% screening coverage every five years, home-based self-sampling was more effective and cost-effective than clinic-based sampling (ICERs $1,380 and $17,560 per DALY averted, compared to do-nothing approach). Home-based self-sampling had >80% probability of being cost-effective at a threshold of >$3,000 per DALY averted. Implementing home-based self-sampling every five-years for women aged 15-30 years in rural areas, with a 90% screening coverage, was found to be highly cost-effective at $480 per DALY averted. A combined screening pathway incorporating home-based self-sampling in rural (80% coverage) and clinic-based screening in peri-urban areas (20% coverage) was valued at US$661 per DALY averted. This pathway would be considered very cost-effective under conservative thresholds (0.5 GDP< $728/DALYs).

Conclusion: Home-based self-sampling for girls and women aged 15-30 years living in high FGS prevalence areas is a cost-effective strategy for FGS screening in Zambia. With the growing interest in decentralising strategies for FGS screening, home-based self-sampling offers an effective approach.

abs-os392 Cost-Effectiveness of High-Dose Versus Standard-Dose Rifampicin for the Treatment of Buruli Ulcer: a Full Economic Evaluation Within a Trial in Ghana

PRESENTER: **Jacob Novignon**, Kwame Nkrumah University of Science and Technology
AUTHORS: Steven Walker, Yohannes Hailemichael, Abigail Agbanyo, Catherine Pitt, Richard Phillips, Yaw Amoako, Dorothy Yeboah-Manu, Michael Marks, Richard Adjei Akuffo

Background

Buruli Ulcer (BU) is a neglected tropical disease prevalent across many countries, particularly in West Africa. Without effective treatment, it can lead to life-long disability and deformities, creating substantial health and economic burden. Standard treatment with rifampicin (SR) and clarithromycin for 8 weeks can clear viable mycobacterium from wounds, but higher dose rifampicin (HR) may improve outcomes and permit shortening of treatment regimes. Treatment choices should reflect their effectiveness and efficiency, but little is known about the costs of experiencing or treating BU or the cost-effectiveness of alternative treatment regimes. We aimed to evaluate the costs and cost-effectiveness of HR vs. SR treatment for BU within a multicentre, individually randomized controlled trial at two hospitals in two regions (Eastern and Western) in Ghana.

Methods

Patients were enrolled in the trial from November 2021 until 31 July 2024. The primary trial outcome was assessed at four months from treatment initation, with follow-up of health outcomes and costs for 1 year where possible. Demographic, economic, and clinical data were collected from patients at enrolment and follow up points, health facilities (reflecting cost of treatment resources used) and project administrative data. Effectiveness was measured using quality-adjusted life-years (QALYs) with data collected using the EQ-5D-5L tool, disability-adjusted life-years (DALYs) and clinical scores. We present the cost per patient to the household and to the health service, and explore variation across socio-demographic characteristics, clinical disease stages, wealth, and trial arm. We examine the incremental cost per QALY gained and per DALY averted of HR vs. SR groups based on intention-to-treat analyses. Univariate and probabilistic sensitivity analysis was conducted to assess the impact of uncertainty and heterogeneity on cost-effectiveness results. All costs were inflated to 2024 values and converted to United States dollars.

Results

Forty two patients have been enrolled with no lost to follow up. Premilinary findings suggest an overall average cost of US$587. Disaggregating this indicate slightly lower average cost for the HR arm (US$551) compared to the SR arm (US$630). The key cost drivers include wound dressing materials and drugs costs. We also found improvements in quality of life across both arms between baseline and endline with higher average utility scores in the HR arm compared to the SR arm. The average utility score was 0.663 and 0.570 at baseline for HR and SR arms, respectively and this increased to 0.938 and 0.878 at endline for the two arms respectively. Additional effectiveness indicators including DALYs and clinical scores are currently being analysed, and an incremental cost effectiveness ratios (ICER) per effectiveness measure will be computed to determine which intervention arm is cost-effective.

Conclusion

Given the substantial health and economic burden of BU disease on households and the health services, our study provides important evidence to inform efforts to scale up cost-effective treatment interventions to improve BU treatment outcomes.

abs-os401 Cost-Effectiveness of RDTs for the Detection of *Trypanosoma Cruzi* Infections in Endemic Areas

PRESENTER: **Iris Lopes-Rafegas**, ISGlobal, Hospital-Clínic-Universitat de Barcelona
AUTHORS: Francesco Ramponi, Joaquim Gascon, Julio Alonso-Padilla, Albert Picado, Lourdes Ortiz, Elisa Sicuri, Faustino Torrico, Maria Jesus Pinazo

Background: Chagas disease (CD) is a vector-borne parasitic disease included in the World Health Organisation's list of neglected tropical diseases. It is caused by the *Tripanosoma cruzi* parasite. Despite being endemic to various regions of Latin America, its prevalence and associated morbidity and mortality remain largely unknown mainly due to scarce investment in efficacious health products, including diagnostic tools. Serology, the main diagnostic strategy in practice, has good performance but it requires lab equipment and capacities that are rarely available where the prevalence is likely to be highest, in rural and poor areas. As a result, the infection is under-detected, and when it is detected, the long time lapse between screening and obtaining the results is likely to reduce linkage to parasitic treatment.

Objectives: We model the cost-effectiveness of diagnostic strategies based on (new) rapid diagnostic tests (RDTs) only, RDTs combined with serology, and serology only as the comparator, for the detection of *Tripanosoma cruzi* in endemic areas.

Methods: We built a decision tree with a Markov model that represents the natural history of the disease. We represent health outcomes using Quality-Adjusted Life Year (QALYs) derived from a primary health-related quality of life data collection undertaken in Bolivia. Conservatively, we assumed most of the parameters to be equal between serology and RTDs and we carried out threshold analyses allowing us to estimate at which values of key parameters such as the linkage to care proportion of positive cases, RDTs would be more cost-effective than serology.

Results: Serology and the mixed strategy dominated the strategy based on RDTs only in our conservative scenario and, *ceteris paribus*, the incremental probability of linkage to treatment would need to reach 50% for the ICER to be as low as 4,000 USD, roughly the Gross Domestic Product (GDP) per capita of Bolivia, per QALY gained, for RDTs to be more cost-effective than serology.

Conclusions: RDTs are certainly key tools to improve the detection and the subsequent management of CD in endemic countries. However, more research is needed to understand the benefits of RDTs over serology and the possible scenarios for their implementation.

Actuarial and Financial Modeling for Universal Health Coverage: A Case Study of the World's Largest Single-Payer System

MODERATOR: **Manuela De Allegri**, University of Heidelberg

CONVENER: **Budi Hidayat**, Center for Health Economics and Policy Studies, Universitas Indonesia

abs-os65 Actuarial and Cost Models for Universal Health Coverage within the SHI Framework

PRESENTER: **Arif Budiman**, BPJS Kesehatan
AUTHORS: Budi Hidayat, Mahlil Ruby, Royasia Viki Ramadani, Taufik Hidayat, Thomas Hone, Judite Gonçalves, Christopher Millett

Background: Social Health Insurance (SHI) systems face significant challenges in ensuring financial sustainability under Universal Health Coverage (UHC). While SHI claims data are primarily used for invoicing, they also offer valuable insights for financial forecasting, pricing, and policy decisions. However, a gap exists in the literature regarding comprehensive actuarial cost models (ACM) that assess the long-term financial impacts of policy changes on SHI revenues and expenditures. This study develops an ACM to project the financial implications of both status-quo and policy-change scenarios for SHI systems.

Research Aim: This study aims to develop an ACM to forecast the financial impact of policy changes within the SHI framework. Specifically, it seeks to: 1) assess the financial state of SHI under the status quo; 2) evaluate the effects of policy changes, including cost-sharing and strategic purchasing, on long-term sustainability; and 3) provide actionable insights for improving SHI financing.

Methods: Two versions of the ACM are developed: the Basic ACM (BAM) and the Extended ACM (EAM). The BAM projects future costs based on historical claims data, including member-months, utilization rates, provider-billed costs, and medical loss ratios. The EAM builds on the BAM by incorporating policy parameters, such as cost-sharing and strategic purchasing, to evaluate their impact on future costs while adjusting for changes in patient and provider behavior. Both models are applied to Indonesia's JKN claims data from BPJS, covering January 2021 to June 2024. The dataset includes membership details, claim frequency, and provider-billed costs, categorized by member group and benefit type (e.g., primary and secondary healthcare services).

Key Findings: Preliminary results from the BAM indicate that JKN has faced a cash deficit since 2023, projected to continue through 2027. Despite deficits, JKN has been able to pay benefits using the Social Security Fund (DJS), established in 2021. Surpluses of IDR 45 trillion (USD 2.86 billion) and IDR 22 trillion (USD 1.4 billion) in 2021 and 2022, respectively, raised the DJS to IDR 68 trillion (USD 4.31 billion). However, a 2023 deficit of IDR 15.6 trillion (USD 991.4 million) reduced the DJS to IDR 52 trillion (USD 3.3 billion). Projections suggest that by 2027, the DJS could turn negative, with the claims ratio possibly reaching 109%. This would lead to annual deficits ranging from IDR 11 trillion (USD 698 million) to IDR 23 trillion (USD 1.46 billion), with a shortfall of IDR 18 trillion (USD 1.14 billion) by 2027.

Conclusions and Implications: This study underscores the importance of actuarial modeling in assessing the financial sustainability of SHI systems. The findings highlight the need for reforms, such as strategic purchasing and cost-sharing, to ensure long-term financial viability. Policymakers can use the BAM and EAM to evaluate the impact of policy interventions, guiding the development of health financing strategies that balance SHI sustainability with equitable access to healthcare.

abs-os67 Designing and Evaluating Cost-Sharing Policies for the Sustainability of JKN in Indonesia: An Actuarial and Financial Modeling Approach

PRESENTER: **Mahlil Ruby**
AUTHORS: Examinar Examinar, Donni Hendrawan, Pujiyanto Pujiyanto, Zahrina Laborahima, Atik Nurwahyuni, Budi Hidayat, Atmi Roseva, Mahlil Ruby

Background: In Indonesia, the Jaminan Kesehatan Nasional (JKN) system is grappling with rising healthcare costs, highlighting the urgent need for cost containment and quality assurance strategies, including a series of strategic health purchasing policies. While cost-sharing mechanisms are allowed under JKN, they have yet to be implemented, and hence their potential impact on the Social Security Fund (DJS) remains largely unexplored. This study aims to fill this gap by developing and evaluating several cost-sharing models to assess their effects on JKN's financial sustainability and long-term viability.

Research Aim: The study aims to develop different cost-sharing policies and evaluate ther potential impact on JKN financial status. Specifically, it seeks to (1) assess JKN's financial status without cost-sharing, (2) evaluate the impact of various cost-sharing models on JKN's sustainability, and (3) provide recommendations for policymakers on the optimal implementation of cost-sharing strategies.

Methods: This study employs two advanced actuarial models—the Basic Actuarial Model (BAM) and the Extended Actuarial Model (EAM). The BAM evaluates the financial health of JKN using historical claims data from BPJS Health (January 2021 to July 2024) under the current policy framework. In contrast, the EAM integrates a range of cost-sharing strategies, including copayments and coinsurance, across multiple scenarios: Base, Exclusion, Combination, and Selected models. These models differ in terms of which benefits and member groups are subject to cost-sharing, as well as the specific cost-sharing amounts. The EAM then analyzes the financial impact of these strategies on JKN's claims ratio, cash deficit, and DJS status, providing key insights into the sustainability of JKN's financing structure.

Key Results: Preliminary findings show that without cost-sharing, JKN is projected to face significant deficits, with the DJS potentially turning negative by 2027. Among the cost-sharing models, the SELECTED model—featuring a copayment of IDR 154,000 (USD 9.8) per outpatient visit and 20% coinsurance for inpatient services—substantially reduces the annual deficit, saving IDR 2.74 trillion (USD 175 million) in 2025. However, JKN is still expected to face a deficit of IDR 6.51 trillion (USD 417 million) by 2027, with the claims ratio consistently exceeding 100%.

Conclusions and Policy Implications: The results demonstrate that cost-sharing mechanisms, particularly the SELECTED model, can improve JKN's financial sustainability by reducing deficits. However, even with cost-sharing, JKN is unlikely to fully eliminate its financial shortfall. Policymakers should consider combining cost-sharing with other strategies to maintain the DJS's solvency. Clear regulatory frameworks and a robust management information system (SIM) are essential for monitoring and adjusting cost-sharing policies. Ongoing stakeholder engagement and regular evaluations will be key to ensuring that these mechanisms effectively balance cost control with financial protection for

JKN participants.

abs-os69 Determining SHI Contribution Levels: Integrating Strategic Health Purchasing, PMPM Costs, and Wage-Based Contributions

PRESENTER: **Royasia Viki Ramadani**
AUTHORS: Judite Gonçalves, Budi Hidayat, Thomas Hone, Christopher Millett

Background: Indonesia's National Health Insurance (JKN) faces persistent financial challenges, with rising cash deficits since 2023. The Social Security Fund (DJS) is projected to become insolvent by 2027 without policy intervention. While medical claim costs have surged, contribution revenues have not kept pace, threatening the program's sustainability. This study explores optimal JKN contribution rates and evaluates the impact of increasing benefit prices and implementing cost-sharing mechanisms to improve financial solvency.

Research Aim: The study aims to determine necessary adjustments to JKN contribution rates and assess the combined impact of increasing SHI benefit prices and the SELECTED cost-sharing model on JKN's sustainability for 2026–2027.

Methods: Actuarial and financial modeling are used to project health claim costs under the status quo and various policy scenarios, including increased SHI benefit prices, cost-sharing (copayments for outpatient visits and coinsurance for inpatient services), and strategic health purchasing policies. The study forecasts financial outcomes through 2027, offering recommendations for adjusting contribution rates for formal sector workers and subsidy levels for health insurance group members.

Key Results: The analysis shows a widening gap between medical claim costs and contribution revenues for JKN from 2022 to 2027. In 2022 and 2023, claim costs rose by 29% and 36%, while contribution revenues grew by less than 5%. Without policy changes, JKN is projected to face rising deficits, with the DJS potentially turning negative by 2027. The SELECTED cost-sharing model could reduce the annual deficit by IDR 2.74 trillion (USD 175 million) in 2025, but a deficit of IDR 6.51 trillion (USD 417 million) is still expected by 2027. To maintain solvency, JKN contributions should increase to IDR 88,100 per person per month (PMPM) for 2026–2027, with PBI participant contributions rising by 55% to 67%.

Conclusion and Policy Implications: To ensure JKN's long-term sustainability, it is critical to raise contribution rates, implement cost-sharing mechanisms, and adjust SHI benefit prices. While the SELECTED model helps alleviate financial pressure, ongoing reforms—including regular contribution increases and cost-sharing adjustments—are necessary. Policymakers should prioritize revising the Presidential Regulation on JKN contributions and consider the financial implications of benefit pricing to secure the DJS's solvency and JKN's viability in providing universal health coverage.

abs-os68 Evaluating the Impact of New SHI Benefit Pricing on Sustainability: An Actuarial and Financial Modeling Approach

PRESENTER: **Atik Nurwahyuni**
AUTHOR: Budi Hidayat

Background: Indonesia's National Health Insurance (JKN) program, a key component of the country's UHC policy, faces significant financial challenges as healthcare costs continue to rise. A major cost driver within the JKN scheme is the INA-CBGs (Indonesian Case Based Groups) spending, which absorb more than 85% of total JKN claims. Given these growing financial pressures, it is crucial to reassess the formulation of INA-CBGs tariffs to ensure they accurately reflect patient care costs. Recent innovations in costing methods aim to improve data quality and introduce more granular cost components, which are essential for generating accurate cost indicators and supporting the program's long-term sustainability.

Research Aim: This study aims to evaluate the potential impact of revised INA-CBGs tariffs, incorporating these innovative costing methods, on the JKN financial sustainability. It also explores how cost-sharing models, such as the SELECTED model, could help mitigate deficits and maintain the solvency of the Social Security Fund (DJS).

Methods: This study uses Actuarial Cost Model (ACM), including both the Basic Actuarial Model (BAM) and the Extended Actuarial Model (EAM), to simulate the financial effects of revised INA-CBGs tariffs with new costing methodologies. These methodologies focus on improving billing quality and cost data accuracy, including detailed breakdowns of direct and indirect hospital costs and the application of cost weights for more accurate procedure cost allocations. The EAM integrates these revised cost data with projections of future healthcare claims, claims ratios, and cost-sharing mechanisms (Study #2). While final simulation results are still pending, the model provides valuable insights into how tariff revisions and cost-sharing affect JKN's financial sustainability, aiding decisions on adjusting contribution levels.

Key Results: Preliminary findings from the BAM indicate that JKN has faced a cash deficit since 2023, with deficits projected to continue through 2027. Although the Social Security Fund (DJS) has been able to cover benefits using surpluses from 2021 and 2022, the DJS is expected to decline significantly by 2027, with estimated deficits ranging from IDR 11 trillion (USD 698 million) to IDR 23 trillion (USD 1.46 billion). The SELECTED cost-sharing model helps reduce the deficit, but the DJS will still face a shortfall, though smaller compared to the no-cost-sharing scenario. Additionally, implementing new SHI benefit pricing, such as a percentage increase in INA-CBGs prices, will inevitably raise JKN spending, further straining the fund.

Conclusion and Policy Implications: While the introduction of cost-sharing mechanisms can mitigate JKN's financial deficits, increasing INA-CBGs tariffs poses a significant risk to its sustainability. These measures alone will not guarantee long-term financial stability. Without an increase in contribution rates, JKN will continue to face mounting financial pressure from rising medical claims. The findings highlight the

urgent need for a comprehensive strategy to safeguard JKN's financial future. Policymakers must carefully assess the combined impact of INA-CBGs tariff adjustments and cost-sharing mechanisms when determining future contribution levels. The results from the EAM offer critical insights to inform decisions on adjusting contribution rates, ensuring the solvency of the Social Security Fund (DJS), and securing JKN's long-term viability.

How Effective is Managed Competition in Health Insurance? - Evidence from Medicare Advantage

MODERATOR: **Michael E. Chernew**, Harvard University

CONVENER: **Joseph G.P. Hnath**, Harvard University

DISCUSSANT: **Randall P Ellis**, Boston University, Department of Economics; **Bianca Frogner**, University of Washington Center for Health Workforce Studies

abs-os66 Competition and Entry in Medicare Advantage

PRESENTER: **Joseph G.P. Hnath**
AUTHORS: J. Michael McWilliams, Mr. Michael E. Chernew

Introduction ** The Medicare Advantage (MA) program enrolls 30 million beneficiaries with annual government expenditures surpassing $400B – a figure that is projected to continue increasing. A key component of the program is competition among firms to reduce prices and improve benefits. Initially, Medicare policy incentivized participation in MA by offering generous payments to plans, which helped establish markets where none existed or where offerings were limited. Early research on this phase found that more competitive markets passed through a greater share of these payments to beneficiaries.

However, the MA landscape has evolved significantly since the last studies on pass-through effects only as recently as 2011. Since then, MA enrollment has more than doubled, and plan bid rebates have increased by about 50%. Given these changes, it is crucial to reassess how competition affects plan bids in today's MA markets. Our research question is to determine the causal effect of additional competitors in MA markets on plan bids.

Methods * *We use publicly available data on MA plan offerings, bids, and enrollment. Since bids are made at the plan level, we aggregate the average number of competitors across markets where each plan is offered rather than conducting a market-level analysis. To identify causal effects, we employ the *Difference-in-Differences for Continuous Treatments* method developed by de Chaisemartin *et al.*, controlling for the average market benchmark rate. The primary outcome is the plan bid rebate, and the treatment variable is the average number of competitors in relevant markets.

Results ** From 2016 to 2021, the average number of competitors that MA plans faced increased from 5.8 to 7.5, although some plans experienced changes as large as losing 7.7 competitors or gaining 6.0 competitors. The preliminary results from our difference-in-differences analysis show a precisely estimated null effect for each additional competitor on plan bid rebates ($0.29; 95% CI: -$1.40, $1.99), with a sample mean rebate of $103. When focusing on the five largest national MA insurers (UnitedHealthcare, Humana, Aetna, Elevance, and Blue Cross Blue Shield affiliates), results are noisier but consistent with the overall findings. Economic theory suggests that entry effects would be more pronounced in less competitive markets; however, even in markets with below-median baseline competition, we find economically small effects (-$2.77; 95% CI: -$5.57, $0.02). Similar results hold when focusing on the aforementioned national insurers. Ongoing analyses explore mergers, competitor exits, and market-level analyses.

Conclusion ** Our findings suggest that firm entry does not lead to reductions in MA rebates, as we might expect if there were increases in competition. This may indicate diminishing returns from payment generosity in stimulating competition. More broadly, our study contributes to understanding how managed competition functions in health insurance markets and informs policy on market participation incentives.

abs-os673 Fewer, Shorter, Cheaper: Perioperative Costs of Elective Surgeries in Medicare's Private Managed Care Plans vs. Traditional Fee-For-Service Medicare

PRESENTER: **Eran Politzer**, Harvard University
AUTHORS: Timothy S. Anderson, John Ayanian, Bruce Landon, Vilsa E. Curto, Jeffrey Souza, Thomas Tsai, Alan Zaslavsky

Background

U.S. Medicare beneficiaries can enroll in private managed care health plans under the Medicare Advantage (MA) program or remain in the traditional fee-for-service Medicare (TM). Although elective surgery utilization rates are known to be lower in MA than in TM, it remains unclear whether the costs of surgical episodes also differ between the two programs for comparable MA and TM patients. This study investigates cost, efficiency, and outcome differences in surgical episodes between MA and TM, highlighting mechanisms by which managed care plans may achieve cost savings.

Methods

Using 2019 TM claims and MA encounter data, this retrospective cohort study compares costs, markers of efficiency, and outcomes of surgical episodes for MA and TM patients. The main outcomes included estimates of 30-day costs of surgical episodes and factors affecting those costs: the share of inpatient procedures, length of stay, share of patients discharged home, and readmission rates. Age- and gender-standardized surgery rates were calculated and 30-day mortality rates were examined as a balancing quality measure. Multivariable linear regression models were used to estimate differences in outcomes between MA and TM, controlling for surgery type, patient characteristics, Elixhauser comorbidity index, and hospital referral region. To differentiate cost differences arising from selection of hospitals and facilities into MA networks versus differential outcomes within the same facility, an additional specification included a fixed effect for the facility where the procedure was performed.

Results

The study analyzed 1.17 million procedures across 11 categories of common elective surgeries that could be performed in either inpatient or outpatient settings. The overall rate of surgery utilization was 4.4% (95% CI: 4.1 – 4.8) lower in MA than in TM, with variation by surgery category. Across procedures, 30-day costs of surgical episodes were on average lower in MA by 1.4% ($345, CI:$322 - $369). MA also had 8.6% (5.4 percentage points (pp), CI: 5.2 - 5.6) lower share of procedures billed at the higher inpatient rate, 6.4% (0.27 days, CI:0.26 -0.29) shorter length of stay in inpatient stays, and a 6.2% (3.8 pp, CI:3.7 – 4.0) higher share of patients discharged home. There was no significant difference in 30-day mortality rates between MA and TM. Seventeen percent of the lower cost in MA was attributed to between-facilities variation.

Conclusions

In addition to lower utilization of common elective surgeries, our results indicate that MA plans achieved lower surgical episode costs compared to TM by shifting procedures from inpatient to outpatient settings, shortening lengths of stay, and avoiding expensive post-acute care. These cost-saving strategies were not correlated with a significant increase in mortality, indicating efficiency gains without compromising patient outcomes. Our estimates indicate that steering patients to specific facilities also played a role in the observed results.

abs-os672 Nursing Homes as Insurers? Provider-Insurer Integration in US Nursing Homes

PRESENTER: **Amanda Chen**
AUTHORS: Michael McWilliams, Mary Beth Landrum, David C. Grabowski

Introduction

Institutional Special Needs Plans (I-SNPs) are a type of Medicare Advantage (MA) plan that allow insurers in MA to differentiate their benefits exclusively for long-term residents of nursing homes in the United States. When I-SNPs were first offered in 2006, the early I-SNP models were insurer-led as the plan was primarily at-risk for long-stay residents' Medicare spending. Today however, nursing homes have increasingly been entering the I-SNP market with I-SNP models differentiated based on the level of risk borne by the insurer and nursing home. When nursing homes offer a provider-led I-SNP, one might expect changes in both enrollment and the quality of care provided. As a result, our research aims to compare differences in enrollment and outcomes between long-stay residents who receive care in nursing homes with a provider-led I-SNP (treated) to long-stay residents who receive care in nursing homes with other types of I-SNPs or nursing homes without I-SNPs (untreated).

Methods

This study leveraged Medicare claims and the Minimum Data Set which provided data on the Medicare long-stay nursing home population from 2004 to 2021. Following the approach of Callaway and Sant'Anna (2021) to address heterogenous treatment effects with staggered treatment times, we used a difference-in-differences design to understand how greater nursing home involvement in the administration and operation of an insurance plan may lead to shifts in I-SNP enrollment. Additionally, because the incentives may differ between nursing homes that have greater risk sharing and stronger financial incentives, we assessed the effect of provider-led I-SNPs on facility-level outcomes, including hospitalizations, medication use, pressure ulcers, physical restraints, falls and mortality.

Results

Using Medicare claims and resident assessments from 2004-2021, we found that the offering of a provider-led I-SNP at a facility led to a 17.0 percentage point increase in I-SNP enrollment among facility residents within four years relative to control nursing homes. We also estimated that offering provider-led I-SNPs significantly decreased hospitalizations and increased the use of hypnotic drugs and reporting of pressure ulcers by nursing facilities. Relative to the baseline mean among treated nursing homes, we found relative declines of 18.2% for hospitalizations and increases of 30.3% for hypnotic drug use and 15.6% for pressure ulcers.

Conclusion

I-SNPs are responsible for a small, but growing, share of insurance among Medicare long-stay nursing home residents. These arrangements between a nursing home and insurer to administer an I-SNP designed to care for the needs of its long-stay population can allow provider-led I-SNP nursing homes to integrate both a tailored clinical and financial model which align their aims to improve cost, quality, and service. Our results suggest that risk bearing by nursing homes in the form of provider-led I-SNPs may successfully reduce utilization, but with unclear implications for quality and competition.

DISCUSSANT: **Lucy Xiaolu Wang**, University of Massachusetts Amherst

abs-os101 Competition in Pharmaceutical Markets: Evidence From the National Centralized Procurement in China

PRESENTER: **Julie Shi**
AUTHOR: Hanyang Li

Many studies have focused on competition in the pharmaceutical market. While the literature primarily focus on the upstream pharmaceutical market, that is, the competition between brand and generic drugs, the competition in the downstream pharmaceutical market receives little attention. Specifically, the research focusing on the drug competition between health care providers and retail pharmacies is extremely rare. Unlike developed countries in which pharmacies serve as the main channel for drug sales, health care providers play an essential role in drug retailing in many developing countries, such as China, India and Nigeria. Therefore, studies concerning the competition between providers and pharmacies in the pharmaceutical retail market is of great importance.

In this paper, we investigate the impact of competition on drug prices between medical providers and pharmaceutical retailers in China. Since 2019, the Chinese government has implemented a policy of centralized procurement on drugs and involved competitive bidding on their prices, which led to a huge price reduction. While this policy mainly applied on drugs in public hospitals, it is unclear how it affects the drugs prices sold at retail pharmacies. From the one hand, hospitals and pharmacies are competitors with each other in providing drugs to patients, so price reduction on one channel would make pressure to the other, and drugs prices in pharmacies tend to go down. From the other hand, however, if the two markets are highly segmented, the prices of drugs in the pharmacies may not be affected. More importantly, if the centralized procurement caused supply shortage or quality deterioration on drugs in public hospitals, the price of drugs sold at pharmacies may even increase. Therefore, the impact of the centralized procurement on drug prices at pharmacies remains an empirical question.

Using data from an online drug retailing platform, we explore the impact of the reduced drug prices in public hospitals on those at retail pharmacies. We find that the price of drugs with the same generic names as those that participated in the centralized procurement reduced by 16.6% on average, as compared to dietary supplements. This result suggests that the price reduction in public hospitals has been transmitted to similar drugs sold at retail pharmacies, but with a limited magnitude.

We then explore the mechanisms that limit the. First, the effect is concentrated on oral drugs treating chronic diseases such as hypertension and diabetes, but not on other OTC drugs or drus requiring injections. Second, price of drugs reduced to a smaller scale in the medical insurance designated pharmacies, where consumers could pay the bill through their medical account. Third, prices of drugs with manufactures that also provide drugs to the hospitals have reduced more than those with other manufactures.

Our work contributes to the literature on drug competition. The evidence suggests incomplete competition between hospitals and retail pharmacies. The work also enhances the understanding on the spillover effect of public policies. It shows that the centraliced procurement in public hospitals has affected the retail pharmacies in the priate sector.

abs-os102 HONORABLE MENTION FOR ADAM WAGSTAFF AWARD: Decentralized Policymaking and Market Distortions: Evidence From China's Drug Formulary Design

PRESENTER: **Chenyuan Liu**
AUTHORS: Haiting Tian, Wanyu Yang

In many countries, central governments establish essential medicine lists and drug formularies as part of public health insurance programs to enhance drug access and improve health outcomes. One open policy question is about whether drug formularies should be managed nationally or sub-nationally. Local governments often possess better information about regional health needs. However, decentralized drug formularies may harm equity, and may cause inefficiency and bias due to potential capture by local interest groups. This paper investigates the trade-offs between national and local policy-making in the context of drug formulary design in China.

China's public health insurance program introduced its first drug formulary in 2000, permitting provinces to adjust 15% of the listed drugs to reflect local conditions. While this decentralized approach aimed to address regional disease prevalence and demand heterogeneity, anecdotal evidence suggests that provincial governments often used it to prioritize local producers, resulting in market distortions. In light of this, the central government unified the drug formulary nationally in 2019.

This study examines whether provincial governments favored local firms in formulary design before 2019 and evaluates the social costs of this decentralization. Using hand-collected data on China's drug formularies from 2005, 2009, and 2017, we examine the relation between local firm presence and insurance coverage for the corresponding drug. To control for common demand factors, we restrict the comparison to drug-provinces with similar indications and mechanisms. We further employ an instrumental variable design, using the uncorrelated portion of historical disease prevalence with current disease prevalence as an instrument for the presence of local firms. Finally, we use the drug sales data

and employ an event study to examine whether drugs added to the provincial formulary experience an increasing pre-trend in demand.

We find robust evidence that the presence of local producers significantly increased the likelihood of their drugs being added to provincial formularies, independent of demand factors. The bias was particularly pronounced for local state-owned enterprises and joint ventures, with stronger effects for firms contributing higher tax revenues. However, firms investing more in research and development or providing significant local employment did not benefit disproportionately.

To assess welfare implications, we construct a conceptual framework comparing centralized and decentralized formulary designs. Decentralization leverages local information to tailor formularies to regional needs but introduces distortions due to local governments' private incentives, such as tax revenues and lobbying payments. Centralization mitigates these distortions but sacrifices responsiveness to local demand heterogeneity. Simulations based on our model reveal that decentralized policy-making achieved less than 20% of the potential social surplus under a first-best policy, whereas a national formulary achieved over 70%. These results support the 2019 reform's shift to centralized policy-making.

Our findings contribute to the literature on preferential policies favoring local firms, highlighting decentralized public insurance programs as an underexplored channel for local protectionism. Additionally, we extend discussions on optimal formulary design, connecting the context of China's healthcare system with broader themes in health economics. The results underscore the trade-offs inherent in balancing equity, efficiency, and responsiveness in public health policy-making.

abs-os134 Improving Regulation for Innovation: Evidence From China's Pharmaceutical Industry

PRESENTER: **Ms. Jianan Yang**
AUTHORS: Xiao Ma, Yiran Zhang, Ruixue Jia

Medical innovation is essential for improving health outcomes and extending life expectancy. However, most research in this field focuses on developed economies, leaving the challenges and opportunities in emerging markets underexplored. These markets face unique hurdles, such as government and market inefficiencies, which hinder pharmaceutical innovation. Traditional strategies like foreign direct investment (FDI) and state-led industrial policies have achieved limited success in this domain. This paper explores regulatory reform as a strategy to enhance medical innovation in emerging economies, focusing on China's experience.

A major barrier in emerging markets is the lengthy approval process for new drug development, which significantly delays innovation. Developed regions enjoy efficient regulatory systems, while developing nations often face substantial delays. For instance, before 2015, China's approval process for investigational new drugs (INDs) could take up to four times longer than in developed nations. Similar challenges led countries like Malaysia and Brazil to introduce reforms in the early 2010s, successfully reducing approval times. In China, regulatory inefficiencies, including a lack of personnel and expertise, caused severe delays and backlogs in drug applications. In response, the China Food and Drug Administration (CFDA) implemented 2015 reforms modeled after the U.S. Prescription Drug User Fee Act (PDUFA), introducing user fees to enhance staffing and infrastructure, which significantly reduced IND approval times.

This paper evaluates the impact of these reforms on the quantity and novelty of pharmaceutical innovation in China. By analyzing variation in reduction time at the drug level, measured over three years before and after the regulatory reform (2015–2017 vs. 2012–2014), and using a difference-in-differences strategy, the study finds that reducing approval time by one standard deviation (227 days) led to a 68% increase in INDs between 2018 and 2021. This growth was evenly split between existing and new firms, with clinical trials increasing across all phases. The reforms also influenced innovation novelty. While within-category innovation remained largely unchanged, shifts in firm composition significantly enhanced aggregate novelty. Specifically, the reforms accounted for 38% of the increase in new drug targets observed post-reform, with new firms contributing 74% of this growth. These firms demonstrated a strong focus on exploring novel targets, elevating overall industry innovativeness.

The study also examines market reactions, revealing that post-reform approvals of new drug applications (NDAs) elicited significantly more positive stock market responses than generic drugs. This suggests heightened market confidence in the reforms' effectiveness.

Overall, the research highlights how regulatory practices shape innovation. In emerging markets like China, inefficient regulation has long hindered innovation by raising costs and discouraging the entry of innovative firms. By addressing these barriers, targeted reforms can enhance both the quantity and quality of pharmaceutical innovation. This study contributes to the broader literature on regulation and innovation, emphasizing the importance of tailoring regulatory practices to the specific needs and challenges of emerging economies. It underscores the potential of strategic regulatory reforms to transform emerging markets into hubs of medical innovation, bridging the gap with their developed counterparts.

PRESENTER: **Madeline Brendle**
AUTHORS: Mr. Anton Avanceña, Jovan Julien

Alcohol use disorder (AUD) is the most common substance use disorder globally and is associated with increased healthcare costs and utilization. This cohort study evaluated the healthcare costs and utilization associated with AUD using Merative ™ MarketScan® Commercial Claims data from 2016-2020. The data contains patient demographics, diagnosis codes, and claims for inpatient/outpatient services and prescriptions. We identified individuals with an AUD diagnosis in each year of the study period (2017, 2018, 2019) based on at least 1 primary/secondary diagnosis of AUD in inpatient and outpatient claims using ICD-9/ICD-10 codes. Individuals were included if they were 18+ years old; had no missing values for key variables; and had at least 6 months of continuous health insurance coverage before and after the earliest date of their AUD diagnosis. We identified and measured patient-level sociodemographic and clinical characteristics. The outcomes estimated included healthcare utilization (i.e., inpatient visits and length of stay [LOS], emergency department [ED] visits, and total and AUD-indicated prescriptions) and costs (i.e., inpatient, outpatient, total and AUD-indicated prescriptions). AUD-indicated prescriptions included acamprosate, disulfiram, and naltrexone. Healthcare costs were estimated as the average per-patient per-month costs over the 6-month pre-index and 6-month follow-up periods. A random control group with no prior or current AUD diagnosis was identified and were matched to the AUD cohort using propensity score matching with a greedy nearest neighbor 1:1 matching approach with no replacement. After matching, generalized linear models were used to estimate the differences in healthcare costs and utilization between the AUD and control groups for the 6-month follow-up period. For healthcare costs, we used a log-link function with a gamma distribution and estimated average marginal effects (AME). For utilization outcomes, we employed a negative binomial regression to estimate incidence rate ratios. We identified 72,410, 76,075, and 73,485 individuals with AUD in 2017, 2018, and 2019, respectively. The study cohort for each year had a mean age of 41 (SD 14) and were predominantly male (63%). During the 6-month pre-index period, the AUD cohorts had the following service utilization: inpatient admissions (2017: 14,022 (19%), 2018: 13,479 (18%), 2019: 12,527 (17%)), outpatient services (2017: 67,088 (93%), 2018: 70,762 (93%), 2019: 68,999 (94%)), ED visits (2017: 25,992 (36%), 2018: 25,818 (34%), 2019: 22,883 (31%)), prescriptions (2017: 54,656 (75%), 2018: 58,123 (76%), 2019: 56,838 (77%)), AUD prescriptions (2017: 348 (0.5%), 2018: 263 (0.3%), 2019: 542 (0.7%)). In the 6-month follow-up period, individuals with AUD had significantly higher total healthcare costs compared to controls (p-value<0.0001), with an AME of $2,291, $2,131, and $1,978, for 2017, 2018, and 2019, respectively. This was primarily driven by inpatient costs, with an AME of $1,791, $1,832, and $1,852 in 2017, 2018, and 2019, respectively. Individuals with AUD in each year had significantly higher healthcare utilization compared to controls for LOS, ED visits, and prescriptions. This study demonstrates the continuing significant disease and economic burden of individuals with AUD. Healthcare cost and resource utilization associated with AUD may be reduced through appropriate treatment that targets reductions in alcohol consumption.

Ind-1002 Opioid Use Disorder Probabilities and Market Share by Use Disorder Status in Two Longitudinal US Medicaid Datasets

PRESENTER: **Ted Miller**
AUTHORS: Sandra Agik, Geetha Waehrer, Samisthra Pal, Allen Dobson

Background /Objectives. Litigation over the US opioid crisis provided temporary access to longitudinal Medicaid claims datasets from New Mexico (NM) and Nevada. Analyzing those datasets as plaintiff experts, we addressed two open questions:

1) From date of first opioid prescription and from date of first high-dosage opioid prescription of 90 morphine milligram equivalents (MMEs) per day, what is the probability of progressing to opioid use disorder (OUD) or overdose over time. 1) What portions of opioid beneficiaries, prescription claims, MMEs, and claims payments are for opioids dispensed to people who have diagnosed OUD/overdose or latent OUD.

Methods: The studied Medicaid programs cover low-income and disabled adults primarily under age 65. Some beneficiaries also are covered by Medicare; the files included all of their claims. Data covered 1/2006-7/2018 in NM and 1/2009-12/2018 in Nevada. Medicaid eligibility expanded in 2015. OUD and overdose were identified by diagnosis code. We defined latent addiction as prescription patterns consistent with opioid misuse or posing a high-risk for dependence and overdose: opioid prescriptions that overlap for at least 15 days, concomitant benzodiazepine and opioid prescriptions, concomitant naltrexone and opioid prescriptions, or an average of at least 90 MMEs per day over a 90-day period. We also studied three other groups: people (a) using less than 90 MMEs of opioids continuously for more than 60 days, (b) with catastrophic diagnoses only controllable with opioids – sickle cell disease, severe burns, or malignant cancer, and (c) intermittently using opioids briefly as in clinical trials. Beneficiaries in probability analyses had >=6 months of claims data before first opioid prescription or prescription pattern commencement. Probabilities we were able to compute varied by state.

Results: Among 342,119 NM beneficiaries prescribed opioids, 2% had catastrophic diagnoses, 12% had OUD/overdose, 8% had latent addiction, 1% used low doses long-term, and 77% used as in clinical trials. In sharp contrast, the percentages were 4%, 37%, 27%, 5%, and 27% for prescription claims and 7%, 53%, 31%, 3%, and 6% for MMEs and claims payments. Among 283,948 NV beneficiaries, comparable beneficiary percentages were 5%, 12%, 14%, 1%, and 68%, with claims and payments again concentrated.

In NM, among 334,926 beneficiaries without catastrophic diagnoses, from first opioid prescription, the OUD/OD probability was 8% within 5 years, 15.5% within 10 years, and 17.5% within 12 years. From latent addiction pattern emergence, it was 29.5% within 5 years, 45.5% within 10 years and 51% within 12 years. It was 29% within 5 years and 50.5% within 10 years in Nevada, with 10-year probabilities of 47%-52% for each component condition except concomitant opioid and naltrexone prescriptions, and a 47% probability with more than 60 days of continuous low-dose use.

Limitations: Some people with latent addiction are never diagnosed with OUD because constant prescription prevents withdrawal symptoms.

Conclusions: Addiction drives opioid demand/prescribing; 20% of users accounted for 84% of sales. Restricting access merely drives these users to street drugs. Had 17.5% and 50% probabilities of serious adverse events been disclosed, opioids probably would not have been approved for general use.

abs-os10 Do Peers Subvert or Support Recovery from Substance Use Disorders

PRESENTER: **Christiern Rose**, University of Queensland
AUTHORS: Jenny Williams, Anne Line Bretteville-Jensen

This research studies peer effects in recovery from substance use disorders. Peers are defined as individuals who share an inpatient treatment episode and reside in the same county, and we examine the impact of peer exposure on post-treatment mortality. The analysis draws on linked administrative data on the universe of individuals who are admitted to inpatient treatment for a substance use disorder in Norway. The impact of peer exposure is identified using variation in the timing of admissions into treatment, which institutional factors ensure is conditionally exogenous. Patients exposed to a greater share of peers from their home-county are found to have a lower mortality risk. A standard deviation increase in the share of home-county peers reduces mortality by 36% relative to the mean, with one additional peer leading to a 5% reduction. The peer-induced reduction in mortality is concentrated amongst individuals admitted for treatment for a drug use disorder (as opposed to an alcohol use disorder) and is driven by peers who themselves receive treatment for a drug use disorder. Informed by our theoretical model, the empirical findings for mortality are consistent with peer effects working through two potential channels; reduced substance use and safer substance use. Examining hospital admission episodes provides further insights into mechanisms through which peers reduce mortality. We find evidence for a dominant mechanism of safer substance use in the first year post-treatment, and for a dominant mechanism of reduced substance use three years after leaving treatment. We conclude that peers from inpatient treatment episodes can be instrumental in supporting recovery outside of clinical settings.

Ind-930 Depression in Ghana: Estimating Prevalence, Health-Seeking Behaviour, and Socioeconomic Drivers

PRESENTER: **Michel Adurayi Amenah**
AUTHORS: Ama Pokuaa Fenny, James Akazili, Irene Agyepong, Tolib Mirzoev, Thomas Mason

Background Depression is a growing global public health issue, affecting approximately 5% of adults. In Ghana, the burden is compounded by limited mental health services, stigma, and socio-economic disparities. Despite increasing recognition of mental health issues, research on depression in Ghana, particularly regarding its socio-economic and demographic determinants, remains limited. There is a significant gap in studies on depression prevalence, health-seeking behaviors, and the underlying drivers in Ghana. This study aims to estimate the prevalence of depression and health-seeking behavior among individuals with depression, and to examine the socio-economic drivers of both depression prevalence and health-seeking behavior. Addressing these gaps is vital for developing targeted interventions and policies for vulnerable populations. **Methods** This study used data from three waves of the Ghana Socioeconomic Panel Survey (GSEPS): 2009/2010 (5,009 households), 2013/2014 (5,010 households), and 2018/2019 (5,669 households), ensuring national representation through a two-stage stratified sampling method. Depression prevalence was assessed using the Kessler Psychological Distress Scale (K10), with participants categorized as "depressed" if they reported mild, moderate, or severe symptoms, and "not depressed" if they reported no significant depression. Health-seeking behavior was defined as consultation with a mental health professional within the past year. Logistic regression models were applied for each survey wave to examine the impact of socio-economic factors (age, gender, region, household size, marital status, education, employment, and religion) on depression and health-seeking behaviors. A random-effects model was used for the panel data to account for unobserved individual characteristics over time. Stata version 18 was used for the analysis. **Results** Approximately 30% of respondents experienced depression in the most recent wave, with severe depression affecting 3.5% of the population. Health-seeking behavior for depression was low, with only 14.9% consulting a mental health professional in 2018/2019, up from 6.38% in 2009/2010. Factors influencing depression prevalence included age, with the elderly (65+) showing higher odds (OR = 1.69, $p < 0.01$), and residents of the Northern Regions (OR = 1.81, $p < 0.01$). Education, particularly secondary education (OR = 0.72, $p < 0.01$), and marital status (OR = 0.601, $p < 0.05$) were protective factors. Health-seeking behavior was influenced by education (OR = 0.398, $p < 0.01$), region (OR = 0.364, $p < 0.01$), communal engagement (OR = 0.752, $p < 0.01$), and income (OR = 1.000, $p < 0.01$). **Discussion/Conclusion** This study highlights the need for targeted mental health interventions for vulnerable populations such as the elderly, widowed, and residents of the Northern Regions, who have higher odds of depression. Expanding mental health services in underserved areas and addressing regional disparities are crucial. The findings suggest that higher education and community engagement protect against depression, indicating that policies promoting mental health literacy in schools and strengthening community support networks could serve as effective preventive measures. The low health-seeking behavior among those with depression points to cultural and structural barriers to care, underscoring the importance of public health campaigns to destigmatize mental health and improve accessibility across socio-economic groups.

abs-os28 Behavioural Traits and Treatment for Substance Use Disorders: Evidence from Indonesia

PRESENTER: **Lisa Cameron**
AUTHORS: Firman Witoelar, Jenny Williams

Recovery from substance use disorders (SUDs) is a slow and difficult process, with relapse common and outcomes uncertain. While much of the accumulated evidence on the efficacy of treatment for SUDs is based on the experience of developed nations, illicit drug use and its associated problems are not confined to prosperous countries. In Indonesia, as with other countries in the Asian region, illicit drug use is a growing challenge. The National Narcotics Agency (Badan Narkotika Nasional, BNN) estimated that there were 6 million illicit drug users in Indonesia in 2017. Indonesia's public health response, underpinned by Law No. 35/2009 on Drugs and Government Regulation No. 25/2011, stipulates compulsory rehabilitation of drug addicts. The scale of the public health response is significant, with a presidential mandate requiring the rehabilitation of 100,000 drug users in 2015, 200,000 in 2016 and 400,000 in 2017. The largest single provider of drug rehabilitation services in Indonesia is the Indonesian government's National Narcotics Agency (BNN). In this research we seek to provide new evidence on the efficacy of BNN's treatment programs, and the role of behavioural traits in recovery from substance use disorders (SUDs). Using individual-level data on patients who undertake high-quality treatment programs at BNN facilities, we find treatment leads to improvements in locus of control (LOC). In contrast, we find no effect of treatment on time preferences or risk attitudes. We show that patients' changes in LOC are associated with a reduction in the frequency of their drug use, and with an increase in both employment and life satisfaction. These findings illuminate a key mechanism through which SUD treatment programs are effective at improving outcomes for people with SUDs in a low income setting.

Ind-1440 Understanding Patient Preferences of Patients with Type 2 Diabetes in Second-Line Drug Intervention: A Discrete Choice Experiment

PRESENTER: **Axel Mühlbacher**, "Gesellschaft f r empirische Beratung GmbH (Berlin), Germany"
AUTHORS: Ann-Kathrin Fischer, Magdalene Bravo Guijarro, Elke Mathey, Andrew Sadler

Background: Type 2 diabetes (T2D) and its treatment plays an increasing role in health care systems. Clinical guidelines provide serval options for second-line therapies without incorporating patient preferences. This study aims to analyze patient's perspective.

Methods: Data was collected between August and November 2023 among German people with diabetes who received metformin monotherapy (inexperienced with study subject) or second-line therapy (prior experiences with study subject). The study developed a discrete choice experiment with literature review, qualitative interviews, pre-tests and quantative online surveys. With a partial profile design, patients were given 12 choice tasks with 3 alternatives. The alternatives differed systematically in terms of benefits, side effects, and administration including risk of myocardial infarction, risk of stroke, risk of nerve damage, risk of nausea, risk of severe hypoglycemia, weight change, type and frequency of intake, and schedule of intake. A random parameter logit model was used for statistical analyses.

Results: A final study population of 583 adult patients (50% in each group) was reached. Risk of nausea, risk of nerve damage, and weight change were the most important attributes influencing choice decision followed by type and frequency of intake, risk of myocardial infarction, risk of stroke, and risk of severe hypoglycemia. In contrast, intake schedule has the least impact. Both study populations seem to have the same preferences on average. However, large standard deviations indicate considerable heterogeneity between respondents, particularly regarding weight changes and type and frequency of intake.

Conclusion: Low to no risk of nausea and nerve damage as well as weight changes are desirable features of treatment regimens for patients with T2D. Risk of myocardial infarction and weekly application also appear to play a crucial role in the evaluation of treatment from patient's perspective. For both groups, some respondents react more strongly to specific attributes than others.

Ind-1906 Societal Preferences for Attributes Associated with Health Gains: a Discrete Choice Experiment in Spain

PRESENTER: **Laura Vallejo-Torres**
AUTHOR: Cristina Valcárcel-Nazco

Background: Most health technology assessment (HTA) agencies exclude distributional concerns in cost-effectiveness analyses (CEA), assuming equal value for everyone's health gains. However, there is growing call for incorporating equity considerations into CEA frameworks. Agencies such as NICE in the UK and ZIN in the Netherlands use severity weights in their evaluations. In Spain, despite the increasing reliance on CEA evidence for decision-making, neither data nor evidence support the use of distributional weights in CEAs. Methods: We conducted a discrete choice experiment on a large and representative sample of the Spanish adult population. Participants were asked to indicate which of two hypothetical treatments they would prefer to be funded by the National Health System (NHS), irrespectively of whether they might ever need it or not. Each respondent was asked to compare eight pairs of treatments. Treatments options varied across five attributes: i) size of health gain achieved by patients, ii) type of the health gain (life expectancy, quality of life or both), iii) income level of target patients, iv) severity level of target patients, and v) cost (expressed as an increase in taxes paid by all citizens, including the respondent). A conditional logit regression model was used to analyse preferences, and marginal rates of substitution were calculated for each attribute relative to cost and health gain size. Results: We obtained responses from 2,500 individuals. Participants significantly preferred treatments with larger health gains,

that improved both life expectancy and quality of life, targeted low-income and high-severity groups, and entailed lower tax increases. Preliminary results show that participants are willing to pay 3.5€ per month in taxes to incorporate a treatment that provides an additional year in good health. They were also willing to pay 6.3€ and 1.8€ per month to incorporate treatments targeting the poorest 25% of the population and individuals with the highest severity level, compared to those targeting the wealthiest and least severe groups, respectively. Additionally, participants were willing to forgo health gains equivalent to six months in good health to prioritize treatments benefiting the most severe patients. These preferences remained consistent after adjusting for demographic and socioeconomic variables. Conclusions: This study provides the first evidence from Spain on societal preferences for attributes associated with health gains. The findings suggest that Spanish citizens assign greater value to health gains for individuals in lower-income or higher-severity groups, highlighting the importance of incorporating equity concerns in health economic evaluations.

Ind-2124 Valuing Preference with DCE By Explicit or Implicit Comparison with ""Immediate Dead"": Feasibility, Utility Distribution and Preference Equivalence

PRESENTER: **Haode Wang**
AUTHORS: Clara Mukuria, Richard Norman, Donna Rowen, Deborah Street

Introduction: Discrete choice experiments (DCEs) are increasingly used in health state valuation studies, though debate persists about the most appropriate method to anchor the utility values on the quality adjusted life year (QALY) scale. This study empirically compares two DCE preference elicitation design approaches for valuing health states, the DCE with a time attribute (DCETTO) and DCE with 2 health profiles and an “immediate death” state as the third option (DCEdeath). The study examines the feasibility, utility distribution and preference equivalence of the two methods using the health and wellbeing measure EQ-HWB.

Methods: Two separate DCE task designs were developed: the DCETTO task was a paired comparison with a varying duration attribute, while the DCEdeath task asked the respondent to select the most and least preferred state from three options, of which one was the dead state. The online survey was administrated to representative samples of the UK and Australian general public. Respondents were randomly allocated to one DCE design and asked to complete 13 tasks. Conditional logit regression was used to generate latent preference values. The coefficients of DCETTO were divided by the duration coefficient and coefficients of DCEdeath were divided by the dead state coefficient to generate the anchored values. Feasibility was evaluated by comparing data quality, decision strategy and feedback. The value set distribution and preference equivalence were evaluated by comparing anchored utility decrements and health state utility values in each country. Regression analyses assessing the impact of anchoring whilst controlling for sub-group characteristics, were used to test the robustness.

Results: Over 2900 respondents completed the DCE survey and passed data quality checks (1453 from UK and 1465 from Australia). Both DCE task designs generated high-quality data and over 90% of all respondents reported no problem in understanding/completing the tasks. Regression analysis produced mainly monotonic coefficients (larger utility decrements for worse health), with a higher proportion of insignificance observed with the wellbeing attributes. Average completion time with DCEdeath task was longer, while the proportion of respondents reporting use of heuristic decision strategies decreased from 47% (DCETTO) to 11% (DCEdeath). The DCEdeath value set has wider utility range with more health states classified as worse-than-death (WTD), increasing from 17% to 24% in the two countries. However, no significant utility value differences identified with health states classified as better-than-death. Significant attribute level disutility differences observed for level 4 and 5. Ranking for EQ-HWB health states remained the same, with a Pearson’s statistic of 0.93. The conclusion remained similar in subgroup analysis.

Conclusion: This is the first study to directly compare the health and wellbeing preferences for a long instrument using both DCETTO and DCEDeath designs. Both designs are feasible but yield substantially different results about whether a state is WTD or not. The study sheds light on the importance of DCE task framing, which should be taken into account in future valuation study design.

Ind-2833 The Effect Between Food Photos and Traffic Light Labelling System in Online Food Choice

PRESENTER: **Dr. Yuan Yuan Wang, PhD**

Abstract **Background:** Consumers are increasingly using online-to-offline (O2O) takeaway apps rather than phone calls to order food from local restaurants. However, the lack of health information may increase the risk of over-intaking unhealthy food. The Traffic Light Labelling System (TLS) uses colour codes to indicate the nutritional quality of food items, providing a quick reference for calorie, fat, sugar, and salt content to nudge consumer’s food choices. It has become increasingly crucial in online takeaway food selection. While previous studies have primarily focused on how TLS assist consumers making healthier food choice on offline food choices, the impact of TLS and food photo on online takeaway choice behaviour and their potential interaction effect have been less explored. **Aim:** This study aims to identify the main effect and interaction effect between food photos and TLS in online food choice. **Methods:** This study combined a Discrete Choice Experiment (DCE) and the 2 × 2 Randomized Controlled Factorial Trial Design. A final list of attributes and their levels for the DCE was generated using a detailed iterative process. This included a literature review, six focus group with those O2O takeaway users. From this process a list of attributes was obtained. Following a three pilot studies, the final list of attributes was selected (meal types, price, online reviews, delivery time and TLS). We used D-efficient design to construct an experimental design for the survey. The survey consisted 24 choice cards, each choice card with three alternatives and one non-purchase option. To ensure reliability, 1,864 aged 18-39 years adult subjects were randomly allocated into one of four DCE surveys: with food photo and TLS, without food photo but with TLS, with food photo but without TLS, without food photo and TLS (Control group). The outcome is the calories, fat, sugar and salt of the chosen food. **Results:** The main effect of TLS is significant on the influence of fat and sugar intake. The main effect of food photos are significant on the influence of salt and calories. The interaction effect between TLS and food photos is only significant on sugar intake. **Conclusions and Implication:** The findings from this study have important implications for online food ordering platforms and public health interventions. The significant interaction between food photos and TLS on sugar intake suggests that the combination of these two elements can be strategically leveraged to

influence consumer behavior.

Ind-1493 Should Willingness-to-Pay Thresholds Change With Disease Severity

PRESENTER: **Erik Grönqvist**, Uppsala University
AUTHORS: Amin Hussain, August Wadell Leimdörfer, Per Johansson

How should limited resources for health care be prioritized? Health economic evaluation can inform policy makers if new medical treatments are good value for money. The standard cost-effectiveness framework maximize QALY gains regardless of how the gains are distributed. However, the way health is produced matters for most people. With general preferences for equity in society, also disease severity would matter for welfare when prioritizing. With public preferences over both disease severity and cost-effectiveness, policy makers need to balance equity with efficiency.

The previous literature on this trade-off is inconclusive (both higher and lower value to disease severity is suggested) likely due to methodological short comings: Using high dimensional DCEs will bias results due to complexity faced by respondents.

To generate consistent estimates, we instead suggest a very stripped down DCE that only compares health related quality of life (HRQoL) and disease severity (DS=1- HRQoL), where both are measured on the same one-dimensional scale 0-1 (0=dead, 1=full health). We also developing a novel and yet very simple way to calculate distributional weights for different level of disease severity in monetary units, which enables an easy scaling up the WTP/ICER thresholds.

Our results show that the Swedish population not only values the amount of health created, but also how it is distributed, prioritizing patients of worse health. The latter supports using higher willingness-to-pay thresholds to treat patients of greater degrees of severity. We find that an HTA-agency should have a twice as high WTP (ICER) threshold for diseases towards patient groups with moderate disease severity (DS=0.5) compared to groups with low disease severity (DS=0.3), and three times as high WTP (ICER) threshold for patient groups with high/very high disease severity (DS=0.7).

Ind-852 Mapping KDQoL-36 Onto EQ-5D-5L And SF-6D v2 in Patients Undergoing Dialysis in China

PRESENTER: **ye zhang**, Renmin University

Background: KDQoL-36 were used widely in clinical settings for dialysis patients but it does not allow for the calculation of a quality of life utility score like the EQ-5D-5L or SF-6D v2 and thus cannot be used to calculate the quality-adjusted life year which is used for conducting economic evaluations that is important for healthcare decision-making. One possible solution is to build a mapping algorithm convert KDQoL-36 into EQ-5D-5L or SF-6D v2. This study for the first time generates mapping algorithms for transforming KDQoL-36 scores to EQ-5D-5L utilities and SF-6D v2 utilities used for health economic assessment in China. **Aim:** To develop the mapping algorithms from KDQoL-36 scores onto the EQ-5D-5L and SF-6Dv2 utility values among the dialysis patients in China. **Methods**: We used data from a cross-sectional multicenter survey study in China to map KDQoL-36 onto EQ-5D-5L and SF-6Dv2. The conceptual overlap between the KDQoL-36 and the EQ-5D-5L or SF-6Dv2 was evaluated by Spearman's correlation coefficients. Direct mapping (including OLS, GLM, BRM, TRM, CLAD and ALDVMM) and response mapping (SUROPM) were used to derive mapping functions using the dataset. The model performance was assessed by mean error (ME), mean absolute error (MAE) and root mean square error (RMSE) using 10-fold cross-validation. The KDQOL-36 is made up of a set of subscales scores: PCS, MCS, Symptoms, Effects, Burden and KDCS. The KDCS has been used as an alternative for the other three subscales scores. We therefore mapped from the KDQOL-36 to EQ-5D-5L or SF-6Dv2 using two sets of explanatory variables. **Results**: A total of 378 patients (50.53% female; mean [SD] age: 49.05 [13.34]) were included in this study. The mean utility values of EQ-5D-5L and SF-6D v2 were 0.72 and 0.57, respectively. The correlation between the KDQoL-36 subscales and the observed SF-6D v2 utilities or EQ-5D-5L utilities was strong ($0.60 < r \leq 0.80$) and moderate ($0.40 < r \leq 0.60$) statistically significant, respectively. When mapping to EQ-5D-5L, the application of each predictor set was combined with each regression method, which resulted in 49 candidate models for the EQ-5D-5L mapping function. The ALDVMM with 1 component was the best-performing model (MAE = 0.1579, RMSE = 0.2289). When mapping to SF-6D v2, the application of each predictor set was combined with each regression method, which resulted in 45 candidate models for the SF-6Dv2 mapping function. The TRM was the best-performing model (MAE = 0.1108, RMSE = 0.1508). Generally, KDQOL-36 subscale scores with their square was the optimal predictor set among each model. Overall, models using KDQOL-36 subscale scores showed better fit than using the KDCS. **Conclusion**: ALDVMM and TRM models with the KDQoL-36 scores can be used to predict the EQ-5D-5L and SF-6Dv2 utility values, respectively, among dialysis patients in China. Our mapping algorithms provide an empirical basis for estimating health utilities in dialysis patients when EQ-5D-5L or SF-6Dv2 data are not available. **Keywords:** EQ-5D-5L; SF-6Dv2; KDQoL-36; Mapping; Dialysis

Ind-453 Productivity-Adjusted Life Years (PALYs) And Condition-Specific PALY Loss Among The Late Middle-Aged Adults in China: a Microsimulation Analysis

PRESENTER: **Yawen Jiang**
AUTHORS: Lei Si, Shan Jiang, Wenjie Hu, Huiqiao Gu, Bingxin Hu, Yuanyuan Gu

Background: While conventional measures like disability-adjusted life years (DALYs) focus on health burden, productivity-adjusted life years (PALYs) specifically capture workforce productivity impact of health, which provide unique insights on disease burden by directly measuring economic productivity losses. Despite established PALY estimates in several countries including Australia, Finland, and South Africa, such estimates remain unavailable for China, limiting evidence-based policy-making for its aging workforce.

Objectives: We sought to estimate both individual-level PALY expectancy and population-level total PALYs for the Chinese population aged 50 to 64years. Specifically, the objectives were threefold: to quantify individual PALY expectancy across different age groups and sociodemographic characteristics, to project total population-level PALYs through 2032, and to estimate condition-specific PALY losses at both individual and population levels.

Methods: Using the previously published and validated China Aging and Retirement Simulation Model (CHARISMA), we calculated individual PALY expectancy and condition-specific PALY losses for three age cohorts (ages 50-54, 55-59, 60-64). The model incorporated data from the 2011-2018 China Health and Retirement Longitudinal Study (CHARLS) and simulated individual life trajectories until age 65 or death. Individual-level PALYs were calculated by integrating three components: workforce participation status, productivity loss due to health-related absenteeism, and mortality risk. The simulation tracked 14 specific health conditions and their impact on productivity using annual cycles. Population-level total PALYs were then projected by combining individual PALY estimates with 2018 Chinese population data, forecasting accumulated PALYs through 2032. A probabilistic sensitivity analysis with 1,000 iterations addressed parameter uncertainties by resampling regression coefficients. Condition-specific PALY losses were estimated at both individual and population levels using a counterfactual approach, nullifying each health condition's risk separately while maintaining other parameters. Results were stratified by sex, residence (urban/rural), educational attainment, and marital status.

Results: Average PALY expectancy was 6.80, 4.35, and 1.50 years for ages 50-54, 55-59, and 60-64 respectively, with consistent sociodemographic patterns across all groups. Gender disparities persisted throughout, with males showing higher PALY expectancy (7.45 vs 6.13 years for ages 50-54; 4.80 vs 3.90 for ages 55-59; 1.75 vs 1.25 for ages 60-64). Rural residents consistently demonstrated higher PALY expectancy than urban residents (rural-urban difference: 2.31, 1.73, and 0.71 years for respective age groups). At the population level, projected total PALYs through 2032 reached 1.24 billion years (95% CI: 1.02-1.46 billion). The most significant condition-specific impacts were from dyslipidemia (>80 million population-level PALY loss) and hypertension ~70 million PALYs), with similar patterns across all cohorts.

Conclusions: This study reveals substantial sociodemographic variations and identifies major health conditions impacting workforce productivity. The findings can guide targeted health interventions and inform policies aimed at sustaining workforce productivity and social security amid China's demographic transition.

Ind-629 Comparing EQ-5D-5L and SF-6Dv2 in Measuring Health Status of People Living with HIV/AIDS in China

PRESENTER: **Qing HE**
AUTHORS: Jia Yin, ZhinXin Fan, Qiang Sun

OBJECTIVES: Globally, an appropriate estimate of the health-related quality of life (HRQoL) of people living with HIV/AIDS (PLWHA) is essential for the economic evaluation of antiretroviral therapy (ART) programs to ensure optimal value for money. AIDS is often accompanied by co-morbidities, which complicate and confound data interpretation concerning AIDS-related mortality, costs and quality of life. There is a lack of performance comparisons of the generic quality of life tool EuroQol Five Dimensions Questionnaire (EQ-5D-5L) against Short Form Six-Dimension (SF-6Dv2) among PLWHA in China. This study aimed to compare measurement properties of EQ-5D-5L and SF-6Dv2 among PLWHA, to evaluate the HRQoL of PLWHA on ART and to explore its predictors. METHODS: All PLWHA were recruited from two hospitals in Jinan and Qingdao, Shandong Province, China from November 2023 to January 2024. Respondents were randomly selected and invited to complete both the EQ-5D-5L and SF-6Dv2 through face-to-face interviews or self-administration. The existing Chinese-specific value sets of EQ-5D-5L and SF-6Dv2 were used to calculate the health utility scores (HUS) . Ceiling and floor effects were firstly evaluated. The agreement of HUSs was evaluated by intraclass correlation coefficient (ICC) and Bland-Altman plot. Convergent validity of HUSs and similar dimensions were assessed using Spearman’s correlation coefficient. Known-group validity of the HUSs and EQ-VAS scores was assessed by comparing the scores of PLWHA at different infection stages, and the scores of PLWHA with and without comorbidities. Additionally, factors affecting HUS difference were explored with Tobit regression analysis. RESULTS: Among 313 respondents (94.3% males, mean age 38.12±11.09 years, 9% CD4<200 cells/mm3) in this study, 48.24% of respondents reported no problems on all dimensions of EQ-5D-5L, whilst 10.22% in SF-6Dv2. The strong correlation and agreement between two measures was observed according to Spearman’s rank correlation (0.71) and ICC (0.74). Bland-Altman plot indicated that HUSs were generally higher in EQ-5D-5L, and the mean HUS was higher in EQ-5D-5L than in SF-6Dv2 (0.92 vs 0.78). Meanwhile, strong correlation was detected for two similar dimensions (Pain/Discomfort of EQ-5D-5L and Pain of SF-6Dv2; Anxiety/Depression of EQ-5D-5L and Mental Health of SF-6Dv2). All the three scores could discriminate the difference in the known-groups. Both HUSs were more sensitive than EQ-VAS score. Tobit regression showed that socioeconomic and clinical factors had a significant influence on the difference in HUSs (P< 0.05) . Co-morbidities, economic level and the economic burden of ART had a large impact on utility. CONCLUSIONS: Both EQ-5D-5L and SF-6D appeared to be valid utility instruments among PLWHA in China. However, they cannot be used interchangeably given only moderate agreement was identified, and differences in utilities and ceiling effect were revealed. Further research is warranted to compare the test-retest reliability and responsiveness. The findings suggest that PLWHA receiving ART had good HRQoL. However, concerted efforts targeted at improving CD4 cell count and reducing the economic burden of PLWHA would enhance their HRQoL.

Ind-965 Estimating the Health and Economic Burden of Stroke Among Informal Caregivers in Australia Using Productivity Adjusted Life Year (PALY)

PRESENTER: **Neha Das**

AUTHORS: Dieu Nguyen, Lan Gao, Suzanne Robinson, Peter Lee

Background: The Productivity Adjusted Life Year (PALY) is a novel measure for exploring the societal impact of health conditions on work productivity. It accounts for productivity loss due to absenteeism and presenteeism, labour force dropout, and premature mortality, representing a comprehensive measure for quantifying the productivity impact at the population level. Given that stroke contributed to 143 million DALYs (disability-adjusted life years) (5.7% of total DALYs) in 2019 and the crucial role of caregivers in post-stroke care, it is imperative to understand the productivity impact on caregivers of stroke patients. Apart from this, studies have also demonstrated that there is a negative impact on the quality of life (QoL) of informal caregivers. Aim: Our study aims to estimate the population-level productivity loss of informal caregiving in stroke by quantifying the PALY loss associated with stroke caregivers and the impact on their QoL by calculating quality-adjusted life year (QALYs). Method: Dynamic life table modelling was used to simulate the Australian working-age population (aged 15–65 years) over 30 years of follow-up (2023-2052 inclusive). The model compared the Australian stroke informal carer group and a matching cohort of non-carers. Data was obtained from literature, and publicly available data such as Australian Bureau of Statistics (ABS) and Survey of Disability, Ageing and Carers (SDAC). The population of informal carers was updated in each annual cycle by considering the new cohort of informal carers due to change in the stroke population (forecasted using simple linear regression) and death of informal carers. Labor force participation rates were applied to population estimates to calculate the full-time equivalent (FTE) which was then multiplied by the productivity index and years of life lived (YLL) to estimate PALYs. Productivity index was calculated using absenteeism and presenteeism, sourced from the literature. The unit cost for a PALY was based on the GDP (gross domestic product) per FTE for the corresponding year. Trend in GDP per hour worked from 1975 to 2023 from the ABS was used to project the GDP per FTE for a given year based on a 40-hour work week and 48 weeks worked per working year. Furthermore, the utility values were multiplied by YLL to calculate QALYs. The model was constructed using Microsoft Excel® (Microsoft Corporation, Redmond, WA, US) and outcomes accrued beyond the first year were discounted at 5.0% per annum. Results: Over a 30-year period, 29,701 QALYs, 69,7488 PALYs were lost due to the health and productivity burden attributed to the provision of informal care for stroke patients. The total cost attributed to lost productivity among informal carers for patients with stroke over 30 years was AU$ 14.7 billion. On average, annual informal carer losses were 990 QALYs and 2,250 PALYs, corresponding to AU$ 490 million per year in productivity loss in Australia. Conclusion: Our analyses demonstrate the health and economic consequences of providing care to stroke patients over the forthcoming decades and highlight the need for interventions to reduce the burden of stroke and its impact on caregivers.

Ind-975 Age-specific Health Utility Decrement Associated with Loneliness: Evidence from Australian Longitudinal Data

PRESENTER: **Muhammad Fikru Rizal**

AUTHORS: Matthew Hamilton, Cathy Mihalopoulos, Lidia Engel, Michelle Lim, Arul Earnest, Sharon Clifford

Objective: Loneliness is increasingly recognised as a public health issue due to its known negative impact on health and quality of life. Accurately measuring the health utility decrement associated with loneliness is important, particularly when assessing the cost-effectiveness of interventions to address loneliness. This study aims to examine the extent to which loneliness is associated with reductions in health-related quality of life (HRQoL) in the Australian population by age groups that reflect different life stages and assessing the impact of adjusting for different set observed individual's characteristics.

Methods: Data were drawn from Household Income and Labour Dynamics of Australia (HILDA) Survey. HRQoL was measured using the SF-6D utility score with Australian population weights. The main exposure variables were loneliness, indicated by respondents reporting a score of 5 or higher (on an agreement scale of 1–7) to the statement, "I often feel very lonely". Age was grouped as 15-24, 25-44, 45-64, and 65+ to reflect varying life stages. The main statistical approach is the within-person analysis using linear fixed effects estimator. Time-varying characteristics were used as control variables. These include sociodemographic factors (age, marital status, education level, and per capita income), a dummy indicator for area of residence, a binary indicator for disability, and serious health conditions (binary indicator for common diseases like arthritis, chronic bronchitis, diabetes, depression or anxiety, other mental illness, heart disease, high blood pressure, and any other serious circulatory conditions).

Results: The study analysed a total of 52,963 person-waves, with 53% female participants and 17.5% aged 65 or older. Among those without loneliness, the mean (and standard deviation) of the SF6D health utility for the age groups 15-24, 25-44, 45-64, and 65+ were 0.737 (0.190), 0.719 (0.20), 0.662 (0.229), and 0.585 (0.255), respectively. The unadjusted utility decrements (with standard error in parentheses) associated with loneliness were 0.098 (0.009) for 15-24 years, 0.090 (0.005) for 25-44 years, 0.059 (0.005) for 45-64 years, and 0.043 (0.007) for those aged 65 and above. After adjusting for sociodemographic factors, disability status, and chronic disease conditions, the decrements were slightly reduced to 0.083 (0.010), 0.076 (0.005), 0.058 (0.005), and 0.036 (0.007) for the respective age groups. Sex-specific results show that loneliness is associated with larger health utility decrements in young females (15-24 years) compared to males of the same age. In contrast, older males (65+) exhibit slightly higher decrements than females.

Conclusion: The findings suggest that loneliness is associated with a substantial reduction in HRQoL across all age groups, even after controlling for individuals' socioeconomic characteristics and health conditions. Young adults were found to be experiencing a more pronounced decrement, especially among females. Overall, this evidence is valuable for guiding targeted, cost-effective interventions to address loneliness.

Individual, Community and Social Preference Elicitation

MODERATOR: **Henry Cutler**,

Ind-2222 What do we Value in Value-Based Health Care? Exploring Social Preferences using a Discrete Choice Experiment

PRESENTER: **Mona Aghdaee**, Macquarie University
AUTHORS: Henry Cutler, Yuanyuan Gu, Dandan Yu, Olukorede Abiona

Background: Healthcare spending in high income countries is often wasteful. The United States wasting between 21-47 per cent of national healthcare expenditure annually. System managers and payers have turned towards value-based healthcare (VBHC) to reduce financial waste and improve health outcomes. Understanding what society values in VBHC is critical for aligning resource allocation decisions with patient preferences, to deliver outcomes that matter to patients. **Aims**: Our study sought to identify and measure social preferences that underpin VBHC. We sought to extend the literature by measuring in detail how social preferences for VBHC vary across respondent characteristics. The purpose was to help system managers and payers make better evidence-based trade-offs when making VBHC resource allocation decisions. **Methods:** We combined semi-structured interviews with 20 local health network executives and a Discrete Choice Experiment (DCE) administered to 1,000 nationally representative Australians. Interviews explored resource decision-making processes and VBHC objectives. DCE attributes included all criteria from the Quadruple Aim framework embraced by the U.S. Department of Health and Human Services (HHS). Two experiments were created using a D-efficient factorial design, with participants randomly allocated to each block. Data were analysed using the mixed logit (MIXL) model. Interactions with individual characteristics explored observed preference heterogeneity. A latent class logit model was also estimated. Relative attribute importance was compared across different classes and the posterior probability of class memberships was regressed against individual characteristics using the fractional logit model. **Results:** All VBHC attributes emerged as predictors of choice. On average, respondents assigned the highest relative importance to health outcomes, followed by the likelihood of achieving the desired health outcome and care efficiency. 'Provider experience' had the least impact on respondent choices. Age significantly impacted choices. Older respondents placed more value on patient experience, timeliness of elective surgery, and health outcomes. Younger respondents placed more value on care efficiency. Respondents with greater education placed greater value on patient experience, while respondents with multiple chronic conditions placed more importance on increased certainty of achieving health outcomes and reduced waiting times. Use of the healthcare system in the last 12 months impacted respondent preferences. Of four identified latent classes, Class 4 was the largest membership group with strong preferences for better patient experience and outcomes. Class 2 and Class 3 represented moderate groups with varying preferences. Class 1 was the smallest membership group with strong preferences for care efficiency. **Conclusions:** Our study provides strong evidence of heterogeneous patient preferences for VBHC attributes. This suggests using one set of patient preferences within priority decision making processes will not optimise welfare, nor lead to a VBHC system valued by patients. The relatively large value placed on efficiency by respondents on average suggests their potential concern with current healthcare system waste. This concern was not being driven by altruism, instead it potentially reflects concerns by respondents on future access to health care.

Ind-1030 Genomic Risk Assessment to Inform Risk-tailored Cancer Screening: Community Preferences in Australia

PRESENTER: **Alison Pearce**, University of Sydney
AUTHORS: Julia Steinberg, Karen Canfell, Michael Caruana, Anne Cust, Amelia Smit, Louisa Collins, Cynthia Low, Richard Norman, Amber Salisbury

Background: Genomic testing (for "polygenic risk scores") can provide valuable information on individuals' risk of different diseases including cancers, presenting an opportunity for risk-tailored cancer screening to improve early detection and health outcomes. Potential programs consist of several stages: initial decision to take the genomic test, risk assessment (test itself and return of results), and subsequent cancer screening. Public preferences for program features at each stage can influence a program's acceptability, uptake, and effectiveness. **Aims:** (1) To quantify the preferences of the Australian general population for potential features of genomics-informed risk tailored screening; (2) To assess heterogeneity of preferences. **Methods:** Two online discrete choice experiment (DCE) surveys were conducted in Australia focusing separately on the decision-making and risk assessment stages. Attributes for the decision-making stage DCE were: when and how you are invited, what information you receive before taking the test, whether there is an appointment to discuss the pros and cons, where you do the test, what the test covers and the cost of the genomic test. Attributes for the risk-assessment stage DCE were: how the genomic results are received, who performs the genomic risk prediction, how representative is the genomic risk prediction, data storage of results, information included in the risk assessment, what the genomic test covers and cost of the genomic test. In each DCE participants answered 12 choice tasks showing two alternative genomic testing programs, and an opt-out option only in the risk assessment DCE. Results were analysed using conditional logit, mixed logit and latent class models, and the willingness-to-pay was calculated. **Results:** There were 821 participants in the decision-making stage DCE and 801 in the risk assessment stage DCE, all generally representative of the Australian population. For the initial decision-making stage, few attributes were significant, with the strongest preference for a comprehensive risk test including multiple cancers ($p<0.01$), or multiple cancers and other serious diseases ($p<0.01$), rather than a single-cancer test. For the risk assessment stage, participants preferred more comprehensive testing, results including advice on non-genomic risk factors, and genomic analysis by a government health department (versus an international company). Some preferences were particularly strong, with willingness-to-pay of $168 for a comprehensive multi-disease test (versus a single-cancer test), and $140 to avoid opting out of risk assessment. Those with negative attitudes towards genomics were more likely to opt-out ($p<0.01$) and indicate concerns about genomic data storage ($p<0.05$). **Conclusions:** This study suggests that the

public would be interested in genomic risk assessment, and have few concerns about deciding to take a genomic test to inform cancer screening. However, they have strong preferences for ow the test is taken and how results are communicated, as well as wanting more comprehensive tests. These findings can help design potential acceptable and effective genomics-informed cancer screening programs tailored to the Australian context.

Ind-1682 Medical Students Preferences for Specialty Choice in South Korea: A Discrete Choice Experiment

PRESENTER: **Moo Hyuk Lee**
AUTHORS: Young Kyung Do, Soela Kim, Eunhye Hyun, Dong-eon Oh, Taehoon Kim

Background:

Physicians' specialty choice arises from complex interactions throughout their careers, beginning in medical school. Medical students' preferences are shaped by various financial and non-financial factors, ultimately influencing the future distribution of physician workforce. Understanding the trade-offs among these factors is crucial for informing policy and education strategies. This issue is particularly pressing in South Korea's crisis-stricken healthcare system. Junior doctors have walked off their jobs and medical students have been on leave for nine months, protesting the government's plan to increase the annual medical school admissions quota by 65% to resolve imbalances in physician workforce distribution.

Previous studies have primarily focused on trade-offs among salary, workload, and working environment in medical students' career decisions. However, the significance of other factors such as legal risk and professional satisfaction remains underexplored, with limited insights into their implications for specialty distribution imbalances. This study aims to fill this gap by quantifying the relative importance of key non-financial attributes that influence medical students' specialty preferences and calculating their trade-offs with salary.

Methods:

A discrete choice experiment (DCE) was conducted with 610 medical students from 26 medical schools across South Korea. Five key attributes – salary, workload, diversity of work opportunities, legal liability and lawsuit risk, and professional job satisfaction as a physician – were identified based on group discussion sessions involving medical students. Levels for salary were presented as percentages of the average salary of medical doctors (50%, 75%, 100%, 125%, 150%). The other four attributes were presented as categorical levels: low, middle, and high. Respondents were asked to choose between hypothetical specialties with varying attribute levels. Coefficients were estimated using a conditional logit model, and willingness-to-accept (WTA) values were calculated to quantify trade-offs between salary and other attributes. A subgroup analysis based on career aspirations was also conducted.

Results:

Medical students were more likely to choose specialties with higher salaries, greater diversity of work opportunities, and higher professional satisfaction, while higher workload and legal liability reduced the probability of selecting a specialty. An increase in workload and legal liability from low to high would require additional compensation of 43.3% ($P < 0.001$) and 60.5% ($P < 0.001$) of the average medical doctor's salary, respectively. In contrast, an increase in diversity of work opportunities and professional satisfaction would allow respondents to accept a salary reduction of 13.1% ($P < 0.001$) and 29.7% ($P < 0.001$) of average medical doctor's salary, respectively. Subgroup analysis revealed that students aspiring to become university hospital professors were willing to accept more salary reductions for increased job satisfaction (WTA = -58.4%) but would require greater compensation for greater workload (WTA = 51.5%) or higher legal liability (WTA = 72.8%).

Discussion:

The findings emphasize that non-financial factors such as workload, legal liability, and professional satisfaction substantially affect specialty choice. The exceptionally high WTA for legal liability underscores that malpractice risk is a significant concern. Our findings suggest that policies should focus on enhancing how non-financial factors such as workload, litigation risk, and professional satisfaction collectively shape aspiring physicians' specialty preferences.

Ind-1876 Preferences for Primary Healthcare Providers among Urban Slum Dwellers of Dhaka City in Bangladesh: A Discrete Choice Experiment

PRESENTER: **Md Zahid Hasan**
AUTHORS: Tim Ensor, Edward JD Webb, Zahidul Quayyum

Background: Strengthening and reforming the urban primary healthcare (PHC) system is essential to efficiently deliver need-based healthcare services to the rapidly increasing urban poor population in Bangladesh. Aligning resource allocation with the preferences of urban slum dwellers is crucial in delivering the services they need in a low-cost and accessible way. However, it is unclear what attributes low-income people prioritise when choosing healthcare provider during their major and minor illness condition. We conducted a discrete choice experiment (DCE) among the low-income slum dwellers to elicit their preference for healthcare providers based on a series of descriptive attributes.

Methods: The DCE was developed through a systematic review along with four focus group discussions with slum dwellers and nine key informant interviews with healthcare providers four one-to-one consultation with health system experts and finally ranking exercise with 15 community people. Six attributes were selected including travel time (15-minutes, 30-minutes, 60-minutes), waiting time (0-minutes, 15-minutes, 30-minutes), recommendation (none, positive, negative), qualification of healthcare providers (not-qualified, qualified general physician, expert physician), consultation fees in Bangladesh Taka (BDT) (Free, 100, 200, 500), and discount on medicines (none, 50%, 100%). A Bayesian D-efficient design was used to construct choice sets using NGene. In each DCE task, participants were shown three choice options;

two hypothetical PHC providers and an opt-out (local pharmacy). They made two choices, first imagining they were seeking healthcare for a minor illness, and then imagining for a major illness. A total of 304, determined using rule of thumb for DCE, face-to-face interviews were completed during January-February 2024 in two selected slums of Dhaka City in Bangladesh. A conditional mixed-logit models and latent class analysis (LCA) were used to analyze the data for each of the two scenarios, separately.

Results: Participants chose the opt-out 28.5% of the times for minor illness and never chosen opt-out for major illness of 3040 choices in both scenarios. Findings showed that for minor illness, among all attributes, the relative importance for consultation fee was the highest. Utility was significantly decreasing with the increasing of consultation fees and was the highest for general physician in the provider qualification attribute. Participants' preferences changed when imagining they had a major illness, with relative importance became higher for provider's qualification.* *They had a significantly highest preference for expert physician and negative preference for 60 minutes to reach facility.** The optimal model had three latent classes in both major and minor illness scenarios with the highest class corresponding to 53.4% and 65.1% respondents, respectively and had similar findings as mixed logit model. Findings will be used to understand how people make trade-offs across the attributes in case of major and minor illness while choosing a healthcare provider.

Conclusion: Understanding the priorities of patients when choosing PHC providers is essential for ensuring equitable access to healthcare in urban areas, especially in limited resource settings. Allocation of resources for strengthening PHC services with the needs and preferences of the urban low-income people can enhance their access to healthcare services towards better health outcomes.

Ind-1844 Economic Optimisation through Adherence to Best Practice Guidelines: A Decision Analysis of Traumatic Spinal Cord Injury Care Pathways in Australia

PRESENTER: **Bharat Phani Vaikuntam**
AUTHORS: Lisa Sharwood, Luke Brian Connelly, James Middleton

Introduction: Traumatic spinal cord injuries (TSCI) have significant health, economic, and social effects on individuals, families, and society. Tailored research is essential to inform policy and clinical practice changes that could yield healthcare savings, productivity gains, and improvements in patient functioning and wellbeing. However, translating research into practice remains challenging.

Methods: In this economic analysis modelling study, we used record-linked administrative patient data from New South Wales, Australia to construct a decision tree model to compare the economic cost of acute care for patients with TSCI under current clinical pathways with a optimal care (consensus guidelines-informed) modelled pathway. The optimal care pathway included direct transfer to specialist SCI Unit(SCIU) or indirect transfer to SCIU within 24 hours of injury, surgical intervention within 12 hours of injury, and subsequent inpatient rehabilitation. Propensity score matching with inverse probability of treatment weighting(IPTW) was used to reduce potential confounding from baseline differences in patient characteristics. A Generalised Linear Model regression with gamma distribution and log link, weighted with IPTW scores, was used for costs and length of stay estimations to reduce any residual bias. Sensitivity analyses quantified the sensitivity of the findings to key model parameters.

Results: From the healthcare payer perspective, our economic analysis found acute TSCI care at a SCIU was more expensive, with delayed patient transfer pathways, surgery, and timing of surgery driving higher per-patient costs ($14,322 at specialist centres). Probabilistic sensitivity analysis(PSA) using 10,000 Monte Carlo iterations showed the modelled optimal pathway as the expensive option in majority (86%) of stimulations. However, the modelled direct transfer care pathway demonstrated economic improvements compared to current care pathways, despite a higher upfront cost ($25,428 per patient), the modelled pathway reduced the episode length of stay by 5 days (23 days vs 28 days) on average, generating system-level savings of $20,628 per patient. In PSA, increasing the proportion of patients directly transferred to SCIU by 25%, the optimised pathway was preferred in 28.3% of the simulations. Furthermore, adopting this pathway lowered the incremental per patient cost to $17,157 while preserving a 5-day length of stay benefit compared to current pathways (22 days vs 27 days), which could generate potential savings of $3,471 per patient.

Conclusion: Our findings show that guideline-based acute care management is initially resource-intensive, but efficient in terms of patient length of stay, with a higher proportion of direct transfers resulting in cost savings of $3,471 per patient, which represent system-level benefits from adopting the modelled pathway, rather than episode-level savings*.* Following consensus guidelines for acute care can provide an economically sustainable approach to resource-intensive patient needs while improving outcomes, as demonstrated in previous studies. In summary, while more intensive, adhering to clinical guidelines of direct transfer to SCIU demonstrates value for patients and health systems. Standardisation to optimise time to surgery can achieve improved outcomes through earlier access to rehabilitation and substantial care efficiencies. These findings highlight the economic case for adherence to best practice care guidelines at the healthcare system-level to inform future healthcare planning for patients with TSCI.

Ind-885 Assessing the Long-term Impacts of Integrated Care on Medical Expenditures and Healthcare Quality: A Matched Cohort Study

PRESENTER: **Yi-An Chen**, "Institute of Public Health, National Yang Ming Chiao Tung University"
AUTHOR: Li-Lin Liang

Background and Objectives

Chronic diseases necessitate long-term management, with rising prevalence and associated healthcare costs posing significant challenges. Integrated care models have been adopted to address these challenges, yet evidence on their long-term impacts remains limited, especially during the COVID-19 pandemic. Taiwan's Family Doctor Plan (FDP), implemented by the National Health Insurance Administration (NHIA), incorporates multidisciplinary care teams, case management, and integrated care pathways to improve outcomes for chronic patients. This study evaluates the long-term effects of FDP on medical expenditures and healthcare quality from 2017 to 2022.

Methods

This longitudinal study utilized data from the NHIA's Applied Health Research Data Integration Service. From a three-million-person random sample, chronic patients not enrolled in FDP between 2014 and 2016 were identified as study subjects to evaluate FDP's impact during the follow-up period (2017–2022). The treatment group included 16,365 patients continuously enrolled in FDP from 2017 to 2022, while the control group comprised 48,925 eligible but non-enrolled patients. The NHIA determined patient enrollment; however, physician participation was voluntary. To minimize selection bias, 1:3 propensity score matching was performed using comprehensive sets of patient and provider characteristics. Control variables included medical resource density and socioeconomic status. Matched difference-in-differences analysis was conducted to estimate FDP's impact, stratified into pre-COVID (2017–2019) and post-COVID (2020–2022) periods. Outcome measures included medical expenditures, avoidable hospital admissions, and potentially avoidable emergency department (ED) visits. Event study analysis confirmed the parallel trends assumption.

Results

Integrated care significantly reduced healthcare expenditures, with an annual average decline of 1,468.6 NTD (95% CI: 560.8, 2,376.5; p=0.002) over six years, equivalent to a 5% decrease based on mean baseline annual expenditure. Cost reductions were more substantial pre-COVID (-1,723.6 NTD; 95% CI: -2,596.8, -850.4; p=0.000) than post-COVID (-1,237.7 NTD; 95% CI: -2,450.1, -25.3; p=0.045). The FDP reduced avoidable hospitalizations pre-COVID (IRR: 0.85; 95% CI: 0.73, 0.98; p=0.03), but this benefit diminished during the pandemic (IRR: 0.95; 95% CI: 0.82, 1.10; p=0.495). No significant reductions in avoidable ED visits were observed across the study periods.

Conclusions

Integrated care effectively reduced medical expenditures over time, though the benefits lessened during the COVID-19 pandemic. The cost-saving effect highlights the importance of FDP in alleviating the burden of chronic disease in the long term. The pre-pandemic reduction in avoidable admissions was not sustained during the pandemic, which could be due to disruptions in chronic care. Additionally, Taiwan's high healthcare accessibility and limited control by FDP physicians over patient-initiated ED visits may reduce the program's impact on avoidable ED visits.

Implications for Policy and Practice

This study highlights the potential for long-term integrated care to save costs and enhance care quality, highlighting cost-effectiveness analysis as an important direction for future research. Policymakers should consider improving integrated care models to sustain chronic care quality during public health crises like COVID-19. Unlike the short-term effects reported in previous literature, which may not fully capture the benefits of integrated care, this research emphasizes the importance of continuous program participation for realizing substantial benefits.

Ind-1858 Adopting a Public-Private Collaboration Model to Strengthen Diagnostics Service Delivery in Public Sector County Referral Hospitals in Kenya

PRESENTER: **Victoria Ngima Wanjohi**, The Robert Gordon University - Scotland
AUTHORS: Gerald Macharia, Fonahanmioluwa Williams, Vincent Omondi

Background

Laboratory services in public sector hospitals remain underfunded and underutilized in Kenya, with laboratories covering <40% of the required test menu with a wide variation across counties. This translates to the availability of approximately 70 tests out of the 250 outlined in the service charter, the majority being basic tests with hardly any offering of specialized tests. Strategic purchasing of laboratory services from the private sector may play a role in addressing gaps, leading to more efficient laboratory operations in the public sector County Referral Hospitals. The Clinical Laboratory Improvement Project is a public-private collaboration (PPC) model to improve the quality of public-sector diagnostics by leveraging the technical and technological expertise of a private-sector laboratory service provider.

Methods

A policy analysis was undertaken to identify potential legal frameworks and commercial options to inform stakeholder engagement. An economic analysis was conducted to assess the current and projected costs of operating a laboratory system for a county government to determine the feasibility and viability of a PPC. The costs assessed included Human Resources for health, infrastructure, reagents, consumables,

Laboratory Information Management Systems, and sample transportation costs. The financial model incorporated facility-level data in making pricing and demand assumptions. Interviews of public and private sector stakeholders were conducted to assess interest in and risk of a PPC.

Findings

A purchasing agreement model, which entails outsourcing of laboratory services through service contracts between county governments and a private laboratory provider, was considered the most feasible approach for the PPC. The model allocates roles to both the county and the private partners over a fixed period and allows the county government to retain control and ownership of facilities, while still benefiting from the efficiency and expertise of private-sector partners. Drivers of financial sustainability included test menu and volume growth, decrease in the cost of goods, no equipment downtime, and labor efficiencies. Potential PPC risks identified include lack of facility autonomy to enable timely payment to the private provider, delayed reimbursement from the National Health Insurance Fund for laboratory services, and lack of a robust waiver policy to curb the abuse of waivers, leading to missed revenue in the laboratory.

Conclusion

Implementing a PPC to improve service delivery in the public health sector is feasible if anchored on a clear legal and regulatory framework, co-created feasibility analyses, sustained government ownership, and political goodwill. To ensure successful implementation, key enablers are operationalizing direct facility financing, timely NHIF reimbursements, and strengthening county-level standard operating procedures for waivers. With one county having put in place these enablers and currently implementing the laboratory PPC contract for one year, an initial assessment revealed that the County Referral Hospital has seen improvements in the number of tests, including highly specialized tests, from 70 to over 1000. The annual test volumes increased from 44,000 to 183,480, with an average monthly revenue of Kshs 4.8 Million from Kshs 697,000. The labor efficiency has increased from 4,520 tests per laboratory technologist to 15,650, with most tests prescribed at the outpatient service delivery point.

Ind-866 Spatial Coverage and Expansion Needs of Lady Health Worker Program in Khyber Pakhtunkhwa (KP), Pakistan: A Population and Distance-Based Analysis

PRESENTER: **Mir Sana Ullah Khan**
AUTHOR: Nida Hameed

Background: Community Health Worker (CHW) programs are critical for expanding primary healthcare access in low- and middle-income countries, yet optimal deployment strategies remain debated. Pakistan's Lady Health Worker (LHW) Program, established in 1994, is one of the world's largest CHW initiatives, providing essential primary healthcare and family planning services to underserved populations, primarily in rural areas and urban slums. But in Khyber Pakhtunkhwa (KP) province, where mountainous terrain and dispersed communities create significant access barriers, the program currently reaches only 48% of the population – well below the provincial target of 61%. While increased coverage is needed, policymakers lack evidence on where to optimally deploy additional LHWs and what resources this would require. This study aims to identify coverage gaps and provide a costed expansion strategy that could inform CHW program planning both within Pakistan and in similar contexts globally.

Research Question: What is the optimal strategy for expanding the Lady Health Worker Program in KP to achieve a 61% coverage rate, considering both population density and geographic terrain?

Methods: We employed a dual-method analytical approach integrating population-based and distance-based assessments of LHW coverage in KP. The population-based method estimated coverage using the national standard of one LHW per 1,200 individuals. The distance-based method assessed spatial allocation of LHWs, setting a benchmark of one LHW per 5 square kilometers to ensure equitable access across diverse terrains. Data sources included the 2023 national census, the KP Multiple Indicator Cluster Survey (MICS 2019), the LHW Management Information System (MIS), and administrative records from the provincial Department of Health. We estimated financial implications using current budget data from the KP government, applying an 8% annual inflation rate (average historical inflation rate for Pakistan) to project costs associated with compensation in each subsequent financial year.

Results: Our analysis reveals significant geographic and population-based coverage gaps across KP province. To reach the 61% coverage target, KP will require 5,072 additional LHWs based on population density standards alone. However, addressing geographic access barriers would require an additional 1,983 LHWs to ensure coverage within a 5km radius. The most severe coverage gaps exist in remote districts where current LHW coverage areas extend up to 38 square kilometres. The projected annual cost for the population-based expansion (5,072 LHWs) is PKR 3.17 billion ($11.4 million), with an additional PKR 1.24 billion ($4.5 million) required for geographic coverage expansion (1,983 LHWs). These estimates include salaries, benefits, and anticipated pension liabilities.

Conclusions and Implications: This research demonstrates that conventional population-based deployment strategies alone may be insufficient to achievee equitable LHW coverage in geographically challenging regions. A comprehensive strategy incorporating both population density and geographic access could significantly improve LHW coverage in KP, though at a substantial fiscal cost. This analysis provides a replicable framework for optimizing CHW deployment in similar settings globally, while highlighting the need to balance coverage targets with financial sustainability. Future research should examine how digital health tools and alternative service delivery models could help bridge remaining access gaps cost-effectively.

Bali International Convention Centre – Karangasem

How Economic Burdens and Social Disparities Shape Health Outcomes

MODERATOR: **Caroline Watts**, The Kirby Institute, UNSW Sydney, NSW

Ind-155 Valuation of Health Losses among Japanese Workers with Children During the COVID-19 Pandemic

PRESENTER: **Narimasa Kumagai**, Seinan Gakuin University

AUTHOR: Aran Tajika

[Background] Women experienced a larger decline in well-being than men did during the COVID-19 pandemic. This loss was greater for parents with childcare responsibilities living in Europe. However, little is known regarding the monetary value of health losses among Japanese workers with children during this time.

[Purpose] To fill this gap, this study attached monetary values to self-assessed poor health (SAPH) due to a lower standard of living among middle-aged Japanese men and women.

[Methods] This study used data on four waves from the Japan Household Panel Survey (JHPS) COVID-19 Special Survey conducted by Keio University to examine the impact of health conditions on life satisfaction among Japanese workers. It used the dichotomous variable PSAH to measure the value lost in moving from good, very good, or excellent health to fair or poor health. To select the explanatory variables for the estimation function measuring the impact of PSAH on life satisfaction, the determinants of PSAH were investigated using the random forest model. Considering the endogeneity between PSAH and life satisfaction, we used the two-stage residual inclusion approach with generalized residuals.

[Results] The results show a significant difference in the monetary value of the loss of life satisfaction due to poor health between adults with children and adults without children. The results support the hypothesis that adults with children experience greater health losses than adults without children do. The health losses of adults with children were approximately 3.49 million Japanese yen (JPY) (7.3 times the average monthly household income), that is, 1.04 million JPY more than that of adults without children. The direct impact of PSAH and severe mental distress on life satisfaction was greater for adults with children than for adults without children.

[Discussion] Adults with children were more likely to experience mental ill-health in the two lowest income classes; thus, the magnitude of the monetary value of the loss of well-being due to poor health during the pandemic increased.

[Conclusions] Higher levels of mental health distress are associated with poorer health; therefore, attention must be paid to changes in income, sleep duration, and job insecurity among adults with children.

Ind-330 Associations Between Socioeconomic Status, Life's Essential 8, and Cardiovascular Diseases in Chinese Hypertensive Patients From Remote Areas

PRESENTER: **Lipei Zhao**

AUTHORS: Jian Wu, Beizhu Ye

Background: Interplay between socioeconomic status (SES) and cardiovascular health (CVH) using Life's Essential 8 (LE8) with cardiovascular diseases (CVD) in hypertensive patients is underinvestigated and necessary for developing prevention strategies for remote areas.** This study aimed to investigate complex relationships between SES, LE8, and CVD in hypertensive patients from remote areas in China. **Methods:** From 1 July to 31 August 2023, a cross-sectional survey of hypertensive patients aged ≥ 65 years was performed in Jia County, a remote area in Henan Province in China, using the cluster sampling method. SES was measured using education, occupation, and annual household income via latent class analysis. According to the updating of the AHA's construct of CVH, the LE8 score (or the number of ideal metrics) was generated. A composite CVD that included coronary heart disease (CHD) and stroke (hemorrhagic stroke and ischemic stroke) was defined as the outcome. Multivariable-adjusted logistic models were used to estimate the odds ratio (OR) for the risk of CVD. A causal mediation analysis under a counterfactual framework was performed to calculate the mediation proportion by the mediator (LE8 score/ number of ideal metrics) for the association between SES and CVD. **Results:** Of 18,963 elderly hypertensive patients, 12437 were eligible for inclusion in our analysis (48.36% with low SES, 40.30% with medium SES, and 11.35% with high SES). In total, 5476 (44.03%) participants had CVD (4321 [34.74%] suffered from stroke and 1982 [15.94%] with CHD). After adjusting for covariates, compared with low SES participants, those with high SES had lower risks of CVD (OR:0.859, 95%CI:0.760-0.971), which was competitively mediated by LE8 score or the number of ideal metrics (mediation proportion: 17.10%, 95%CI:9.52-64.85; 6.54%, 95%CI:2.77-19.12, respectively). Participants with high SES and high LE8 score had a 58.2% lower risk of CVD (OR:0.418, 95% 0.261-0.671) than participants with low SES and low LE8 score. Additionally, participants with high SES and 4-7 LE8 metrics had a 48% lower risk of CVD (OR:0.520, 95% 0.399-0.677) than participants with low SES and 0-1 LE8 metrics. **Conclusion:** A high SES was found to be associated with a lower CVD risk among elderly patients with hypertension. Especially, the LE8 score plays a part in the association between SES and CVD. However, only a small proportion of the socioeconomic inequity in CVD risk was mediated by LE8 score or the number of ideal metrics, which indicates that measures other than healthy behavior and clinical factors promotion to improve social determinants of health are warranted. Meanwhile, hypertensive patients with disadvantaged SES and low LE8 score (or 0-1 number of ideal metrics) have the highest risk of CVD, highlighting the importance of modifying behaviors and clinical factors to reduce CVD burden for hypertensive patients, especially for those of low SES. **Keywords:** Cardiovascular Diseases, Life's Essential 8, Socioeconomic Status, Hypertension, Remote

Ind-541 Prescription-Based Comorbidity Index and Its Association with Pharmaceutical Costs in Australians with Multiple Sclerosis

PRESENTER: **Ting Zhao**, University of Tasmania

AUTHORS: Hasnat Ahmad, Ingrid van der Mei, Bruce Taylor, Andrew Palmer

Background
Multiple sclerosis (MS) is the most common acquired chronic neurological disease affecting young adults in Australia. MS poses a significant economic burden to patients, their care givers, government and the broader community, with pharmaceutical costs being the largest component of direct costs of managing this condition. MS often co-exists with other comorbidities, significantly impacting healthcare costs. While data on comorbidities associated with MS is often limited, utilising the Rx Risk Index based on prescription medication data can help effectively identify both the types and number of comorbidities with a high degree of confidence. Understanding the relationship between comorbidities and pharmaceutical costs is crucial for optimising resource allocation and improving patient care.

Objective This study examines how different levels of comorbidity, as measured by the prescription medication-based Rx-Risk Index, associate with pharmaceutical costs in the Australian MS population using a nationwide cohort.

Methods The study included 1,647 participants from the Australian Multiple Sclerosis Longitudinal Study (AMSLS). Data from the Pharmaceutical Benefits Scheme (PBS) in 2022 were extracted for consented participants. The Rx-Risk Index was used to capture 46 comorbidities. Annual patient out-of-pocket costs, government-paid costs, and total prescription costs for 2022 were calculated for each participant. Baseline regression models on costs were fitted using age and gender as covariates. Rx-Risk scores, ranging from 0 to 46 indicating the number of different comorbidities, and individual comorbidities, indicating the presence or absence of each condition, were added to the base models.

Results The five most common comorbidities identified by the Rx-Risk Index in Australians with MS were depression (42%), gastroesophageal reflux (27%), hyperlipidaemia (26%), hypertension (22%), and pain (20%). Higher Rx-Risk Index scores were significantly associated with increased pharmaceutical costs, with each one unit increase in Rx-Risk score resulting in increases of $41, $741, and $783 in out-of-pocket, government-paid, and total pharmaceutical costs, respectively. Specific comorbidities contributing to higher *total* costs included malignancies, anxiety, epilepsy, hyperlipidaemia, and depression, with respective increases of $8,912, $4,342, $3,654, $1,919, and $1,678 in total pharmaceutical costs. Comorbidities associated with higher *out-of-pocket* costs included malignancies ($145), ischaemic heart disease: hypertension ($126), hypertension ($89), depression ($54), and hyperlipidaemia ($54). Higher *government-paid* costs were associated with malignancies ($8,767), anxiety ($4,337), epilepsy ($3,594), and depression ($1,624).

Conclusion This study utilises the Rx Risk index to capture the comorbidity profiles of Australians with MS using their prescription medication records. It highlights the significant positive association between comorbidities and pharmaceutical costs in the MS population. By focusing on managing high-cost comorbidities, healthcare providers and policymakers can develop strategies to optimise care and reduce costs. Future studies should incorporate clinical or patient-reported data on comorbidities and compare the findings with the outcomes of the Rx Risk Index. This will help assess the reliability and predictive power of the Rx Risk Index within the MS population, allowing for an evaluation of its sensitivity and specificity in identifying comorbid conditions and predicting health outcomes and costs.

Ind-649 Healthcare and Productivity Costs of Diabetes in Finland: A Register-Based Study from 2002 to 2023

PRESENTER: **Olli Kurkela**
AUTHORS: Neill Booth, Kamilla Ryöti

Background

Diabetes continues to be a major public health issue in Finland, placing a considerable economic burden on society. Over the past two decades, Finland has witnessed a substantial increase in the prevalence of type 2 diabetes, along with a shift in the complication profile from macrovascular to microvascular complications. Additionally, the impact of diabetes on the ability to work of the entire working-age population remains largely unexplored. Given these changes in diabetes epidemiology, and earlier difficulties in fully capturing all main cost drivers, there is a pressing need to reassess the economic burden of diabetes in Finland.

Study aim

This study aims to evaluate the healthcare and productivity costs of patients with diabetes, as well as their development, from 2002 to 2023.

Methods

The study is based on data from the FinDM project, including individuals with diagnosed diabetes in Finland identified from national registers from 1964 to 2023. Healthcare resource use is quantified using individual-level records, including both primary and specialized outpatient and inpatient care, as well as medication purchases. Estimates from national unit-cost reports and Diagnostic Related Group (DRG)-based costs will be used to value the resource use. Productivity costs will be assessed using individual-level data on sick leave and disability pensions, and quantified using both human-capital and friction-cost -approaches. Costs will be reported for the total diabetes population and across several subgroups categorized by diabetes type, complication status, and several demographic and socioeconomic factors. The costs attributed to diabetes will be calculated by subtracting the average healthcare costs of the general population from those of diabetic patients. Appropriate regression techniques will be employed to examine the associations between various factors and costs.

Results

Fully-updated data will be available for researchers at the end of November 2024, after which the research is scheduled to begin immediately and full results are expected to be available prior to the 2025 iHEA conference. According to results from preliminary data, the number of people with diabetes has continued to increase since previous estimates from 2017. The number of newly-diagnosed individuals with type 1 diabetes in 2023 were 8% higher than in 2017 (1 685 vs 1 557), while the number of newly-diagnosed individuals with type 2 diabetes were

13% higher between those years (33 469 vs. 29 618). Overall, the numbers of individuals with type 1 and type 2 diabetes in Finland has increased by approximately 10% and 18%, respectively.

Conclusions

This study will provide a comprehensive understanding of the healthcare and productivity costs associated with diabetes in Finland, as well as their distribution across different healthcare sectors and various subgroups. By detailing the resource utilization in diabetes care and identifying major cost drivers, the study will provide valuable insights for the ongoing policy debate surrounding recent healthcare reform in Finland and the role of diabetes care within it. Furthermore, the study highlights important areas for future research with the aim of improving diabetes care in Finland and should also serve as a useful basis for international comparisons.

Ind-748 Trends in the Number and Costs of Suicide Attempts, Suicidal Ideation and Self-Harm Incidents in Youth: Evidence From a Dutch Hospital

PRESENTER: **Naomi van der Linden**
AUTHORS: Christien van der Linden, Larissa Amirjalali, Leona Hakkaart-van Roijen, Shanna Van Der Linden, Merel van Loon-van Gaalen, Kinke Lommerse

Introduction While suicide is the leading cause of death in Dutch youth, the number of suicide attempts (SAs), suicidal ideation (SI) and self-harm incidents (SHI) is substantially larger. It is unknown whether the number of suicide-related emergency department (ED) visits has changed over time. Also, costs of hospital treatments for these patients are unknown. **Aims** This study examines: (1) trends in ED-recorded SAs, SI, and SHI incidents in youth, (2) related hospital costs for these patients, from a health insurer perspective, (3) key changes in the youth mental healthcare landscape over the same period, to provide context to any identified trends. **Methods** Hospital databases were combined to identify all youth ≤27 years visiting a Dutch inner-city ED between 2016-2023 for an SA, SI or SHI. Definitions for these categories were taken from 113 (suicide prevention organization), refined for practical use based on ED literature and case discussions. Hospital records were reviewed manually to determine if the patient met the definitions. Unclarities were discussed within the study team or, subsequently, in an expert panel including a psychiatrist and emergency physician. Descriptive analyses were used to determine trends in the number of primary and repeated SAs. For a random subset of patients (preliminary data, n=10), invoiced hospital care products related to the SA were multiplied by their average tariff in the Netherlands in 2024. Grey and scientific literature were reviewed to identify policy and funding changes related to youth mental healthcare between 2015 and 2023, and any events for which literature reported an association with the mental health of youth in this period. **Preliminary results** The number of SAs increased from 101 in 2016 to 149 in 2023, with the peak in 2022 (n=169), 74% female, median age 21, range 13-27. Recorded cases of SI without SA increased from 7 in 2016 to 16 in 2023, again with the peak in 2022 (n=33), 49% female, median age 22, range 12-27. Recorded SHIs reduced from 34 in 2016 to 24 in 2023 (74% female, median age 20, range 14-27). 18% of patients (n=176) had one or multiple repeat visits for the above reasons, with a median of 2 visits (range 2-12). Based on preliminary data (n=10), median hospital costs related to a SA are €2,813 per patient, ranging from €385 (ED episode) to €14,149 (in-hospital admission including intensive care). The figure below shows a timeline of the most important national events related to youth mental health in the Netherlands between 2015-2023. **Conclusions and implications for policy and practice** The number of ED visits for youth SAs and/or SI increased over time, with a peak in 2022, in the aftermath of COVID-19. ED visits for SHIs decreased. The substantial number of repeated SAs underlines the importance of suicide prevention measures. Further trends will be studied. Hospital-invoiced costs represent only a small part of healthcare costs for these patients, and differ substantially between patients. Future analyses should include societal costs within and outside the healthcare sector.

Ind-915 The Burden of Type 2 Diabetes on the Productivity and Economy in Sub-Saharan Africa: A Life Table Modelling Analysis from a South African Perspective.

PRESENTER: **Assegid Hellebo**
AUTHORS: Andre Pascal Kengne, Zanfina Ademi, Olufunke Alaba

Background Type 2 Diabetes (T2D), a chronic and costly disease, presents a significant public health challenge in developing countries. This challenge is driven by its rapidly growing prevalence, associated complications, and the need for sustained care. T2D burdens individuals, families, societies, and national economies. While the economic impact of T2D is somehow documented in high-income countries, with only six global studies addressing this issue, there is a notable gap in research within Sub-Saharan Africa (SSA). This study aimed to fill the knowledge gap on the economics of T2D in SSA, focusing on South Africa, where an estimated 4.2 million people aged 20–79 live with diabetes, and the economic burden of T2D is growing. **Method** A life table modelling was used to simulate the follow-up of individuals aged 20–65 (working age) with T2D in South Africa. Two life table models were developed to simulate health outcomes for a cohort with and without diabetes. The difference in the number of deaths, years of life lost (YLL), and productivity-adjusted life years (PALYs) lost between the two cohorts represented the burden of diabetes. Scenarios were simulated in which the proportions of gross domestic product (GDP), productivity indices, labour force dropout, and mortality risk trends were adjusted to lower and upper uncertainty bounds. Data were sourced from the International Diabetes Federation, Statistics South Africa, and both publicly available and published sources. The WHO standard annual discount rate of 3% was used for YLL and PALYs. **Results** In 2019, an estimated 9.5% of South Africa's working-age population (7.68% men and 11.37% women), or 3.2 million people, had T2D. Simulated follow-up until retirement predicted 669,427 excess deaths, a loss of 6.2 million years of life (9.3%), and 13 million PALYs (30.6%) in South Africa. On average, this resulted in 3.1 PALYs lost per person. Based on GDP per full-time employee in 2019, the PALYs loss equated to US$223 billion, or US$69,875 per person. **Conclusion** This study underscores the significant economic and societal impact of T2D. Relatively modest improvements in T2D prevention and treatment management could yield substantial economic benefits for South Africa. **Keywords:** South Africa, Diabetes, T2D, Gross Domestic Product, Productivity Loss, Years of Life Lost, PALYs, Productivity-Adjusted Life Years, Life table model 1

Ind-937 Childbirth and Gender Disparity in Labour Market Outcomes: Evidence From an Event Study

PRESENTER: **Souvik Banerjee**, Indian Institute of Technology Bombay
AUTHORS: Preeti Jaiswal, Sankar Mukhopadhyay

Despite increasing economic growth, rising educational attainment, and lowering fertility rates, there exists persistent gender divergence in labour market outcomes in almost all countries. One of the significant factors, discussed widely in developed countries contributing to this existing gender gap is the 'motherhood penalty'. It is defined as the negative impact on various labour market outcomes such as labour force participation, earnings, and work hours resulting from the disproportionate burden of childcare falling exclusively upon the mothers. The Indian labour market has consistently demonstrated significant gender inequality over the past two decades. In 1993-94, male labour force participation was 54.49% and female was 28.56% and by 2023-2024, these rates rose to only 58.2% and 31.7%, underscoring continued gender disparity. There exists scarce literature focusing on the impact of childbirth on female labour market outcomes at the extensive and intensive margins in the Indian context, and particularly its dynamic impact as a child grows up. The present study aims to estimate the causal impact of new childbirth on mothers' labour force participation, earnings, and work hours compared to fathers and married women without children to isolate the gender-specific effect of motherhood.

Using the longitudinal data from the Consumer Pyramids Household Survey (CPHS), conducted by the Centre for Monitoring Indian Economy (CMIE) over the period 2016 to 2023, we employ the dynamic difference-in-differences method, also known as the difference-in-differences event study, including the individual fixed effects, using fathers and married women without children as control groups for the analysis. To address the self-selection of the event (childbirth), we perform kernel matching, nearest neighbour matching, and entropy balancing, which largely validate the parallel trends assumption.

The likelihood of mothers' labour force participation shows a decline of 4% at the time of childbirth in rural regions, while in urban regions, it shows an immediate decrease of almost 4% which further decreases to 10%, four years after childbirth compared to fathers. We find no significant decline in mothers' earnings post-childbirth in rural regions, instead, earnings increase sharply by 25% a year later compared to fathers with no effect in urban regions. Moreover, relative to married women without children, we find a significant increase of 6% in the likelihood of mothers' labour force participation two years post-childbirth in rural regions with no impact in urban regions and an increase of 33% and 18% in mothers' earnings a year after childbirth in rural and urban regions, respectively. We do not find a significant impact on work hours.

The decline in labour force participation reveals the immediate impact of childbirth, but unlike other countries, this decline is temporary and eventually becomes negligible. Our findings on the motherhood penalty, independent of the gender-specific effects, suggest that mothers prioritise their labour market potential compared to non-mothers, though this shift usually takes about two years to materialize. These findings underscore the need for policy interventions that offer affordable childcare and more flexible work arrangements to support a smoother, more timely reintegration of mothers into the workforce.

Ind-1243 Infecting the Wallet: The Economic Burden of Healthcare Associated Infections in Malawi

PRESENTER: **Wala Kamchedzera**, Malawi Liverpool Wellcome Program
AUTHORS: Laura Rosu, Lucky Ngwira, Thomasena O'Byrne, Dorica Ng'ambi, Gabriel Bunduki, Nicholas Feasey, Eve Worrall

Introduction: Healthcare associated infections (HAI) are a leading cause of morbidity and mortality amongst hospitalised patients globally and low resource healthcare systems in low-and-middle-income countries (LMICs) are disproportionately affected. HAIs not only drain a health system's resources but also place considerable economic burden on the patient. Due to increased length of hospital stay because of infection, patients experience increased out of pocket expenditure and large productivity losses. These challenges can be detrimental to the welfare of the patients' household as the risk of incurring catastrophic health expenditure increases, especially for LMICs like Malawi, where the poverty rate is high. Literature on the economic burden of HAIs is growing, yet information from Africa is sparse. Costs are context specific therefore there is a need for country specific estimates of the economic burden of HAIs. Such information will help advocate for resources to be channelled towards innovative infection prevention and control (IPC) interventions. Additionally, it will provide insights on whether new social protection policies that ease the financial burden faced by households are needed. This study aims to measure the costs incurred by hospitalised patients with HAIs in Malawi.

Methods: This study took place at three public hospitals in Malawi, of which two were tertiary/referral and one was a district/secondary-care hospital. Participants were adult patients (≥18) that were hospitalised for >48 hours. Participants with HAIs were matched to those without. Matching was done by ward, age group, type of HAI, and admission to time to infection period at a 1:1 ratio. The direct and indirect costs incurred by the participants during hospital stay were collected through structured interviews. To compare costs, mean cost differences between those with and without HAIs were calculated. As the data was skewed, non-parametric bootstrap methods were used to derive 95% confidence intervals for mean cost differences. We estimated proportion of participants falling into catastrophic expenditure (costs exceeding 40% of annual household income). We used multivariable analysis to find the independent effect of infection on the total cost and determine the main cost predictors.

Preliminary results: Mean total cost incurred by 320 participants was $241.74 (standard error [SE]: 42.4). Patients with HAIs had a higher total cost than those without (mean difference $144.14 [95% confidence interval [CI]: 10.90-335.90]). Total direct costs were higher among those with HAIs by $31.53 (95% CI: 31.53-82.81). However, the total indirect cost faced by patients with HAIs was non-significantly higher than those without. Patients with surgical site infections faced the highest mean total cost, followed by those with catheter-associated urinary tract infections and blood stream infections. For those with complete household income data, 34.1% (105/308) experienced catastrophic expenditure; 44.1% of participants with and 25.5% without HAIs.

Conclusion: Malawian patients incur large economic costs during admission to hospital, some of which are catastrophic. These costs are worsened by the presence of HAIs. Therefore, IPC interventions that can effectively reduce the burden of HAIs are needed. Additionally, these interventions should be implemented alongside social protection policies to protect the most vulnerable households.

Ind-1549 Socioeconomic Value of Ado-trastuzumab Emtansine for HER2+ Breast Cancer Therapy in China

PRESENTER: **Yijia Feng**
AUTHORS: Luying Zhang, Dennis A. Ostwald, Malina Müller, Wen Chen

Background： Breast cancer's incidence rate ranked second among female tumors in China, with 360,000 new breast cancer patients and 75,000 deaths in 2024. Breast cancer has caused a serious economic burden of disease in China, of which HER2+ breast cancer account for up to 20%. Although effective treatment options exist, patients are often not completely cured and are prone to recurrence. Ado-trastuzumab emtansine is mainly applied in the early adjuvant therapy of HER2+ early breast cancer patients with residual invasive lesions and the second-line therapy of patients with unresectable localized or metastatic terminal breast cancer. It can significantly improve quality adjusted life years(QALYs) of patients, enabling them to pursue daily activities and participate in the labor market, which denotes a great socioeconomic value. **Method：** The socioeconomic value of ado-trastuzumab for early adjuvant therapy and terminal second-line therapy of HER2+ breast cancer patients in China were calculated and summed, mainly based on the social impact framework provided by WifOR institute with the input of Chinese localized data. QALYs were applied as an evaluator of health improvement. Gross value added (GVA) was used to measure labor productivity. Number of patients covered by each indication per year was obtained from Roche corporate data. Average hours of paid work and unpaid work for males and females were acquired from Chinese Third National Time-use Survey in 2024. An annual inflation rate of 5% and discount rate of 3% were also set to assess the socioeconomic value of ado-trastuzumab emtansine among Chinese HER2+ breast cancer patients from 2024 to 2032. **Results：** Total socioeconomic value of ado-trastuzumab emtansine applied in Chinese HER2+ breast cancer patients over 9 years is $327,762,612.2. The value generated in early adjuvant therapy is $186,587,525.8, accounting for 56.97%; while the value generated in terminal second-line therapy is $141,175,086.4, accounting for 43.03%. The socioeconomic value of ado-trastuzumab emtansine applied to early adjuvant therapy is significantly higher than that of terminal second-line therapy. Meanwhile, results of the socioeconomic value show a developmental pattern of increasing and then decreasing in both two indications. In the early adjuvant therapy of HER2+ positive breast cancer, predicted socioeconomic value gradually increases from 2024 to 2027, reaching a peak of $26,975,699.1 in 2017, and then declines year after year. In contrast, the value in terminal second-line therapy peaks at $17,921,947.6 in 2025 and also declines annually from 2026 to 2032. Under the assumption of a consistent distribution of patients in both indications, the number of patients may be the main factor affecting above results of socioeconomic value. **Conclusions：** Our study has shown that application of ado-trastuzumab emtansine in Chinese HER2+ breast cancer therapy produces extremely high socioeconomic value, especially in the early adjuvant therapy. It indicated that benefits of ado-trastuzumab emtansine are beyond clinical advantages. The value is mainly influenced by the number of patients to whom ado-trastuzumab emtansine is applied. The larger the number of patients covered is, annual socioeconomic value is higher.

Ind-1581 Estimates of The Value Per Statistical Life in China, Based on The Data From China Family Panel Studies

PRESENTER: **Can Wang**
AUTHORS: Fengyi Sun, Zhan Zhao, Jixuan Wang, Jialong Tan, Jian Wang

Background: The Value of a Statistical Life (VSL) plays a crucial role in cost-benefit analyses, enabling economists to quantify reductions in mortality risk. This tool is particularly valuable for prioritizing projects or policies in resource-constrained settings, especially in public health, workplace safety, transportation, and environmental protection. While OECD and other developed countries have conducted extensive research on VSL, recent estimates in developing countries, including mainland China, remain outdated, largely unchanged from a decade ago.

Objective: This study aims to calculate and compare the 2010 and 2020 VSL estimates in China and explain the reasons for their changes. We explore the income and regional differences in VSL within the country and illustrate the policy implications. The analysis is based on the China Family Panel Studies (2010 and 2020).

Methods: This study adopts the hedonic wage model. It uses the China Family Panel Studies (2010 and 2020) to obtain individual wage rate and personal characteristics data, and integrates industry-specific fatality and incident statistics from the *China Yearbook of Work Safety* (2010) and the *China Yearbook of Emergency Management* (2020) with employment figures from the *China Population Census Yearbook* (2010 and 2020) to calculate industry-specific fatal and non-fatal job risks. The relationship between the individual wage rate and the fatal job risks can be expressed by the hedonic wage regression.

Results:

1. The average age of respondents in 2010 is about 40.66 years old, and the average wage rate is CNY 1.67 per hour; The average age of respondents in 2020 is about 37.36 years old, and the average wage rate is CNY 5.56 per hour.
2. The analysis reveals that for every unit change in fatal job risk, wage rate adjusted by 0.00146 ($P<0.01$) in 2010 and 0.00448 ($P<0.01$) in 2020. For every unit change in non-fatal job risk, wage rate adjusted by -0.000397 ($P<0.01$) in 2010 and -0.00257 ($P<0.01$) in 2020.
3. The resulting VSL is estimated at CNY 0.49 million in 2010, approximately 16 times the national per capita GDP (CNY 29940), and at CNY 4.98 million in 2020, approximately 69 times the national per capita GDP (CNY 72447). After accounting for inflation, China's VSL has grown 4.3 times over the past 10 years. Notably, among different income groups, VSL in the low-income group is CNY -865.59 in 2010, while positive and significant in other groups in 2010 and 2020.

Conclusion: The increase in China's VSL and VSL/GDP ratio reflects a growing societal recognition of life's value and an improvement in economic conditions. At the income level, low-income earners are uncompensated to take on high-risk work in 2010, and improve but still lag

behind high-income groups in 2020; at the regional level, the fatal risk coefficient is high in the Northeast region in 2010, and changes to the West in 2020, and the changes in VSL in each region are closely linked to the economy, industry, and policies. This study provides an important reference for the design of social systems and resource allocation decisions, and deepens the understanding of risk compensation mechanisms in the labour market.

Ind-2049 Socioeconomic-related Inequalities in Multi-dimensional Health Among Older Adults in China: A Population-based Cross-sectional Study

PRESENTER: **Jingxian Wu**
AUTHORS: Yaping Deng, Cong Li

Background Healthy aging, defined as a dynamic process involving the development and maintenance of essential functions, is a multi-dimensional concept relevant to all older adults. As the global population ages, socioeconomic-related health inequalities among older adults have become a critical public health challenge. However, exiting studies on health inequalities in older populations have primarily focused on self-reported or single health dimensions, often neglecting the multi-dimensional nature of healthy aging. This study aims to comprehensively measure and decompose the socioeconomic inequalities across physical, mental, cognitive, and social dimensions of health among older adults in China. **Methods** A cross-sectional analysis was conducted using data from the 2018 Chinese Longitudinal Healthy Longevity Survey, covering 14,310 older adults aged 65 and above. Physical health was assessed using Katz Index of Independence in Activities of Daily Living (ADL) and Nagi Index of Instrumental ADL (IADL). Mental health was evaluated through the 10-item Center for Epidemiologic Studies Depression Scale (CESD). Cognitive health was measured using the Chinese version of the Mini-Mental State Examination (MMSE), and social health was assessed through levels of social participation. All health indicators were unified so that higher scores indicated better health outcomes. Wagstaff's corrected concentration index (CI) was calculated to quantify the socioeconomic-related inequalities for each health dimension, with self-rated household economic status taken as the ranking variable. Pairwise *t*-tests were used to compare CIs across different health dimensions, and WDW decomposition analysis was conducted to identify the contribution of various determinants to inequalities in each health dimension. **Results** All four dimensions of health exhibited significant pro-rich inequalities, with positive and statistically significant CIs ($p<0.001$). Cognitive health, as measured by the MMSE, had the highest degree of pro-rich inequality (CI = 0.0929), followed by physical health as measured by ADL (CI = 0.0726), social health (CI = 0.0692), mental health (CESD, CI = 0.0627), and physical health as indicated by IADL (CI = 0.0589). Pairwise *t*-tests indicated that cognitive health inequality was significantly greater compared to other dimensions. Decomposition analysis revealed that household-level economic factors, including sufficient financial resources and self-rated economic status, were the primary contributors to inequalities across all health dimensions. Additionally, timely access to healthcare significantly contributed to inequalities in physical and cognitive health, while poor sleep was a key factor increasing mental health inequality. For social health inequality, early-life factors, including higher educational attainment and stable job before age of 60, were identified as significant contributors. **Conclusion** This study identified significant pro-rich inequalities in multi-dimensional health among older adults in China, with cognitive health displaying the most pronounced inequalities. Targeted interventions promoting equitable healthcare access, health literacy, and healthy lifestyles are urgently needed, particularly for socioeconomically disadvantaged older adults, to reduce these disparities and advance healthy aging for all. Additional efforts should be made to improve social participation opportunities for economically disadvantaged older adults through community engagement and supportive programs.

**This study is funded by the National Natural Science Foundation of China (No. 72104196).

Ind-2671 Future Productivity Loss Due to Death Related to Road Traffic Injuries in the Guadalajara and Mexico City Metropolitan Areas

PRESENTER: **Andrés Vecino Ortiz**, Johns Hopkins University Bloomberg School of Public Health
AUTHORS: Mauro Razuk Filho, Abdul Bachani, Angélica Lopez Hernandez

Road traffic injuries (RTIs) are a leading cause of mortality and economic loss worldwide, with low- and middle-income countries (LMICs) disproportionately affected. In Mexico, RTIs account for 3.5% of disability-adjusted life years (DALYs) and 2.9% of deaths, translating to substantial societal and economic burdens. Despite this, limited studies have evaluated the economic impact of RTI-related fatalities in urban areas. This research addresses this gap by systematically quantifying future productivity losses due to RTI-related fatalities in the Guadalajara Metropolitan Area (GMA) and CDMX, using a human capital approach. The study aims to provide region-specific estimates of the economic impact of RTIs by analyzing mortality and income data across variables such as age, gender, and education. Data were sourced from the National Institute of Statistics and Geography (INEGI), the National Survey of Household Income and Expenditure (ENIGH), and local authorities. The methodological framework involved projecting future income lost due to premature death by combining age-specific annual income with life expectancy estimates, adjusted for inflation, and standardized to 2024 United States Dollars (USD). Statistical analyses were conducted using STATA BE 18.0. The findings reveal a total productivity loss of 300,415,294 USD for the GMA (2015–2022) and 788,590,148 USD for CDMX (2008–2024), representing 1% of each region's GDP in 2021. Gender disparities were evident, with males comprising the majority of RTI-related deaths (81% in GMA; and 77% in CDMX). Noticeably, females in the GMA exhibited lower per capita productivity losses (2,003 USD) compared to males (3,163 USD), reflecting underlying wage inequalities. Educational attainment also influenced outcomes: individuals with higher education levels experienced greater per capita losses due to higher average earnings, but the majority of fatalities occurred among those with lower education levels, exacerbating inequities. This study underscores the critical economic toll of RTIs on urban centers and highlights disparities based on gender, education, and geography. The results indicate that localized interventions are essential, particularly in high-burden areas like Guadalajara and CDMX. While Mexico has implemented national road safety strategies, the persistent economic losses and mortality rates signal the need for more targeted, equitable, and effective policies. The implications of this research extend to public health and economic policy. It emphasizes the necessity of integrating educational and infrastructure improvements into road safety measures. Additionally, the findings support the need for inclusive road safety campaigns addressing gender and socioeconomic disparities. Future research should expand on this work by incorporating non-fatal injuries, healthcare costs, and societal impacts to develop a comprehensive understanding of RTI burdens and guide sustainable, impactful policy reforms.

Ind-974 Impacts of Family Caregiving Intensity and Duration on Working Caregivers in Japan: Balancing Work and Caregiving

PRESENTER: **Saki Sugano**

As the number of individuals balancing caregiving and employment rises in Japan, this study investigates the impact of informal caregiving for parents – including caregiving provision, intensity, duration, and nursing home use - on the labor supply of middle-aged children. Using panel data and instrumental variable estimation with parents' certified long-term care levels as instruments, the results show that caregiving, as well as its duration and intensity, significantly reduces both the likelihood of employment and working hours, especially for women. Beginning to give care more than doubles the odds of labor force exit. When caregiving duration expands over multiple years, each additional caregiving wave (about two years) leads to a 8.4 percentage point reduction in employment probability, highlighting the cumulative burden of prolonged caregiving. Caregiving intensity is strongly associated with reduced work hours, with a 1% increase in caregiving time leading to a 0.41% reduction in working hours. Caregiving also affects mental health adversely for women and even for full-time workers. These findings emphasize the need for targeted policies to support caregivers who need to balance between working and caregiving.

Ind-1364 Mother's Time to Return Home From Work and Obesity

PRESENTER: **Akiko Oishi**

AUTHOR: Takuya Hasebe

Background: There is a persistent concern about child obesity among many countries, and this concern is growing in Japan, where adult obesity rates are relatively low compared to other countries. Obesity in childhood, which impairs human capital accumulation, is associated with adverse health, educational, and labor market outcomes in later life. Given the crucial role of parental time inputs in child development, extensive research has examined the relationship between child obesity and parental employment. However, the impact of parents' specific work schedules on child obesity remains unexplored. As more mothers engage in diverse work schedules, understanding the effects not only of their employment status but also of their work timing is crucial. Using Japanese data, this study empirically investigates how parental work schedules relate to child obesity, focusing specifically on the ' timing of parents' return home from work. Understanding the potential impacts of parents' timing to return home late on children offers valuable insights into work-family conflicts.

Methods: We use nationally representative data from the *Longitudinal Survey of Newborns in the 21st Century*, conducted by Japan's Ministry of Health, Labour and Welfare. This survey has annually tracked all children born in Japan during specific weeks in 2001. We estimate lagged-dependent variable models to control for unobserved time-varying confounding factors. First, we focus on children's health-related behaviors—such as time spent sleeping, watching TV, and playing video games—and treat these as outcome variables to examine their relationship with parents' timing of returning home. Next, we analyze children's anthropometric indicators. Specifically, we use children's body mass index (BMI) and indicators of overweight and obesity as outcome variables. Our primary explanatory variable is the timing of parents' return home from work, defined as a set of dummy variables for each one-hour window. Due to the availability of this variable, we focus on the 7th, 10th, and 12th survey waves, corresponding to children ages 7, 10, and 12 -– crucial development stages.

Results: We find that mothers' late return home significantly affects children's behaviors, including bedtime routines, TV watching, and video game playing. Specifically, when mothers return home late, children's weekday bedtimes are delayed, sleep duration is reduced, and time spent watching TV and playing video games increases. Additionally, when mothers return home from work later, their children's BMI tends to be significantly higher for both girls and boys, even after accounting for unobserved heterogeneity. The increase in BMI is primarily due to greater weight gain among girls and reduced height growth among boys. Although the timing of mothers' return home from work is significantly associated with these child health-related outcomes, fathers' return home timing shows no such associations.

Discussion: Our study highlights the importance of maternal work timing, which has received little attention in the existing literature. Differences between mothers' and fathers' return-home timing may indicate an uneven gender division of child-rearing responsibilities among Japanese parents, which should be considered when designing policies promoting female employment.

Ind-1370 Working Conditions and Health Over the Life-cycle: Evidence From Europe

PRESENTER: **Paolo Micera**, Catholic University of the Sacred Heart

AUTHORS: Michele Belloni, Claudio Lucifora

The study explores the long-term impact of working conditions on the health of European workers over their life cycle, particularly around retirement. Driven by the aging population and tightening pension reforms, many workers face extended careers under varying occupational stressors. This research builds on economic theories that view health as a durable capital stock, shaped by investments in well-being and subject to depreciation due to aging and adverse work environments. Poor working conditions and career instability are strongly correlated with physical and mental health deterioration, with gradients varying across occupational classes and intensifying with age.

The research utilizes data from SHARE (Survey on Health, Ageing, and Retirement in Europe), which offers longitudinal insights into individuals' work history, health, and socio-demographic characteristics. The Job Episode Panel (JEP) within SHARE enables retrospective tracking of labor market experiences using detailed ISCO-08 occupational codes. Additionally, the O*NET dataset provides granular

information on present and past working conditions, including physical, social, and environmental stressors, categorized by occupation.

To measure the cumulative impact of job stressors, the study constructs a composite indicator of career-long exposure to harmful conditions, weighted by job duration and employment status (e.g., full-time or part-time). This measure is correlated with various health outcomes - particularly chronic disease measured by an index of the (Instrumental) Activity Daily Limitations, but also the EUROD mental health indicator - revealing significant relationships between cumulative exposure and deteriorating health, particularly in dimensions such as physical environment and working prospects.

A key challenge is addressing endogeneity, particularly initial selection into jobs, job changes depending on health status leading to reverse causation and the "healthy worker effect," where healthier individuals are more likely to remain employed. To overcome possible biases, the study employs an individual fixed effects instrumental variable (IV-FE) approach using Bartik (1991) types of instruments, leveraging technological shocks that exogenously alter occupational task structures. This method isolates variations in working conditions caused by external factors like computerization, ensuring a more robust estimation of their impact on health. The Bartik's instrument is constructed using data from the antecedent of O*NET, namely the Dictionary of Occupational Titles (D.O.T.) reporting working conditions for the year 1969 which serve as initial conditions for the cohorts in our sample.

Preliminary findings highlight the detrimental effects of cumulative exposure to adverse job conditions on health, with older workers experiencing more pronounced declines. For instance, high physical strain in later career stages equates to health declines typically associated with over a year of aging. The research also emphasizes the role of career instability in compounding health risks. These insights have broad implications for labor market and health policies, emphasizing the need for interventions to improve job quality and support workers transitioning into retirement.

This research contributes to the literature by examining cumulative career-long exposures rather than isolated job conditions. It underscores the importance of addressing occupational health disparities, which vary across countries, sectors, and demographic groups, to promote healthier, more sustainable working lives in an aging Europe.

Ind-1649 Minimum Wage Effects on Mental Health of US Adults: Event Study Evidence from BRFSS, 1993-2019

PRESENTER: **Jaclyn Schess**

AUTHORS: Chris Lowenstein, Michael Reich, William Dow

Background: Given the strong socioeconomic gradient in most health outcomes – especially mental and behavioral health outcomes – the minimum wage may be an effective policy tool to improve population health among low-income populations. Despite the growing number of studies examining this association in the United States, there has been a dearth of research on the differential effects across racial and ethnic groups. This knowledge gap is especially surprising, since Black and Hispanic workers are disproportionately represented in the low-wage workforce. Moreover, the studies that have examined this heterogeneity have employed two-way fixed effects approaches that are potentially biased due to staggered policy adoption and dynamic treatment effects. The recent methodological advances – and the growing prevalence of poor mental and behavioral health among racial and ethnic minorities –warrant a re-evaluation of the effects of minimum wages on mental health outcomes. Research aim: The purpose of this study is to examine the effect of state-level minimum wage increases on self-reported mental, physical, and general health status and alcohol use among a sample of young adults likely exposed to minimum wage hikes. We add to the literature by documenting differences in these outcomes across race and ethnicity and by using event study methods to examine how minimum wage policies may differentially affect mental health outcomes across subgroups of the low-wage workforce. Methods: Our outcomes of interest are obtained from the Behavioral Risk Factor Surveillance System (BRFSS), a telephone-based cross-sectional survey of US adults with approximately 400,000 annual respondents. In this analysis, we use data for survey years 1993 to 2019. Using an event study approach we examine the effect of state-level minimum wage increases on self-reported mental, physical, and general health status and alcohol use among a sample of young adults likely exposed to minimum wage policies. In our event study design, we define qualifying minimum wages as those with year-on-year increases of at least $0.25 (2019$) with at least 2 full calendar years without a minimum wage change prior to the event. To examine dynamic effects over time, we include 5 years following a state-level change. Key results: Our analysis finds that increased minimum wages improve the self-rated health of non-Hispanic Black workers, particularly improving self-rated general health and mental health. We find no overall or group-specific effects on other outcomes (e.g. physical health, frequent mental distress, drinking). In addition, we estimate a placebo of minimum wage effects among working age adults with a Bachelor's degree, and find no effects. Conclusions: This analysis highlights the differential mental health impacts of US labor market policies among racial groups. The results suggest that minimum wage policy can improve mental health among Black young adults.

Economic Evaluation of Care and Programs

MODERATOR: **Mercy Mvundura**,

Ind-1693 Cost Analysis of Sexual and Reproductive Health and Rights Services in Kano and Kaduna States, Nigeria

PRESENTER: **Abubakar Yerima Mohammed**

AUTHORS: Kabiru Gulma, Olufunke Fasawe, Gafar Alawode

Background: Access to comprehensive Sexual and Reproductive Health and Rights (SRHR) services remains limited in Nigeria due to supply-and-demand bottlenecks and inadequate public financing. For instance, the Basic Health Care Provision Fund (BHCPF), a key pro-poor health financing reform, covers only 2 of the 9 essential SRHR services defined by the Guttmacher-Lancet Commission. While national and sub-national governments show growing interest in funding comprehensive SRHR services, there is a lack of data on the financial implications of integrating these services into the public health system. This study addresses the gap by employing a bottom-up cost analysis to estimate the unit costs of SRHR services in Kano and Kaduna—covering family planning, maternal health, and STI prevention—and projecting financial requirements under four coverage scenarios (25%, 50%, 75%, and 100%).

Methodology: The study employed a mixed-method approach to estimate SRHR costs from a health systems perspective. A desk review of the Guttmacher-Lancet SRHR framework defined a comprehensive scope of services across nine domains. A workshop with state officials prioritized interventions and service delivery levels (primary or secondary care). Data was collected from 10 health facilities per state (5 primary, 5 secondary), focusing on facilities with functional pharmaceutical units. Additional population and coverage data were gathered from state documents and surveys. These inputs were analyzed using the OneHealth Tool to estimate costs under four coverage scenarios (25%, 50%, 75%, 100%), disaggregated by service type, human resources and capital investments (equipment and infrastructure).

Results: The analysis revealed significant variations in the per capita and total costs of delivering comprehensive SRHR services in Kano and Kaduna States over a five-year period. In Kaduna, the mean per capita cost ranged from N9,524 ($6) at 25% coverage to N17,072 ($10.7) at 100% coverage. In Kano, the mean per capita cost was slightly higher, ranging from N10,457 ($6.5) at 25% coverage to N16,163 ($10.1) at 100% coverage. Total annual SRHR costs in Kano ranged from 36 to 90 billion Naira, with over 55% of the budget allocated to HIV/AIDS and STI services, followed by maternal and child health (MCH) and sexual health services. Similarly, in Kaduna, total annual costs ranged from 20 to 57 billion Naira, with the largest cost share also dedicated to HIV/AIDS and STI services. Additionally, across both states, direct intervention costs, primarily for drugs, consumables, and supplies, account for over 90% of the costs

Conclusion: This study highlights the significant financial investment required to deliver comprehensive SRHR services in Kano and Kaduna States, emphasizing the critical role of direct intervention costs like drugs and supplies. Variations in costs between states reflect differences in service delivery models and demographic factors. These findings provide a strong evidence base to guide health financing reforms and advocate for integrating comprehensive SRHR services into Nigeria's health system to improve equity and access.

Ind-486 Evaluation of a Graded Care Model for Miscarriage in the UK: Results from a Pilot

PRESENTER: **Corneliu Bolbocean**, University of Oxford
AUTHOR: Adam Devall

Background and Objective: The Birmingham Women's Hospital has implemented a novel Graded Model of Care aimed at standardizing the therapeutic approaches for women experiencing miscarriage in the UK. This 'graded' approach encourages healthcare professionals and patients to take action after the first miscarriage and the response is tapered according to the number of miscarriages. Between January 1, and September 12 2024 a total of 260 women who experienced either sporadic (up to two pregnancy losses) or recurrent miscarriage have been enrolled into the study. Participants have completed the EQ-5D-5L, SF-12, cost questionnaire and the iMTA Questionnaires (iMCQ and iPCQ) at baseline, six-weeks and three months follow-up. The pilot aims to enrol a total of 367 women, with assessments scheduled at baseline, six weeks, three months, and six months post-miscarriage. The objective of this study is to evaluate differences in health outcomes and costs by the type of miscarriage as well as to assess cost-effectiveness and overall health economic implications of the Graded Model of Care. **Methods**: Differences in multi-attribute utility scores, and health utilization and healthcare costs were compared across sporadic vs recurrent miscarriages. These differences were ascertained using the Student t-test for unequal variances, Fisher's exact test to assess differences for categorical variables as well as Kolmogorov–Smirnov tests. For the adjusted analysis, we utilised generalised linear models, regression adjustment matching and entropy matching to examine differences by type of miscarriage. Subgroup analysis by age, ethnicity, and occupation was implemented. **Results (preliminary)**: Women diagnosed with recurrent miscarriage compared to those experienced sporadic miscarriage had lower multi-attribute utility score measured using EQ-5D-5L (-0.03, $p<0.042$), and higher overall total costs. Multi-attribute utility scores and total costs showed substantial variation between ethnicity, age, and occupation. **Conclusion (preliminary)**: Recurrent miscarriage is associated with lower overall health-related quality of life, particularly in terms of pain/discomfort and anxiety/depression and usual activities. EQ-5D-5L is likely able to discriminate between women who experienced sporadic vs recurrent miscarriage.

Ind-759 Value Assessment of Subcutaneous Depot Medroxyprogesterone Acetate (DMPA-SC) in Low-and Middle-Income Countries: Using a Cost-Effectiveness Framework

PRESENTER: **Ranju Baral**, PATH
AUTHORS: Marley Gibbons, Mercy Mvundura, Bonnie Keith, Ashley Jackson, Clint Pecenka

Background: The injectable contraceptive, subcutaneous depot medroxyprogesterone acetate (DMPA-SC), is shown to be effective, feasible, and acceptable. DMPA-SC is easy to use, enabling any trained person to administer it, including clients themselves through self-injection (SI). Mainstreaming DMPA-SC and self-injection (SI) within national family planning programs can reach new users, improve contraceptive continuation rates, and reduce burdens on health care providers and facilities. A few studies have evaluated the costs and the cost-effectiveness of DMPA-SC, primarily in pilot implementation settings. However, health economic evidence to inform policy decisions on scaling up DMPA-SC access remains limited in low- and middle-income countries (LMICs). In this analysis we evaluate cost-effectiveness of DMPA-SC self-injection compared to provider-administered injectable contraceptives in three countries: Kenya, Nigeria, and Pakistan. **Methods:** We developed a static decision tree model for a cohort of injectable contraceptive users in each study country over a period of 12 months. The model will estimate the incremental costs per unintended pregnancy averted and the cost per disability-adjusted life year (DALY) averted, both from societal and health systems perspectives. Data on rate of contraceptive continuation and input costs will be derived from peer-reviewed

literature and supplemented by operational data, as available, with inputs from key stakeholders from each country's national family planning program. Cost-effectiveness will be evaluated under several program implementation scenarios such as task-sharing—including with community health workers, and alternative job aids; the quantity of take-home devices for self-injection and intensity of client training time; including value to potential clients in terms of time and resources saved. One-way and probabilistic sensitivity analysis will be conducted to test the robustness of cost-effectiveness estimates. **Results:** This study is currently underway with results anticipated in March 2025. Initial engagements with key in-country stakeholders are ongoing to inform the cost-effectiveness model and the input data parameters. Health systems costs will include both direct and indirect costs. Direct costs will include product, training of health workers and counselors, training materials, and health worker time spent training and counseling. Indirect costs will include client travel expenses and the cost-savings from opportunity cost of traveling to health facility. **Conclusions:** Evidence on cost-effectiveness of public health interventions is critical to inform decisions around their introduction and use. Results generated from this study will fill current gaps in health economic evidence around DMPA-SC in select LMICs which remain crucial for countries' contraceptive method mix prioritization and resource allocation.

Ind-55 A Systematic Review on Health Economic Evaluations of Telemedicine

PRESENTER: **Dr. Cheryl Chong Zhiya, MBBS, MPH**
AUTHORS: Jonathan Chng Jia Hao, Ray Chong Junrui

Introduction Telemedicine has emerged as a viable healthcare delivery model, particularly following the COVID-19 pandemic. Its potential to reduce healthcare costs and improve patient outcomes has garnered significant attention. This systematic review aims to evaluate the existing literature on the economic evaluation of telemedicine interventions. Methods A systematic review was performed based on a systematic search of literature published from 2014 to 2024, conducted in MEDLINE and PubMed, using keywords "telemedicine," "telehealth", "teleconsults", "economic evaluation", "cost-effectiveness", "cost-benefit" and "cost-utility". The search was limited to studies published in English-language journals between 2014-2024. The 10 year publication limit was applied as there has been significant changes and advancements in telemedicine in recent years, and older publications may not be as relevant. The inclusion criteria for the study were studies that discussed telemedicine and its associated costs. Studies which did not discuss telemedicine were excluded. Prior to inclusion, the studies were also evaluated for their relevance and applicability to the research question. Included studies were analyzed for methodology, sample size, data collection methods, and key findings. Results The majority of studies included in this review employed cost-effectiveness analysis to evaluate the economic implications of telemedicine in primary care. However, a few studies also utilized cost-benefit analysis and cost-utility analysis, providing a more comprehensive assessment of the potential benefits and costs. Findings suggest that telemedicine can offer economic advantages compared to traditional in-person consultations. This is particularly evident for certain conditions and patient populations, such as those with chronic diseases or limited mobility. However, the extent of cost savings varies across studies, highlighting the importance of considering specific contexts and patient characteristics. Conclusion Various economic evaluation methods performed in a variety of contexts suggest the advantages of telemedicine. Factors such as the type of condition, the complexity of care, and the implementation of telemedicine services can influence the economic benefits realized. Therefore, further research is needed to establish the long-term cost-effectiveness of telemedicine in different primary care settings and for diverse patient populations.

Ind-545 The Impact of Surgical Robotics on Surgical Risk and Uncertainty: A Comprehensive Economic Evaluation

PRESENTER: **Ermo Chen**

The widespread adoption of surgical robotics in clinical practice stands in stark contrast to the inconsistent findings in health technology assessment (HTA) studies. This divergence likely stems from the inability of mean-based HTA tools to capture the risk mitigation capabilities of surgical robotics. While surgical robotics may not fundamentally alter the clinical mechanisms of certain surgeries, their standardization and stability mitigate the inherent uncertainties of human actions, potentially leading to more consistent outcomes. This distributional aspect of outcome warrants discussion in HTA evaluations.

This paper evaluates the impact of introducing surgical robotics in healthcare institutions on the risk and uncertainty of service outcomes. The variation in hospital stay duration, clinical outcomes, postoperative complications, clinical errors, and intervention costs are all incorporated into the assessment. Utilizing service records from a market-dominant surgical robotics supplier and statistical data from an IT provider covering over four thousand hospitals in China, a sample set of 4,231 hospitals with 30,936 hospital-quarters, covering 15 years (2007 - 2022) and 29 provinces, is analyzed in this paper.

To analyze the overall effect on hospitals by introducing surgical robotics, the evaluation is made on model points made of hospital-quarters, as only grouped attributes contain distributional information. A time-varying difference-in-differences approach is introduced to identify the causal effects of introducing surgical robotics. A mixed causal inference test is used to ensure robust conclusions. Additionally, we developed a novel generalized linear regression method tailored for variance decomposition, which is proposed for a coherent framework of uncertainty analysis.

Empirical results indicate that, for each 1% increase in the proportion of surgeries performed by surgical robots, it leads to a 0.0288% (p-value: 0.018) reduction in surgical mortality rates, with no significant change in hospital stay duration. Also, there is a 2.12E-6 (p-value < 0.001) reduction in the rate of surgical errors and a 6.19E-6 (p-value: 0.009) reduction in postoperative complications for each 1% increase in the proportion of surgeries performed by surgical robots, at the cost of a $369.26 (p-value < 0.001) increase in average intervention cost.

In conclusion, this paper shows that the introduction of surgical robotics significantly reduces surgical mortality rates and substantially diminishes the uncertainty associated with medical errors and postoperative complications. These benefits are under a considerable but

acceptable cost. These findings underscore the importance of considering the risk-mitigating aspects of surgical robotics in economic evaluations of this health technology, which may lead to more consistent HTA findings.

Ind-1140 Evaluation Cost-Effectiveness of Importing Metagenomics in China ICU Surveillance: The Acute Respiratory Distress Syndrome Modelling Analysis

PRESENTER: **Zhongzhou Yang**
AUTHORS: Liwei Diao, Haiyan Zhang, Eric HY Lau, Na Liu, Shaolin Liang, Yang Yang, Yu Cheng, Yanru Guo, Yinhua Zhou

Introduction: Though the rapid pathogen investigation metagenomics (mNGS) is available in China's independent clinical laboratory (ICL), it has yet been introduced into the surveillance and is hence not accessible to ICU pneumonia inpatients.* *This study targeted to evaluate the cost-effectiveness of incorporating mNGS in high mortality acute respiratory distress syndrome (ARDS) from pneumonia inpatients.* ***Methods:*** *We developed a decision-tree model to estimate the cost-effectiveness of incorporating mNGS into the Clinical laboratory department for ARDS in hospital ICU (CAI) compared to the conventional culture followed by Consolidated Health Economic Evaluation Reporting (CHEERS) guidelines.** ARDS mortality was sourced from the Clinical Diagnosis and Prognosis by Severe Pneumonia (CDPSR) study, whereas incidences were sourced from the prospective Incidence and Outcomes Multicenter Prospective Longitudinal (IOMPL) cohort. The model accounted for three scenario combinations: scenario 1(100% culture), scenario 2 (100% mNGS), scenario 3 (both culture and mNGS). The number of ARDS death, incremental cost per death averted and TAT were estimated at the provincial levels. Both DSA and PSA were conducted to investigate model uncertainty. **Results:** Compared with baseline scenario 1, mNGS prominent inpatient for scenario 2 would reduce 1843 ARDS death (25%), shorten 600,883 turnaround time (TAT) days and $39,595 per death averted among the standardized 100,000 pneumonia inpatients, with two cost-effective regions among 13 regions. Compared with scenario 1, performing the scenario 3 would avert 814 ARDS deaths (11% reduction) and extended 265,590 TAT days on $14,791 per death averted among 100,000 pneumonia inpatients and more effective, if the scenario 3 achieved 55% culture and 45% mNGS. Two comparisons implied the robust results when fluctuating all 26 model parameters, which PSA showed the most influential parameter was probability from ARDS to ICU death and mNGS cost might reduce $170 to the merit for TAT. **Conclusion:** Our findings emphasize the cost-effectiveness of incorporating mNGS in China ARDS surveillance. Regional findings supported the optimal import of mNGS priority should be provided to pneumonia inpatients. 1

Ind-1815 Estimating the Societal Willingness-to-Pay per Quality-Adjusted Life Year to Aid Health Technology Assessment in India

PRESENTER: **Yashika Chugh**
AUTHORS: Gaurav Jyani, Aarti Goyal, Sitanshu Kar, Binod Kumar Patro, Mayur Trivedi, Sandra Albert, Prakash Singh, Swati Raman, PVM Lakshmi, Kavitha Rajsekar, Cam Donaldson, Shankar Prinja

Objective: The study aimed to estimate the willingness to pay (WTP) for a quality-adjusted life year (QALY) to help determine the threshold for cost-effectiveness in India. We also assessed the factors affecting WTP/QALY. *Methods:* We used a multi-stage stratified random sampling strategy to select 5460 respondents across six Indian states. Participants were interviewed to gather household socioeconomic and demographic data, followed by assessments of health gains using time trade-off (TTO) and WTP. Respondents were presented with 12 hypothetical health states to gauge health gains and their WTP to restore health. These values were combined to determine WTP per QALY using an aggregated approach. Weighted estimates based on state, residence, gender, age, and education were computed. A mixed-effect regression model explored the relationship between socio-demographic variables and WTP/QALY. *Results:* Based on 21,640 observations, we found that mean weighted WTP/QALY was estimated to be INR 2,12,307 (USD2,535) which is 1.24 times the gross domestic product (GDP) per capita. Based on the different health states, the WTP/QALY ranged from USD 2,034 for mild conditions to Rs. USD 3,092 for severe health conditions. Health state utilities ranged from 0.156 (advanced lung cancer) to 0.846 (mild allergy). Age, gender, family size, education, marital status, occupation, presence of health insurance, consumption expenditure, and number of earning members in the household significantly impacted WTP per QALY. *Conclusion:* Our study reports the first-ever estimate of WTP/QALY for the Indian population. The WTP/QALY ranges from 1-1.52 times the GDP per capita. This is a valid estimate for setting a cost-effectiveness threshold for health technology assessment in India.

Ind-2641 Beyond Realist Evaluation: Review of theory-informed Economic Evaluation: Evidence From Published Realist Economic Evaluation

PRESENTER: **Olawale Joshua Oladimeji**, Obafemi Awolowo University
AUTHORS: Tim Tenbensel, Karen Bissell, Paula Lorgelly

Realist Economic Evaluation (REE) is a developing methodology in health economics that builds on the existing knowledge and principles of both realist evaluation and economic evaluation. Applying a realist approach to analyze economically sensitive program theories may elicit limited findings because the underpinning concepts of realism are not structured to explore the cost and consequences of health interventions. A limitation of economic evaluation when applied to complex health interventions includes a minimal focus on how or why the outcomes were produced and how context and mechanisms affect cost-effectiveness. These are some key limitations the REE approach attempts to address by providing a theory-informed economic evaluation that would generate comprehensive evidence for policymakers. Over the last ten years, there has been a gradual increase in published literature related to the realist economic evaluation approach. However, no review of the realist economic evaluation studies has been conducted. This scoping review aims to determine how realist economic evaluation is applied in the health system space, justification for the use and identify the methodological challenges while applying this approach. **Methods:** We started our scoping review with terms such as theory-informed, complex theory, economic evaluation, theory-driven, and realist evaluation. Our initial Scopus search results showed that the search strategy was neither specific nor sensitive. It led to a very large number of publications that were not relevant and missed important papers we already knew. We reviewed Mesh vocabulary and definitions to improve the sensitivity and specificity. We interchangeably added the terms theory-informed economic evaluation, theory-driven economic evaluation, and realist economic evaluation. This resulted in 218 initial hits. These were reviewed based on the set inclusion and exclusion criteria, such as conceptual or

theoretical papers, studies reporting on health system research, papers published in English language and over the last ten years. The review was concluded in September 2024. **Findings:** We found 8 papers published between 2016 and 2023. All the studies were either United Kingdom- or Australia-based. There was some diversity in the justification for the use of REE, such as the opportunities to combine the benefits of realist and economic evaluation approaches in research, to explore economically related and non-related contextual factors and mechanisms, and being able to address the questions of what works for whom, how and under what circumstances while exploring resource use and cost. A lack of firm methodological guidance because it is a new approach was reflected in the findings. **Conclusion:** The realist economic evaluation approach is relevant in evaluating complex health interventions. However, there is diversity in the justification for its application. More clarity on methodological guidance and application in complex interventions that are cross-cutting in health systems will expand its use in research methods and policymaking.

Ind-1847 The Cost and Cost-effectiveness of a Cash Transfer Plus Economic Empowerment Intervention for Promoting Caregiver Wellbeing in South Africa

PRESENTER: **Darshini Govindasamy**, MRC South Africa
AUTHORS: Nwabisa Shai, Arvin Bhana, Stanley Carries, Nokwanda Sithole, Lovemore Sigwadhi, Audrey Moyo, Andrew Gibbs, Angela Kaida, Kalysha Closson

Background: The wellbeing among caregivers of children and adolescents living with HIV/AIDS (CALHIV) was compromised during COVID-19, further widening health, gender and economic inequities. As part of South Africa's post-pandemic recovery policy to improve wellbeing among the most vulnerable, national roll-out of the COVID-19 Social Relief of Distress (SRD) grant continues. Leveraging the SRD grant through combining it with a caregiver-centered gender-transformative economic empowerment programme could amplify the policy's wellbeing effects for caregivers. Given constrained HIV/AIDS budgets, understanding the delivery costs and wellbeing gains will support the investment case for prioritising caregivers of CALHIV in pandemic recovery efforts. We report on the cost and cost-effectiveness of the caregiver wellbeing Plus (CWEL+) intervention, comprising a cash transfer, resembling South Africa's SRD grant, plus a gender-transformative economic empowerment programme.

Research question: Is the CWEL+ intervention a cost-effective strategy for South Africa's post-pandemic relief policy?

Methods: The CWEL+ intervention was evaluated via a two-arm pilot cluster-randomised trial, conducted between July 2023-July 2024 with women caregivers (n=273) from 20 HIV clinics (10 clusters per arm) in the eThekwini Municipality, KwaZulu-Natal, South Africa. Intervention clusters (n=149 caregivers) received a monthly cash transfer to the value of the SRD grant (US$19) and the gender-transformative economic empowerment programme over 6-months. Control clusters (n=124 caregivers) only received the monthly cash transfer (US$19). The primary outcome was change in psychological wellbeing (measured using the Mental Health Continuum-Short Form) at 7-months follow-up. We conducted prospective cost data collection from intervention manual development through to delivery of the trial. Cost data were obtained from multiple sources (project accounts, trial database, time-and-motion study). The costing analysis was conducted from a provider perspective. We estimated the average cost per increase in psychological wellbeing score by arm. We fitted a Markov model to estimate the incremental cost effectiveness ratio (ICER) in terms of quality-adjusted life years gained in the long-run and assessed robustness of results via a one-way sensitivity analysis. All costs were reported in 2023 USD ($).

Results: Among the sample, the mean age was 37 years (SD: 9.06), with a high prevalence of HIV (84%), unemployment (99%), low to moderate psychological wellbeing (52%), and intimate partner violence (63%). Socio-demographic characteristics were balanced across arms. We found an increase in psychological wellbeing in the intervention versus the control arm (β=3.17, 95% CI:1.35, 5.00). The average provider cost per participant was higher in the intervention (US$ 575) versus the control (US$ 121) arm, largely driven by variable costs such as venue and staffing for the empowerment sessions. The ICER was US$1,413 suggesting that the CWEL+ intervention is cost-effective as below the threshold of <3 x South Africa's 2023 gross domestic product per capita of $6,018. Results were robust to changes in model parameters.

Conclusion: Our findings demonstrate that augmenting South Africa's SRD grant with a gender-transformative economic empowerment programme is cost-effective and a potentially affordable strategy to improve caregiver wellbeing in pandemic recovery efforts. A larger scale trial incorporating a cost-benefit analysis is needed to confirm results.

Ind-2186 Methods for the Economic Evaluation of Health Impacts of Climate Action: When, Why, and How Best to Use Them? A Literature Review

PRESENTER: **Mireia Jofre-Bonet**, Office of Health Economics
AUTHORS: Patricia Cubi-Molla, Paul Oyalo, Caitlin Macclancy, Jane Falconer, Mr. Andrew Briggs, Sarah Whitmee, Chris Skedgel

Background and Motivation: Climate action holds the promise of delivering significant health benefits, including increased life expectancy, improved quality of life, and enhanced global well-being. Despite this potential, there is no standardized methodology to quantify these health impacts and assess the cost-effectiveness of climate action interventions throguh economic evaluation frameworks. This review seeks to address this gap by analysing frameworks from health economics and environmental economics that assess the economic value of health co-benefits from climate action. The objective is to guide policymakers toward adopting consistent and evidence-based methods to prioritize interventions that yield both environmental and health benefits. **Methods:** A systematic literature review was conducted to explore the research landscape on the economic evaluation of health impacts arising from climate action. Policy reports and grey literature were also reviewed to ensure comprehensive coverage. Methodological frameworks from health and environmental economics were compared to evaluate their respective strengths, limitations, and gaps in capturing health co-benefits in climate policy assessments. **Results and Expected Contribution:** Preliminary findings suggest that health economics provides detailed and robust methodologies for quantifying health outcomes, but these methods are often underutilized in climate policy evaluations. Conversely, environmental economics offers a broader assessment of climate impacts but frequently lacks standardized and rigorous health metrics aligned with health economics frameworks. This review synthesises these insights to propose an

integrated framework for evaluating the economic value of health co-benefits in climate policies. **Conclusion:** This study lays the groundwork for advancing economic evaluations of health impacts in climate action. By integrating approaches from health and environmental economics, the findings aim to inform policymakers in designing evidence-based, systematic, and coherent climate policies that reflect both economic and health benefits.

Ind-2664 The Cost-Effectiveness of Social and Behavior Change Interventions and Cessation Services in Reducing Alcohol-Related Health Harms in the Philippines

PRESENTER: **Andrea Margreth Ora-Corachea**

Background: No level of alcohol consumption is without risk. According to the World Health Organization (2023), there is no safe level of alcohol consumption; even at low levels, there are potential risks to human health, including an increased risk of cancers, liver diseases, and cardiovascular problems. In the Philippines, alcohol consumption is one of the leading risk factors for combined death and disability, with 3.1% or approximately 27,477 Filipino deaths attributable to alcohol in 2021 (Global Burden of Disease [GBD], 2021). National policies have been enacted to improve health outcomes linked with alcohol consumption, including Sin Tax Reforms, the Anti-Drunk Driving Act, and the Mental Health Act. Despite these measures, between 2015 and 2021, the Philippines consistently recorded that about half (48.4%) of its adult population and at least 1 in every 10 adolescents (14.9%) are current alcohol drinkers. It is estimated that alcohol consumption costs the government about PhP 200 billion annually, with the majority spent on treating individuals with alcohol problems.

Objective: The study aims to assess the cost-effectiveness of instituting social and behavior change interventions and alcohol cessation services to avert alcohol-related harms in the Philippines.

Methods: A mixed-method approach combining policy analysis and economic evaluation was employed. The policy analysis assessed the public health impact, budgetary impact, and operational and political feasibility of four policy options: (1) status quo (ad hoc education campaigns integrated into health messaging during major celebrations or holidays), (2) social and behavior change campaign, (3) alcohol cessation services, and (4) combination of the social and behavior change campaign and cessation services. A Markov model was used to estimate costs, disability-adjusted life years (DALYs), and the incremental cost-effectiveness ratio (ICER) from a public health perspective. The base case model assumes a lifetime horizon, with a 3.66% annual discount rate applied to future costs and benefits.

Results: Analysis of the policy options shows that implementing social and behavior change interventions, cessation services, or their combination would yield significant public health impact, albeit with substantial budgetary requirements. The cost-effectiveness analysis indicates that implementing the combined strategy of social and behavior change communication and cessation services yields the highest ICER, within the willingness-to-pay threshold.

Conclusion and Policy Implications: The study underscores the importance of a comprehensive program that delivers a package of health interventions—ranging from health promotion to treatment and rehabilitation—aimed at reducing the prevalence of alcohol consumption and its associated morbidity and mortality. The findings will offer evidence-based recommendations on the cost-effectiveness of implementing various policy interventions across the continuum of care and guide resource allocation, including the potential development of a social insurance benefit package for alcohol prevention and control. These findings may also serve as a reference for other low- and middle-income countries seeking to implement policies to reduce alcohol consumption and its related harms.

Ind-145 Economic Evaluation of Caregiver Interventions for Children With Developmental Disabilities: a scoping review

PRESENTER: **Angela Kairu**

AUTHORS: Edwine Barasa, Amina Abubakar, Rosa Hoekstra, Charles Newton, Edwin Dzoro, Vibian Angwenyi, Charlotte Hanlon

Introduction Globally, families with children with developmental disabilities (DDs) may experience several challenges, including social isolation, stigma, and poverty especially in low-income settings in Africa. Most children with DDs in Africa remain unidentified and receive no formal support. Caregiver interventions focusing on education and training for carers of children with DDs have been shown to be adaptable and low intensity in implementation. However, economic evaluation evidence on caregiver interventions for DD, which is important for effective resource allocation, is limited. This review aimed to describe the nature of evidence available and methodological aspects of economic evaluations for caregiver interventions for DDs. **Methods** This scoping review employed the Arksey and O'Malley framework and aligned with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR). Seven electronic databases, grey literature and cited references were systematically searched to identify eligible studies on economic evaluations of caregiver interventions for children with DDs published in 1993-2024. We assessed the quality of the included studies using the Drummond checklist. Data were systematically extracted, tabulated, and qualitatively synthesised using inductive thematic analysis. **Results** The searches yielded 7811 articles. Twenty studies all in high-income countries met the inclusion criteria which focused on caregiver interventions for autism spectrum disorder (n=7), attention deficit hyperactivity disorder (ADHD) (n=6), disruptive behaviour and behaviour problems with ADHD (n=5), intellectual disabilities (n=1) and language delay (n=1). The most used economic evaluation approach was trial based models (n=14), followed by decision analytic models (n=5)). The methods were not explicitly stated in 1 study. Economic evaluation analyses included cost effectiveness (n=11), costing (n=3), cost utility (n=2), cost consequence (n=1) cost benefit (n=1), and combined analyses (n=2). Nine studies reported the interventions as cost effective, five studies reported the intervention to be cost saving, and one identified caregiver costs as a cost driver. The main identified methodological challenges were related to costing, outcome measurement in children and the appropriate time horizon for modelling. **Conclusion** Caregiver interventions demonstrate cost-effectiveness, with the available evidence supporting the adoption of the interventions evaluated. Caregiver interventions are a promising avenue to strengthen access and reduce costs associated with health services for children with DDs. Additionally, this review identified key methodological challenges and highlighted areas for further research to address these limitations. Prioritizing more economic evaluation studies in this area would inform decision-making on efficient resource allocation, promote inclusivity and equitable access to services for children with DDs. **Key words:** developmental disabilities, caregiver

interventions, economic evaluation, scoping review

Ind-331 The Cost of Eating Disorders for Australia's Health System: A Linked Health Administrative Data Analysis from 2005 to 2019

PRESENTER: **Moin Ahmed**
AUTHORS: Kelly Dann, Stephen Touyz, Jane Miskovic-Wheatley, Amy Hannigan, Sarah Maguire, Francisco Schneuer, Natasha Nassar, Morgan Sidari, Michelle Cunich

Background and objective Eating disorders (EDs) are serious, complex psychiatric disorders that lead to significant health and psychosocial complications, along with increased mortality rates. In particular, EDs are a concern for healthcare administrators due to the associated severity of effects on physical and mental health, critical and complex healthcare needs, and high costs to health systems. However, there is a lack of studies investigating the health system cost of EDs and its trend using linked health administrative data in Australia. To address this research gap, this study aims to estimate the annual hospital costs (hospital admission, emergency department visits, outpatient/clinic visits) for people with EDs in New South Wales (NSW) and Queensland (QLD) from 2005 to 2019. Further, it also investigates the main factors of these healthcare costs in the two states using econometric methods. **Methods** Several linked health administrative health datasets in NSW and QLD, including hospital data, emergency department data, and outpatient data from 2005 to 2019, are used for this study. Individuals with EDs are identified from data using relevant ICD-10 AM (F50.x), ICD 9 CM and SNOMED CT AU diagnostic codes. A healthcare provider perspective using a bottom-up costing method is utilised to estimate annual costs. Costs are standardised to Australian dollar ($) 2024. Multiple regression analysis (two-part model) is used to estimate the marginal cost due to EDs, and to identify the factors associated with these healthcare costs. **Results** This study will be the first to examine the longitudinal trends in, and factors for, the various hospital costs associated with EDs in two of the most populated states in Australia, NSW and QLD. Results will reveal variations, if any, in healthcare costs over the study period, and by types of EDs, by estimating annual average cost per patient and annual total cost. The analysis will show the share of cost for hospital admissions, outpatient visits and emergency department visits. The study will also identify the influence of demographic factors, socioeconomic status, and remoteness of residence on the cost distribution. Trends over time will reveal an overall pattern in costs, indicating changes in demand for healthcare services related to EDs. **Conclusions** The findings from this study will highlight priority areas for policy intervention/ resource allocation by identifying variations in costs across hospital services, demographic factors, socioeconomic status and geographic remoteness. Such information can be used by healthcare executives and policymakers to make decisions regarding the optimum allocation of resources within the health sector. Up-to-date estimates of the hospital costs provided in this study can also be used in economic evaluations of preventive and treatment strategies designed to improve the quality of life of people with EDs in a cost-effective way. **Keywords:** healthcare cost; health system cost; economic cost; eating disorders; Australia

Ind-604 Community Action for Health in India: At What Cost?

PRESENTER: **Apoorva Nambiar**
AUTHORS: Neymat Chadha, Devaki Nambiar

Community Action for Health (CAH) initiatives are integral to India’s public health strategy, enabling community involvement in setting health priorities, delivering services, and monitoring health outcomes. Despite their recognised impact, there remains limited understanding of the financial dimensions of CAH, particularly the range of costs borne by stakeholders such as government bodies, NGOs, and local communities. Existing studies lack a detailed breakdown of these costs, posing challenges for policymakers and health planners in assessing the sustainability, scalability, and cost-effectiveness of CAH programs. To address this critical gap, this study, for the first time, develops a comprehensive costing framework that captures the full spectrum of costs associated with CAH initiatives across India’s diverse socio-economic and geographic contexts. This framework encompasses direct, indirect, fixed, and variable costs, providing a structured view of resource allocation. Guided by the question, “At what cost are CAH initiatives implemented in India?” this study employs a realist review methodology, synthesizing data from peer-reviewed literature on CAH alongside empirical program-specific cost data from multiple Indian states. The framework includes core cost components spanning human resources (e.g., salaries for civil society implementers, Accredited Social Health Activists, Auxiliary Nurse Midwives, stipends for community health volunteers), infrastructure (e.g., office and space rental, health center upgrades, maintenance costs), service delivery (e.g., preparatory and final meeting costs, health (information) kits and materials, other coordination activities and outreach), monitoring and evaluation (e.g., data collection tools, feedback mechanisms), and community engagement (e.g., inclusion of awareness materials, ancillary support provided to communities (like childcare), support for cultural events), among others. Costs are systematically categorized as fixed or variable, direct or indirect, based on their frequency and type, offering a detailed picture of financial responsibilities and burdens across stakeholders, including lay, state, and community actors. Preliminary findings also indicate substantial cost differences across regions. For instance, transportation costs are notably higher in rural and remote areas with challenging terrain, while human resource costs fluctuate due to state-specific salary scales, socio-economic factors. Region-specific analysis reveals both actual costs, representing immediate expenditures, and normative costs, reflecting the resources ideally required to meet program goals effectively. Substantial indirect costs, such as NGO staff, and community volunteer time and opportunity costs, place a considerable financial burden on community members and local organizations supporting CAH activities. By providing a structure, itemized view of CAH costs within an adaptable framework, this study holds significant implications for policy and practice. The framework provides policymakers and health economists with a practical tool for evaluating financial sustainability, optimizing resource allocation, and making data-driven decisions to strengthen CAH programs. In highlighting areas for potential cost savings and equitable funding strategies, this research underscores the importance of integrating economic evaluations into community health planning to develop sustainable, scalable, and equitable CAH programs. Furthermore, this framework serves as a replicable model for economic assessments of similar community-based health interventions, contributing to a deeper understanding of the financial realities of participatory health programs.

Financing Emergency Response and Preparedness

MODERATOR: **Gavin Surgey**,

Ind-1514 Optimizing the Procurement of Covid-19 Vaccines: A Case for a Pooled Procurement Model for Medical Supplies in the Asia-Pacific

PRESENTER: **Udeni De Silva Perera**
AUTHORS: Kaung Mon Winn, Maame Esi Woode, Benjamin Coghlan

Background: The COVID-19 pandemic exposed significant gaps in global health systems and timely access to medical products including vaccines by low- and middle-income countries. Unlike countries that benefited from pooled procurement mechanisms, countries in the Asia-Pacific (APAC) region found it difficult to secure sufficient COVID-19 vaccines and at reasonable prices.

Methods: Using data on vaccine volumes, prices and coverage from verified sources, this study explores the COVID-19 vaccine procurement mechanisms in the APAC region and its impact on health outcomes, comparing it with those in the Latin America and the Caribbean (LAC) region, where countries benefited from existing pooled procurement mechanisms through the Pan American Health Organization (PAHO).

Results: Results indicate that countries in the LAC collectively procured more vaccine doses per 100 population, particularly in 2021 (10.8 doses/100 for LAC countries compared to 9.3 doses/100 for APAC). In terms of procurement cost, the highest average per-capita cost over 2021-2023 period within the LAC region was recorded in Colombia (US $5.24); considerably lower than the highest average per-capita cost recorded within the APAC region (US $7.48 for Tuvalu). Significant heterogeneity in prices paid for different COVID-19 vaccine brands, across the two regions was observed with some APAC countries paying significantly higher prices, per dose for certain brands, across 2021-2023. Using hierarchical mixed effects models, we show consistently stronger positive impact of COVID-19 vaccine coverage on daily case fatality rate and mortality within the LAC region with even stronger results observed for lower-middle income countries.

Conclusions: Overall results suggest that countries in the APAC region could have realised cost savings and improved health outcomes through a collaborative procurement mechanism during the pandemic.

Keywords: Vaccine procurement, COVID-19, regional cooperation, Asia and the Pacific, Latin America and the Caribbean, Pan American Health Organization

Ind-622 Utilizing the WHO's System of Health Account Dimension for Tracking the Financial Flows of Indonesia's COVID-19 Vaccination Program

PRESENTER: **Olivia Herlinda**, Center for Indonesia s Strategic Development Initiatives (CISDI)
AUTHORS: Ayudina Larasanti, Sayyid Muhammad Jundullah, Sinta Amalia Kusumastuti Sumulyo, Indra Yudha Mambea

Introduction: The COVID-19 vaccination program is essential for preventing the spread of COVID-19, and it requires dedicated funding to ensure equitable vaccine access. Despite available funding mechanisms for the COVID-19 vaccination program, disparities remained in certain areas. This study aims to track the source, allocation, and utilization of province and district-level expenditures on the COVID-19 vaccination program in order to discover financial gaps that affected coverage. **Methods:** This study used a mixed-methods approach using dimensions of the system of health account (SHA) framework to track expenditure of Indonesia's COVID-19 vaccination program. We collected expenditure data and conducted in-depth interviews from four provincial health offices (PHOs) and four district health offices (DHOs) in Indonesia. To gather more comprehensive insights, three focus group discussions (FGDs) were held with ministries and government agencies, subnational bodies, and civil society organizations. **Results:** Expenditure tracking is classified through the dimensions of the SHA framework, including financial sources, healthcare functions, programs, health activity, and health input. The results of expenditure tracking show that the COVID-19 vaccination program in Indonesia is primarily covered by the national or regional budget. The largest expenditures generally included funding for the cold chain, distribution, vaccinator incentives, and per diem. **Discussion:** There is variation in the expenditure for the COVID-19 vaccination program across subnational levels based on factors such as government fiscal capacity, institutional capacity, and geographical barriers. Numerous factors other than the amount of health expenditures can influence the outcomes of health programs, including maximizing the involvement of the private sector, which are essential elements. **Conclusion:** This study found that Indonesia's complex health financing mechanism, coupled with limited fiscal capacity, struggles to ensure equitable vaccination delivery, especially in underserved areas. The budget transfer process from central to subnational levels is inadequate to account for vulnerabilities like geographical challenges. These disparities underscore the need for more coordinated and flexible health financing mechanisms during pandemics. Developing resource allocation guidelines and improving national-to-local resource distribution during health crises are essential for better outcomes. **Keywords:** Expenditure, COVID-19, Vaccine, Health, Government, Financing

Ind-2119 The Role of Public Financial Management in Strengthening Health Emergency Preparedness and Response

PRESENTER: **Jacopo Gabani**, University of York

Background: The emergence of global pandemics such as COVID-19 has underscored the critical importance of robust public financial management (PFM) systems in health crisis preparedness and response. Effective PFM enables governments to mobilize, allocate, and utilize

financial resources efficiently and transparently, which is essential for timely intervention during health emergencies. This study investigates how PFM practices enhance or hinder health emergency preparedness and response and provides. **Methods:** The study develops a logical framework on how PFM relates to health emergency preparedness and response. A systematic literature review of publications from 2000 to 2023 was performed, sourcing articles from databases including PubMed, Scopus, and the World Bank Repository. The review focused on PFM components such as budgeting flexibility, procurement processes, expenditure tracking, and financial accountability in the context of pandemics. Additionally, case studies of countries affected by recent pandemics (e.g., SARS, H1N1, Ebola, and COVID-19) were examined to assess practical applications and outcomes of PFM strategies during health crises. Findings from the literature review and case studies were applied to dimensions mapped out in the logical framework. **Results:** The study found that countries with agile and transparent PFM systems demonstrated more effective pandemic responses. Key findings include: - **Budget Tagging:** Identifying what interventions across sectors relate to health emergency preparedness in the budget preparation process helps foster political support and prioritization during quiet years. - **Surge Financing Capacity and Budget Flexibility:** Countries with mechanisms for emergency funding and reallocation of budgets were able to respond more swiftly to emerging health needs. Flexible budgeting practices allowed to act as a first line of defense for the rapid deployment of resources to critical areas such as healthcare infrastructure, personnel, and vaccine procurement. - **Efficient Procurement Processes:** Streamlined procurement regulations facilitated quicker acquisition of essential medical supplies and equipment. Countries that adapted their procurement laws to allow for emergency procedures avoided delays commonly associated with standard bureaucratic processes. - **Financial Accountability and Transparency:** Strong oversight and audit systems mitigated risks of corruption and mismanagement of funds. - **Intersectoral Coordination:** Effective collaboration between ministries of finance and health, along with other stakeholders, improved resource mobilization and allocation. Integrated PFM and health planning resulted in more coherent and comprehensive pandemic responses. Challenges identified included rigid budget structures that limited rapid funding allocation, complex procurement regulations causing delays, and insufficient financial management capacity within health ministries. **Conclusion:** Strengthening PFM systems is crucial for enhancing health emergency preparedness and response capabilities. Key recommendations include adopting flexible budgeting practices, streamlining procurement processes, enhancing financial accountability mechanisms, and fostering intersectoral collaboration. By addressing these areas, governments can improve their ability to respond effectively to health emergencies, minimize economic disruptions, and save lives. Policymakers should prioritize PFM reforms that enable swift action during crises without compromising transparency and accountability. Investing in capacity building for financial management within the health sector and leveraging technology for better expenditure tracking can further enhance preparedness.

Ind-1539 Understanding the Financial Hardships Faced by TB and HIV Patients during the COVID-19 Pandemic: a Mixed-method Study in Indonesia

PRESENTER: **Nasser Fardousi**
AUTHORS: Srila Nirmithya Salita Negara, Siska Dian Wahyuningtias, I. Wayan Cahyadi Surya Distira, Riris Andono Ahmad, Yusuf Ari Mashuri, Virginia Wiseman, Ari Probandari, Marco Liverani, Qinglu Cheng, Yanri Yanri Wijayanti Subronto, Hasbullah Thabrany

Abstract

Introduction

The COVID-19 pandemic had major financial impacts on patients with tuberculosis (TB) and human immunodeficiency virus (HIV) globally, reducing household income, increasing unemployment, and disrupting the availability of health services. However, research on the financial difficulties faced by HIV and TB patients in Indonesia during the pandemic is limited. Indonesia provides an opportunity to address this limitation as the country had the highest number of COVID-19 cases (6,815,156) among Southeast Asian countries while also dealing with the dual burden of HIV and TB. This study examines the catastrophic health spending and determinants of out-of-pocket costs during the pandemic. Further, it explores patients' financial hardship experiences and coping mechanisms in two major cities in Indonesia. The results are expected to inform the design of resilience-building approaches for TB and HIV programs.

Methods

This study employed a parallel convergent mixed-method approach involving a quantitative analysis of out-of-pocket (OOP) costs and qualitative interviews. Out-of-pocket costs were recorded using diaries. The incidence of catastrophic health spending (CHS) was defined as the sum of direct medical and non-medical costs that exceed 10% of a household's annual income. The determinants of incurred health costs were investigated using a two-part mixed-effect model regression, whereby the first part models the probability of incurring any OOP costs, while the second part evaluates the intensity of expenditure among those who incurred any costs. We collected qualitative data using in-depth interviews with TB and HIV patients and healthcare workers to document financial challenges and strategies to mitigate and adapt to financial stressors. Data were collected between January and October 2022.

Results

In our sample of 409 patients, 5.13% [95%CI: 2.99 - 7.28] of the households incurred costs exceeding 10% of the household's annual income. The median direct cost was USD 8.48 [Interquartile range (IQR): 2.76-21.89], with non-medical costs comprising the majority of expenses, at a median of USD 5.93 [IQR: 1.82-11.58], especially transport costs at USD 2.56 (IQR: 0.61-6.06). Predictors of higher spending included being located in the city of Yogyakarta (adjusted effect 23.84 [95% CI: 9.90-37.77], p-value=0.0008); seeking care from public hospitals (17.37 [8.83-25.90], p-value<0.001), and being uninsured (10.49 [2.40-18.58], p-value= 0.0110). Job loss due to lockdowns and subsequent disqualification from the national health insurance scheme were perceived as major factors contributing to financial hardship. We documented several coping strategies, such as borrowing from relatives or friends, relying on contributions from family and friends, and selling assets.

Conclusion

Our study reveals that during the pandemic, some households with HIV and TB patients faced financial stressors, including catastrophic health costs and loss of income. Measures can provide better financial protection by targeting poorer households and individuals experiencing job loss. Further research is needed to develop interventions that address these difficulties and enhance national health system preparedness while maintaining financial support for those impacted. 1

Population Level Impact of National Health Policies and Trends

MODERATOR: **Marisa Domino**,

Ind-2189 Examining the Health Legacy of the NHS: Short- and Long-Term Effects on Infant Mortality and Adult Health Outcomes

PRESENTER: **Nicolau Martin Bassols**

This paper examines both the short- and long-term health impacts of the introduction of the National Health Service (NHS) in the United Kingdom in 1948. The NHS revolutionized the healthcare landscape by providing universal healthcare free at the point of use. We examine the effects of the NHS's provision of free hospital access for childbirth on children born just before and after its implementation. Using a Regression Discontinuity Design (RDD), we analyze both infant mortality rates at the time of the NHS implementation and health outcomes measured at later ages (45 to 80), including self-reported health, BMI, and obesity rates. Our study uniquely incorporates genotypic data to capture and correct for survival bias, which has been previously overlooked. By using polygenic indices (PGIs), we enhance the precision of our estimates and account for the influence of genetic predispositions on health outcomes. Using data from the General Registrar of Statistics, we show that the NHS significantly improved infant mortality rates in the short run. The children who would not have survived unless delivered at hospital facilities were likely the most vulnerable. We explore this hypothesis by comparing the prevalence of polygenic indices in individuals born before and after the NHS. Using the nationally representative sample from the English Longitudinal Study of Ageing (ELSA) and the large sample sizes of the UK Biobank, we find that post-NHS, there is a higher prevalence of individuals with higher loads in PGIs associated with 'detrimental' phenotypes, such as migraine or chronic pain, while there is a lower proportion of those with 'beneficial' phenotypes, such as general cognition, educational attainment, and IQ. The effect sizes are large, ranging from 10-40% of a standard deviation, and significant at the 95% confidence level. These results remain robust across different bandwidths, kernels, quadratic fits, multiple hypothesis testing, and comparisons of observed versus randomized treatments. Finally, we explore the longer-term impacts of the NHS and examine health outcomes measured between ages 45 and 80. Our findings indicate that the NHS led to improvements in self-reported health, BMI scores, and obesity rates. Interestingly, we find that including PGIs as control variables helps correct for survival bias and enhances precision. Overall, these results suggest that incorporating genetic information accounts for part of the survival bias and improves estimate accuracy. These findings are robust across different bandwidths, kernels, quadratic fits, and methods for extracting health outcomes. Additional sanity checks, including placebo outcomes, further confirm that the results are not driven by random fluctuations or the data structure.

Ind-1178 The Intended and Unintended Consequences of National Volume-based Procurement of High-value Medical Consumables in China

PRESENTER: **Yiru Wang**

Rising healthcare expenditures remain a critical concern in China. Since 2009, the Chinese government has implemented various healthcare reforms, including social health insurance and zero mark-up of drugs and consumables, to control costs and improve access to care (Meng et al., 2019). However, challenges persist, particularly due to the escalating costs of high-value medical consumables driven by an aging population, the increasing prevalence of chronic diseases, and profit incentives among healthcare providers (Yi, et al., 2014; Fu et al., 2018; Liu et al., 2019). To address these challenges, the Chinese government launched a national volume-based procurement (NVBP) policy for high-value medical consumables, starting with coronary stents in January 2021. This study evaluates the impact of the NVBP policy for coronary stents on healthcare expenditures, intensity of care, treatment outcomes, and service volume. Using inpatient records of all percutaneous coronary intervention (PCI) patients from a large pilot city between 2020 and 2021, we employ a time regression discontinuity (time RD) design. The results indicate that the NVBP policy reduced average total expenditures for PCI patients by 35.2%, driven primarily by a 65.4% reduction in costs for medical supplies and consumables, with no significant effects on other expenditure categories. Regarding intensity of care, while the length of inpatient stays remained unchanged, the number of coronary stents implanted increased. For the treatment outcomes, it showed no significant effect on 30-day readmission rates, though a slightly positive association was observed with in-hospital mortality. Weekly PCI service volumes increased by 43.3%, indicating improved accessibility. These results are robust to a variety of robustness checks. Heterogeneous analysis reveals that the expenditure-reducing effects were smaller among older, female, and less-severe (with smaller number of ICD codes) patient groups, potentially due to significant increases in stent usage in these populations. An event study model further shows that reductions in healthcare expenditures persist over time, while effects on care intensity diminish within a few months. Our findings suggest that the NVBP is an effective policy to reduce healthcare expenditures, especially compared with other policies with the same purposes (such as the zero markup of drug price) (Fu, et al., 2018). However, the observed increase in stent utilization raises questions about potential overuse, warranting further investigation. These results underscore the importance of policy designs that balance cost reduction with clinical appropriateness and quality of care.

Ind-1292 Potentially Preventable Hospitalizations for Non-communicable Diseases in China: Recent Trends and Macro- and Micro-level Determinants

PRESENTER: **Peipei Chai**
AUTHORS: Hao Wang, Yohannes Kinfu, Tiemin Zhai, Ran Xin

Objective Hospital care represents the largest component of healthcare expenditures in China. Consequently, reducing potentially preventable hospitalizations (PPHs) has become a priority for policymakers to improve health system performance. Although PPHs have been widely studied in developed nations, research in low- and middle-income countries, including China, is limited. This study aims to examine the incidence, associated costs, and potential determinants of PPHs related to non-communicable diseases (NCDs) within the Chinese context. **Methods** The incidence and associated costs of PPHs for six NCDs—angina, asthma, chronic obstructive pulmonary disease (COPD), congestive heart failure, diabetes mellitus (DM), and hypertension—were estimated by analyzing national administrative data from 2004 to 2021 in China. Changes at the aggregate or macro level were analyzed using Das Gupta's decomposition method, separating effects attributable to population growth, aging, disease prevalence, per-case utilization, medical price inflation and unit cost. To explore potential factors influencing PPHs at the individual level, a two-stage selection model was applied to the latest available wave of the National Health Service Survey in China, conducted in 2018. **Findings** In 2021, the total number of PPHs reached 19.5 million admissions, representing 9.69% of all hospital admissions—a five-fold increase since 2004. Expenditure on PPHs rose even more dramatically, escalating from 21.70 billion Chinese Yuan (CNY) in 2004 to 190.75 billion CNY in 2021 (adjusted to 2021 price levels), reflecting an annual growth rate of 13.64%. Decomposition analyses revealed that about 70% of the increase in PPHs from 2004 to 2021 was due to higher inpatient-care utilization, adding approximately 1.13 million admissions. Population growth and ageing contributed an additional 5.19% and 15.44%, respectively, while changes in disease prevalence rates accounted for the remaining 9.98%. The relative contributions of each factor varied by conditions. For example, changes in disease prevalence accounted for 47.56% of the observed changes in admissions for hypertension, while it contributed -6.04% to the changes for COPD. Regarding inpatient expenditure, more than half (51.73%) of the changes between 2004 and 2021 were due to increased utilization rates, followed by medical price inflation (16.26%) and the aging effect (12.48%). In contrast, the contributions from high unit costs, disease prevalence, and population growth were relatively minor, at 9.41%, 6.37%, and 3.75%, respectively. At the individual level, the incidence of PPHs was positively and significantly correlated with factors such as age, per capita consumption expenditure, and local hospital bed density. Conversely, it was negatively associated with educational attainment, self-reported health status, local physician density, and the time required to reach the nearest health facility from home. **Conclusions** The incidence of PPHs in China is high and has been sharply increasing, leading to a significant waste of medical resources. Interventions at the health system level, such as optimizing the allocation of health resources between human capital (e.g., health workforce density) and infrastructure (i.e., hospital bed availability), alongside improvements in individual-level sociodemographic factors, such as education, should be prioritized to address the escalating burden and financial impact of NCDs in China.

Ind-1964 Estimating the Economic Impact of the UK Infected Blood Scandal: Report of the Health Economics Expert Group to the UK Infected Blood Inquiry

PRESENTER: **Laura Downey**
AUTHORS: Prof. Katharina Hauck, PhD, Timothy Hallett, paul mccrone

Context: The UK infected Blood Inquiry was set up to investigate how tens of thousands of individuals came to be infected by HIV, Hepatitis, and other blood-borne infections through the National Health Service (NHS) in the 1970's and 1980's. The paper reports on the report of the Health Economics Expert Group (2023) who were tasked to estimate the economic and health costs of infected blood and blood products (IBBPs) to the United Kingdom between 1970 and 2021.

Methods: We undertook a comprehensive mixed-methods approach utilising both qualitative and quantitative methods. Thematic analysis of 63 witness statements was undertaken to document the wide-ranging economic, social and health impacts of infections by mode of transmission of infection. We employed a cost-of-illness model to quantitatively estimate the aggregate economic impact of infected blood and blood products to UK society of infection of the cohorts of persons infected with hepatitis C (HCV) and human immunodeficiency virus (HIV) by the NHS.

Results: The qualitative analysis identified the multiple impacts and sources of suffering associated with treatment with infected blood and blood products, including physical and mental impacts and severe side effects of treatments, impacts on employment, financial difficulties, and stigma. These impacts were particularly severe due to relatively low success rates of treatments, limited financial assistance, and the high prevalence of stigma in the population. The sum of healthcare and productivity costs ranges between £1.8 billion to £4.1 billion for the time period 1970 – 2021, when converted to 2021 values. This is comprised of health and social care costs ranging between £900 million and £1.6 billion, and productivity costs ranging between £900 million and £2.5 billion. The total loss in healthy life years due to ill-health and early deaths ranges between 70,000 and 190,000 QALYs. Around 60,000 – 100,000 QALYs were estimated to be lost to premature deaths and 10,000 – 90,000 QALYs to ill health during the lifetime of the infected persons. The total valued health losses ranged between £2bn and £5.8bn (for a £30,000 valuation of a QALY), and £4.1bn and £11.6bn (for £60,000 valuation of a QALY). The average healthcare and productivity costs per infected person range between about £45,000 and £193,000 over the period 1970 – 2021. Lost QALYs ranged between 1.8 and 9.3 per infected person, that is between £53,000 – £279,000 (for a £30,000 valuation) and £107,000 – £559,000 (for a £60,000 valuation) per infected person.

Summary: The infected blood scandal caused substantial economic and social impact to the UK population that are likely to be grossly underestimated in this analysis. The quantitative cost estimates were highly uncertain due to the considerable limitations on available data, and many assumptions and model simplifications that were required. This report is one of many sources of evidence requested by the Chair of the Inquiry to inform our understand of the impact of infected blood on the British public and how we can prevent a scandal of this nature and magnitude in future.

Ind-1783 Does National Health Insurance Prioritize Health Service Equity? a Retrospective Analysis Based on the Heart Disease Claim in Referral Healthcare

PRESENTER: **Muhamad Faozi Kurniawan**
AUTHORS: Laksono Trisnantoro, Ardhina Nugrahaeni

Background. Universal health coverage (UHC) ensures that all individuals can access a comprehensive range of quality health services as needed without experiencing financial hardship. The National Health Insurance (JKN) in Indonesia ensures equitable access to excellent health services for all levels of society. Since 2014, JKN has strived to provide financial protection to all segments of society, particularly marginalized and disadvantaged populations, within a universal health insurance framework. However, there exists a lack of equity in the provision of health services. Cardiovascular disease is an example of an inequitable benefit package that leads to higher hospital claims compared to other diseases, primarily due to the limited availability of hospitals, the uneven distribution of health workers, and other disparities between different regions in Indonesia. This study endeavors to pinpoint the discrepancies in benefit package utilization across various regions in Indonesia, attributable to unequal access and restricted health resources.

Method. We used secondary data analysis from the Social Security Agency (BPJS) Health for the years 2015 to 2022 as our methodology. This BPJS sample data accounts for 1% of the total JKN membership. STATA software processes the data, grouping variables into regional categories for specific areas, segments for different types of JKN membership, and the number of hospital claims for each regional. Excel graphs and tableau applications visualize the STATA-processed results in the form of Excel tables.

Result. Region 1 in Indonesia boasts the highest health resources compared to other regions, particularly regions 4 and 5. JKN participants visited the hospital from 25.5 million in 2014 to 276.6 million in 2023. This condition also shows that the number of hospital claims increased from 30.44 trillion rupees in 2014 to 138.36 trillion rupees. However, if we look at the number of claims per region, the total hospital claims between regions show a large disparity. In 2022, the number of hospital claims in region 1 was 28 times higher than region 5, or 3.49% of the number of claims in region 1. The highest heart disease claims were in Region 1, and the participant segments that used them the most were the independent participants and the worker sector.

Conclusion. The study concluded that although JKN has made substantial progress in improving equity in access to health care, the limited number of hospitals and adequate resources to meet service needs such as heart disease in regions 4 and 5 has reduced the equity in health services for certain diseases.

Costs, Costing and Resource Allocation

MODERATOR: **Zanfina Ademi**, Monash University

Ind-2622 Optimizing Healthcare: The Importance of Understanding Primary Healthcare Facility Running Costs in Nigeria

PRESENTER: **Nkoli Pamela Uguru**, University of Nigeria
AUTHORS: Chinyere Okeke, Obinna Onwujekwe

Introduction

Nigeria's primary healthcare system struggles with funding shortages, resulting in high user fees and decreased public trust, pushing people to more expensive options. The government created the Basic Health Care Provision Fund to address this, but key challenges include determining necessary funding and understanding costs for better management and efficiency.

Method

The study investigated primary health care (PHC) facilities in Nigeria's six geopolitical zones between June and July 2024. It employed mixed methods, including a desk review and data collection from 24 PHCs across six states: Kano, Lagos, Adamawa, Nasarawa, Rivers, and Enugu. Using a multistage sampling method, two local government areas per state were selected to represent urban and rural contexts, with two public PHCs chosen in each LGA based on their activity levels. The research assessed the operational and comprehensive expenditures of these facilities using a full costing approach to calculate monthly, bi-annual and annual expenses in Naira, considering the inflation rate. Descriptive statistics, especially the mean, were applied to analyze costs, enabling comparisons among different states and types of facilities.

Results

The operational expenditure analysis of primary healthcare centers (PHCs) in Nigeria shows significant cost differences based on location (urban vs. rural) and activity level (busy vs. not busy). Generally, urban busy (UB) PHCs incur higher costs, except for Lagos and Nasarawa States, where rural busy (RB) PHCs have greater expenses due to increased logistics and utilization demands. Busy PHCs experience higher costs due to greater patient turnover and staffing needs, highlighting the importance of prioritizing rural busy facilities, which face funding gaps despite high patient inflows. Lagos and Rivers States have the highest expenditures, with the RB PHC in Lagos costing approximately ₦13.2

million and the UB PHC in Rivers State costing around ₦13.6 million annually. Personnel costs are a significant driver of these expenses, as indicated by the steep rise from ₦4.1 million for RB PHCs to over ₦13.2 million for comprehensive expenses. Operating a PHC costs about ₦18.7 million annually or ₦1.6 million monthly, with urban and busy PHCs incurring even higher monthly expenses.

Conclusion

Expenditure levels in Nigeria's healthcare system vary by geopolitical zone and facility type. More utilized primary health centers (PHCs) face higher operational and staffing costs due to increased demand and logistical requirements. The study provides insights into the spending trends of health facilities, detailing costs, revenue, and funding shortfalls. The findings aim to guide future funding allocations to strengthen the PHC network, improve healthcare access, reduce patient financial burdens, and enhance the overall efficiency of the health system.

Ind-2822 Resource Gap Analysis Using Normative and Actual Costs: A Tool for Efficient Resource Allocation

PRESENTER: **Tushar Mokashi**
AUTHORS: Rajeev Prasad, Arun Nair, Maulik Chokshi

Introduction The growing demand for primary healthcare (PHC) in India, combined with limited public resources, highlights the importance of efficient resource allocation. With the Government of India enhancing PHC through the Comprehensive Primary Healthcare Package (CPHC) under Ayushman Bharat's Health and Wellness Centers (AB-HWCs), understanding the cost of PHC delivery and identifying financing needs becomes essential. This study focuses on analyzing PHC network costs in Tamil Nadu, estimating both actual and normative costs of PHC services, and identifying resource needs to guide effective decision-making in resource allocation. **Methodology** The study adopts a public-sector perspective to assess facility-level recurrent costs for PHC services during April 2019 to March 2020. The methodology involved two key components: 1. Actual Costs: Data was retrospectively collected from 25 sampled health facilities in Tamil Nadu, focusing on key recurrent expenses. 1. Normative Costs: These were derived from Standard Treatment Protocols (STPs) developed by clinicians, population in need (PIN), and associated costs. The normative costs reflect the resources required for quality PHC delivery. The comparison of actual costs with normative benchmarks allowed the identification of resource needs at each facility level, providing insights into the extent of financing gaps. **Results** The findings highlight the following: - The direct network cost per capita was INR 398.3 (USD 5.6). - The normative CPHC cost per capita was estimated at INR 1,211.5 (USD 17.1). - This revealed a 67% resource gap, assuming 100% rural population coverage by the public sector. Recognizing varying care-seeking behaviors, the study also considered different coverage levels to better reflect actual utilization. These findings demonstrate financing shortfalls and a need for alignment between resource allocation and service utilization. **Conclusion** This study provides critical insights into the costs of delivering PHC and the associated financing needs in Tamil Nadu. By identifying the resource gaps and presenting normative benchmarks, it offers policymakers evidence to optimize resource allocation, address health burdens, and plan for equitable healthcare delivery. The findings emphasize the importance of strategic investments in PHC, development of electronic health data systems, and refinement of STPs for standardized care. These contributions aim to strengthen India's PHC system, ensuring accessible, high-quality healthcare for all.

Ind-1925 Long-term Costs of Healthcare Among Survivors of Infant Group B Streptococcus disease in Denmark

PRESENTER: **Simon Procter**, London School of Hygiene and Tropical Medicine
AUTHORS: Erzsébet Horváth-Puhó, Henrik Toft Sørensen, Bronner Gonçalves, Malene Risager Lykke, Joy Lawn, Proma Paul

Group B Streptococcus (GBS) is a leading cause of neonatal invasive bacterial disease worldwide. Invasive GBS (iGBS) disease in neonates and young infants can lead to sepsis and meningitis, and survivors are at risk of long-term neurological sequelae, with an estimated 37,000 surviving infants globally developing long-term moderate or severe neurodevelopmental impairments (NDI) each year. However, there is little quantitative evidence available on the healthcare costs associated with iGBS beyond infancy. In this study we aimed to estimate the long-term healthcare costs in a population-based cohort including children with history of iGBS disease in Denmark.

Exposed children with history of iGBS disease (sepsis, meningitis or pneumonia) within the first 89 days of life were identified using the Danish National Patient Registry (DNPR) based on discharge diagnosis classified using International Classification of Diseases (ICD)-10 codes. For each exposed child, ten unexposed children were randomly selected and matched by sex, year, and month of birth. Participants were included in the analysis for the period from Jan 2007, until Dec 2017. Overall, we included 670 iGBS exposed individuals and 6720 matched unexposed individuals.

Participants were included in the analysis for the period from Jan 1, 2007, until 31st Dec 2017. Information on whether children in either group developed NDIs was obtained from the DNPR using ICD-10 codes for mental, behavioural, and nervous system disorders. We assessed NDI based on any NDI diagnosis at 5 years of follow-up from the index date.

Cost data was obtained by linking individuals records from the DNPR to the following national registers: primary care reimbursement (primary care costs, including general practitioner care, diagnostic costs, dentistry, and other ancillary care), pharmaceutical (community-dispensed prescriptions, including both the out-of-pocket co-payment and the government subsidy) and hospital (combining all in- and out-patient visits). Longitudinal data was used to estimate annual costs according to the time from the year of diagnosis (from birth and up to 10 years of follow-up). Mean costs in each category were estimated from a health system perspective for iGBS and comparison groups, and all costs were inflated in Danish Crowns (DKK) using the consumer price index and converted to 2017 Euro.

We will present a descriptive analysis comparing annual costs by category and year of follow-up, and additionally present a stratified analysis showing how costs in the exposed and unexposed groups are influenced by prematurity and by the presence of NDI diagnosis. We will also conduct a statistical analysis using Generalised Linear Models to assess the association between iGBS disease and different cost categories.

Our analysis will add to the very limited literature on the costs of GBS infections in young children, and notably will include longer follow-up

later into childhood than previous studies allowing us to investigate the costs of long-term sequelae caused by GBS. These findings will also be informative for economic evaluations of interventions to prevent GBS including maternal vaccines that are anticipated to become available in the next few years.

Ind-1433 Epilepsy Projections in Australia 2024-2033: A Dynamic Lifetable Model of Population, QALYs, PALYs, and Healthcare Costs

PRESENTER: **Gopisankar Mohanannair Geethadevi**
AUTHORS: Graeme Jackson, For the Australian Epilepsy Project Investigators, Kristoffer Jarlov Jensen, Zanfina Ademi, Patrick Kwan, Emma Foster, Zhibin Chen

Objectives: This study aimed to project years of life (YL), quality-adjusted life years (QALYs), productivity-adjusted life years (PALYs), and healthcare costs associated with epilepsy in Australian adults aged 18 to 80 years from 2024 to 2033.

Methods: A dynamic model was created to capture both incident and prevalent cases of epilepsy in Australia using five health states: Not Seizure-Free Non-Drug Resistant (NSF-NDRE), Seizure-Free Non-Drug Resistant (SF-NDRE), Not Seizure-Free Drug Resistant (NSF-DRE), Seizure-Free Drug-Resistant (SF-DRE), and death. The model cycled annually and incorporated data from the largest cohort study of epilepsy patients (n = 1,795) conducted in Glasgow between 1982 and 2014, as well as data from the Australian Epilepsy Project (AEP), an ongoing cohort study with 485 participants that evaluates the use of advanced MRI, neuropsychological assessments, and genetic testing. Population dynamics over time were modelled using estimates from the Australian Bureau of Statistics. YL was calculated by summing up individuals in each health state by year, age, and sex. QALY estimations were derived from EQ-5D-5L utility values for each health state, multiplied by YL. PALY estimates were based on the average annual working days and sick leave attributed to epilepsy, comparing the data for each health state against the general population. Discounting values of 5% were applied to costs and outcomes as per Australian guidelines.

Results: By 2033, there were 82,723 new cases of epilepsy, including 42,127 (50.9%) females and 40,594 (49.1%) males. In 2024, the total prevalent cohort numbered 125,223, comprising 65,911 (47.4%) females and 59,311 (52.6%) males. Across the 10-year period, the population accrued 1,209,280 years of life, distributed as follows: 23.6% NSF-NDRE, 58.3% SF-NDRE, 15.8% NSF-DRE, and 2.1% SF-DRE. The total healthcare cost reached $19.8 billion AUD, with the highest contributions from NSF-DRE ($6.7 billion; 34%) and NSF-NDRE ($5.6 billion; 28.6%). The total accrued QALYs and PALYs were 990,387 and 434,660, respectively. The number of epilepsy-related deaths was 15,227. In 2024, 10,665 individuals with focal DRE were eligible for surgical evaluation, with an additional 383 projected annually through 2033.

Conclusions: This comprehensive forecast of epilepsy in Australia highlights that patients with DRE will disproportionately drive healthcare costs over the next decade. Expanding epilepsy care programs is essential to reduce the burden of DRE. This dynamic model, which accounts for the natural progression of epilepsy, aims to inform decisions on interventions that can reduce healthcare and productivity burdens while enhancing the quality of life for individuals with epilepsy.

Ind-246 Predictions for Dementia Prevalence and Socioeconomic Costs in China by 2050: A Markov Modelling Study

PRESENTER: **Jing Liao**
AUTHORS: Yixuan Liu, Ruini Sun, Piotr Bandosz, Yuntao Chen, Eric French, Eric J Brunner, Sophia Lobanov-Rostovsky, Yanjuan Wu, Yuyang Liu

Background: Accurate forecast of future dementia burden is essential is important for preventive strategy for fast-ageing China. Yet it remains unclear how temporal trends in dementia incidence and shifting demographics will shape China’s future dementia burden. Understanding primary drivers of future dementia burden is crucial for identifying areas where policy interventions could yield future savings. Aim: This study aims to project the future dementia prevalence, socioeconomic costs (healthcare, formal social care, and informal care costs) and value of quality adjusted life years (QALYs) lost to dementia, and to assess drivers of dementia burden in China by 2050. Methods: Using data from two national representative Chinese aging cohorts (CHARLS, CLHLS), we applied a ten-state Markov model (IMPACT-CAM) to project the dementia burden among individuals aged 50+ by 2050, factoring in population trends in dementia incidence, mortality, and dementia-related comorbidities. Three scenarios for future dementia incidence were simulated: increasing (+2.9%), stable (0%), or decreasing (-1.0%). We estimated its future socioeconomic costs and calculated QALYs lost corresponding to the three incidence trend scenarios. To identify main drivers, the projected dementia burden was further decomposed into population growth, population ageing, changing dementia prevalence and average socioeconomic cost per dementia case. Results: In the scenario with increasing dementia incidence, an estimated 66.3 million people could have dementia by 2050, representing 10.4% of the population aged 50+, with associated annual socioeconomic costs reaching $1,233 billion and $702 billion in QALYs lost. If dementia incidence remains stable or decreases, the number of dementia cases would be significantly lower to 43.9 million or 37.5 million respectively, with socioeconomic costs reduced by 34% or 43% compared to an increasing incidence trend. Informal care constitutes the largest portion of socioeconomic costs, a trend expected to continue. Population aging and increasing dementia prevalence are identified as the primary drivers of rising dementia burden through 2050. Conclusion: Our findings underscore a looming increase in dementia burden in China over the coming decades if incidence rates continue to climb. The socioeconomic costs and QALYs lost to dementia are projected to rise steeply, with informal care costs making up the largest proportion. Public health strategies focused on dementia prevention could play a critical role in mitigating this growing disease burden. As population aging and dementia prevalence are the primary cost drivers, public health efforts aimed at dementia prevention and promoting healthy aging are essential.

Maternal and Child Health, and Gender Issues

MODERATOR: **Mario Martinez-Jimenez**, Imperial Business School

Ind-153 Mind the Gap: The effect of Gender Wage Gap on Mental Health

PRESENTER: **Seetha Menon**

AUTHOR: Miriam Jensen

Background: Depressive and anxiety disorders are twice as common among women than men. Research shows women with lower income than matched male counterparts report higher depression and anxiety rates and perceived workplace gender discrimination has been shown to negatively impact women's mental health but not men's. **Research Question:** While previous studies have highlighted the influence of workplace dynamics on mental health, many rely on self-reported data, which are prone to biases such as social desirability, non-response, miss-classification, and under-reporting. To address these limitations, we leverage objective administrative data on healthcare utilization. We hypothesize that actual or perceived structural gender inequality in the workplace partially explains the gender disparity in mental health outcomes. **Methodology:** Using matched employer-employee data, we calculate an individual specific gender wage gap (GWG) and examine its effect on visits to psychologists and psychiatrists, and associated insurance costs for all full-time employees in Denmark between 2008-2018. Estimating this effect is challenging due to two reasons. Firstly, unobserved factors such as personality, productivity, gender identity or parenthood can influence both wages and mental health. Thus GWG may not reflect structural gender inequality but could instead reflect underlying differences of male versus female employees. Second there may be reverse causality in that adverse mental health may affect productivity and lead to lower wages at the individual level. To address these challenges, we develop a measure of benchmark GWG (BGWG) using the Bartik approach, inspired by recent economics literature such that BGWG in industry, occupation, year, and firm is the average of the GWG in the same industry, occupation, and year across all firms excluding the firm the index individual is employed in. BGWG thus captures potential GWG (as opposed to realized GWG) that an individual is exposed to. **Key Results:** Both GWG and BGWG significantly increases women's visits to mental health professionals, with no similar effect for men. The effect of BGWG on mental health visits suggest that broader structural inequalities contribute to women's adverse mental health. Next we plan to extend this analysis by examining drugs prescribed for anxiety and depression as an additional outcome. We hypothesize that this effect is more pronounced among women who are more acutely aware of wage differentials. To test whether the effect size is greater for these women, we will use union membership as a proxy for awareness of GWG. Additionally, we will extend the data to take advantage of a 2006 legislative change in Denmark that required firms to report gender-disaggregated wage statistics. We will use this law as an exogenous shock to the gender wage gap (GWG) to validate our main findings. **Implications:** Given the costs of poor mental health—such as healthcare expenses, reduced productivity, and unemployment—there is a strong case for policy interventions to reduce wage inequality. This study contributes to literature by focusing on a Scandinavian context, showing that even relatively equitable societies like Denmark face mental health consequences from wage disparities.

Ind-1651 Gender Differences in Time Preferences Across Health and Financial Domains: Do Elicitation Approaches Matter?

PRESENTER: **Danlei Chen**, Xi'an Jiaotong University

AUTHORS: Cong Li, Jingxian Wu

Background: Time preference, which reflects individuals' propensity to prioritize immediate benefits over future gains, play a significant role in decision-making across domains such as health and finance. Gender differences in time preferences have been proposed as a potential explanation for behavioral variations between males and females. However, empirical findings on the existence of gender differences in time preference remain inconclusive, as most studies rely on a singular method to measure time preferences. Considering the diverse methods available for elicitation time preferences, this study aims to address these inconsistencies by examining how different elicitation approach influence gender differences in time preferences. **Methods:** Data were collected through a pencil-and-paper household survey conducted in six counties of Shaanxi province, China, using multistage stratified random sampling. The sample comprised 2,878 individuals aged 18 to 65 from 1,377 households. Time preferences were assessed in both health and financial domains using self-reported and incentivized experimental methods. Self-reported methods involved standardized scales for respondents to measure their degree of time discounting, while incentivized experiments presented participants with choices between immediate and delayed gains or losses. Time preference indicators were standardized with means of 0 and standard deviations of 1 to ensure comparability across different elicitation methods. Stepwise ordinary least squares (OLS) regression analyses were conducted to examine the correlations between gender and time preference, controlling for individuals' demographic, socioeconomic, and health-related characteristics as well as the county fixed effect. **Results:** In the health domain, incentivized experimental methods with health-related outcomes revealed no significant gender differences in time preferences, both before (crude coefficient = 0.029, *p* = 0.431) and after (adjusted coefficient = 0.033, *p* = 0.381) controlling for covariates. In contrast, self-reported time preference indicators showed that females exhibited significantly greater patience than males, both without (crude coefficient = 0.168, *p* < 0.001) and with control variables (adjusted coefficient = 0.156, *p* < 0.001). Similar patterns were observed in the financial domain: incentivized experimental methods with monetary outcomes showed no significant gender differences, while self-reported indicators revealed greater patience among females, both before (crude coefficient = 0.125, *p* < 0.001) and after (adjusted coefficient = 0.139, *p* < 0.001) controlling for covariates. **Conclusion:** Gender differences in time preferences are significantly influence by the elicitation methods used. Females consistently exhibit more patient time preferences in self-reported methods across both health and financial domains, while incentivized experimental methods fail to reveal such differences. These findings suggest that the observed gender differences may reflect self-perceptions rather than actual decision-making behaviors, highlighting the importance of considering elicitation approaches when interpreting time preference data. Future research should explore the cognitive and contextual factors underlying these gender differences and their

implications for health and financial decision-making. (This study is funded by the National Natural Science Foundation of China (No. 72104196))

Ind-810 Effect of Pre-exposure Prophylaxis on Risky Sexual Behaviour of Female Sex Workers in Dakar, Senegal: A Randomised Controlled Trial

PRESENTER: **Aurelia Lepine**, University College London
AUTHORS: Wally Toh, Abdou Khoudia Diop, El Hadji Alioune Mbaye, Owen O'donnell, Khady Gueye, Mame Mor Fall, Cheikh Tidiane Ndour

Background HIV prevention through pre-exposure prophylaxis (PrEP) may encourage riskier sexual behaviours that undermine the protection afforded by PrEP and generates negative spillovers on sexually transmitted diseases. Tests for such risk compensatory behaviour in high-risk populations, such as for female sex workers (FSW), are lacking.

Methods We stratified a sample of 500 female sex workers in Dakar, Senegal by self-reported sexual risk-taking and prior PrEP experience and randomly assigned them to PrEP referral in October 2021-January 2022 (treatment, n=300) or to deferred PrEP referral after the endline survey in April-May 2022 (control, n=200). We randomised 500 FSWs to start PrEP and included 308 FSWs in the final analysis (T=182, C=126). We compared outcomes in the period preceding PrEP referral of the control group. The primary outcome was self-reported condom use with clients. Secondary outcomes were self-reported sexual risk taking, number of clients, proportion of regular clients, perceived HIV risk of clients, and type of sex act. We estimated intention-to-treat effects of PrEP referral and both average treatment effects on the treated and local average treatment effects of PrEP utilisation. The trial is registered with ISRCTN (ISRCTN16445862).

Findings PrEP referral increased the probability of using PrEP by 34.5 percentage points (pp) [95% CI: 25.4, 43.6; p<0.0001, control group mean: 11.1%]. Estimated effects of PrEP referral and PrEP use on condom use with the last client were 3.3 pp [95% CI: -4.0, 10.6; p=0.376] and 7.9 pp [95% CI: -10.4, 26.3; p=0.397 respectively (control group mean: 84.9%). When looking at condom use with all last three clients, these effects were 11.0 pp [95% CI: 0.8, 21.1; p=0.034] and 25.8 [95% CI: 5.2, 46.4] respectively (control group mean: 67.5%) There were no notable effects on other risky sexual behaviours.

Interpretation This randomised experiment did not give strong grounds for concerns that PrEP encouraged sexual risk-taking by FSWs, at least in the short-term. Robustness of this finding should be tested in larger, longer-term studies and in other contexts. Whether PrEP users are more likely to overreport condom use than non-PrEP users should also be further investigated.

Ind-1930 Preferential Treatment in Health and Well-Being: Measuring Pluralistic Ignorance Around Son Preference in Urban India

PRESENTER: **Vasanthi Subramonia Pillai**, Technical University of Munich
AUTHOR: Henrike Sternberg

Background and Research Question: Gender discrimination remains a prevalent issue in India and worldwide. Its manifestation in the form of preferential treatment of sons versus daughters before birth (e.g., sex-selective abortion) and after birth (e.g., unequal healthcare/educational investments) threatens gender equality and economic efficiency. While strong gender norms have been identified as one of the most important drivers of parental son preference, they are often misperceived by the population. For instance, Indian citizens drastically underestimate public support for affirmative action policies. Such misperceptions may also exist for gender norms about son preference, resulting in a state of pluralistic ignorance: A situation where the majority of individuals in a group privately oppose a certain norm, but because they wrongly believe that all other group members support it, they end up acting in conformity with the norm rather than with their own conviction. We identify two important gaps in the current literature: First, to the best of our knowledge, there is limited evidence of a comprehensive measurement of son preference in daily decision-making in terms of children's health and well-being. Second, no study has examined pluralistic ignorance around son preference, which may be a key driving force resulting in preferential treatment of sons vs. daughters. This study aims to investigate the existence of misperceived norms in the context of son preference in India and its relationship with preferential treatment by parents in various dimensions of daily life, including health and nutrition.

Methods: We conducted a cross-sectional study with embedded randomized experiments among 300 households in Chennai, India. Interviews were conducted both with the wife and the husband, separately (total observations: 600) The study administered a quantitative household survey to measure (1) wives' and husbands' own attitudes toward son preference, (2) their perception of their community's and their spouse's attitudes toward son preference, and (3) actual and hypothetical gender-preferential treatment by parents across various dimensions of daily life. We introduce a novel "twin game" to estimate the extent to which husbands and wives exhibit tendencies of preferential treatment. In addition, we also collected insights to potentially inform the design of a future intervention to reduce son preference.

Results: A first-cut analysis reveals evidence of pluralistic ignorance in several dimensions of son preference, including health outcomes. Specifically, both women and men in our sample significantly underestimate, especially men's support of equal treatment of sons and daughters. For instance, in terms of prioritizing the son over the daughter regarding health and educational investments, actual support of this preferential behavior is much lower (around 30 percentage points) than the support perceived by survey participants when asked about their community. We aim to complete our analysis by January 2025.

Conclusions and policy implications: The (preliminary) findings from our study suggest that pluralistic ignorance also exists in the context of son preference. Thus, simple and scalable interventions providing information about norm perceptions show the potential to be highly effective.

Ind-2513 The Mediation of IADL Limitations on Chronic Pain Affecting Depressive Symptoms and Its Gender Differences in Middle-aged and Older Chinese

PRESENTER: **Xinpeng Xu**
AUTHORS: Qifeng Wu, Hua You, Kangkang Zhang

Abstract

Background: Chronic pain is more prevalent in middle- and low-income countries and associated with depressive symptoms. Most studies have examined the biological and psycho-behavioral mechanisms by which chronic pain affects depressive symptoms while neglecting the exploration of the social mechanisms involved in this relationship. The ability to perform instrumental activities of daily living (IADL) is essential for maintaining social networks and engagement in society but studies have not validated its mediating role. Additionally, previous evidence suggests that there may be gender differences in the relationship between chronic pain, IADL limitations, and depressive symptoms. This study aims to investigate the longitudinal mediating role of IADL limitations in the impact of chronic pain on depressive symptoms and its gender differences among Chinese middle-aged and older adults.

Methods: We obtained data from 2011 (Time 1, T1), 2015 (Time 2, T2), and 2018 (Time 3, T3) waves of the China Health and Retirement Longitudinal Study, involving 17,302 middle-aged and older adults aged 45 years or above. Chronic pain situation was assessed by calculating the total number of sites where chronic pain occurred, IADL limitations were derived from the participants' reports of difficulties in IADL, and depressive symptoms were measured using the ten-item short form of the Center for Epidemiologic Studies Depression Scale. Finally, we constructed comprehensive longitudinal mediation models utilizing the cross-lagged panel model, with covariates including age, gender (not for gender comparison), residence, marital status, education attainment, income, working status, body mass index, disability, walking aids use, smoking, drinking, and chronic conditions.

Results: We observed a significant positive total effect of T1 chronic pain on T3 depressive symptoms (β = .051, $P < .001$), which was partially mediated by T2 IADL limitations (β = .006, $P < .001$, 95% CI .003–.010, 11.76% of the total). Specifically, T1 chronic pain predicted T2 IADL limitations (β = .058, $P < .001$), which subsequently was predictive of T3 depressive symptoms (β = .108, $P < .001$). The results revealed gender differences, with the longitudinal mediation effect of IADL limitations being significant for females (β = .008, $P = .01$, 95% CI .003–.015, 18.18% of the total effect) and of no significance for males (β = .003, $P = .09$).

Conclusions: This study supports that IADL limitations mediate the pathway from chronic pain to depressive symptoms among middle-aged and older Chinese, but the mediating role may not apply to males. The tentative proposal is to tailor and prioritize public health initiatives targeted at the protection of IADL functioning for females with chronic pain. Subsequent investigations could further substantiate these findings and implications by incorporating a broader range of confounders, exploring potential interactions, and enhancing model performance.

Keywords chronic pain; depressive symptoms; IADL limitations; longitudinal mediation; gender differences

Ind-2718 The Role of Gender in Early Childcare Practices in Low- and Middle-Income Countries: a Systematic Review and Meta-Analysis[JM1]

PRESENTER: **Manzura Jumaniyazova**
AUTHORS: Friederike Suhr, Eliana Chavarría Pino, Janina Steinert, Cecilia Michelle Argueta

***Summary**:*

Background: Gender disparities in early childcare not only disadvantage girls in early childhood but also reinforce societal structures that impede gender equality, creating long-lasting barriers to their well-being and future opportunities. Existing reviews focus on a limited number of countries and specific outcomes, often relying solely on narrative syntheses.

Methods: This systematic review and meta-analysis aim to quantitatively synthesise evidence on the role of gender in early childcare practices in low- and middle-income countries (LMICs), focusing on breastfeeding, immunisation, pre-and post-natal check-ups, and healthcare expenditure of children under five using robust variance estimation technique. We conducted a comprehensive search across various scientific databases, repositories, and journals in November 2021 and re-run the searches in January-February 2024 with no publication type and date restrictions. We restricted our search to studies written in English and had a sample size of more than 30 children. The protocol of this study was registered at PROSPERO (CRD42021286151).

Findings: We identified 79 eligible studies covering 65 LMICs, with 50 studies included in the meta-analysis. The sample size of included studies ranged from 102 to over six million children, accounting for a total sample of nearly 16 children included in the meta-analysis. The pooled analysis reveals significant gender discrimination against girls across outcomes (Hedge's g = -0.081, 95% CI [-0.137, - 0.028], I2=98.8%). This discrimination is particularly pronounced in breastfeeding practices (Hedge's g = -0.05, 95% CI [-0.093, - 0.007], I2=96.08%) and immunisation (Hedge's g = -0.07, 95% CI [-0.131, - 0.011], I2= 99.22%). While significant differences are observed in pre- and post-natal check-ups (Hedge's g = -0.029, 95% CI [-0.058, 0.000], I2 =73.39%), the results are driven by a limited number of studies. We find no gender differences in healthcare spending patterns (Hedge's g = -0.276, 95% [-0.64, 0.87], I2=91.43%).

Interpretation: Our findings emphasise significant gender disparities in early childcare practices, particularly in India. Future studies should explore gender differences in access to and expenditure on healthcare services. Our results do not apply to high-income countries.

Keywords: Son preference, breastfeeding, immunisation, pre- and post-natal check-ups, healthcare expenditure, systematic review, meta-analysis, meta-regression

Ind-8 The Impact of Spousal Bereavement on Cognitive Function of Taiwanese Elderly Population

PRESENTER: **YA-MING LIU**, National Cheng Kung University
AUTHOR: Yi-Syuan Lai

OBJECTIVES: The impact of widowhood affects most individuals. Losing a spouse or partner, who serves as a pillar of support, can have significant repercussions on one's life, which even affect psychological well-being, physical health, and cognitive functioning. Previous studies in Taiwan have explored the impact of widowhood on various aspects of middle-aged and older adults, but most focused on the effects of widowhood on mental health and well-being. Few have examined the impact of widowhood on cognitive function. Therefore, this study aims to examine the impact of widowhood on cognitive functioning among middle-aged and elderly individuals in Taiwan by utilizing data from the "Taiwan Longitudinal Study on Aging (TLSA)" conducted in 2003, 2007, 2011, and 2015

METHODS: The study utilizes four waves of surveys conducted in 2003, 2007, 2011, and 2015, with a sample size of 5,377 people and a total of 16,634 data points for analysis. Focusing on middle-aged and elderly individuals aged 50 and above from TLSA, the Short Portable Mental Status Questionnaire (SPMSQ) is used to measure cognitive function. After widowhood status is matched to non-widowed individuals by propensity score matching, we employ the Difference-in-Differences (DID) method and fixed-effect models to investigate the effect of spousal bereavement on cognitive behavior. Control variables, such as demographic characteristics, ADL scores, cardiovascular disease, and stroke history, were included in the analysis to account for potential confounding factors.

RESULTS: We found that individuals who have experienced widowhood resulted in a more significant decline in cognitive function compared to those who have not experienced such a loss. Our results show that individuals with the following characteristics - female gender, living with fewer than five family members, educational level of high school or below, household with lower annual income - experience a significant decline in cognitive function after experiencing the loss of a spouse.

DISCUSSION: Our findings suggest there is a heterogeneity effect of spousal bereavement on cognitive function. Women may experience more economic hardship after becoming widowed, which can further affect their cognitive function. When living with fewer than five family members, the bereaved individual has fewer people to interact with at home, leading to a greater impact on their cognitive function. Those with lower household annual incomes experience a greater impact of widowhood, because they not only endure the pain and stress of losing a spouse but also face financial and life worries after widowhood. Individuals with higher levels of education tend to have greater adaptability, leading to better cognitive ability and psychological state after the impact of widowhood. For individuals with a history of cardiovascular disease and stroke, who inherently have a higher risk of cognitive impairment, their cognitive function likely declines after experiencing widowhood.

Ind-116 Nudging Vaccination Intentions: Who are More Affected by Information About Herpes Zoster Vaccines?

PRESENTER: **Yiqi Xia**
AUTHORS: Xin Ye, Zhenyu Shi, Dawei Zhu, Ping He

Background: Despite the availability of effective vaccines, vaccination rates remain suboptimal in many populations, highlighting the need for novel strategies to promote vaccine coverage. Nudges, which subtly influence decision-making by framing information, have been proved to increase Covid-19 and influenza vaccination intentions. However, evidence is limited on whether nudges are effective for vaccines with lower awareness, and who is more likely to be affected by nudging information. Herpes zoster (HZ) is a viral infection that can lead to severe pain and impair daily activities, particularly in older adults. With an aging population, the incidence of HZ is rising, creating a growing medical and economic burden globally.

Objective: This study aims to evaluate the effect of nudges on the intention to receive the HZ vaccine, with an emphasis on understanding how diverse subgroups respond to nudging information.

Methods: From July to September 2024, we conducted a randomized controlled experiment with 4370 participants aged over 40 in China Participants were randomly assigned to one control group or six treatment groups, each receiving a standard introduction to HZ. The treatment groups received additional nudging messages, including clinical evidence, clinical professional recommendations, low or high descriptive norms, and positive or negative framing. Demographic data, HZ awareness, health status, and subjective attitudes were collected, and HZ vaccination intentions were measured on a 1–10 scale. We compared each nudging effects against the control group, adjusting for baseline characteristics. Subgroup analyses were performed across gender, age, health status, as well as subjective attitude such as perceived well-being, self-perceived economic and social status.

Results: We found that nudges based on clinical evidence, descriptive norms and positive attribute framing significantly increased HZ vaccination intentions compared to the control group. These results remained robust after controlling for participants' awareness of HZ severity, susceptibility, and vaccine safety and efficacy. Subgroup analyses revealed substantial differences in how individuals responded to the nudges. Female and younger participants were more influenced by positive attribute framing, while male and older participants responded more to descriptive norms. Moreover, HZ vaccination intentions increased primarily among participants who had not been infected with HZ, had higher self-rated health status, and had no depressive symptoms. Additionally, individuals with higher perceived well-being, life satisfaction, confidence in the future, and higher self-perceived social status, as well as those with lower self-perceived economic status, were more responsive to the nudges.

Conclusions: This study is the first to demonstrate that informational nudges, specifically influence from clinical evidence, descriptive norms and positive attribute framing, can significantly enhance HZ vaccination intentions. The results also highlight important subgroup differences, suggesting that tailored messaging strategies may be necessary to optimize vaccine uptake across diverse populations. These findings underscore the potential of applying nudges to improve vaccination rates and provide actionable evidence to increase vaccine coverage.

abs-os218 E-Cigarette Taxation and Queer Youth

PRESENTER: **Mr. Joseph Sabia**
AUTHORS: Michigan State University Cotti, Erik Nesson, Charles Courtemanche, Anthony Chuo, J. Catherine Maclean

Background: Electronic nicotine delivery systems (ENDS) use among lesbian, gay, bisexual, and questioning (LGBQ) teenagers is over 30 percent higher than among their heterosexual counterparts. Yet little is known about how recent efforts to curb nicotine vaping through ENDS taxes impact sexual minorities. This study was the first to explore this question. **Aims of the Study:** The current study sought to explore whether ENDS tax differentially affected LGBQ-identifying teenagers and young adults as compared to heterosexual-identifying teenagers and young adults. The study also sought to explore whether other public policies that affected access to ENDS products exacerbated or narrowed disparities in ENDS use between sexual minorities and other youths. **Methods:** Data were available for n=434,665 heterosexual identifying youths and 91,823 LGBQ-identifying youths in the State and National Youth Risk Behavior Surveys. The independent variable was the ENDS tax per mL of e-liquid equivalent and the dependent variables included prior-month ENDS use, prior-month ENDS use on at least 20 of the last 30 days, and ENDS use everyday in the last 30 days. In addition, the study measured combustible cigarette smoking along the same margins. Two-way fixed effects logistic regression models were used to estimate the relationship between ENDS taxes and youth ENDS use. Models were adjusted for respondent's demographic characteristics and state-level controls for combustible tobacco policies, ENDS policies, alcohol policies, and drug policies. **Results:** ENDS taxes were associated with a statistically significant ($p < .05$) reduction in ENDS use among heterosexual-identifying youths, as measured by any, frequent, and everyday ENDS use. However, for LGBQ youth, ENDS taxes were not significantly associated with ENDS use. We find that ENDS taxes had the unintended consequence of widening disparities in LGBQ versus heterosexual youth tobacco use. **Discussion:** The findings show that a one dollar (in 2021$) increase in ENDS taxes reduces prior-month ENDS use among heterosexual teens by 4 percentage-points and habitual ENDS use by 2 percentage-points. In sharp contrast, queer youths' ENDS use is largely unresponsive to taxes. Taxes significantly widen disparities in vaping between queer and straight teens. Descriptive analyses suggest that LGBQ youths' tax insensitivity may be explained by their use of e-cigarettes to cope with unique stress-related psychological challenges, including those associated with targeted bullying victimization. **Implications for Health Policies:** The findings suggest unintended consequences of ENDS taxes on disparities in ENDS use. They also suggest that ameliorating psychological trauma of LGBQ youth could result in tobacco control policies being more effective at curbing LGBQ youths' ENDS use. **Implications for Further Research:** Our findings highlight challenges to policymakers aiming to curb queer teens' tobacco use. They also that supply-side restrictions, such as raising the minimum legal purchasing age from 18 to 21 may be more effective at curbing tobacco use among LGBQ young adults.

Violence: Impacts of and Policies to Address

MODERATOR: **Yuki Kanayama**, Keio University

Ind-22 The Impact of Intimate Partner Violence on Healthcare Utilization: Evidence From Vietnam

PRESENTER: **Dung Le**

The World Health Organization recognizes violence against women as a violation of human rights, a barrier to gender equality, and a global public health problem. The most prevalent form of VAW is intimate partner violence (IPV). Women experiencing IPV are significantly more likely to experience physical and mental health problems. While evidence on the relationship between IPV and healthcare utilization in low-imcome countries is scarce, studies in high-income countries have found that women experiencing IPV are more likely to use medications for pain and mental compared to non-abused women. However, these studies on healthcare utilization in high-income contexts cannot establish causality because none have addressed the endogeneity of IPV. Unobserved factors influencing both IPV and healthcare utilization could bias the results. For example, an addicted husband can affect both the likelihood of experiencing IPV and healthcare service utilization of his wife. In addition, the results estimated from high-income countries may not be directly applicable to low-income countries due to notable differences between these two economic regions in IPV prevalence, healthcare systems, economic development, and social norms. To address this research gap this study examines the effects of IPV on healthcare utilization among women in Vietnam, a lower-middle income country with a strong gender role within families. We employ an instrumental variable (IV) based on whether women report their mothers-in-law being beaten during their husbands' childhood. This approach leverages the potentially exogenous variation in a mother-in-law's exposure to violence during his son's childhood, which may influence a husband's propensity for violence later in life, but is unlikely to directly affect his wife healthcare utilization. It is crucial to note in our context that daughters-in-law did not witness their mothers-in-law being beaten and that the relationship between daughters-in-law and mothers-in-law only forms upon marriage. Thus, knowledge of a mother-in-law's experience with domestic violence during her son's childhood is unlikely to directly influence a daughter-in-law's healthcare utilization. Utilizing the National Survey on Domestic Violence against Women in Vietnam, our two-stage least squares (2SLS) estimations show that a one standard deviation increase in the IPV index led to an increase in the use of medication and outpatient visits by about 36.1% and 37.4%, respectively. These results are robust to several checks, including an alternative measure of IV and IPV, estimation using a control function instead of 2SLS, and placebo outcomes. Further analyses reveal that the effects were heterogeneous by women's and their husbands' education, place of residence (e.g., urban and rural

areas), and ethnicity. As guided by the Grossman demand-for-health model, we examine possible mechanisms through which IPV might influence the outcomes and find that IPV appears to increase the use of medication and outpatient healthcare services due to its negative effects on health outcomes. By understanding the complex interplay between IPV and healthcare utilization within the Vietnamese context, this study informs the development of effective interventions to improve women's health and well-being.

Ind-474 Bidirectional Intimate Partner Violence during pregnancy and Symptoms of Anxiety and Depression in Pregnant and Postpartum women in China

PRESENTER: **Rong Li**
AUTHOR: Li Lu

Background Intimate partner violence (IPV), remains a critical public health concern, especially bidirectional IPV (BIPV) that involves both victimization and perpetration. Pregnant and postpartum women who exposed to BIPV may experience adverse effects on maternal and infant health. This study aims to explore the contribution of BIPV on mental health of pregnant and postpartum women.

Method Pregnant and postpartum women visiting outpatient clinics of six hospitals were recruited through random sampling. Questionnaires were used to collect information on sociodemographic characteristics, BIPV during pregnancy, and anxiety and depressive symptoms. Machine learning algorithms and multinomial logistic regressions were employed.

Results Of the 1,522 pregnant and postpartum women, 10.1% and 9.5% reported ever being IPV victims and perpetrators during pregnancy, while 8.1% reported with BIPV, 5.7% and 3.9% were with psychological and physical BIPV, respectively. Random forest model identified IPV status contributed the most to comorbid anxiety and depression symptoms, followed by household income and relationship with partner. Compared with individuals without any IPV exposure, those with BIPV, psychological and physical BIPV exhibited greater associations with comorbid anxiety and depressive symptoms (OR: 11.49, 95% CI: 6.39-20.07; OR: 11.42, 95% CI: 5.97-21.86; OR: 13.96, 95% CI: 6.81-28.62). Subgroup analyses showed that participants with lower house income and poorer relationship with partner presented greater odds compared with their counterparts while with overlapping 95% CIs.

Conclusion BIPV during pregnancy was associated with highly increased odds of comorbid anxiety and depression symptoms, with strongest association being noted for physical BIPV. Tailored prevention and intervention strategies are imperative.

Key words: Intimate partner violence; Pregnant and postpartum women; anxiety symptoms; depression symptoms; China

Ind-658 Healthcare Responding to Violence Against Women and Girls in Brazil: A Difference-in-Difference Analysis of a Case-Control Observational Study

PRESENTER: **Estela Capelas Barbosa**, City, University of London
AUTHORS: Stephanie Pereira, Ana Flavia Oliveira

Background: Violence against women and girls (VAWG) is a global public health issue and a breach of human rights, with consequences that affect physical and mental health and that have cost implications to healthcare systems. Globally, it is estimated that between 15% to 70% of women and girls experience violence at least once in their lifetime. Yet evidence of effective healthcare-based interventions is still sparse, particularly in low and middle income countries (LMICs). This paper evaluates an intervention implemented within the primary care system with and embedded referral pathway of specialist support for identified victim-survivors within the Brazilian National Health service (SUS – Sistema Unico de Saude).

Methods: The intervention was delivered across two regions of the metropolitan area of Sao Paulo between November 2018 and August 2021. For each outcome (identification and referral), we compared the eight intervention practices (four per region) to the remaining (untrained) clinics in those areas (11 in West region and 22 in South region). Thus we ended with a final sample of 41 clinics (8 intervention / 33 control). We used a difference-in-difference design and explored absolute effects of the intervention on outcomes, controlling for panel and time only and using negative binomial regressions controlling additionally for patient inflow, clinical supervision, covid lockdown, region and clinic for a more nuanced understanding of the effects of the intervention.

Findings: We found that the intervention increased the probability of identification by 47·2p.p. (95%CI 0·177-0·766) and the probability of referral by 38·4p.p (95%CI 0·033-0·734), when adjusting for panel effects and time and that the results are even larger when additionally controlling for patient inflow, region, clinical supervision, clinic, covid lockdown (82·5p.p for identification [95%CI 0·444-1·207] and 87·6p.p for referrals [95%CI 0·465-1·289]). Given there was no randomisation of clinics and that this was an observational study, we also found that intervention practices were significantly more likely to identify and refer patients at baseline. While controlled for COVID lockdown in Sao Paulo, due to our expectation that it would reduce the capacity of clinics to see patients, but found no significant effect of the lockdown.

Conclusion and policy implications: This study is, to our knowledge, the first to use a quasi-experimental design to evaluate a complex intervention in violence prevention, implemented in primary care settings in Brazil. The intervention was effective at increasing identification and referral of women experiencing violence and presenting at primary care settings and most have accepted the specialist support provided by the referral pathway. Intervention clinics were more likely to identify and refer before the intervention, suggesting the clinics that enrolled in the programme were *a priori* more engaged in violence response. This suggests that the intervention may be more effective in clinics that find VAWG prevention interventions more acceptable, at least in Brazil. Given reducing VAGW is one of the sustainable development goals, policy makers and funders should explore expanding this tested intervention into other regions of Brazil and possibly exploring effects in a randomised controlled trial.

Ind-682 Can Marijuana Legalization Impact the Prevalence of Domestic Violence?

PRESENTER: **Sara Hutchinson Tovar**

AUTHORS: Rachel Knott, Umair Khalil, Sonja De New

Substance use—particularly alcohol and opioids—is a significant risk factor for intimate partner violence (IPV), through mechanisms such as heightened household stress, impaired self-control, and increased aggression. In contrast, less is known about the effects of marijuana, despite it being one of the most widely used psychoactive substances globally. Marijuana use may theoretically reduce aggression due to its sedative properties, but high doses can also induce paranoia and agitation. Moreover, marijuana laws may influence the use of other substances, acting as substitutes or complements, thereby indirectly affecting IPV risk.

This study estimates the causal effect of Recreational Marijuana Laws (RMLs) on IPV using variation in the timing of RML adoption across U.S. states from 2000 to 2019. We combine administrative crime data from the National Incident-Based Reporting System (NIBRS)—which includes incident-level reports involving intimate partners—with policy data on marijuana legislation. The primary outcome is the number of IPV incidents at the city-year level, disaggregated by severity: aggravated assault, simple assault, rape, and intimidation. We employ a staggered difference-in-differences design using the Callaway and Sant'Anna (2021) estimator to account for variation in treatment timing.

We find no significant impact of Medical Marijuana Laws (MMLs) on IPV. In contrast, RMLs are associated with an 18% decline in aggravated assault and a temporary reduction in rape (7.4–11.5%) in the four years following legalization. Simple assault increases by 8%, while intimidation shows no clear trend. As potential mechanisms, we show that RMLs increase adult marijuana use by 38% without affecting alcohol consumption, while MMLs lead to smaller increases in marijuana use (10%) and a slight decline in alcohol use (3%). These patterns suggest that RMLs may reduce more serious forms of IPV, potentially due to substitution away from more violence-inducing substances. The findings are consistent with prior evidence linking marijuana legalization to declines in other violent and property crimes.

Ind-2393 The Impact of Pacification Police Units on Healthcare Service Provision in Rio de Janeiro's Favelas

PRESENTER: **Vinicius Pecanha**

AUTHORS: Rudi Rocha, Thomas Hone, Julia Guerra, Christopher Millett, Joana Monteiro

We investigate the impact of Rio de Janeiro's favela pacification program initiated in 2008 on healthcare utilization. Before the implementation of Pacifying Police Units (UPPs), Rio de Janeiro faced persistent violence driven by drug trafficking factions that controlled favelas, leading to frequent armed conflicts with police and rival groups; the UPPs aimed to reduce violence by establishing a permanent police presence in some of these areas to reclaim state control and improve security. Using a difference-in-differences model, we analyzed detailed data from 128 healthcare clinics near pacified and non-pacified favelas between 2009 and 2016. Our findings reveal that the UPP program significantly increased health procedures in clinics near pacified areas, stressing the role of improved safety in reducing barriers to healthcare use. These results shed light on the broader implications of violence reduction on public service utilization and emphasize the need for integrated policies to address social determinants of health in vulnerable communities.

Organization and Management at the Provider and Condition Level

MODERATOR: **Emma Dean**,

Ind-2757 Hospital Market Dynamics: Prices, Capital Expenditures and Hospital Withering

PRESENTER: **Michael Chernew**

AUTHORS: Mr. Michael E. Chernew, Andrew Hicks

Hospital prices have attracted considerable policy attention because they are on average high, growing rapidly, and vary considerably within markets. Research and policy attention has centered on hospital and physician consolidation. We investigate another potential mechanism driving price increases involving shifts in market share towards higher price hospitals. We believe capital expenditures play a pivotal role in these market dynamics. Specifically, we hypothesize a positive feedback loop beginning with higher-priced, more profitable hospitals disproportionately undertaking capital projects that expand existing capacity, add service lines, improve amenities, or support entry into adjacent geographic markets. These capital investments lead to shifts in patient flows toward hospitals investing heavily and away from rivals that are investing less. These shifts in demand translate into larger price increases at expanding hospitals thus positioning these higher-priced hospitals for future expansion. Over time, these market dynamics have the potential to contribute to higher concentration of market share (some hospitals grow and others wither) and higher prices – both at investing hospitals and market wide.

We use annual 2010-2019 data from government reporting systems on hospital characteristics, capital expenditures, and volume of services delivered. We use a national commercial claims data set to compute standardized prices. The study sample includes 2,501 hospitals geographically distributed across 262 markets. In our first set of analyses, we characterize the distribution of capital expenditures and examine the relationships at baseline between capital expenditures, price, and hospital characteristics to assess whether hospitals with larger capital investments had higher baseline prices. In our second set of analyses, we examine the relationships between capital investment and changes in hospital volume, market share, and prices. Our hypothesis is that hospitals that invest more in capital gain market share and raise prices whereas hospitals that invest relatively less in capital lose market share and increase prices less.

We find that hospitals in better financial health [total margins (6.0 vs. 2.3), net income (946 vs. 218)] and higher baseline prices (1.02 vs. 0.94) made capital investments that were more than five times larger than those of financially weaker hospitals with lower baseline prices. Second, we find that capital expenditures were positively associated with changes in hospital volume and market share; a 10% difference between the hospitals' capital expenditures was associated with a 2.0% difference in percent change in market share. Third, we find that hospitals with larger capital investments experience greater price increases than rivals with lower capital investments; the difference in estimated prices between hospitals in the lowest and highest deciles of capital expenditures nearly doubled between 2012 and 2019.

In summary, we find that hospitals investing more in capital gain market share and raise prices whereas hospitals investing relatively less in capital lose market share and increases prices less. Taken together these forces perpetuate a cycle of expanding and withering hospitals. Study findings suggest important limits to antitrust as a mechanism to address high and rising prices and could inform policies to forestall or eliminate the financial decline of withering hospitals thereby preserving access and promoting competition.

Ind-766 Does Algorithmic Risk Assessment Affect Physician Prescribing? Understanding Aggregate Versus Micro-Level Impacts

PRESENTER: **Emma Dean**
AUTHORS: Daniel Kaliski, E. Mallick Hossain

Background

Artificial intelligence (AI) tools have the potential to improve medical decision making, but their adoption has outpaced regulatory frameworks and quality assessments. This leaves open questions as to their real-world applicability and reliability.

In the U.S., many AI decision-support systems are implemented in clinical practice without regulatory approval or clinical validation on the part of manufacturers, which involves assessing their accuracy and effectiveness in the real-world. We examine the impact of one such widely used tool, NarxCare, a proprietary AI algorithm that generates a score indicating a patient's risk of unintentional opioid overdose. The U.S. opioid epidemic, a severe public health crisis, caused over 81,000 opioid-related deaths in 2023. In response, many U.S. states provide NarxCare scores to physicians as part of their Prescription Drug Monitoring Programs, with some requiring physicians to view NarxCare output before prescribing opioids. NarxCare's widespread use has the potential to impact one billion patient encounters annually, but it is unregulated and has not been clinically validated* by the manufacturer*.*

Research Question

How does NarxCare impact physician prescribing and patient outcomes, and how do these effects vary by patient characteristics?

Methods

We develop a theoretical model of Bayesian updating to develop hypotheses of physician behavior changes in reaction to NarxCare. We test these hypotheses using hand-collected data on NarxCare implementation dates across U.S. states and 2015-2022 MarketScan medical claims data from over 250 million patients. This detailed billing data includes physician characteristics as well as patient demographics, procedure and diagnosis codes, prescription fills, and insurance information.** Exploiting the fact that U.S. states introduced NarxCare at different points of time, we run a staggered difference-in-differences model, allowing for dynamic heterogeneity in treatment effects by following Calloway and Sant'Anna (2021).

Results

Our national analysis shows no overall impact of overdose algorithms on opioid prescriptions. However, this aggregate null effect masks significant heterogeneity across patient groups: physicians increased prescribing for opioid-naïve patients (a continuous rise of 0.0032 percentage points over time, $p < 0.001$) but decreased prescribing for patients with a history of safe opioid use (an immediate reduction of 0.0287 percentage points, constant over time, $p < 0.001$). Consistent with our theoretical model, physicians responded more strongly to the algorithm when treating a patient for the first time.

Significance

We find that physicians are most likely to rely on algorithms or decision-support tools when they have limited background or history with a patient. However, this behavior change varies across patient types: physicians initially reduce prescribing for patients with a history of opioid use, while they increase prescribing for opioid-naïve patients. This raises two concerns: 1) a low NarxCare score does not necessarily indicate a low risk of long-term addiction but leads to increased opioid prescriptions, and 2) patients with limited access to care are more likely to see different doctors at each visit, raising both the risk of "false positives" and reliance on the algorithm. Our findings underscore the need for clinical validation of AI tools, as their use in practice may affect patient safety outcomes.

Ind-340 Managed Care Mechanisms, Patient Selection and Provider Behavior: How Do Provider Networks Reduce Medical Spending?

PRESENTER: **Lukas Kauer**
AUTHORS: Daniel Ammann, Tobias Müller, Aurélien Sallin

Objective: Managed care systems often incentivize the utilization of provider networks which aim to improve the treatment of patients by

coordinating the entire course of care. We study how managed care mechanisms change physician behavior through provider networks. A special focus is laid on cost implications and unnecessary screenings. **Methods:** We analyze the effect of provider networks on costs as well as the provision of unnecessary care based on a staggered difference in difference design. We follow patients enrolled in the family doctor model whose physician joins a provider network at some point in time. We use patients whose physician joins the network at a later point as a comparison group. We focus on one large physician network in the French-speaking part of Switzerland that obliges members to participate in periodical quality circles. The quality circles focusses, among other things, on clinical guidelines regarding unnecessary care such as the "top-5-list" of "smarter medicine–Choosing Wisely Switzerland". In addition, the network provides software and feedback on their practice to the physicians. No other managed care mechanisms are employed. Our primary cost outcomes include inpatient and outpatient services, medications, laboratory testing and vaccination costs. Outcomes indicating unnecessary screenings are the number of vitamin D tests and PSA screenings. **Results:** Preliminary results show a post treatment level shift in total costs. The point estimates indicate cost reductions of up to 15%. The main drivers of the cost reductions seem to be outpatient and medication costs. This finding indicates that the managed care mechanisms used by the network might systematically change medical practice and reduce resource use through changes in examination and prescribing behavior. We are waiting to receive more data to reveal whether physicians see their patients less often or for a shorter time, refer them to less costly specialists and whether they prescribe cheaper drugs. The network switch, on the other hand, seems to have no effect on the number of vitamin D tests and PSA screenings which are often considered of low value for patients. Here, the point estimates are close to zero and not statistically significant. This indicates that physicians do not adjust their own testing behavior when joining a physician network. **Discussion:** Our results are relevant for policy makers insofar as that they show that managed care systems can reduce costs in the medical sector even if no financial incentives are utilized on the physician level. On the other hand, they seem to have no effect on the administration of the unnecessary screenings we observe.

Ind-781 Practice of Chronic Disease Management at County Level in China from the Perspective of Professional Integration: A Qualitative Case Study

PRESENTER: **JIA HU**
AUTHORS: YING ZHENG, LI LI

Background: Chronic diseases have become an important factor affecting global people's health, mostly in low- and middle-income countries, which aggravates the health inequity and affects the achievement of Universal Health Coverage and the Sustainable Development Goals.** It is currently the most cost-effective management model to have multiple professionals from relevant institutions collaborate so as to provide integrated chronic disease management services. The "classified, color-coded, hierarchical and regionalized" chronic disease management model in Youxi County, Fujian Province is a typical case in China. However, related research is limited. This paper aims to analyze the practice measures and lessons learned in Youxi County, focusing on the professional integration of service providers. **Methods:** From January to March 2021, interviews with 15 key informants including policy makers and implementers of chronic disease management in Youxi County were conducted to collect qualitative data, which was analyzed by the thematic framework method as well as the policy data, using the professional integration dimension in the evaluation framework of the integrated healthcare system. **Results:** Under the governmental institutional supply and the organizational support of the county healthcare alliances, Youxi County selected four types of the main chronic diseases (hypertension diabetes, severe mental disorders and pulmonary tuberculosis) to conduct the management model. A series of measures were taken, such as improving the professional division and collaboration mechanism, establishing the incentive and restraint mechanism geared toward chronic disease management, formulating norms and standards of chronic disease management for patients with different color labels, and promoting the compatibility of inter-professional value and culture under the governmental institutional supply and the organizational support of the tight county healthcare alliance in Youxi County, to prompt professionals of different levels and types to collaborate in order to provide integrated chronic disease management services. However, some problems remained, such as limited capacity of primary health care, the relatively narrow range and weak effect of the incentive and restraint mechanism, inadequate implementation of the norms and standards, and so forth. **Conclusions:** The chronic disease management model in Youxi County of Fujian Province is a beneficial exploration and innovative practice of an integrated chronic disease management model on the basis of county healthcare alliances reform, which provide reference for other regions in China and other low and middle-income countries. Targeted measures should be taken to improve the model, and long-term follow-up surveys and mixed research designs are required in the future to enrich relevant evidence.

Ind-791 Length of Stay and Healthcare Costs in Chinese Middle and Older Adults with Cardiometabolic Disease and Different TCM Syndromes

PRESENTER: **Dr. Jingjing Zhou, MD**, School of Public Health and Management, Guangzhou University of Chinese Medicine
AUTHORS: Xiyin Chen, Anran Li, Yulin Gao, Guanyang Zou, David Bishai

Background: Previous studies have shown variations in Length of Stay (LOS) and healthcare costs between Traditional Chinese Medicine (TCM) and non-TCM care. However, little is known about the predictive value of an assigned TCM syndrome for LOS and healthcare costs. TCM hospitals where both Western Medicine (WM) and TCM are dually practiced can offer an opportunity to discover systematic differences in LOS for cases with the same International Classification of Diseases, Tenth Revision (ICD-10) code based on the TCM syndromes that patients were assigned at admission.

Objectives: To assess the predictive value of an assigned TCM syndrome in predicting LOS in Chinese middle and older adults with cardiometabolic diseases (CMD).

Methods: This retrospective cohort study analyzed 553,781 admissions (2017–2022) of patients aged ≥45 with CMD across 25 TCM hospitals in a city in China. Inclusion criteria required the LOS to be between 24 hours and 90 days. Fixed-effects panel regression models were developed to identify predictors of the log value of LOS, with subgroup analyses stratified by hospital level (Tertiary-A vs. non-Tertiary-A). The incremental explanatory power of TCM diagnoses was quantified through adjusted R^2 comparisons between baseline models (demographic, clinical, and administrative covariates) and models incorporating TCM syndromes or ICD-10 codes.

Results: Median LOS was 8 days (IQR 5-12) at baseline. Data on assigned TCM syndrome improved model explanatory power by 32%. The adjusted R^2 for the log value of LOS increased from 0.0490 to 0.0648 (ΔR^2=0.0158), surpassing the incremental contribution of ICD-10 codes (ΔR^2=0.0100). Tertiary-A Hospitals demonstrated stronger TCM-LOS associations (R^2=0.0703 vs. 0.0411 in non-Tertiary-A Hospitals).

Conclusions: This study successively incorporated WM and TCM syndromes into LOS models. TCM diagnosis improved the statistical prediction of the log value of LOS. Actuarial predictions of a population's expected utilization will be improved by adding data on TCM diagnoses in systems where those data are available. Policy implications highlight that adding TCM diagnosis to diagnosis-related groups (DRGs) will improve statistical prediction capabilities.

Key words: cardiometabolic diseases, TCM syndromes, length of stay, middle and older adults, fixed effects model

Ind-2205 Challenges to Integrated Care under China s New Case-Based Payment System: Impacts on Inpatient Volume Distribution within Medical Alliances

PRESENTER: **xinyi peng**
AUTHOR: yingchun chen

Background In 2020, China introduced an innovative case-based payment method called"Diagnosis-Intervention Packet (DIP)". It expected to achieve cost containment and improve service efficiency. However, similar to DRG, the DIP uses a single hospitalized case as the unit of payment. We concerned that this fragmented payment system could undermine the existing integrated healthcare service structures, specifically medical alliances—collaborative networks of hospitals and primary medical institutions. The economic incentives created by DIP may exacerbate competition for patients within these alliances, leading to a redistribution of inpatient volume. This study aims to examine the impact of DIP on the structure of inpatient volume distribution within medical alliances. **Methods** We collected monthly inpatient service volume data from 28 healthcare institutions within two medical alliances in County X, covering a continuous 36-month period from 2020 to 2022. We employed a single-group interrupted time series analysis (ITSA) to perform a stratified analysis of hospitals and primary medical institutions within the medical alliances. Considering the potential for distinct economic incentives resulting from differences in payment standards across different health insurance types (UEBMI and URRBMI), we further conducted a heterogeneity ITSA analysis based on insurance type. **Results** After the DIP reform, the number of patient discharges in hospitals for both UEBMI and URRBMI inpatients has shown an upward trend. The number of discharges for URRBMI inpatients increased by an average of 179 per month (P=0.028), while UEBMI inpatients saw an average increase of 15 per month (P=0.094). However, there was no significant change in the discharge numbers for primary medical institutions. The proportion of discharges from hospitals within the medical community also showed an upward trend. For URRBMI inpatients, the proportion increased by an average of 0.0135% per month (P=0.094), while for UEBMI inpatients, the proportion increased by an average of 0.0153% per month (P=0.03). **Conclusion** The DIP has intensified internal competition within medical alliances. Hospitals with greater medical capabilities, driven by the economic incentives of case-based payments, treat increased inpatient volume as a profitable opportunity. This has led to the inducement of unnecessary hospitalizations and the siphoning of inpatient cases from primary care institutions, resulting in a concentration of patients at hospitals. **Keywords** Innovative payment method, Medical alliances, inpatient volume distribution

Ind-808 Comorbidity Pattern of Depression and Anxiety and Difference of Core Symptoms in the Elderly With Multiple Chronic Conditions: a Network Analysis

PRESENTER: **Junjie Jiang**
AUTHORS: Qiwen Song, Wenbin Liu

Background: Multiple chronic conditions (MCCs) seriously worsen the health status of the elderly, resulting higher prevalence of depression and anxiety and more severe symptoms. Previous studies regarded depression and anxiety as a single construct to examine the linear association between depression, anxiety and MCCs. A lack of attention to specific manifestations of depression and anxiety may lead to an incomplete understanding of the mechanisms underlying the comorbidity of these two disorders. Furthermore, individuals may exhibit markedly disparate patterns of symptoms and outcomes, despite a comparable overall level of anxiety or depression. However, the heterogeneity of the pattern of anxiety and depression comorbidity and the interrelationship between symptoms in the elderly with MCCs have not been fully studied. **Methods:** We included 4176 participants with MCCs and aged above 65 from Chinese Longitudinal Health and Longevity Survey (CLHLS 2017-2018). Depression was assessed with the 10-item Center for Epidemiologic Studies Depression Scale (CESD-10) while anxiety was measured by the Generalized Anxiety Disorder scale-7 (GAD-7). Latent profile analysis (LPA) was employed to identify the subgroups of the elderly with MCCs with similar patterns of symptoms. Network analysis (NA) was used to elucidate the structural characteristics of the depression-anxiety comorbidity network with utilized "bridge strength" as centrality indices to characterize this network. Network stability was tested using a case drop bootstrap program. A Network Comparison Test (NCT) was performed to examine the differences in network characteristics across LPA subgroups.* ***Results:*** *LPA identified two distinct patterns of comorbidity: high comorbidity (n = 709) and low comorbidity (n = 3467). The value of centrality indices was 0.75, indicating that the network structure was sufficiently stable. NCT revealed a significant difference in global strength between the networks (S = 0.733, *p* < 0.001). GAD1 (nervousness), CESD1 (bother by things), GAD3 (excessive worry) were identified as common bridge symptoms for both networks. CESD10 (sleep quality) was exhibited as a unique bridge symptom in the high comorbidity network while CESD4 (Everything was an effort) presented as a unique bridge symptom in the low comorbidity network. **Conclusion:** Depressive-anxiety pattern in Chinese elderly with MCCs can be categorized into a high comorbid or a low comorbid group. Implementing targeted interventions are effective in regulating sufferers' mood and improving their mental health. In addition to GAD1 (nervousness), CESD1 (bother by things), and GAD3 (excessive worry) can be common targeted interventions, CESD10 (sleep quality) and CESD4 (Everything was an effort) were respectively recommended as unique targeted interventions for the two group. **Keywords:** Depression, Anxiety, Elderly with MCCs, Latent profile analysis, Network analysis

Ind-998 The Effect of Psychological Contract on Employee Turnover in the Public Hospitals: Evidence from China

PRESENTER: **Yiya Zhao**
AUTHORS: Huatang Zeng, Yao Chen, Shuying Yin

Background: The quality of the staff and the stability of the team in public hospital are directly related to the quality and effectiveness of healthcare services. However, the healthcare work environment has become more tense and severe, and gradually healthcare staff have resigned or transferred. The shortage of healthcare staff not only disrupts the order of diagnosis and treatment, hinders the normal operation of the healthcare system, but also affects the lives and health of the people. Previous studies have highlighted that the fulfillment of psychological contracts fosters positive employee behavior, whereas unfulfilled psychological contracts are prone to incite negative emotions and increase turnover intentions. Many countries are paying more attention to the inner demands of healthcare staff, especially in low/middle-income countries. Analyzed the psychological contract status of staff in public hospitals and its effect on the tendency to leave, which will help hospital managers take corresponding measures to stabilize the professional team of physicians. **Methods:** This cross-sectional study was conducted among healthcare staff at 11 public hospitals in Shenzhen, and 674 valid questionnaires were collected. By collecting sociodemographic information of healthcare staff, levels of psychological contract and intentions turnover, and using logit regression to analyze the impact of psychological contract on turnover intention. **Results:** Combined with China's cultural and social background, the psychological contract can be divided into three dimensions (normal, interpersonal and developmental). Normal contract refers to the working environment and material benefits. Interpersonal contract means that the organization provides a good interpersonal environment for employees. Developmental contract is an organization that provides employees with professional development space that enables them to realize their full strengths and potential. The overall score of health staff in public hospitals was 3.57±0.70; the average scores of the three dimensions in the psychological contract were 3.70±0.71 for developmental, 3.69±0.75 points for interpersonal, and 3.32±0.85 for developmental contracts from high to low; the differences in psychological contract among healthcare staff of different genders, ages, education, hospital types, years of work, and income levels were statistically significant ($P<0.05$). The average score of turnover intention was 2.54±1.12. The main reasons for turnover include the reward is not proportional to the return (26.7%), inappropriate workload (15.6%), and incomplete security welfare system (14.0%). The regression results show that after controlling for relevant factors, psychological contract has a significant impact on turnover intention. Among them, the normal contract (OR=2.09, $P<0.001$) and developmental contract (OR=2.27, $P<0.001$) have a significant positive predictive effect on turnover intention, and the contribution rates of normal and the developmental contracts to turnover intention are 30.32% and 29.42% respectively. **Conclusions:** The psychological contract of health staff in Shenzhen public hospitals is above average, and the overall turnover intention is low. The turnover intention of health staff is affected by the psychological contract. Hospital managers should take effective measures in transaction responsibility and development responsibility, to protect the reasonable rights and interests of health staff and reduce their willingness to leave.

Ind-1052 Using Systems Dynamics to Model Policies Influencing the Supply and Demand for Dialysis Services in Thailand

PRESENTER: **Siobhan Botwright**
AUTHORS: Kinanti Khansa Chavarina, Natcha Yongphiphatwong, Itamar Megiddo, Jeerath Phannajit, Jiratorn Sutawong, Yot Teerawattananon, Le Khanh Ngan Nguyen

Background

Kidney failure represents a growing burden globally, particularly in settings with limited resources and infrastructure to provide life-saving access to dialysis or transplant. Given the considerable budget and healthcare resources required, many governments are seeking to incrementally expand access to dialysis, requiring policies that build supply whilst managing demand within resource constraints. In Thailand, access to dialysis was initially provided through peritoneal dialysis (PD), with patients only reimbursed for haemodialysis (HD) if contra-indicated. Whilst successful in increasing access, the policy was criticised as restrictive and changed in 2022 to free choice between HD and PD. Contrary to initial projections, there was an unforeseen explosion in total dialysis patients, overwhelming the healthcare system and resulting in significant budget overspend.

This study was undertaken as part of a broader programme of work to understand the factors influencing dialysis supply and demand following the 2022 policy change, to propose policy goals, and to evaluate policy interventions to achieve those goals. In this study, we aimed to model the dynamics of supply and demand, to project the impact of proposed policy options over a 5-year horizon.

Methods

We adopted a systems dynamics approach, to account for health system complexity, delays between cause and effect, and feedback loops between supply and demand. In consultation with stakeholders, we iteratively developed a causal loop diagram, to incorporate multiple views around supply and demand of dialysis services. The resulting causal loop formed the structure of a system dynamics model built in R. The model was populated with data from national databases, published studies, and surveys to dialysis providers. For parameters with no available data, we determined feasible ranges through expert opinion and conducted multi-parameter optimisation for calibration. Structural uncertainty analysis was conducted on the functions of equations and structure of feedback loops. Parameter uncertainty was assessed through one-way sensitivity analysis and Latin hypercube sampling. Steps for model validation included face validity, extreme condition, and model behaviour tests. The model was calibrated using 2022 data and showed a good fit to service utilisation in 2021 and 2023.

Results

Under the current policy, the model projected 126,000 new dialysis cases from 2025-2029. Due to the widespread but unofficial practice of

paying doctors for referral of patients to HD, it was estimated that 24% of projected new cases would come from premature dialysis initiation. Only policy interventions directly or indirectly addressing these financial incentives for doctors were projected to achieve the policy target of more than 50% new dialysis cases on PD. Effective interventions in the literature, such as education by multi-disciplinary teams and bundled payment, had lower impact. A fixed global dialysis budget was estimated to have the greatest reduction in HD cases, but at the expense of equal access, with low profits causing private HD centres to close.

Discussion

Successful interventions in other countries had limited impact, highlighting the low transferability of health system interventions between settings. Our study illustrates system dynamics as a tool to inform context-specific policies for health service supply and demand.

Ind-2204 Home-Based Pharmacy Care Setting for Paediatric Epilepsy: Insights from Quasi-Experimental Research in Bali, Indonesia

PRESENTER: **Kadek Hendra Darmawan**
AUTHORS: Ayu Made Dwijayanti, Dewa Ayu Putu Satrya Dewi, I Gusti Ayu Rai Widowati, Ni Made Maharianingsih

Background: In Indonesia, epilepsy is a chronic disease that can be diagnosed in individuals of all ages and genders. It is estimated that there were between 700,000 and 1,400,000 cases of epilepsy in the country in 2016. In low- and middle-income countries including Indonesia, epilepsy is associated with high morbidity rates, primarily due to an underprepared healthcare system. Additionally, the nature of epilepsy, which requires a complex regimen of medications, often leads to ineffective treatment, particularly among children, whose medication adherence rates range from 50% to 60%. To address this issue, a new healthcare setting provision of home pharmacy care presents a plausible solution to bridge the gap in adherence to epilepsy treatment regimens, especially for children, as demonstrated by this interventional case study in Bali, Indonesia.

Research purpose: This study aims to provide evidence on the effectiveness of home-based pharmacy care setting as an alternative healthcare provision to improve adherence to epilepsy medications in children.

Methods: A quasi-experimental research design with control and intervention groups and a time-series approach was applied. Purposive sampling was used to determine the intervention and control groups, with pre- and post-tests conducted twice during the period of March-April 2024. Children aged 1-12 years diagnosed with both common seizures (*tonic, tonic-clonic, and absence*) as well as partial seizures were included. The pill count observational method was used to assess adherence, with categorical scores of $80 \geq x \leq 80$. To assess the significant changes in adherence before and after the home pharmacy care intervention in both study groups, dependent and independent t-tests were applied.

Key results: In the intervention group (n=7), the adherence rate of children with epilepsy to their medication increased from 28.57% to 85.71% after receiving a series of interventions through home pharmacy care. In contrast, the pre-test and post-test results for the control group (n=7) showed a steady adherence rate of 28.57%. The dependent t-test for the intervention group showed p-values of 0.015 and 0.014 (<0.05), while the control group had p-values of 0.573 and 0.573 (>0.05). The independent t-test comparing the intervention and control groups resulted in a p-value of 0.022 (<0.05). These t-test results consistently indicated a significant difference in adherence levels between the intervention and control groups of paediatric epilepsy patients.

Conclusions and implications: Home pharmacy care has been evidence to provide improved medication adherence for paediatric epilepsy patients and could be considered a supplementary healthcare provision, particularly for managing the complex medication requirements of epilepsy in children.

Ind-1715 Prioritizing Stakeholders for TB Diagnostics Adoption in Indonesia: A Multi-Criteria Decision Analysis Approach

PRESENTER: **Gressdilla Geovani Pottera**
AUTHORS: Rozar Prawiranegara, Naufal Febryan Azzahra, Panji Fortuna Hadisumarto, Raspati Cundarani Koesoemadinata, Ari Natalia Probandari, Nury Fitria Dewi, Bachti Alisjahbana

Background: Tuberculosis (TB) remains a significant public health challenge in Indonesia, necessitating the adoption of innovative diagnostic tools to improve early detection and effective treatment. This adoption hinges on meaningful stakeholder engagement, but involving all potential stakeholders can be overwhelming and inefficient. This study identified and prioritized key stakeholders to form a Project Steering Committee (PSC). The PSC will drive the adoption of new TB diagnostic tools in Indonesia. **Methods**: This study incorporated Multi-Criteria Decision Analysis (MCDA) commonly used for health priority setting. The salience model was used as criteria to assess the relevance of potential PSC members based on their power to influence decision-making, legitimacy within the Indonesian healthcare system, and urgency of their involvement in relation to TB diagnostics. Our research involved a multi-stage process: (1) a comprehensive document review to map the TB diagnostics pathway in Indonesia and identify relevant actors; (2) the development of a stakeholder mapping matrix outlining potential PSC members and their attributes; (3) a criteria elicitation workshop; and (4) assigning scores stakeholder salience based on the identified criteria. This exercise resulted in a detailed stakeholder analysis, generating individual profiles, and potential engagement strategies. **Key Results**: From an initial pool of 30 potential individuals, MCDA analysis prioritized 16 key stakeholders for the PSC based on their composite salience scores. This data-driven approach ensured a rational and deliberative selection process, balancing representation from diverse perspectives including patients, healthcare providers, researchers, policymakers, and TB experts. The prioritized stakeholders demonstrated high levels of influence, legitimacy, and urgency within the Indonesian healthcare system, maximizing the potential for impactful engagement in TB diagnostics adoption. **Conclusion**: This study demonstrates the value of a structured, context-specific salience model for stakeholder prioritization. This

approach offers a robust and transparent method for identifying key actors in health interventions and policy formulation. The findings of this study provide practical guidance for researchers and policymakers seeking to optimize stakeholder engagement for TB diagnostics adoption and other settings. **Keywords:** MCDA, Stakeholder Engagement, Salience Model, Tuberculosis, Diagnostics

Ind-2145 Community Health in the Global Financing Facility (GFF) Planning Documents: Insights From Six West African Countries

PRESENTER: **Mr. Joël Arthur Kiendrébéogo**, University Joseph Ki-Zerbo
AUTHORS: Meghan Bruce Kumar, Issa Kaboré, Orokia Sory, Yamba Kafando, Asha S. George, Rosie Steege

Background Community health (CH) plays a critical role in ensuring equitable access to healthcare, particularly in settings where health systems face significant resource constraints. In francophone West Africa, where Reproductive, Maternal, Newborn, Child, and Adolescent Health and Nutrition (RMNCAH-N) indicators remain a concern, CH has the potential to bridge gaps in service delivery, especially for hard-to-reach populations. However, how CH supports integrated RMNCAH-N service delivery in this region is under-researched. This study examines how six francophone West African countries – Burkina Faso, Côte d'Ivoire, Guinea, Mali, Niger, and Senegal – support CH through the Global Financing Facility for Women, Children, and Adolescents (GFF). The GFF is a global health initiative that aims to accelerate progress toward universal health coverage and improve RMNCAH-N by mobilizing and aligning domestic and international financing. **Methods** We conducted a content analysis of Investment Cases and Project Appraisal Documents from the selected countries between July 2022 and October 2023. These documents outline strategic priorities and financing plans under the GFF. To guide our analysis, we defined the scope and developed a list of key search terms related to CH, including community health workers (CHWs), service delivery, governance, and financing. Using an iterative hybrid inductive-deductive approach, we identified themes for data coding and extraction. The extracted data were analysed to identify patterns, compare findings within and across countries, and group them into meaningful categories. **Results** Our analysis revealed a strong commitment to CH across all six countries. Each country's GFF documents highlight the importance of CHWs, who perform a wide range of preventive, promotive, and curative roles. These include immunization, antenatal care, family planning, and nutritional support, all of which contribute to improving RMNCAH-N. However, while CHWs' contributions are recognized, their remuneration and incentives vary considerably across countries, with some relying heavily on volunteerism or donor funding to sustain CHW programs. Most CH indicators in the analysed documents focus on CHWs' deliverables, including the number of home visits, immunizations administered, and pregnant women reached. However, few indicators address broader governance aspects, such as community participation in health planning or the integration of civil registration and vital statistics systems. Key challenges identified include weak leadership and governance structures, which undermine the coordination and oversight of CH initiatives. Additionally, financial and material resource shortages constrain CHWs' performance and limit service utilization. While some countries invest in CHW training and capacity building, these efforts are often insufficient to address systemic gaps. Structural reforms and broader community engagement remain underdeveloped, limiting the potential impact of CH interventions. **Conclusions** There is a need for more comprehensive and integrated approaches to CH, and to prioritize and mainstream CH interventions by embedding them into national health system planning and budgeting processes. This would help ensure sustainable financing and more effective use of CH to improve RMNCAH-N. Strengthening leadership, governance, and community engagement is essential to fully harness the potential of CH in francophone West Africa.

Value of Applying Artificial Intelligence in Health: Case Studies From China

MODERATOR: **Xuefei Gu**, China National Health Development Research Center

CONVENER: **Huanhuan Xu**, School of Health Management, Harbin Medical University

abs-os373 A Health Economic Evaluation of an Artificial Intelligence-Assisted Prescription Review System in a Real-World Setting in China

PRESENTER: **Xueqing Tian**, China National Health Development Research Center
AUTHORS: Di Wu, Liwei Shi, Kejun Liu, Wenqi Fu, Mr. Mao You, Ping Ren, Yingpeng Qiu, Ms. Yue Xiao, Junrui Pei

Background: Medication safety and irrational prescriptions have long been a concern in China. Primary healthcare institutions (PHIs), particularly village clinics, lack pharmacists and prescription review processes. **Objective:** This study aims to estimate the cost and evaluate the economic impact of a pilot using a artificial intelligence-assisted prescription review system (AIAPRS) in a rural county in China. **Methods:** A pilot project was conducted in Shucheng County, Anhui Province (a central province in China), which installed the AIAPRS in all 21 township health centers and 286 health clinics in 2024. A pre-post study with self-matched controls was conducted to examine the cost-effectiveness of the AIAPRS. The information platform designed for the pilot project facilitated the evaluation of both the quantity of irrational prescriptions across different risk levels and the associated drug expenses from March (established as the baseline) to June. Additionally, from the healthcare system perspective, the unit cost (in RMB per prescription audited) was estimated using the Activity-Based Costing approach. **Results:** The introduction of AIAPRS incurred a cost of 2.40 Yuan (CNY) per prescription audited, compared to zero prior to the pilot. During the baseline period, there were 18,527 irrational prescriptions per month, with a drug cost totaling CNY 1.9 million. Following three months of

implementation, the number of irrational prescriptions decreased to 11,564 per month, resulting in a total cost of CNY 1.6 million. This reduction represented a 6.0% decrease in the proportion of inappropriate prescriptions ($P < 0.05$). At the county level, the AIAPRS led to a 3.5% reduction in monthly irrational prescriptions over four months, yielding an average monthly cost savings of 125,929.4 CNY. **Conclusion:** The AIAPRS significantly enhances prescription quality at the grassroots level and reduces costs. **Keywords:** Artificial intelligence; Prescription review; Health economic

abs-os369 Economic Evaluation of Artificial Intelligence-Assisted Diagnosis of Coronary Heart Disease

PRESENTER: **Liwei Shi**
AUTHORS: Jiayu Zhao, Ms. Yue Xiao, Yingpeng Qiu

Objective Using coronary CT angiography intelligent assisted diagnosis (CCTA-AI) as the experimental group and coronary CT angiography manual diagnosis (CCTA-senior physicians, CCTA-junior physicians) as the control group, this study measured the cost-effectiveness and efficiency of the AI-assisted diagnosis system for the diagnosis of coronary heart disease from the perspective of the health system, and explored the clinical application value of AI-assisted diagnosis technology. **Methods** The study used activity-based costing to calculate the changes in CCTA examination costs and efficiency before and after the application of AI technology in five sample hospitals in Beijing; systematically searched Chinese and English databases such as PubMed and CBM, screened literature for meta-analysis based on inclusion and exclusion criteria, and calculated the combined effect size of the experimental group and the control group; used diagnostic accuracy as the effect value to calculate the cost-effectiveness of the experimental group and the control group; and constructed a decision tree model to simulate the cost-effectiveness of using CCTA-AI technology for one year in patients with suspected coronary heart disease. **Result** The cost calculation results showed that the average cost of CCTA-AI examination in the sample hospitals was 1,074.90 yuan (778.87-1,374.95), which was 191.71 yuan (15%) lower than that in the control group. Affected by factors such as "annual examination number" and "number of CT units involved in CCTA examination", the examination costs among institutions varied greatly. After the application of AI, 0.46 man-hours (0.17-0.67) could be saved for each patient examined. The results of meta-analysis showed that the diagnostic efficiency of the CCTA-AI group was significantly higher than that of the CCTA-low-senior physician group ($p<0.05$) and slightly higher than that of the CCTA-high-senior physician group ($p=0.73$). The combined sensitivity and specificity values of the CCTA-AI group were 0.86 (95%CI, 0.81-0.89) and 0.83 (95%CI, 0.77-0.87), respectively, and the AUC value was 0.91 (95%CI, 0.88-0.93). The cost-effectiveness analysis results based on diagnostic accuracy showed that the experimental group had an absolute advantage over the control group. The cost of the CCTA-AI group was 1,074,900 yuan and the effectiveness was 855.05. The model analysis results showed that the CCTA-AI group had the highest expected cost (50,656.74 yuan) and the highest utility value (0.82). Compared with the CCTA-senior physician group, the ICER value of the AI group was 2,969,386.32 yuan/QALY. **Conclusion** The diagnostic performance of the CCTA-AI group is comparable to that of senior physicians, and its application can, to a certain extent, promote the improvement of quality and efficiency of public hospitals. In the future, AI technology is expected to continue to be promoted and deepened in the medical field, optimize the overall layout of medical resources, improve the level of medical services, and continuously improve patient health. In the future, the analysis of the application value of AI technology at the system level should be further strengthened to comprehensively evaluate its actual contribution to the medical system.

abs-os335 Health Economic Evaluation of Artificial Intelligence-Assisted Diagnosis For Early-Stage Lung Cancer Screening

PRESENTER: **Yingpeng Qiu**
AUTHORS: Liwei Shi, Di Wu, Huanhuan Xu, Ms. Yue Xiao

Background: Lung cancer is one of the malignant tumors with the highest incidence and mortality in the world. With artificial intelligence (AI) technology widely applied in lung cancer, it has shown high applicability and can improve work efficiency and diagnostic accuracy. **Objective:** This study aims to evaluate the cost-effectiveness of artificial intelligence-assisted physician diagnosis in early lung cancer (stage I) screening from the perspective of the Chinese health system. **Methods:** A decision tree model was developed based on community population to simulate the cost-effectiveness of 10,000 patients for the diagnosis of pulmonary nodules by AI-assisted physician reading and physician reading, and calculating the incremental cost-effectiveness ratios, and evaluating the robustness of the model through one-way sensitivity and probabilistic sensitivity analysis, with the simulated end-point age of 78.6 years old. **Results:** In basic analysis, taking the number of early-stage lung cancer detections as the effectiveness indicator, the AI-assisted group discovered 40 more early-stage lung cancer cases than the physician group. The detection rate of early-stage lung cancer increased by 0.4%. Moreover, the AI-assisted group has a higher detection rate for lesions with diameters between 4-10mm. When using Quality-Adjusted Life Years (QALY) as the effectiveness indicator, the average cost per person in the AI-assisted group and the physician group were 1,483 RMB and 1,489 RMB respectively. The per capita effects of the AI-assisted group and the physician group are 17.02 QALYs and 16.99 QALYs respectively. Compared to the physician group, the AI-assisted group could save 6 RMB per case and gain 0.03 additional QALY per case, the ICER value was negative. The AI-assisted intervention was an absolute superior strategy. Threshold analysis showed that after the cost of AI-assisted physician reading screening was rose to 428 RMB, the ICER value was positive and below the willingness-to-pay range (893,598 RMB), which showed the AI-based intervention is economical. The results of the one-way sensitivity analysis and probabilistic sensitivity analysis showed that the model had good stability. **Conclusion:** Artificial intelligence-assisted diagnosis was cost-effectiveness in early lung cancer screening, and which can help "early detection, early diagnosis and early treatment" of lung cancer. Additionally, by controlling the costs of AI-assisted examinations appropriately and setting reasonable prices, the economic feasibility of AI medical technology can be further enhanced. **Key words:** decision tree model; artificial intelligence; lung cancer; cost-effectiveness analysis

Costs and Utilisation in Mental Health Care: A Lifespan Perspective

MODERATOR: **Adrián Villaseñor**, University of York

abs-os174 Does Improving the Quality of Child and Adolescent Mental Health Services in the English NHS Have the Potential for Cost Savings?

PRESENTER: **Amy Barker**
AUTHORS: Jinyang Chen, Mr. Adrián Villaseñor, Rowena Jacobs, Maria Ana Matias

Background: Mental health conditions in children and young people (CYP) are high and rising. Consequently pressure has been placed on Child and Adolescent Mental Health Services (CAMHS) in England where referral rates almost doubled between 2017 and 2021. This trend is expected to have continued post covid-19 pandemic. Mental health conditions in CYP have both short- and long-term impacts on individuals' educational attainment, economic outcomes and overall health. In England, policies have prioritised care expansion and quality improvement for CAMHS services. However, little is known about the cost implications of quality improvement initiatives within CAMHS. **Objective:** We aim to address this knowledge gap by estimating the marginal cost of quality for a range of quality indicators including readmission rates, follow-up post discharge, waiting time for assessment and treatment, and clinician-reported outcome measures in CAMHS services. **Methods:** We use a large administrative data set covering all secondary mental health services for CYP (under 18) in England - the Mental Health Services Data Set (MHSDS) from 2016/17 to 2021/22. We calculate 10 generic quality measures some at either individual or trust level covering both inpatient and outpatient care. Total costs were calculated based on activity reported in the MHSDS using average unit costs at a hospital level from submissions to the National Cost Collection. We use a Generalised Linear Model (GLM), given the skewed nature of the dependent variable, total cost. The model adjusts for fixed effects including year, month and mental health provider, as well as patient demographics including age, sex, ethnicity, deprivation and case mix. Marginal cost is calculated at the patient mean. **Results:** The analysis includes over 2 million CYP. Preliminary results suggest small and often non-significant marginal costs associated with both urgent and non urgent waiting times to assessment and treatment and change in a Clinician Reported Outcome Measure (HONOSCA). However large positive marginal costs were seen for quality measures associated with inpatient treatment - readmission rates and post-discharge follow-up. This was most noted for reduction in potentially preventable readmission rates, possibly because the cost of inpatient care is high. **Conclusion:** This study suggests quality improvement initiatives in the outpatient setting can be associated with minimal cost changes and there may be cost savings if outpatient quality improvement initiatives generate reductions in inpatient bed days (either through reduced admissions or decreased inpatient length of stay).Our analysis points to areas where policymakers and providers might focus quality improvement efforts in CAMHS, especially in a resource constrained environment.

abs-os175 Excess Resource Use and Costs of Mental Health Problems in Swedish Children: A Longitudinal Register-Based Study

PRESENTER: **Ingyin Moe**
AUTHORS: Natalie Durbeej, Claire de Oliveira, Filipa Sampaio

Background

Mental health problems among children has become a major public health concern worldwide, warranting attention and action. If left untreated, mental health problems can persist into adulthood and lead to negative outcomes, including mental illness, school dropout, and unemployment. Yet, the economic burden of early childhood mental health problems in Sweden remains unquantified. This study examined the excess health care resource use and costs related to early mental health problems in preschool children.

Methods

This study uses data from a cohort of 6957 children aged 3–5 in Uppsala, Sweden. Early mental health problems were assessed using the Strengths and Difficulties Questionnaire (SDQ). These data were linked to longitudinal national register data on inpatient and specialized outpatient care from the National Patient Registry, primary care from Uppsala Region administrative database, as well as prescribed medication from the Prescribed Drug Register. Cumulative resource use and associated costs over a 4-year time horizon were estimated from a healthcare sector perspective, utilizing Diagnosis Related Groups, the Swedish cost per patient database and market prices, expressed as 2024 U.S. dollars (US$). Excess resource use and costs for children with early mental health problems were estimated compared to those without using Hurdle models for resource use and generalized linear models and two-part models for costs.

Results

Children with early mental health problems consumed approximately 3 units more prescribed medication and incur $299 more in medication costs than those without early mental health problems. Additionally, children had on average 1 more visits to specialized outpatient care at an additional cost of $622; and 5 more primary care visits at an additional cost of $376. No significant differences were found in inpatient care stays. Children with early mental health problems consumed overall significantly 9 more healthcare resources at an additional cost of $1457.

Conclusions

Children with early mental health problems incurred greater healthcare resource use and costs in terms of medication, primary care, and

specialized outpatient care compared to children without such problems. Our findings may inform healthcare planners and policy-makers of the economic impact of mental health problems among children in Sweden. Additionally, results may highlight the value of early identification of mental health problems, which in turn could facilitate delivery of appropriate treatment interventions.

abs-os177 The Economic Benefits of a Model of Pediatric Acute Mental Health and Addictions Care to Increase Value to Children, Youth, and the Healthcare System

PRESENTER: **Lola Ibraimova**, School of Public Health, University of Alberta
AUTHORS: Amanda Newton, Dat Tran, Arto Ohinmaa, Stephen Freedman, Jennifer Thull-Freedman, Bruce Wright

Background: Innovative solutions resulting in better outcomes, fewer healthcare resource use (HCRU) and lower costs for children and youth with mental health needs are integral components of an efficient healthcare system.

The objective of this study was to evaluate the cost benefit of implementing an acute mental healthcare bundle for improved mental healthcare delivery.

Methods: An observational cost analysis was conducted using data from two pediatric tertiary care emergency departments (EDs) in Alberta, Canada. Patients under 18 years with mental health issues were enrolled during a pre-implementation (standard care) and implementation (mental health bundle) periods. HCRU and associated costs were compared over 12 months following the initial ED visit.

Results: There were 686 pre-implementation (mean age 13.0 years) and 692 implementation (mean age 12.6 years) participants with no difference in terms of sex distribution ($p=0.04$). During the follow-up period, implementation participants were less likely to be admitted (4.6% vs. 9.8%; $p<0.001$) at the index ED visit and had fewer hospitalizations (mean=0.4 vs. 0.5; $p<0.001$), non-ED ambulatory care visits (mean=2.7 vs. 10.0; $p<0.001$), and practitioner claims (mean=34.3 vs. 46.8; $p=0.001$). ED visits were same for both cohorts (mean=1.5 vs. 1.5; $p=0.95$) during the follow-up period. Implementation participants incurred lower healthcare costs ($12,408 vs. $19,326; $p<0.001$) driven by lower hospitalization ($6,845 vs. $9,994; $p=0.01$), ambulatory care ($1,711 vs. $4,027; $p<0.001$), and practitioner ($3,851 vs. $5,306; $p<0.001$) expenses during the follow-up period. After risk adjustments, implementation participants had 40% (95%CI: 26%-52%) lower healthcare costs than pre-implementation participants ($p<0.001$).

Conclusions and Relevance: Participants who sought ED care after implementation of the bundle consumed fewer healthcare resources and had lower healthcare costs during the subsequent follow-up period (12 months). The integration of the bundle in tertiary care pediatric EDs is cost-saving to mental healthcare delivery.

abs-os195 The Marginal Cost of Mental Healthcare Quality for Adults in England

PRESENTER: **Mr. Adrián Villaseñor**, University of York
AUTHORS: Jinyang Chen, Rowena Jacobs, Maria Ana Matias, Adriana Castelli, Nils Gutacker, Amy Barker, Anne Mason, Maria Goddard

Background: Mental health services have been under pressure in England over recent years, with growing numbers of referrals, and large waiting lists. The government has sought to expand and improve NHS-funded mental health services, but providing quality mental healthcare at a reasonable cost is a challenge. For example, achieving quality improvements could be costly but they could also reduce costs in the long-run. There is currently a significant evidence gap in understanding the cost-quality relationship in mental healthcare and what areas policymakers might be best placed to focus quality improvements. **Objective:** This study addresses the evidence gap by estimating the marginal cost of healthcare quality for adults in England. **Methods:** We use data from the Mental Health Service Dataset (MHSDS), a large administrative dataset covering all secondary mental health services for adults in England for 2016/17-2021/22. We calculate several quality indicators at the individual (e.g. continuity of care, avoided readmissions, improvements in clinician reported outcome measures and mortality) and at the hospital level (e.g. waiting times, inappropriate out of area placement). To cost all care activity we use unit costs from the National Cost Collection and the Patient-Level Information and Costing Systems. Using a Generalised Linear Model (GLM) framework with fixed effects for time and provider, adjusting for outliers, and controlling for clinical, individual, and hospital level variables, we estimate the marginal costs of improving quality measures individually and jointly. **Results:** Our preliminary results are heterogeneous, depending on the quality indicator used, but we find predominantly negative marginal costs, suggesting that quality improvement efforts amongst mental healthcare providers might not necessarily be more costly. In keeping with previous research, we find large negative marginal costs for avoided readmission, suggesting that this is one of the most cost-effective quality indicators. There are also potential trade-offs and interactions amongst different quality indicators. **Conclusion:** To our knowledge, these are the first estimates of marginal costs for mental healthcare quality in England. Policymakers should consider the important nuances between the different quality measures for targeted quality improvement strategies in mental healthcare in the English NHS.

Theory Driven Economic Evaluation in Health and Social Care - a Disciplinary Turn or Bend in the Road?

MODERATOR: **Angela Bate**, Northumbria University

CONVENER: **Sonia Dalkin**, Northumbria University

DISCUSSANT: **Sam Redgate**, Northumbria University; **Andrew Briggs**, London School of Hygiene and Tropical Medicine; **Andrew Fletcher**, Northumbria University; **Hareth Al-Janabi**, University of Birmingham; **Sedighe Hosseini-Jebeli**, University of Birmingham; **Igor Shagalov**, London School of Economics and Political Science; **Stirling Bryan**, University of British Columbia

abs-os234 A Rationale for Theory Driven Economic Evaluation: Economic Evaluation in the Absence of Experimentation

PRESENTER: **Ms. Angela Bate**, Northumbria University

It is well documented that the most pressing challenges in health and social care require well-designed, often complex solutions. Interventions can be considered to be complex for several reasons including but not limited to: the number of components of the intervention (including people, skills, processes, organisations, and systems), the scale of the intervention (numbers of groups or settings), and the interaction and dynamic nature of these. Complexity also arises from external factors and the fact that the intervention exists in a complex world, including social, political and economic factors. Complexity thus has many implications for evaluation, not least, requiring methodological approaches and designs that embrace and account for complexity, identifying not just if an intervention works but understanding 'how', 'why', (in which circumstances, for whom?) interventions work and the implications for costs and outcomes. Impact evaluations using probabilistic/experimental methods have tended to dominate questions of effectiveness, controlling for processes and mechanisms and minimising biases to establish if there is causal effect from the intervention. Economic evaluations, often conducted as an extension of an impact evaluation have thus tended to be rooted in the experimental model in pursuit of establishing the relative cost-effectiveness of interventions. However, these methods cannot answer questions of how and why interventions work and often lack transferability in the real world. This represents a key limitation to providing applicable evidence for policy and service delivery, and highlights a methodological gap in the evaluation of complex interventions. Drawing on Tony Lawson's work alongside other ongoing and published examples of theory driven economic evaluation, this paper will explore economic evaluation in the absence of experimentation.

abs-os238 Is it Time to Rethink our Approach to Economic Evaluation Alongside Clinical Trials?

PRESENTER: **Mr. Andrew Briggs**
AUTHORS: Ms. Sam Redgate, Nicola McMeekin

In the field of evidence-based medicine, the randomised controlled trial (RCT) is widely considered at the top of the evidence hierarchy for its ability to estimate unbiased, causal effects of treatment on heath outcome. Yet the reliance on randomisation to infer causation only tells us whether treatment impacts outcome, it does not tell us 'how' such treatment effects are achieved.

In contrast to RCT-based analyses, health economic models describe how treatment impacts health outcomes, often mediated through surrogate outcomes. Using examples form previously published trial-based economic evaluations, the authors explore the potential for analysing clinical trials in such a way that the elucidates how treatment is impacting health outcomes, not just whether they impact health outcomes.

Developing an underlying conceptual/theoretical model that is then operationalised using the trial data can lead to a number of advantages for the interpretation of the results of such analyses, conditional on the underlying theoretical model being correctly specified. Such theory-driven analyses would aid our understanding of how treatments work and for whom such treatments are cost-effective. We compare such an approach for relatively 'simple' interventions (such as pharmaceuticals) with theory-driven models for more complex interventions. In particular, we ask the question of whether theory-driven economic evaluation necessarily needs to adopt a realist philosophy, and consider how doing so adds further benefits to the questions that economic evaluation can potentially answer.

abs-os243 The Application of Theory Driven Economic Evaluation in Practice 2: Process Tracing Methods in Economic Evaluation

PRESENTER: **Mr. Hareth Al-Janabi**, University of Birmingham
AUTHORS: Mr. Igor Shagalov, Ms. Sedighe Hosseini-Jebeli

Background: Economic evaluation generates evidence on the costs and benefits of health interventions, often in the form of a cost-effectiveness ratio. The idea is that a decision-maker can compare this to a threshold to determine whether the intervention is value-for-money (i.e. it will improve efficiency). This presupposes a decision-maker who uses evidence in a 'problem-solving' way to maximise health from a financial budget. It is questionable whether resource allocation works in this way in the real world and particularly outside in educational settings that are making investments in mental health and wellbeing.

Aim: To use process tracing methodology to (i) characterise resource allocation in school settings; (ii) identify where this deviates from the rational, problem-solving, model; and (iii) to generate insights for economic evaluation in these settings.

Methods: In the *Wellbeing Investment in School and Employers* (WISE) study, we used process tracing methodology to build and test theory to characterise decision-making. We used interviews and document analysis within a set of 9 case study schools and conducted an online survey to measure resource allocation practices with a wider set of schools (> n=100). The initial findings from these empirical studies have been synthesised into a set of eight features of resource allocation practice.

Results: The following features of resource allocation practice were all emphasised to varying degrees across UK schools: (i) diversity of decision-makers; (ii) conflicting objectives; (iii) workforce decisions; (iv) external search for resources; (v) contexts and constraints; (vi) practice wisdom; (vii) multiple sources of evidence; and (viii) varying evidence utilisation models.

Conclusion: The process tracing work generated important insights for economic evaluation. This includes paying close attention to (i) identifying decision-makers and their goals and constraints prior to analysis; (ii) engaging with different models of evidence use; and (iii) supporting schools with real world trade-offs around time use and external searches for resources. Process tracing may be a useful method for understanding resource allocation practices, and structuring economic evaluations, particularly in settings that are 'complex' or outside healthcare.

abs-os240 The Application of Theory Driven Economic Evaluation in Practice: Realist Methods in Economic Evaluation

PRESENTER: **Ms. Angela Bate**, Northumbria University
AUTHORS: Ms. Sonia Dalkin, Andrew Fletcher

The REEM study aims to improve evaluation by developing better ways to integrate realist and economic evaluation methods. Realist evaluation is distinct among other theory-driven approaches in that it uses a configurational approach to generative causation. Despite being amenable to using multiple methods and data types, realist evaluators rarely address economic considerations. Consequently, there are many detailed evaluations of complex interventions that open the explanatory 'black box' but do not indicate whether the intervention provides value for money.

Aims. This study therefore aims to develop *realist economic evaluation*; to determine if and how realist and economic evaluation approaches can be brought together, to produce an evaluative method that can determine what works, for whom, in which circumstances, why, and with what related resource impacts and opportunity costs.

Methods. An initial scoping review and expert stakeholder workshops were conducted to develop draft REE guidance. The guidance was then tested through three pilot evaluation studies, to a) evaluate whether REE was useful and b) further refine the guidance. Our RQs for this phase were therefore: 1) Is REE a feasible approach? And 2) what are significant challenges and enablers, or considerations required, which should be encompassed in the guidance?

One pilot evaluation, 'Waiting Well', focused on an NHS social prescribing intervention designed to enable 'prehabilitation' for people on surgical waiting lists. An estimated 70% of health outcomes are determined by social factors1 and social prescribing can be used to address multiple determinants of health. The core idea behind Waiting Well is that healthier patients will have better surgical outcomes and faster recovery times.

Initial programme theories were developed, based on patient pathways, then tested and refined using a combination of realist interviewing and a costing exercise, formulated around the realist 'context, mechanism, outcome' heuristic. The data were analysed and coded to identify causal configurations within the programme theories.

Results. Findings of the Waiting Well pilot evaluation are forthcoming in Q1 2025. We will present the refined programme theories and costs of different patient pathways though alternative models of prehabilitation, and how those work in different circumstances for different patient sub-groups.** We will also present briefly the inputs to the guidance refinement from the other two pilot evaluations in abstract terms.

Discussion. The three pilot evaluations have indicated: 1) REE is a feasible approach and 2) there are significant differences between REE and traditional EE approaches that require further elucidation through field testing and iterative refinement. Building on the UK Medical Research Council guidance and gradual acknowledgement of complexity in health economic evaluations, we see this as a way forward for HE to engage with the mechanisms of change. As such, EE findings will potentially become more useful to decision-makers, as they can consider the aspects of context essential for the desired outcomes and increase transferability of evidence.

Making the Economic Case for Halving Premature Mortality by 2050: Insights From the Lancet Commission on Investing in Health

MODERATOR: **Stéphane Verguet**, Harvard University

CONVENER: **David Watkins**, University of Washington

abs-os349 Quantifying the Economic Value of Mortality Change and Full Income Change for 1990- 2019 and the COVID-19 Pandemic 2020-2023

The world has experienced large declines in mortality since 1990. However, commonly used economic welfare measures do not include these gains. This paper adds the value of changes in mortality risk to that of income growth to estimate recent changes in full income, 1990–2019 and during the COVID-19 pandemic (2020-2023).

We calculated the economic value of mortality change as a percentage of income at the start of each decade 1990–2023, for global regions and the 30 most populous countries. To estimate change in full income, we add age-weighted value of mortality change to the change in a conventional measure of income—gross national income (GNI). We also estimated the value of a one-year gain in life expectancy (VLY). Pandemic mortality was estimated using two approaches: 1) excess mortality and 2) P-score.

Globally, the value of mortality change was 18% of the global GNI at the start of the decade in 1990-2000, 23% in 2000-2010, and 14% in 2010-2019; or 55%, 50%, and 37% of the change in full income in the three decades, respectively. The VLY globally was 7%, 6%, and 6% of the starting income in the three decades, respectively. We observed wide variations across regions. Cumulatively, the value loss due to excess deaths during the COVID-19 pandemic were estimated at about 16-34% of the 2019 global income, with the largest loss in Central and Eastern Europe, Latin America, India, and the United States.

We conclude that mortality changes play a large role in the measurement of population well-being, accounting for almost half the gains in full income 1990–2019. However, most regions experienced major—although temporary—setbacks during the pandemic. Our estimates of the full income change suggest a more comprehensive view of changes in population well-being than either income change or mortality change alone. The estimates can also be used to advocate to finance ministries and legislatures for increased budget allocation to the health sector to support the “50 by 50” goal.

abs-os353 Modular Cost-Effectiveness Analysis: A Novel Approach to Priority-Setting for Health Benefits Package Design and Health System Development

Many countries are implementing reforms to support health system development, including revisions of health benefits packages (HBPs). However, conventional cost-effectiveness analysis (CEA) and health technology assessment methods have notable limitations when applied to maturing health systems. This paper describes a new approach to priority-setting called “modular cost-effectiveness analysis” that the Commission developed to address these limitations.

The starting point for modular CEA is to map all the interventions being considered for the HBP to local service delivery configurations and financing arrangements. Analysts then define a set of “modules” within which priority setting is done. Modules may be designed around delivery platforms (e.g., clinics, hospitals), disease areas (e.g., infectious diseases, cancer), or other dimensions relevant to implementation. Modular CEA entails two stages. First, health planners determine the available budget space for each module based on economic, strategic, and ethical (e.g., equity) considerations. Second, technical staff with expertise relevant to each module determine the optimal mix of interventions within each module given the budget constraint and module-specific objectives.

A key analytical dimension of modular CEA is its explicit handling of fixed costs and potential (dis)economies of scope within a given module. Leveraging modeling tools and approaches we developed previously, we present some worked examples to illustrate how modular CEA provides insights that are missed when conventional CEA is done on candidate interventions one by one. For example, the cost-effectiveness of various surgical procedures within a district hospital surgical program differs greatly depending on whether they are analyzed in isolation or in combination. As another example, treatment of high blood glucose in primary care is not cost-effective in isolation but is cost-effective when bundled with treatment of high blood pressure and cholesterol for the same high-risk populations. On the other hand, bundling mental health interventions with vascular disease prevention would not substantially change the cost-effectiveness of either set of interventions.

We also propose that analysts cost out realistic increments for expansion of each module, e.g., as an additional 10% population coverage over 10 years. Planners could then choose how much additional budget space to allocate to each module considering the overall health strategy. We did this exercise for a set of stylized modules based on the major health conditions that could help achieve “50 by 50.” For example, the cost of expanding a tuberculosis program by 10% would be 0.9 basis points of GDP in the average lower-middle-income country, whereas the same expansion of a basic mental health program would cost 3.6 basis points.

We conclude that modular CEA could be a useful adaptation of CEA to inform HBP design and health sector strategic planning. However, the idea is still in its infancy. Soon we plan to work with analysts in a few partner countries to test and validate the approach and iteratively refine the methods.

abs-os355 Health System Financing in Turbulent Times

The global landscape for health system financing is increasingly characterized by volatility, driven by compounding factors such as economic downturns, geopolitical instability, and the aftermath of the COVID-19 pandemic. This paper explores the shifting dynamics of health financing, focusing on how low- and middle-income countries can navigate this turbulence to achieve sustained health improvements.

How can health systems adapt their financing strategies amidst economic uncertainties to achieve "50 by 50" and improve health outcomes efficiently? We conduct a comprehensive review of recent global health expenditure trends and case studies of successful health financing reforms in low- and middle-income countries. Data sources include the World Bank, International Monetary Fund, and the World Health Organization's Global Health Expenditure Database.

Key results indicate a stark reversal in domestic health financing trends since the pandemic, with a decline in health's share of government budgets, particularly in lower-income countries. Despite temporary increases in health spending during Covid-19, many countries have reverted to pre-pandemic expenditure levels, jeopardizing progress towards universal health coverage and mortality reduction goals. To facilitate achievement of the 50 by 50 goal, most low- and lower-middle-income countries will need to allocate an additional 1-2% of GDP to government health expenditure on high-priority conditions and interventions.

The paper proposes a two-pronged approach to financing the "50 by 50" agenda. First, sustained domestic resource mobilization will need to involve cross-sectoral collaboration to enhance taxation capacity and increase the share of government revenue to health, as well as improve public financial management capacity. Second, action must be taken to improve the availability and affordability of essential medicines that address the 15 priority health conditions. The Commission proposes the "Arrow mechanism" as a pragmatic workaround to this problem. Named after the late Kenneth Arrow, who first proposed the idea for antimalarials, the Arrow mechanism involves (1) redirection of general budget transfers to ministries of health to line-item budget transfers for specific priority drugs, (2) centralized pooled procurement (by government or internationally), (3) procurement of large volumes to ensure availability, and (4) use and strengthening of both public and private supply chains.

The findings of this analysis underscore the need for renewed policy focus on health financing reforms tailored to the current economic context. The two recommendations from the commission could help mitigate the financial headwinds that governments face, make progress on "50 by 50," and improve health system resilience.

abs-os356 Achieving 50 by 50 through Strategic Financing: A Modular Political Economy Approach to Domestic Resource Mobilization

The Commission report calls for increased health financing amidst significant post-Covid-19 fiscal constraints, competing demands on government budgets, and economic headwinds. Mobilizing substantial new resources, primarily from domestic government revenues, is essential to fully implement the recommended interventions to achieve "50 by 50". This is especially true in especially for low- and lower-middle-income countries. Bearing in mind the Commission's recommendations for resource mobilization, policymakers must focus on creating conditions for the successful implementation of financing reforms. This study explores some proven political economy approaches in resource-constrained settings and frames them into health financing strategies that can respond to the resource mobilization recommendations in the Report.

This study employs a mixed-methods approach. The first component is a literature review of political economy analyses (PEA) in health financing reforms and fiscal strategies. Key sources include the WHO PEA guide and analyses on resource advocacy, investment case development, and health taxation frameworks. The second component examines public financial management (PFM) reforms, emphasizing fiscal decentralization. Data sources include World Bank, IMF, and country-level health financing data. Analytic techniques include stakeholder mapping, scenario modeling for health investments, and efficiency analysis to assess value for money. This approach contextualizes global strategies within local governance and fiscal realities.

Emerging findings suggest that coordinated financing strategies across national, subnational, and local governments are critical for achieving sustainable health investments in high-priority health conditions. Early analysis highlights the political complexities of implementing and earmarking new health taxes. It emphasizes the need for a careful implementation strategy to balance fiscal and budget feasibility of resource reallocations and public acceptance, especially in high-cost, non-essential treatments. Contextualized PFM reforms, particularly tailored line-item budgeting, are promising to improve the efficiency of priority drug procurement. Findings also underscore the importance of prioritizing health financing reforms that recognize fluctuations in external financing, complement existing efforts, and avoid "reform fatigue", overlaps, and excessive administrative burdens on health and fiscal authorities.

We conclude that unfavorable health financing trends demand a deeper understanding of constraints before mobilizing additional resources. Identifying effective reforms and generating policy recommendations is challenging, but implementation is just as complex and needs guidance and elements that ensure success. Insights from the literature and best practices highlight the need for context-specific strategies that address political, fiscal, and administrative barriers. Policymakers must prioritize not only what to reform but also how to create conditions for success, ensuring sustainable progress toward the "50 by 50" goal.

abs-os442 Adolescents' Utility Values for the CHU9D tool in Uganda: Application of the Profile Case Best-Worst Scaling and Composite Time-Trade-off Methods

PRESENTER: **Rebecca Prah**
AUTHORS: Stephen Lagony, Ms. Giulia Greco, PhD, Donna Rowen, Helen A. Weiss, Aggrey Tumuhimbise, Fred Matovu, Jonathan Reuben Enomut, Levicatus Mugenyi, Prossy Namirembe

The Child Health Utility 9 Dimension (CHU9D) tool measures the quality of life of children and adolescents aged 7–19 years across 9 dimensions: worried, sad, pain, tired, annoyed, schoolwork/homework, sleep, daily routine, and activity participation with 5 response levels (1=best, 5=worst). It generates utility values for economic evaluations. Currently, values only exist for UK, China Netherlands and Australia. To estimate values for an African country is important as the health preferences of African children and adolescents may differ from other regions, potentially biasing economic evaluation results. The aim of this study was to generate CHU9D values among adolescents in Uganda.

I used profile case best-worse scaling (BWS-Case2) and composite Time Trade-Off (cTTO) methods. A total of 50 health states were selected with fractional factorial design from 1,953,125 states, blocked into five-choice task versions with 10 BWS tasks each. We randomly sampled 440 male and female adolescents from 12 secondary schools which were part of a cluster-randomized controlled trial (MENISCUS). Each participant was randomly assigned to a choice task version where they selected their best and worst attributes for each BWS task.

144 parents were purposively selected to complete the cTTO with 5 health states of varying impairment levels each. For health states 'better than dead', participants chose between living 10 years in the specific state versus fewer years (x) in full health. TTO score was calculated as x/10, with x adjusted until the participant was indifferent between the two choices. For health states 'worse than death' (WTD), a modified TTO approach was used: participant chose between immediate death and a period (x years) in the health state followed by 10 years in full health. TTO score was calculated as – (10 – x)/10.

For both cTTO and BWS exercises, participants completed the CHU9D and responded to questions about their overall health and quality of life.

BWS analysis is ongoing. Conditional Logit Model (CLM) is used to estimate preference weights. If preference heterogeneity is detected, I will fit a Latent Class Model (LCM) and compare both models using BIC and log-likelihood. If the LCM fits better, I will identify subgroups, generate class-specific weights, and compute their mean. With mapping, I will rescale the BWS values onto the TTO values to generate values from 0 (death) to 1 (full health).

BWS was completed by 438 adolescents with a mean age of 17 years (SD: 0.85). 74.2% were female, 91.7% understood the tasks well, and 75.2% found them easy or very easy. The cTTO tasks were completed by 127 parents, 74% were female, and the mean age was 41 years (SD: 7.5). The tasks were well understood with 14.96% finding them difficult to complete. The mean TTO values (generated with the parents) for the 5 CHU9D health states ranged from 0.16 to 0.45 (SD: 0.44). Results will be finalized in March 2025.

The study generates Ugandan-specific CHU9D values, capturing the preferences of African children and adolescents. Using these values will improve economic evaluation estimates, and result in better-informed resource allocation decisions.

abs-os461 Valuing the EQ-5D-Y-5L and EQ-5D-5L a New Zealand Adolescent Feasibility and Acceptability Study

PRESENTER: **Ms. Trudy Sullivan**, University of Otago
AUTHORS: Robin Turner, Paul Hansen, Franz Ombler, Emma Wyeth, Nancy Devlin, Sarah Derrett

Background:

There is increasing interest in understanding the acceptability and feasibility of asking adolescents to value health states, particularly for states 'worse than dead'. Research into methods for eliciting adolescents' preferences has mostly avoided asking adolescents to complete tasks to anchor values at dead=0 which is required for calculating quality-adjusted life years. The objectives of this study were to investigate the feasibility and acceptability to older adolescents of valuing health states including health states worse than dead using the EQ-5D-Y-5L (Y-5L) and EQ-5D-5L (5L), and to compare their preference weights for the Y-5L and 5L to gain an understanding of the transition between corresponding value sets.

Methods:

Two online surveys were created for the Y-5L and 5L, using the Potentially All Pairwise RanKings of all Possible Alternatives (PAPRIKA)

method, a type of adaptive discrete choice experiment (DCE), and a binary search algorithm to identify health states worse than dead. Convenience sampling was used to recruit 24 adolescents aged 16-19 years. Participants individually attended two think-aloud sessions about two weeks apart and completed the Y-5L or 5L respectively. At the end of each survey, participants were shown their ranking of the five EQ-5D dimensions and asked if the ranking was as they expected. The sessions concluded with a semi-structured interview. Paired t-tests were used to compare The rankings of dimensions were compared using paired t-tests and participants' Y-5L and 5L preferences weights were graphically compared using Bland-Altman plots. Participants' feedback was summarized.

Results:

Participants found the introductory video helpful, the survey easy to understand and could capably value health states, including those worse than dead. Though some participants found the DCE questions and binary search questions difficult to answer most participants (83% Y-5L; 79% 5L) said their ranking of dimensions was as they expected. Completing the survey in the presence of two researchers made them take the survey more seriously.

The overall ranking of dimensions was similar between the Y-5L and 5L with Feeling worried, sad or unhappy / Anxiety/Depression 1st, Pain/ Discomfort and Usual Activities 2nd or 3rd, Mobility 4th and Looking after myself/Self-Care, 5th. There was no evidence of a difference ($p>0.57$) in mean differences in preference weights (by dimension) between the Y-5L and 5L. The mean value for dead (i.e. before rescaling the preference weights so dead=0), the lowest health state value and the percentage of health states less than zero were 0.410, −0.796 and 17.8% respectively for the Y-5L and 0.417, −0.884 and 21.2% for the 5L.

Conclusion:

It is feasible and acceptable to elicit health state preferences of older adolescents including for health states worse than dead suggesting that adolescents' preferences can be used when creating value sets. Completing the survey in a supportive environment likely contributes to data quality. The differences in Y-5L and 5L preference weights were small indicating that the corresponding value sets could be similar.

abs-os489 Valuing the ICECAP-CYP:6-11 Capability Wellbeing Measure: a Best Worst Scaling Study in the UK

PRESENTER: **Mr. Paul Mitchell**, University of Bristol
AUTHORS: Samantha Husbands, Tim J. Peters, Sarah Byford, Philip Kinghorn, Paul Anand, Louise Proud, Joanna Coast, Isabella Floredin, Katie Breheny

Background

A new measure of capability wellbeing for children and young people (CYP) aged 6-11 years old has recently been developed. This measure is part of the ICECAP family of capability wellbeing measures, for use in the economic evaluation of health and care interventions. The ICECAP-CYP:6-11 has four levels for each of seven attributes: fun and play; learning and experiencing; attachment, stability and support; physical protection and security; achievement; freedom and having choices; well-becoming/aspiration. For the ICECAP-CYP:6-11 to be used in health and care economic evaluations, it is important that population values are attached to the attribute levels so that decision makers understand the relative importance of attributes and levels to the public.

Aim

To develop a UK population value set for the ICECAP-CYP:6-11.

Methods

An online panel company was used to recruit parents/guardians of 6-11 year olds in the UK. Parents/guardians were chosen to complete the valuation task due to limited evidence of validity on valuation methods in this age group. We undertook a best worst scaling (BWS) case 2 (profile) to generate population values for the ICECAP-CYP:6-11. Parents/guardians of 6-11 year olds completed 16 BWS tasks each, where they were asked to choose the best and worst part of varying attribute levels, thinking about their child as they made their choices. Parents/ guardians completed a proxy ICECAP-CYP:6-11 measure first to familiarise them with the seven ICECAP-CYP:6-11 attributes. Piloting suggested introducing a minimum time period to read the BWS instructions, complete a practice and the 16 BWS tasks. For participants to be included in the final analysis, they needed to complete the 16 BWS tasks in two minutes or more. They were also required to not report any errors that would violate a weak monotonicity rule (i.e. the desirability of an attribute) – this occurred when participants suggested the top level for an attribute was worst when a bottom level on another attribute was available in that task, and vice versa.

Study design included the completion of four blocks of 16 BWS tasks. Initial unadjusted analysis describes the best-worst pairs chosen most often in one of the four BWS blocks. Full analysis of the BWS data and estimation of the population valuation set will be completed and presented at the conference.

Results

Data were collected from 24 July-25 August 2023. From a potential pool of 5,992 parents/guardians, 2,645 completed the survey, with 711 of those completing the BWS tasks over the minimum time without errors. Best-worst pairs show that that *attachment, stability and support*, and *physical protection and security* were chosen as the top two attributes for best and worst, with the former top level being chosen as best most often and the latter bottom level being chosen as the worst most often.

Discussion

Initial evidence suggests that attachment, stability and support (written as “Being able to feel loved and have people who are there for me”) and physical protection and security (written as “Being able to stay safe from harm”) are the two most important capabilities on the ICECAP-CYP:6-11.

abs-os481 Valuing the Subjective Well-Being of Young People in Australia

PRESENTER: **Kaung Mon Winn**
AUTHORS: Mr. Gang Chen, Maame Esi Woode

Background:

The subjective well-being of young people can be effectively achieved by targeted policies and interventions that increase satisfaction in their specific life domains. Understanding the relative importance or weight of key life domains for adolescents enables policymakers to design targeted strategies that effectively enhance their subjective well-being, aligning policies with their unique needs and priorities.

Aim and Objective:

This study aims to elicit the utility weights and relative importance of key life domains for Australian young people from their own perspectives.

Methods:

An online survey was conducted in 2024, targeting Australian young people aged 15 to 19 years. A Discrete Choice Experiment (DCE) technique was employed to assess how young people perceive the importance of twelve key life domains, including physical health, mental health, family, friends, neighbourhood, life at school, choice, future, safety, time use, appearance, and things they have. Each domain was described using 4 levels. The DCE data was analysed taking into account potential preference heterogeneity using both latent class conditional logit and mixed logit models.

Findings:

A total of 799 Australian young people (53% female), with a mean age of 17 years (range: 15–19), completed an online DCE survey. All 12 domains were found to be statistically significant with varying importance. Based on the percentage of utility ranges within each domain relative to the total utility ranges across all domains, it is revealed that family, physical health, and mental health are the top three life domains for enhancing the subjective well-being of Australian adolescents, whilst neighbourhood, things you have and time use are three least important domains.

Conclusion:

The stated preference evidence from this study provides new knowledge on the relative importance of key life domains that matter the most for the subjective well-being of Australian young people.

DISCUSSANT: **Josephine Borghi**, Department of Global Health and Development, London School of Hygiene and Tropical Medicine

abs-os495 Emergency Hospitalizations and Related Economic Burden of Heat Exposure: A Nationwide Time-Series Study in Germany

PRESENTER: **Hedi Katre Kriit**
AUTHORS: Alina Herrmann, Raeleesha Norris, Ms. Manuela De Allegri, Joacim Rocklöv

Background: Climate change increases the frequency and intensity of extreme heat events, which are associated with adverse health impacts. Europe is warming twice the rate of global average and in 2024 record number of days with strong heat stress was recorded. Europe’s population is especially vulnerable to heat events due to the large proportion elderly and people living in of urban areas. Heat effects on mortality has been widely studied, however, little is known about heat impacts on health care systems in terms of increases in emergency hospitalizations (EH) and their related economic costs in continental Europe.

Aim: This study aims to describe the relationship between daily mean temperature and EHs in Germany and to establish the risk among different demographic groups (age, gender) and for different disease diagnostic categories. Secondly, the study aims to estimate both the

number of EHs attributable to heat and the related economic costs from statuary health insurance perspective.

Methods: In this study an anonymized statuary health insurance data of 4.3 million individuals (approximately 5% of the total population) were linked with daily temperature data. We used distributed lag non-linear models with quasi-Poisson regression to estimate the risk of EH in relation to mean temperature during summer months of Maj to September in 2017-2022. Moreover, the number of EH and the costs attributable to heat was estimated.

Findings: We demonstrated an increased risk for EH with increasing temperature across Germany. We observed immediate risks increase among children ((6-17% (95% CI: 1-38%)) and the elderly ((3-11% (95% CI:1-17%)) in relation to extreme heat, and for adults ((2% (95% CI: 1-4%)) in relation to low and moderate heat. For diagnostic categories the highest increased risk for EH was observed for metabolic disease ((43% (95% CI: 30-60%)), followed by skin and subcutaneous tissue diseases ((13% (95% CI: 3-27%)), kidney and urinary tract diseases ((10% (95% CI:1-19%)), respiratory diseases ((7% (95% CI: 1-15%)) and injuries ((5% (95% CI: 1-8%)). We estimate 8.42% of the EH to be attributable to heat, corresponding to €35 millions for the study period.

Discussion: This is first nationwide study examining the relationship of summer ambient temperature and EH in Germany and quantifying the attributable economic burden to heat. If scaling the heat attributable economic burden to the total population, we estimate that 5-6% of the annual health expenditure was attributable to heat for this study period. Suggesting that increasing heat events already cause a substantial health economic burden, which has not been quantified before. This study provides valuable information for strengthening the health care system responsiveness for rapidly increasing number of heat events to guarantee high quality of care, but also essential for designing and evaluating the effectiveness of heat adaptation policies.

Conclusion: Our study demonstrates that heat increases the risk for EH. This calls for adequate preparedness planning in the health care sector, including effective adaptation policies to minimize the adverse health and economic effects of heat.

abs-os459 Extreme Heat and Mental Health: A Cross-Sectional Study Among Healthcare Workers in the Matam Health District, Senegal

PRESENTER: **Makhan Danfakha**
AUTHORS: Adama Faye, Valery Ridde, Jean Marc Goudet, Emmanuel Bonnet, Veronique Filippi

Background

Extreme temperatures (ET), exacerbated by climate change, represent a growing threat to global health. The Matam region, located in northeastern Senegal, is the most affected by ET in the country, experiencing increasing temperatures and frequency of extreme events. According to the Intergovernmental Panel on Climate Change (IPCC, 2021), these events are expected to intensify, significantly impacting population health, particularly mental health. Recent studies have demonstrated that prolonged exposure to heat can exacerbate pre-existing mental health disorders, increase psychiatric consultations, and heighten the risk of suicidal behaviors, including among healthcare workers who are on the frontline (Charlson et al., 2021; Lawrance et al., 2022; Thompson et al., 2023). As part of the EXTRAM Sen research project, we conducted a quantitative survey among healthcare workers in the Matam health district.

Objective

This study aimed to assess the impacts of extreme temperatures on the mental health of healthcare workers in the Matam health district, identify associated risk factors, and document the perceptions and strategies of healthcare professionals in response to these climatic conditions.

Materials and Methods

We conducted a cross-sectional descriptive study from October 20 to 27, 2024, involving a sample of 218 public and private healthcare workers operating in 45 service delivery points within the Matam health district. A digital questionnaire, adapted from the HIGH Horizons survey on the impact of heat on workers' health, was designed using Kobotoolbox. It incorporated internationally validated psychometric tools: WHO-5 (mental well-being), PSS-4 (perceived stress), GAD-7 (generalized anxiety), PHQ-9 (depression), Mini-International Neuropsychiatric Interview (psychiatric disorders), Maslach Burnout Inventory (professional burnout), and PSQI (sleep quality).

Data analysis is ongoing to examine associations between extreme temperatures, observed psychological symptoms, mental health impacts, and coping strategies.

Preliminary Results

Out of the 250 targeted participants, 218 healthcare workers responded, achieving a response rate of 87%. Data were collected from 45 out of the 47 service delivery points in the district. Regarding respondent characteristics, 66.5% were women, and the average age was 35.6 years. The most represented professional categories included community health workers (18.35%), nurses (17.89%), midwives (14.22%), nursing assistants (12.84%), and physicians (6.42%).

Preliminary analyses reveal significant impacts of ET on the mental health of healthcare workers. Two cases of suicidal risk were identified during data collection and received immediate medical care. The collected data will be analyzed considering temperature variations recorded on the days of the survey.

Conclusions

Mental well-being of healthcare workers is essential for a well-functioning health system. Our study will provide insight into the magnitude of the problem, orienting possible solutions to tackle this emerging health system challenge through concerned action at system level.

abs-os444 Health and Economic Assessment of Extreme Temperature and Late Preterm Births in Germany - A Space-Time-Stratified Case-crossover Study

PRESENTER: **Hannah Lintener**
AUTHORS: Raeleesha Norris, Ms. Manuela De Allegri, Falko Sniehotta, Hedi Katre Kriit

Background: With climate change, the intensity and frequency of heat events is increasing. Pregnant women have been shown to be particularly vulnerable to extreme heat exposure. Literature suggests increased risk for PTB due to extreme heat, even in temperate climates.

Study aim: In this study, we aimed to assess the association between extreme heat days and PTB using a nationally representative sample of statutory health insurance (SHI) data in Germany and estimate the heat-attributable economic burden of PTB from the SHI perspective.

Methods: We applied a retrospective, time-space-stratified case-crossover study design using R Studio. PTB hospital cases were extracted from the InGef database, a nationally representative sample of anonymized SHI data and matched with mean daily temperatures on federal state level from the ERA-5 dataset by the European Centre for Medium-Range Weather Forecasts. We calculated relative risks (RR) using distributed lag non-linear models (DLNM) using a quasi-Poisson regression during 2017-2022 from March to September. The economic burden was estimated by multiplying the attributable number (AN) of heat-associated PTB with the additional mean direct hospitalization costs associated with PTB (inflation-adjusted).

Results: The association between temperature and PTB suggests an increasing risk for PTB with increasing temperature, displaying a U-shaped curve. We estimate an increased risk of 1.32 (95% CI 0.84-2.07), 1.19 (95% CI 0.89-1.60) and 1.13 (95% CI 0.92-1.40) for PTB outcomes in relation to the 99^{th}, (26°C), 95^{th} (23°C) and 90^{th} percentile (21°C), respectively. The AN of PTB in relation to temperatures between reference and maximum temperature (15°C-29°C) is estimated to be 144 cases (95% CI 0-347). With an average additional cost of PTB of € 18,915 (19,917 USD) per case, the economic burden of PTB attributable to heat in the sample is estimated to 2,718,895 € (2,862,996 USD).

Conclusion: The findings suggest that heat may potentially be associated with an increased risk of PTB as well as a substantial economic burden of up to 2,718,895 € due to PTB associated with daily mean temperatures between 15°C-29°C. However, the actual societal costs of heat-associated PTB are underestimated as only a subsample of the SHI population and direct hospitalization costs was considered with no inpatient, long-term, indirect or intangible costs accounted for in this analysis. Future studies need to explore effects further; however, findings already suggest a need for heat adaptation measures targeted at pregnant women to reduce the health and economic burden of heat.

abs-os478 The Effect of Extreme Weather Events on The Utilisation of Routine Maternal and Child Health Services in Zambia

PRESENTER: **Chris Mweemba**
AUTHORS: Moses Chisola, Cherie Part, Dell Saulnier, Josephine Borghi, Chitalu Chama Chiliba

Background: Extreme weather events, such as floods and heatwaves, are becoming more frequent due to climate change, and present substantial risks to health systems from shifting demand patterns and service disruptions. These risks are especially high in resource poor settings, with potential to hinder routine health services, such as for maternal and child health (MCH) care, with implications for health outcomes. Although evidence is growing of the effects of floods and heatwaves on MCH, there has been less attention to service utilization effects, yet maintaining healthcare access could reduce adverse health effects.

Aim: This study examines the effect of floods and heatwaves on utilization of four routine maternal and child health services (antenatal care, institutional delivery, postnatal care, and childhood immunization) using secondary data in Zambia.

Methods: We use monthly district-level service utilization data (visit/delivery counts) from Zambia's District Health Information System (DHIS) 2 for 2014-2022, alongside data on district socio-economic status, health sector funding, population density, and health worker and facility density.

Flood exposure is assessed through three district-level measures, taking the highest monthly value: (1) share of land with floodwater, (2) share of human settlements with floodwater, and (3) share of facility catchment areas with floodwater. Floods are mapped by comparing satellite data with water reference maps using NASA's MODIS Near-Real Time Global Flood Product and the Global Surface Water database. Heatwave exposure was assessed using ERA5-Land re-analysis data from the Copernicus Climate Data Store, aggregated to district level. Monthly heatwave exposure was defined by three or more consecutive days above the 90th, 95th, and 99th percentiles of daily maximum temperature, calculated for the three hottest months (1990-2019 reference). Monthly counts of heatwaves and 'hot days' (above the 90th, 95th, and 99th percentiles of daily max temperature) were also considered. Absolute temperature values (continuous) were converted to percentiles by district and month to assess impacts of relative exposure.

To examine the relationship between flood exposure and service utilization, we compare quasi-Poisson regression with distributed lag nonlinear models (DLNM) to capture delayed effects, with fixed-effects panel regression with month and district fixed effects. Heterogeneity in exposure effects is examined by urban/rural districts, socio-economic status (above/below median), and health facility/worker and population density.

Key results: We present the relationship between flood and heatwave exposure and utilization of MCH services across districts in Zambia,

comparing the findings from the different regression models, and identify temperature and flood intensity thresholds above which services are impacted. We also show differential effects across provinces and by subgroups.

Conclusions: It is important to examine the impacts of weather extremes on routine services and drivers of vulnerability to understand the need for and targeting of adaptation measures to ensure continued Universal Health Coverage progress. Our presentation will conclude by reflecting on the opportunities and challenges in using routine data to monitor climate impacts on MCH care.

abs-os656 Development of a Health Technology Assessment (HTA) Registry for Asia

PRESENTER: **Ryan Jonathan Sitanggang**

Background: The volume of Health Technology Assessments (HTAs) in Asia is steadily increasing, providing valuable evidence for healthcare decision-making. However, access to this growing body of research remains fragmented, with limited sharing practices and minimal representation in global repositories. To address this gap, HTAsiaLink is developing a regionally maintained HTA registry to centralise information on planned, ongoing, and completed HTAs across Asia. This initiative aims to enhance collaboration among HTAsiaLink members, reduce research duplication, accelerate policy decisions, and support regional harmonisation efforts, such as standardising clinical reporting in the Association of Southeast Nations (ASEAN). **Objective:** The aim of this study is to review experiences of existing registries and learn from member perspectives about the requirements of the registry to facilitate data sharing among HTAsiaLink members, strengthen evidence-informed decision-making and advance the integration of HTA ecosystems across the region. **Methods:** A review of existing HTA registries to identify best practices and challenges. Repositories such as Tufts Cost-effectiveness Analysis (CEA) Registry, INAHTA, and ClinicalTrials.gov were analysed for features, strengths, and limitations. In parallel, in-depth interviews with HTAsiaLink Board members from Singapore, the Philippines, Indonesia, and Malaysia provided insights on registry design, user engagement, sensitive data considerations, and usability features. A survey distributed to the HTAsiaLink Council members to further refine priorities, ensuring the registry aligns with stakeholder needs. The HTAsiaLink Board was consulted on the design and development of the registry. **Results:** Preliminary results indicate strong stakeholder support for the initiative, emphasising its potential to streamline processes and improve collaboration. Feedback from the global review highlighted the need for clear inclusion standards and intuitive interfaces. Stakeholders prioritised transparency, usability, and regional relevance, all of which are guiding the registry's prototype development. The registry will track HTAs from planning to completion, offer multilingual accessibility, provide user-friendly search functionalities, and ensure robust data security. It will integrate into the HTAsiaLink website for accessibility and serve as a centralised platform to reduce inefficiencies and enhance the dissemination of HTA evidence across Asia. Final consultations with stakeholders will be used to refine the registry’s design and functionality to ensure it meets regional needs effectively. Long-term sustainability is emphasised through a management plan that accommodates potential transitions in HTAsiaLink’s institutional arrangements. **Conclusion:** By centralising HTA efforts, the registry will enhance regional collaboration, improve access to evidence, and support timely and informed policy decisions. It will also contribute to on-going efforts to harmonise HTA in the region. This initiative aligns with HTAsiaLink’s mission to drive innovation and efficiency in HTA activities in Asia.

abs-os636 Navigating the Health Technology Assessment (HTA) Guideline Development: a Special Task Force Between HTAsiaLink, HTAi, and ISPOR

PRESENTER: **Kinanti Khansa Chavarina**

Background: Health technology assessment (HTA) is increasingly being adopted as a multidisciplinary, systematic, and participatory tool for priority setting and to inform decision-making. In many countries, HTA has been used to support health policy decisions regarding health services and technologies for the population and promote efficient resource allocation. Alongside political will, strong governance, data infrastructure, and capacity building, national HTA guidelines have been identified as a key factor in establishing a well-functioning HTA system. More countries are developing their national guidelines, including those that are relatively in a nascent stage of HTA development, such as low- and middle-income countries (LMICs) that have limited resources and context constraints. Although there are several international organisations that offer support in developing HTA guidelines, there are limited resources and literature that could provide an overview to develop HTA guidelines. **Objectives:** This special task force aimed to provide a report of good practices and practical recommendations for developing or updating HTA guidelines to facilitate the guideline development process and ensure successful implementation. **Methods:** The Task Force, established in 2022, brought together experts and academics from diverse regions worldwide, each with extensive experience in developing HTA guidelines for national health policymaking. A mixed-methods approach was used to develop good practices and context-dependent recommendations. This approach included a literature review and key-informant interviews. The synthesised recommendations were validated through stakeholder consultations, open peer reviews, and expert feedback. Additionally, a series of teleconferences among Task Force members were held to iteratively refine the report. **Results:** This report presented a set of resources and context-appropriate practices for developing or updating HTA guidelines. The recommendations outlined six key aspects throughout the guideline development cycle. These

included (i) setting objectives, scope, and principles of the guideline, (ii) building the team for a quality guideline, (iii) defining the stakeholder engagement plan, (iv) developing content and utilising available resources, (v) putting in place appropriate institutional arrangements, and (vi) monitoring and evaluating guideline success. **Conclusion:** Across all contexts, the recommendations emphasised transparency, building trust among stakeholders, and promoting a culture of ongoing learning and improvement. The report advocated for aligning the development and revision of guidelines with the evolving HTA landscape and the pace of HTA institutionalisation. As HTA continues to be used to inform diverse decision-making processes across various country contexts, it will be important to monitor lessons learned to ensure the recommendations remain relevant, practical, and effective.

abs-os642 Strategic Priorities and Goals for HTAsiaLink

PRESENTER: **Lapad Pongcharoenyong**

Background: HTAsiaLink is a regional collaboration in HTA and health systems policy research, recognized for its strong relationships and collaborative approach among its over 50 organisational members from across 20 countries. As the network grows, maintaining focus on HTA development becomes increasingly challenging, particularly given the diverse income levels of its member countries. A strategic plan will guide HTAsiaLink's expansion, address the needs of non-member countries, and build capacity across varying HTA systems. This plan will outline goals, objectives, and strategies for advancing HTA research, capacity building, and policy engagement across the region. **Objective**: The objective of this initiative is to develop a strategic plan for the HTAsiaLink network, aiming to understand the landscape and strategic plans of other networks on HTA and the needs of members in the region for building capacity for and institutionalising HTA. **Methods:** The "Individual, Node, Network and Environment" or INNE framework for capacity building was used as a conceptual framework for the study. A targeted review was conducted on HTA and health system strategic plans for networks. A survey was conducted with members to understand their needs and expectations from the networks with six sections: (1) Organisational Profile, (2) Current Engagement with HTAsiaLink, (3) Role of HTAsiaLink, (4) Organisational Priorities, (5) Network Management, and (6) Additional Inputs. Based on the survey data, Key Informant Interviews (KII) with selected members was conducted. Data was synthesised and summarised thematically. **Results:** The review of strategic plans from nine organisations highlights common themes in health and policy environments, by focusing on HTA as a core objective. Common goals include capacity building, evidence-based decision-making, and long-term objectives like strengthening public health systems. Stakeholder engagement through surveys and expert reviews is central to all plans. Strategic priorities center on capacity building, enhancing organizational value, and long-term impact. Communication strategies, including publications, workshops, and online platforms, align with HTAsiaLink's practices. Regular monitoring and impact assessments are used to track progress. Challenges identified include financial constraints, diverse stakeholder needs, and dynamic policy environments. Based on these results, key areas and indicators were identified for consultation with members. **Conclusion:** The development of HTAsiaLink's strategic plan will be instrumental in guiding the network's growth and addressing the diverse needs of its members across the Asia-Pacific region. By reviewing strategic plans of key organisations along with insights from HTAsiaLink members will help shape the roadmap that aligns with regional HTA capacities and promotes collaboration. Over the next 5-10 years, the strategic plan will help HTAsiaLink advance HTA research, support policy development, and build capacity, while addressing challenges such as financial constraints and stakeholder diversity. This approach will strengthen HTAsiaLink's role in supporting health systems and improving health outcomes across Asia.

Licensed and Unlicensed Workers in Residential and Community-Based Long-Term Care

MODERATOR: **Bianca Frogner**, University of Washington Center for Health Workforce Studies

CONVENER: **Joanne Spetz**, University of California, San Francisco

DISCUSSANT: **Alicia Plemmons**, West Virginia University; **Jack Needleman**, University of California, Los Angeles, Fielding School of Public Health; **Fangli Geng**, Brown University

abs-os163 Services, Regulations, Training, and Staffing in U.S. Residential Care Facilities

PRESENTER: **Joanne Spetz**, University of California San Francisco
AUTHORS: Lela Chu, Timothy Bates

Background and Aims: Residential care communities (RCCs), which are also known as assisted living facilities and residential care facilities for the elderly, provide long-term services and supports in a residential setting. They provide care to both older and younger adults who need assistance due to disability or cognitive impairment. In 2016, it was estimated that more than 800,000 people lived in nearly 29,000 RCCs in the United States, and spending on residential care has been projected to nearly double between 2015 and 2030. The U.S. Bureau of Labor Statistics estimated that facilities that provide care for the elderly, which includes both RCCs and nursing homes, employed 888,500 workers in 2021, and employment will surpass 1.03 million workers by 2031. Home care aides and nursing assistants accounted for more than 380,000 of these jobs. This study will provide detailed information about staffing in RCCs using a nationally-representative survey, exploring relationships between residential care facilities' resident characteristics, services offered, state regulations of RCCs, and staffing.

Methods: The principal data source for this study will be the RCC component of the National Post-Acute and Long-Term Care Study (NPALS). The 2020 dataset had 4,312 respondents, and a weighted response rate of 45%. We are finalizing access to the restricted-use microdata for 2020 and 2022, which are needed to access state identifiers and all variables required for this study. We will use both descriptive statistics and

multivariate regression to examine staffing patterns of residential care facilities in general, and how they vary by facility size, ownership type (chain, for-profit vs non-profit), resident demographics (age, race/ethnicity), and geographic location (Census region, rural vs. urban). We also will examine training required of and offered to unlicensed aides and how this varies by facility and geographic characteristics. Finally, we will assess whether state staffing regulations for RCCs are associated with different staffing patterns, holding other facility and resident characteristics constant.

Key Results: We are finalizing data on regulations of RCCs for all 50 states. Prior research has documented that home care aides and nursing assistants accounted for more than 380,000 of jobs in RCCs. Average staff hours per resident day are higher in RCCs with more than 75% of their residents diagnosed with dementia compared with RCCs with small percentages of residents with dementia. An analysis of 2014 data found that staffing of licensed nurses was higher in RCCs located in states that required a licensed nurse be available or on staff; 38 states had such a requirement at that time.

Conclusions and Implications for Policy and Practice: This study will provide valuable information to regulatory agencies, training programs, and RCCs themselves about staffing patterns and training received in RCCs, including whether there are differences in these characteristics that are associated with the degree to which these communities include people living with Alzheimer's disease and related dementias and with state policies and regulations.

abs-os162 The Prevalence of Multiple Job Holdings Among Regulated and Unregulated Care Workers in Ontario and British Columbia Nursing Homes

PRESENTER: **Ms. Amy T. Hsu**

Background: In Canada, the demand for long-term care (LTC) services is anticipated to increase ten-fold by 2038. The provision of direct care to LTC residents falls primarily on unregulated workers, such as personal support workers (PSWs) or care aides. Despite their essential work, PSWs face limited job security, with many working multiple jobs or more than full-time to earn a living wage. Given the increasingly challenging work environment, understanding multiple job holdings among unregulated LTC workers is necessary.

Approach: This study examines sociodemographic, employment, and self-reported psychosocial and health characteristics of single and multiple job holders among both regulated and unregulated care workers in Canadian LTC homes in Ontario and British Columbia (BC). We used survey data collected as part of a prospective cohort study between March 2021 and November 2022. The study population consisted of regulated and unregulated care workers in Ontario and BC LTC homes, including nurses, PSWs, food service workers, rehabilitation assistants, and recreation assistants. Job holding was defined as the number of jobs held prior to pandemic single-site restriction policies were enacted in each province.

Results: A total 417 regulated and 701 unregulated care workers from 27 Ontario and 12 BC LTC homes were included in our study. Overall, our sample consisted predominantly of PSWs, women, individuals who held a certificate or diploma, and/or worked in urban homes with 100 or more beds. In terms of job holding, 885 workers (79.2%) held a single job, while 233 (20.8%) held two or more jobs. Almost 50% of multiple job holders were of Asian descent and nearly 70% were immigrants to Canada, while approximately 50% of single job holders were white and 55% were immigrants to Canada. We found a higher percentage of multiple job holders (38.9%) reported being quite a bit or extremely stressed at work compared with single job holders (27.6%).

Conclusion: We observed a high prevalence of multiple job holding within the LTC sectors in Ontario and BC. Our findings aim to inform LTC workforce planning and supports required given the aging population and growing workforce. Future research is needed to better understand the drivers and impacts of multiple job holding.

abs-os165 Workplace Absences in the Homecare Sector: Applying Time-to-event Regression Analysis to Model Personal Support Worker Unplanned Absences

PRESENTER: **Katherine A.P. Zagrodney**, University of Toronto

Background: Unplanned healthcare worker absences are a global challenge, affecting those seeking care, fellow employees through added responsibility and coverage, employers, and the healthcare system. Healthcare workers, and particularly personal support workers (PSWs), are more likely to experience absences than other occupations. In many countries, PSWs provide the majority of paid homecare, thus their high unplanned absence rates are particularly impactful to homecare delivery. Existing quantitative literature focuses on sickness absences pre-pandemic, while qualitative studies capture PSW experiences during the pandemic. Applying quantitative models to better understand contemporary factors influencing homecare PSW absences is important for the design of evidence-informed labour supply policies.

Objectives: To examine the frequency of homecare PSWs' unplanned absences and to determine the relative effects of demographic, workplace, and contextual factors on the likelihood of a PSW having an unplanned absence in a given week.

Data: The open cohort design utilized weekly longitudinal administrative data for approximately 2,000 PSWs providing over five million hours of publicly funded homecare services within a homecare organization in Ontario, Canada from January 2019 to June 2024.

Analysis: Descriptive statistics were applied to describe changes in absences trends over time. Cox proportional hazard models (time-to-event regressions) across stratified periods (pre-, early-, mid-, late- and post-pandemic) were used to model unplanned absences for homecare PSWs, controlling for individual baseline heterogeneity. Predictor variables captured the relative effects of demographic, workplace, and contextual factors on the hazard of an individual PSW experiencing an unplanned absence in a given week.

Results: Unplanned absence rates spiked early-pandemic before returning to relatively stable pre-pandemic rates. In Ontario, school closures

were prevalent throughout pandemic periods and were significantly correlated with unplanned absences. While late- and post-pandemic findings are forthcoming, stratified models for pre-, early-, and mid-pandemic periods found that PSWs with higher income, shorter travel distance, and older age, were the least likely to have an unplanned absence across multiple periods. Specifically, higher income significantly reduced the hazard of an unplanned absence by 10.2-16.4% (pre: HR 0.836; 95% CI [0.786, 0.889; early: HR 0.898; 95% CI [0.824, 0.980]; mid: HR 0.879; 95% CI [0.803, 0.961]). PSWs who travelled further distances the previous week had higher odds of an unplanned absences in pre- and mid-pandemic periods (HR 1.166; 95% CI [1.092, 1.246]; HR 1.252; 95% CI [1.139, 1.377], respectively).

Conclusion: Understanding homecare PSW unplanned absences will be increasingly relevant for health workforce planning in the context of limited labour supply and rising needs from an aging population. Based on time-to-event stratified regression models, key predictors of unplanned absences were lower income and further travel distances. Additionally, school closures had a significant effect on absences for this highly gendered workforce which highlights the impact of disruptions in the broader care economy on this vital component of the healthcare workforce. As the need for homecare PSW services continues to expand, it will be increasingly important to design data-informed policies that can improve workforce stability and continuity of care.

Payments, Pricing and Price Transparency

MODERATOR: **Bruno Ventelou**, CNRS - Aix Marseille University

Ind-408 Alternative Pricing Policies for Multi-Indication Products: A Quantitative Analysis

PRESENTER: **Carlos Rojas Roque**

ABSTRACT

Background. Various pricing models have been proposed for multi-indication drugs, including uniform pricing across all indications and indication-based pricing (IBP). While existing studies have examined the effects of these pricing models on access, quality-adjusted life years (QALYs), and healthcare costs, few have assessed their overall impact on population health. Moreover, most studies overlook elements such as launch timing, post-patent value, and the influence on innovation. A thorough evaluation of IBP is increasingly relevant, as several countries are adopting IBP policies, and spending on multi-indication drugs is rising, especially with new products like immunotherapies demonstrating efficacy across diverse cancer types.

Objectives. To assess the population health impact of three pharmaceutical pricing policies for multi-indication drugs: uniform pricing, IBP, and a hybrid model called commercial flexibility.

Methods. We develop a quantitative framework to compare how these pricing policies affect drug access, health benefits, innovation, and pharmaceutical costs over a product's lifecycle. The outcome of the analysis is the net health effects, encompassing both the health benefits derived from the utilisation of a new drug and the health opportunity costs linked to the extra expenses required for its funding. To reflect current policies in the UK, uniform pricing and IBP are implemented with an approval norm (γ) of £30,000/QALY for all indications, and £20,000/QALY for indications requiring commercial flexibility. The framework is illustrated with numeric examples and two case studies (nivolumab and pembrolizumab) relevant to the UK, yet the framework and qualitative findings have broad application across health care systems.

Results. Implementing IBP reduces overall population health by 521-5,719 QALYs (range across product value profiles, with and without innovation effects) compared to uniform pricing. Commercial flexibility results in lower population health than uniform pricing (0-229 fewer QALYs) when innovation effects are not considered, but somewhat higher outcomes (0-1,795 more QALYs) when innovation effects are included. For IBP to improve health outcomes in the UK, where pricing decisions are not expected to substantively influence pharmaceutical R&D decisions, it would require a γ of £20,000/QALY or below. For commercial flexibility to be beneficial, it would require a γ of £15,000/QALY or below for indications where commercial flexibility applies. Introducing nivolumab under IBP is projected to result in a population health loss of 69,747 QALYs, higher than the 17,333 QALYs lost under uniform pricing. Pembrolizumab's introduction under IBP is expected to a loss of 102,467 QALYs, compared to 19,603 QALYs lost under uniform pricing. Thus, introducing IBP at current γ would approximately double expenditure for those products without improving access to medicines. An approach that seeks to maximise long-term population health, balancing innovation incentives with the opportunity costs of higher pharmaceutical expenditure for these products, would involve IBP with a γ of approximately £10,000/QALY.

Conclusions. IBP and commercial flexibility can improve access to new drugs but must be carefully designed to avoid cost increases that could harm overall population health. Lower cost-effectiveness thresholds are required for these policies to contribute positively to population health.

Ind-1935 How Does the Spanish National Health System Set Price of Non-Industrial Advanced Therapy Medicinal Products?

PRESENTER: **Zuzana Spacirova**
AUTHORS: Juan Carlos Rejón-Parrilla, Jaime Espín

Background: Chimeric antigen receptor (CAR) T cell therapies (CAR-T therapies) are a type of advanced therapy medicinal products (ATMPs) that belong to the family of personalized cancer immunotherapies. They are indicated for patients with relapsed or refractory haematological malignancies (i.e. B-cell acute lymphoblastic leukaemia, diffuse large B-cell lymphoma, Mantle cell lymphoma and multiple myeloma). Long-term follow-up data indicate prolonged remission rates and improved survival. They can be produced by pharmaceutical companies, but the majority of ATMPs originates from research performed in specialized academic facilities, through public support or the support of non-for-profit funds; the development and manufacture is at small scale, not for commercial purposes and at a national level only. This last route for development has been enabled by the so-called 'hospital exemption' (HE), which is a clause that was added to the European ATMP regulation EC1394/2007 (Article 28), to allow manufacturing of ATMPs outside the standard centralized marketing authorization. In Spain, there are five ATMPs produced under HE up to now, but only one of them (CAR-T ARI-0001 developed by *Hospital Clìnic* in Barcelona) is financed by the Spanish National Health System (NHS). However, it is unclear what resources (cost elements) required for its manufacturing were considered when setting price; this price (89,270€) is one third of price of commercial CAR-Ts financed by the Spanish NHS (i.e., 320,000-360,000€).

The objective is to describe the landscape around the pricing and reimbursement of ATMPs that are developed by academic and non-profit developers, to understand the pricing dynamics that apply to this family of products.

Methodology: First, we did targeted reviews of selected literature based on our knowledge of the field and targeted ad-hoc searches of relevant sources to inform this work, including peer-reviewed literature and grey literature (including reports and articles by specialist or mainstream news-outlets). Second, we designed a semi-structured questionnaire that has been sent to the manufacturers of non-industrial ATMPs in Spain.

Results: The Spanish Ministry of Health has elaborated a guideline on what cost elements required for manufacturing of academic ATMPs should be considered in price setting. The answers to the questionnaire will reveal if this guideline had to be completed by the ARI-0001 manufacturer in price & reimbursement process. In the Netherlands, the researchers have developed a guideline to calculate price of ATMPs from the manufacturer point of view. Both guidelines exclude the cost of amortization of the building and the cost of the alternative use of land, building and other assets the belong to the hospital. Additionally, the Dutch guideline excludes the cost of failure.

Conclusions and implications: We have identified differences in guidelines to be used in price setting of academic ATMPs across the European countries. Greater methodological harmonization across Europe is needed. Additionally, if academic ATMPs are allowed to compete with commercial ATMPs with prices calculated as they are now, this could result in unfair competition.

Ind-1381 Intermediaries Under the Spotlight: Transparency of Pharmacy Benefit Managers and Drug Spending

PRESENTER: **Nicola Maria Fiore**
AUTHORS: Ms. Oriana Ciani, Joseph Ross, Simone Ghislandi

Background: In the US, prescription drug prices are negotiated between pharmaceutical companies, pharmacy benefit managers (PBMs), and plan sponsors, resulting in complex and often opaque pricing structures. PBMs negotiate drug prices with manufacturers on behalf of plan sponsors, and may profit by charging plan sponsors more than they reimburse pharmacies (a practice known as "spread pricing"). Since 2018, amid heightened scrutiny over rising prescription drug costs, several states have implemented laws banning PBM spread pricing in an attempt to reduce drug costs for patients. We study how banning specific contracting practices in the drug supply chain can reduce drug costs for consumers, specifically examining premiums, deductibles, list prices, and cost-sharing paid by beneficiaries.

Objectives: Regulators argue that banning spread pricing will better align what plan sponsors pay with what pharmacies receive, reducing hidden PBM profits and ultimately lowering patient costs. We investigate whether these bans effectively reduce total and out-of-pocket costs for consumers.

Methods: We use the staggered adoption of state-level PBM spread pricing bans to study their impact on Medicare Part D drug plans. Comprehensive plan–drug–county data are obtained from the "Quarterly Prescription Drug Plan Formulary, Pharmacy Network, and Pricing Information" dataset, covering 2016 to 2024. The unit of observation is at the plan–county–drug–year level. For each plan, we collect data on premiums, deductibles, drug prices, and cost-sharing for DPP-4 inhibitor drugs (ATC A10BH). We compute total and out-of-pocket costs and analyze whether spread pricing bans decrease drug spending for beneficiaries. Our staggered difference-in-differences design accounts for potential heterogeneity across plan types and affiliations.

Results: Spread pricing bans lead to significant reductions in the total cost of DPP-4 drugs, primarily through lower patient cost-sharing, rather than changes in premiums or list prices. The effects are strongest for branded drugs and for plans unaffiliated with PBMs, where PBM profit margins were likely highest before the bans.

Discussion: Our results suggest that targeted contracting regulation in the drug supply chain can lower prescription drug costs, especially for patients using high-margin branded drugs and in plans without PBM affiliations. We contribute to policy discussions on pharmaceutical pricing by providing new evidence on the effectiveness of state-level spread pricing bans and highlight the importance of considering contracting structures in regulatory design.

Ind-1724 Price Transparency in Hong Kong s Private Healthcare Services: Usage and Usability of Price Information Among Private Healthcare Facilities Users

PRESENTER: **Ho Man Shum**, Centre for Health Systems & Policy Research, Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong
AUTHORS: Chi Tim Hung, April Yushan WU, Chiu Ha Kong, Wai Ling Cheung, Ho Kwan Yam, Eng-kiong Yeoh, Eliza Lai Yi Wong

Background: Price transparency initiatives for healthcare services have been implemented in health systems with large private sectors to reduce costs by encouraging consumers to select cheaper providers. A prevalent strategy involves publicizing prices for "shoppable" healthcare services, which, however, have shown limited effectiveness. Low utilization of price information by patients and poor usability are often cited as reasons, but evaluation of price information usability from a consumers' perceptions is lacking. Since 2021, private hospitals and day procedure centers in Hong Kong have been required to publicize prices for major chargeable items. Evaluation of these initiatives is needed. **Objectives**: This study aims to evaluate the usage and usability of published price information, including fee schedules and bundled pricing, from patients' perspective. It also seeks to identify factors associated with the usability of price information and to explore patients' barriers in utilizing price information. **Methods**: This is a cross-sectional survey followed by in-depth interviews conducted in Hong Kong from October 2023 to April 2024, targeting local residents aged 18 or older who had undergone at least one common non-emergency procedure in private healthcare facilities. The survey included questions about the usage of published price information, reasons for not using, experience and perceived usability of price information. We assessed perceived usability through an average score derived from 14 statements based on the validated System Usability Scale. Descriptive statistics were summarized, and multivariate linear regression was applied to identify factors associated with perceived usability. Semi-structured qualitative interviews were conducted by inviting survey participants as a supplementary approach to better understand patients' experience when utilizing price information. **Results**: From the 500 respondents in the survey, there were 215 (43.0%) who referred to price information for their most recent non-emergency operation/procedure. Among non-users, 180 (63.2%) had no intention to seek price information, primarily due to trust for their doctors (67.2%) and having adequate affordability or insurance coverage (54.4%). Among users, the overall perceived usability of price information was satisfactory, with mean score of 3.90 out of 5. Statements with highest and lowest ratings were future use of price information (Mean= 4.27, SD= 0.66) and easiness to compare price (Mean= 3.59, SD= 0.94) respectively. Multivariate analysis indicated that respondents who utilized bundled pricing information was the only factor significantly associated with higher perceived usability. In the qualitative part, 30 interviews were conducted and three major barriers of using price information were identified: insufficient comprehensiveness; low understandability; and difficulties in estimating total price. **Conclusions**: This study is the first to assess users' perceived usability of published price information. While the utilization rate was not high, they significantly exceeded those reported in US studies, likely due to lower insurance coverage in local context. Overall, the usability of price information was considered satisfactory, but with significant room for improvement. Bundled pricing information could be a preferrable solution. Further study is warranted on the effectiveness of price information locally.

Ind-1080 Health Insurance Payment for Telehealth Services: Scoping Review and Narrative Synthesis

PRESENTER: **Qingqing Li**
AUTHOR: Junfang Xu

Background: As the telehealth services have demonstrated significant advantages in the providing of qualified and accessible care, health insurance payment for telehealth services have been issued by various countries. However, the optimization of health insurance payments for telehealth services remains uncertain. Therefore, we conducted a systematic review of the current situation regarding health insurance payments for telehealth services, with the aim of providing evidence to enhance policies related to health insurance payments for such services. **Methods:** This systematic review was conducted by comprehensively retrieving date from six electronic bibliographic databases from inception until October 2023. The databases included China National Knowledge Infrastructure (CNKI), Wan Fang, Weipu Database (VIP), Web of Science, PubMed, and Embase, following the PRISMA guidelines. Two authors independently assessed search results, extracted data, and evaluated the quality of the included studies. After the initial screening of titles and abstracts, full texts were obtained and examined. The following data were extracted and analyzed: first author, date of publication, country, type of telehealth services introduced in health insurance, health insurance reimbursement providers, reimbursement standards for telehealth (e.g., the condition for the reimbursement and reimbursement rate), and key findings of studies. Moreover, we also conducted a narrative synthesis to summarize and report the findings. **Results:** A total of 7232 articles were retrieved. Following quality assessment, 23 articles were finally included, with the covered countries including China, the United States, Australia, France, Japan, UK, and Germany. The forms of the services vary across different regions, mainly including online consultation services, online medical monitoring services, online mental health services, online health education services, online surgical guidance services and other services. Payment standards are generally categorized into fee-for-service and global budget payment, with clear health insurance payment quotas or proportions and certain restrictions (e.g., specifying the location of medical visits, setting the limitation on distance from home to hospitals or setting a prerequisite for reimbursement is the referral of primary doctors). The paying entities for health insurance payment include national health insurance and commercial health insurance. In addition, there are two kinds of reimbursement rates: a comparable rate for both telehealth and in-person healthcare services, and a lower rate for telehealth services compared to in-person healthcare services. **Conclusions:** To enhance the accessibility of telehealth services through health insurance payment, it is crucial to further refine the design of health insurance payment for telehealth and strengthen the supervision of services quality, bridging the gap between telehealth and in-person healthcare services.

Bali International Convention Centre – Magnolia

Analysis of Health Expenditure

MODERATOR: **Pratik Khanal**,

Ind-2091 Ship in a Storm? Public Debt, Health and Other Social Spending in Developing Countries.

PRESENTER: **Charles Birungi**
AUTHORS: Jaime Atienza Azcona, Lazarus Muchabaiwa, Benard Musekese Wabukala, Ramathan Ggoobi, Michael A. Obst, Melissa Sobers

Background

Social spending is in a crisis. In developing countries, there are troubling trends. This is in part due to a growing public debt deluge. Governments in developing countries are increasingly turning to public debt to navigate the persistent financing challenges. Scholarly debate on the linkage between public debt and social spending such as on health is inconclusive. This paper tests the displacement effect of debt servicing on government spending away from education, health, and HIV spending.

Data and methods

The study uses publicly-accessible panel data for 26 Low-Income Countries (LICs) and 51 Lower Middle-Income Countries (LMICs) for the period 2010 – 2022. Based the "displacement effect" hypothesis, the analysis employs the Driscoll-Kraay (DK) standard errors approach to panel data estimation to test whether debt servicing obligations constrain government budgets and shift spending away from social sectors.

Results

The impact of public debt on social spending varies depending on the country's income level. A 1% increase in total debt is associated with 1.3% increase in education spending, while debt servicing shows no significant impact in LICs. In contrast, both total debt and debt servicing negatively affect education expenditure in LMICs. Specifically, a 1% increase in debt servicing is associated with a 0.04% decrease in education spending in LMICs. Additionally, results show that debt servicing has a negative effect on current government expenditure on health in LICs. A 1% increase in debt servicing results in approximately 0.7% reduction in current expenditure on health by the governments in LICs. However, the effect on total debt stock on health spending is insignificant. For the LMICs, total debt stock and debt service are associated with 1.2% and 0.3% increase in health expenditure respectively. Finally, on HIV spending, results show a positive relationship between public debt and spending on HIV for both LICs and LMICs. A 1% increase in debt service is associated with 0.6% and 0.2% increase in HIV expenditure for LICs and LMICs respectively.

Conclusions

Whereas public debt can be a benefit and not a burden, overall, debt servicing displaces much-needed investments in education and health in developing countries. However, this study highlights the complex and varied relationship between public debt and social spending across different economic contexts. Regarding global social spending policies, the findings suggest a need to recognise public debt servicing is a critical barrier to social spending and the modalities of debt servicing should thus be re-oriented to minimize the negative impacts of debt on social sector outcomes. By extension, treating the debt deluge has potential to expand fiscal space for social sectors and move the world towards achieving the social sector-related Global Goals by 2030. Increase in HIV spending associated with increased debt servicing could, in part, be due to strong advocacy for increased domestic resource mobilization given the current heavy donor dependence for financing national HIV responses. Building on and strengthening systems that are working for the HIV response, there is need to strengthen advocacy for increased social spending as well as rethinking and restructuring current and future debt.

Ind-1560 South Korea's Healthcare Expenditure Across Health Conditions, Demographics, and Payer Types (2011-2020)

PRESENTER: **Katelyn J Yoo**
AUTHORS: David Bishai, Bryan Patenaude, Yoonkyung Lee, Tae-jin Lee, Sooyeol Park, Junghoe Kim, Yerin Cha

Background South Korea has witnessed a rapid increase in health expenditure, reaching USD 135 billion in 2021 and accounting for 9.3% of its GDP, surpassing the OECD average. Despite achieving universal health coverage, significant gaps remain in service coverage, leading to high out-of-pocket (OOP) expenses that expose households to financial burdens.

Methods This study examines healthcare spending in South Korea from 2011 to 2020 using national datasets, focusing on expenditures across two primary payer categories: public insurance and OOP payments. Data were stratified by health condition, age group, sex, type of care, and income level. A combination of the National Health Insurance (NHI) dataset and the Korea Health Panel Survey (KHPS) was used to estimate total health expenditures, with multiple imputation methods applied to address data gaps.

Findings Healthcare expenditure in South Korea rose significantly from $45.6 billion in 2011 to $76.9 billion in 2020, placing an increasing economic burden on the system. Public health insurance spending grew at an annual rate of 5.1%, while OOP expenses rose by 5.0% for covered services and 6.7% for uncovered services. Despite a shift toward greater public funding—with public expenditure comprising 64.4% of total spending in 2020—OOP payments still accounted for 35.6%, remaining above the OECD average. Individuals aged 60 and above contributed to 51.3% of total expenditures. Gender disparities emerged, especially in high-cost areas like obstetrics and gynecology, where

women incurred higher OOP costs. Additionally, uncovered services experienced significant spending growth across all income levels, with major cost contributors including musculoskeletal disorders, urinary tract disorders, and chronic diseases such as hypertension and diabetes.

Interpretation This study highlights the need for targeted healthcare policies in South Korea to address rising costs and persistent inequalities. High OOP expenses disproportionately impact vulnerable groups, especially women and the elderly, while uncovered medical costs are growing across income levels, straining households. Conditions like musculoskeletal disorders, hypertension, and diabetes, along with gender-specific costs such as obstetric care, emphasize access inequities. Uncovered OOP expenses are rising faster than covered services, particularly among older adults. Addressing these issues requires policies to ease financial burdens and ensure equitable healthcare access.

Ind-707 Sources of Regional Variation in Healthcare Expenditure in Japan: Evidence from Movers

PRESENTER: **Sayaka Nakamura**
AUTHORS: Haruko Noguchi, Shiko Maruyama

Significant regional variation in healthcare utilization is observed across many countries, and understanding its drivers has important policy implications. A seminal study by Finkelstein, Gentzkow, and Williams (2016) (henceforth FGW) exploit patient migration to decompose regional variation in healthcare utilization into differences in patients' characteristics and differences in place effects. The former represents the demand-side component, and the latter reflects the supply-side component, such as the market structure and providers' characteristics, as well as geographic factors. They conclude that the major source of regional variation in the U.S. is differences in place effects rather than patient effects. Conversely, several studies applying FGW's methodology to data from European countries find that regional variation in healthcare utilization is primarily driven by differences in patients, which might be attributable to universal health insurance and stronger government-controls over prices in Europe. However, previous findings are mixed even among European countries, which might suggest the role of other aspects of the health care system.

This study investigates the sources of regional variation in healthcare expenditure in Japan using administrative insurance claims data from 2015 to 2022, obtained from a large insurer that provides mandatory health insurance to employees of small and medium-sized enterprises and their families, covering about one-third of the Japanese population. Japanese data offers valuable insights into how the share of place-specific factors varies in the context of differing institutional frameworks across countries and differing market structures across service areas. Japan shares a universal health insurance system and government-controlled prices for healthcare services with previously studied European countries, but direct government control over health care providers appears weaker in Japan, with little standardization of care, lack of monitoring, absence of strong incentive schemes for cost containment, and geographic maldistribution of physicians. We compare across different service categories; medical care, dental care, and prescription drugs to study how the results vary with market characteristics of the service category, exploiting scarcity of physicians in non-urban areas and overall abundance of dentists.

Following FGW, we exploit migration to decompose regional variation in Japanese healthcare expenditure into patient factors and place-specific factors. We build on FGW's methodology by using the raw healthcare expenditure as the outcome variable, rather than conventional log-transformed expenditure with an added constant, using demography-adjusted means, and studying migration across Secondary Medical Areas and across prefectures (Tertiary Medical Areas).

Our analysis finds that regional variation in total healthcare expenditure is primarily driven by demand-side factors. When we analyze expenditure by service category, we observe the same pattern for medical expenditures. However, for dental and prescription expenditures, about a half of prefectural variation is explained by place effects, which might suggest excessive care provision due to surplus of dentists and prefectural variation in prescription and supply of generic drugs. Additionally, correlation between place effects and patient effects is positive for dental expenditure, consistent with sorting of physicians and patients and with previous findings, but negative for total expenditure, medical expenditure, and prescription drug expenditure.

Ind-1405 Variation in Healthcare Expenditure across Health Institutions: The Role of Physician

PRESENTER: **Shiko Maruyama**, University of Technology Sydney
AUTHORS: Jiahui Guo, Hang Zou

Background: Geographic variation in healthcare expenditures and its drivers are well-documented. To understand the source of regional variations in healthcare, researchers have explored the drivers of geographic variation by applying the mover design. However, few studies have investigated another large variation and its drivers: expenditure variation across health institutions. Even fewer studies have explored the drivers of such variation in developing countries. Our study fills this gap by applying the mover design to isolate the role of physicians in driving expenditure variation across health institutions. Physicians, who make critical decisions in testing, prescription drugs, and overall treatment plans, exhibit substantial variation in practice styles and beliefs about effective treatments. Additionally, physicians may respond strategically to financial incentives. Quantifying the contribution of physician factors provides important policy implications for policymakers who hope to curb the increase in healthcare costs by reducing medically unjustified variations. **Objectives:** Using administrative data of outpatient and inpatient services from 2007-2017 in Sichuan Province, China, we first examine variation across Chinese health institutions. We then investigate the role of physicians in explaining the variation in expenditure across health institutions. **Methods:** To separately identify the relative contribution of the physician factor from other determinants of expenditure (eg. patient factor), we employ the mover design, which allows us to separate the contribution of physician factors from the overall variation by exploiting physicians' move across healthcare institutions. Specifically, we use two empirical approaches: a fixed-effects model to decompose expenditures and calculate component shares, and an event-study analysis to visualize the dynamics of physician contributions in the years surrounding a move. Additionally, we use LASSO and k-means methods to select variables and categorize institutions into groups, exploring physician contributions within these categories. **Results:** First, we document a large variation across Chinese health institutions with a growing variation in inpatient expenditures, particularly after 2010, whereas outpatient expenditure variations remain relatively stable over the years. Second, our event study analysis reveals that expenditure in physicians' changes rapidly when and after physician move to other institutions, with little pre-trend before physicians move.

Moreover, by decomposing the expenditure, our fixed effect model infers that the physician factor accounts for 5 percent and 20 percent of the difference in expenditure between above- and below-median health institutions for outpatient and inpatient, respectively. Finally, when categorizing institutions into different groups and analyzing the movers within the groups, we observe a larger physician role in explaining expenditure differences, particularly in smaller institutions. **Conclusion and Implications:** We find that physician factors explain only 5 percent of the variation in outpatient expenditure but 20 percent in inpatient expenditure. These findings suggest that policies regulating physicians' behavior have limited effectiveness in alleviating the burden of healthcare costs in China overall, especially for outpatient services. Furthermore, greater focus should be placed on regulating smaller institutions. **Keywords:** Expenditure variation, Health institution, Physician, Mover design, China

Cost-Sharing, Insurance Design, and Patient Behavior

MODERATOR: **Karen Eggleston**,

Ind-120 Patient Responses to Declines in Cost-Sharing: Telehealth and High-Deductible Health Plans

PRESENTER: **Risha Gidwani**
AUTHORS: Steven Asch, Lane Burgette, Aaron Kofner, Veronica Yank, Zachary Wagner

A majority of privately-insured Americans are enrolled in high-deductible health plans (HDHPs), which are characterized by 100% cost sharing for most services until a high deductible is met. A host of evidence indicates that as patient cost-sharing increases, patients reduce their use of both high-value and low-value health care. This may be especially problematic for the 60% of Americans that are chronically ill and require regular access to medical care to manage their diseases. Using quasi-experimental techniques, we study what happens to care utilization when patient cost-sharing *decreases* and whether patients are responsive to selective declines in cost-sharing, in a national cohort of 1.4 million chronically-ill adults. Using difference-in-differences and event study models, we evaluate the effect of a 2020 policy change to $0 cost sharing for telehealth services, and how utilization changed differently for HDHP enrollees compared to nonHDHP enrollees. Due to this policy shock, HDHP enrollees experienced substantial declines in cost-sharing for telehealth, while nonHDHP enrollees experienced small declines in cost-sharing. Entropy balancing weights were used to address confounding from time-varying factors that might have changed differently between HDHDP and nonHDHP groups. Our outcomes included the following: 1) use of any outpatient care; 2) use of $0 telehealth; and 3) use of $0 telehealth as a proportion of outpatient care. To test whether any differences were due to preferences for care modality versus cost-sharing, we further evaluated: 4) use of non-$0 telehealth. Difference-in-differences results indicate no difference in change in overall outpatient visits between groups ($p = 0.84$). However, HDHP enrollees increased their use of $0 telehealth by 0.08 visits more over an 8-month period than did nonHDHP enrollees ($p < 0.001$) and shifted more of their care to $0 telehealth ($b= 0.01$, $p < 0.001$) following the policy change. HDHP enrollees also had lower uptake of non-$0 telehealth compared to nonHDHP enrollees (($b= -0.01$, $p = 0.04$). Event study models allowing for monthly changes in behavior across different disease states revealed similar results. Results show that HDHP enrollees with chronic conditions responded to a sudden decrease in (selective) cost-sharing for telehealth by increasing their use of such services more so than enrollees in non-HDHPs. That HDHP enrollees had lower use of telehealth services that retained cost-sharing provides support for the argument that the causal mechanism for their relative increase in $0 telehealth utilization was due to the larger decline in cost-sharing rather than a stronger preference for the telehealth modality. This is the first study to rely on a policy shock – the shift to $0 telehealth – to evaluate the effects of HDHPs on consumer behavior. Our results indicate that patients respond in economically rational – and selective – ways to changes in cost-sharing. Our findings have implications for the Consolidated Appropriations Act of 2023, which allows HDHPs to offer first-dollar coverage for telehealth for 2023 and 2024, and indicate that extending such legislation beyond 2024 can help ensure receipt of outpatient care for chronically-ill patients.

Ind-1553 The Effect of Cost-Sharing on Medical Care Demand: Insights from Novel Real-World Data for the Oldest-Old in Japan

PRESENTER: **Rong Fu**
AUTHORS: Haruko Noguchi, Akira Kawamura, Masato Oikawa

Objective: This study evaluates the impact of Japan's Ministry of Health, Labour and Welfare increasing cost sharing for medical care services from 10% to 20% for those aged 75 and older with a specified income in October 2022. This primary focus is on assessing effects on medical care utilization and out-of-pocket expenses among the oldest-old adults.

Methods: Using a regression discontinuity design with an event study (RDD-event study), this study focuses on single-person households near a 2 million JPY income cutoff. The treatment group, just above the cutoff, experiences a cost-sharing increase, while the control group, below the cutoff, maintains a 10% cost sharing. Income, with a 0.5 million JPY bandwidth, serves as the running variable. Data from the National Database of Health Insurance Claims linked to taxable income records (n=19,264,480 as of January 2023) provide a monthly longitudinal dataset from November 2021 to March 2023.

Results: The RDD-event study includes around 1.37 million individuals, averaging 82 years old with an annual income of 4 million JPY. One month before the cost-sharing increase, total medical care expenditure rises by 4%, decreases by 6% in October 2022, remaining negative and statistically significant from November 2022 onwards (3-4% range). Similar trends are observed in medical care utilization, with a smaller and insignificant impact on utilization rate three months after the cost-sharing increased. Notably, 16 diseases exhibit negative and statistically

significant impacts post-increase, ranging from approximately -17% for dental caries and -3.6% for diabetes. Six months later, impacts decrease by 20% for 10 diseases (e.g., hypertensive, asthma), stay consistent for 2 diseases (cataract and Musculoskeletal disorders), and become statistically insignificant for 4 diseases (e.g., diabetes, Alzheimer's).

Discussion: Findings suggest a "last-minute surge in demand" before the cost-sharing increase, causing to an initial spike in medical care expenditures. Post-increase, individuals markedly reduce costs, linked to prior medical care service utilization. Oldest-old individuals tend to reduce service quantity (intensive margin) rather than abstain completely (extensive margin). On average, simulated out-of-pocket expenses surge by 95%, with around 85% experiencing nearly twofold increases during the observational periods. The study indicates sustained access to medical care services, even with increased cost-sharing for elderly incomes above a specific threshold. But, elasticity varies significantly by disease, emphasizing the need for comprehensive considerations beyond income, including the health status of the oldest-old adults when contemplating adjustments.

Ind-2633 The Impact of Pharmaceutical Copayment Reduction on Healthcare Use and Out-of-Pocket Costs in Australia

PRESENTER: **Thomas Plunkett**

Background: Within Australia, medications have been subsidised under the Pharmaceutical Benefits Scheme (PBS) for over 75 years, with the copayment amount increasing each year in line with inflation. Amidst cost of living pressures, in January 2023 the Australian government reduced the prescription medication patient copayment from $42.50 to $30 (approximately a 30% decrease) for general patients, but not for concessional patients (welfare recipients, low-income patients, and pensioners). Exploiting the framework of a natural experiment, we analyse the impact of this policy on out-of-pocket expenditure (OOPE) and healthcare use.

Methods: We analyse the impact on a 10% random sample of adults (18 years and older) from a whole-of-population pharmaceutical (PBS), out-of-hospital healthcare use, and Census-linked administrative dataset for all Australians, for the years 2021 to 2024. Using a matched sample of concessional patients (who did not experience a copayment change) as a control group, we implement a difference-in-differences approach to investigate the average OOPE savings experienced by patients, as well as the impact on out-of-hospital healthcare usage, such as general practitioner and specialist visits.

Results: Preliminary analyses suggest a modest OOPE saving experienced by the average Australian general patient, with minimal impacts on additional healthcare usage. Additional analyses suggest that the policy impacts were small as the majority of medications are already priced below the general copayment levels.

Conclusion: Given the current state of increased cost-of-living pressures worldwide, Government policies offering relief to a crucial expenditure such as medications is seemingly a welcome initiative. However, our results suggest that this policy is insufficient to address OOPE towards prescription medicines. Given the majority of prescription medicines are already below the general copayment, future iterations of the policy should consider further reductions to the copayment and employ better targeting to benefit patients. Moreover, as this Australian policy affects all general patients (i.e., those from higher socioeconomic classes as well), this renews the discussion around inequalities in OOPE within Australia and whether more targeted policies for those most in need should be implemented instead.

Ind-119 High-Deductible Health Plans and Receipt of Guideline-Concordant Care for Chronically-Ill Persons

PRESENTER: **Risha Gidwani**

AUTHORS: Alex Peltz, Steven Asch, Lane Burgette, Zachary Wagner, Aaron Kofner, Veronica Yank

Importance: High-deductible health plans (HDHPs) are a highly-common insurance mechanism in the United States, enrolling 57% of privately-insured persons. We evaluate whether HDHPs meet the medical needs of chronically-ill people, who require regular access to health care. More than 50% of Americans have one or more chronic illness. **Data and Cohort:** We study a longitudinal cohort of chronically-ill adults aged 18-64 in the 2016-2018 MarketScan data. MarketScan contains administrative and claims data from approximately 350 payers nationwide. Cohort members had asthma, diabetes, hypertension, coronary artery disease, heart failure, or major depressive disorder. **Outcome Measures:** Use of annual recommended medical care, which was abstracted from disease-specific evidence-based clinical practice guidelines and consisted of: 1) clinic visits; 2) lab tests; 3) prescription drugs; and 4) a composite measure evaluating all three. Results were pooled across disease type to improve the policy relevance of findings; disease-specific analyses were also conducted. **Methods:** Our identification strategy leveraged multiple quasi-experimental approaches: difference-in-differences models combined with instrumental variables and entropy balancing weights. The treatment group consisted of persons forced to enroll in a HDHP; the control group consisted of persons in nonHDHPs. Forced new enrollment in a HDHP was instrumented by employment in a full-replacement firm (an employer that only offered HDHPs). Entropy balancing was used to address any residual confounding. We also conducted triple-difference models to assess any sex-based disparities, using the same identification strategy. **Results:** We followed 537,092 adults over 3 years. Groups exhibited covariate balance after entropy balancing. In this multiply-morbid cohort, forced enrollment into a HDHP reduced use of recommended medical care, with persons in HDHPs reducing their use of recommended clinic visits by 2.1 percentage points (95% CI -3.3 to -0.1), $p < 0.001$), their use of recommended annual labs by 3.5 percentage points (95% CI -5.0 to -2.0, $p < 0.001$), and their use of recommended prescription drugs by 12.0 percentage points (95% CI -14.1 to -9.8, $p < 0.001$). Overall, HDHP enrollees were 3.4 percentage points less likely to recommended medical care compared to nonHDHP enrollees (95% CI -4.4 to -0.26 percentage points, $p < 0.001$). The direction of effect was consistent across disease types. Results from triple-difference models females forced to enroll into HDHPs had a greater reduction in use of recommended clinical care compared with males forced to enroll into HDHPs ($p = 0.021$). **Conclusions and Relevance:** HDHPs do not support receipt of recommended medical care, across a variety of chronic conditions. HDHPs may be particularly problematic for females, who experience income and wealth disparities that may leave the same cost-sharing more burdensome for females than for males. Our results have important implications for recently-proposed U.S. federal legislation that proposes to exempt chronic illness management from HDHP deductibles.

Ind-2656 Investigating Behavioural Changes in Response to Medication Copayment Reductions Across Different Therapeutic Groups in Australia

PRESENTER: **Thomas Plunkett**

AUTHORS: Karinna Saxby, Yuting Zhang

Background: In Australia, most prescription medications are subsidised under the Pharmaceutical Benefits Schemes (PBS), which has two tiers: concessional (i.e., low income patients, welfare recipients, and pensioners) and general patients. Unfortunately, many individuals still report delaying or not filling a prescription when needed, due to cost. As a measure to prevent this, once patients' spending on medications reaches certain thresholds in a calendar year, they can obtain medications at reduced cost for the rest of that year under the PBS's Safety Net program. In 2021, the PBS Safety Net threshold for concessional patients was $316.80 (equivalent to 48 prescriptions) and $1,497.20 for general patients (equivalent to approximately 37 full copayment prescriptions). We aimed to study how people respond to reaching their safety net. Specifically, how they change their medication consumptions after reaching the threshold and whether this could be indicative of delayed or missed prescription in the pre-period. We also aimed to explore if this varies across therapeutic groups. **Methods:** We used a national administrative dataset containing PBS data linked with Australian Census data, for 2021. We identified general patients and concessional patients through their first identified copayment after reaching the safety net threshold, and then examined their medication use patterns each month before leading to, and after reaching, the safety net threshold. We utilised a dynamic difference-in-differences approach to study the effect of reaching the safety net on individuals' medication consumption. Analyses were stratified by concessional status and Anatomical Therapeutic Chemical (ATC) classification, with results presented in event-study analyses. **Results:** We found that individuals filled more prescriptions after reaching the safety net. This varied significantly between concessional (i.e., lower income) individuals and general patients, and with ATC groups consisting of more chronic medications than acute medications. **Conclusion:** We identified that individuals fill more prescriptions after reaching the safety net, especially lower income individuals, suggesting that individuals are delaying or not filling prescriptions before reaching the threshold, which harms adherence. This is in line with recent surveys. We also found this is more pronounced for therapeutic groups associated with more chronic medications. Recent policy changes have lowered copayment amounts and safety net thresholds, resulting in cheaper medication for patients. However, these policies have not impacted all groups equally, and our research contributes to the idea that the PBS Safety Net program could be improved to reach individuals who would benefit most from it.

Ind-355 Understanding the Impact of Maternal Depression on Offspring Later Life Socioeconomic Outcomes in Canada

PRESENTER: **Claire de Oliveira**, Centre for Addiction and Mental Health

AUTHORS: Emmanuelle Arpin, Jemimah Ride, Margaret Jamieson

Abstract

Background: According to the World Health Organization, depression is a leading cause of disability worldwide and a major contributor to the overall global burden of disease. Depression can affect not only the depressed individual but also those with whom they interact, such as their children. The negative effects of maternal depression on offspring can occur as early as in utero and infancy to childhood and remain through adolescence. Some research has also found that maternal mental health can continue to impact offspring psychosocial health into adulthood. However, few studies have examined the impact of maternal depression on socioeconomic outcomes of offspring in adulthood largely due to the lack of suitable, longitudinal data. Furthermore, existing work has mainly relied on survey data, which can be subject to self-reporting biases. To date, no related work has been done using Canadian data.

Objectives: Using a novel linkage between Statistics Canada's National Longitudinal Survey of Children and Youth (NLSCY) and the T1 family file tax return (T1FF), this study seeks to understand the role of maternal depression on offspring adult socioeconomic outcomes and, if present, determine whether this impact differs by offspring socio-demographic characteristics (sex, race and ethnicity) and family/household characteristics (household income, maternal education, single vs. two-parent household, family size, frequency of maternal depressive periods). In addition, this work aims to explore the mechanisms through which maternal depression affects offspring adult outcomes via adolescent outcomes.

Methods: This analysis is guided by the Cunha and Heckman's skills production model, where adverse conditions (i.e., presence of maternal depression) occurring during the developmental period have the potential to hinder the production of health and skills and ultimately impact later life outcomes. This analysis also draws on Jacobson's extension of Grossman's model, where the family is conceptualised as a producer of health. Several models are estimated to understand the role of maternal depression (measured by a shortened version of the CES-D), during childhood and early adolescence, on post-secondary education, after-tax individual income, and receipt of social assistance when offsprings are young adults, while controlling for relevant covariates. A covariate decomposition approach, commonly used in the intergenerational income mobility literature, is employed to explore the mechanisms through which maternal depression affects offspring adult outcomes via adolescent outcomes (e.g., test scores).

Results: The NLSCY-T1FF linked dataset produced a sample of 15,000 individuals between the ages of 0 to 11 years in 1994 whose socioeconomic outcomes were examined in 2015, when they were between the ages of 21 and 32. Descriptive and regression analyses are currently under way by the research team. **

Discussion: Depression exerts enormous health and economic burdens on the health care system. Little work has examined maternal depression as a determinant of offspring adult socioeconomic status. Developing interventions and programs that target maternal mental health (in addition to offspring health) may help impede the negative trajectories of functioning that can extend into adolescence and adulthood and, in turn, increase the likelihood that children of depressed mothers grow into healthy, capable individuals later in life.

Ind-911 Beyond Health Care Costs: Drivers of Health-Related Production Losses in Switzerland

PRESENTER: **Mr. Simon Wieser**, University of Zurich
AUTHORS: Christina Vetsch-Tzogiou, Christoph Thommen Sr., Xavier Schärer, Andreas Kohler, Michael Stucki, Yaroslava Zemlyanska

Background: Production losses caused by temporary or permanent reductions in working capacity constitute a substantial economic impact of poor health. However, they are rarely analyzed beyond isolated cost-of-illness studies. While most countries systematically monitor health care spending, there is no equivalent framework for measuring production losses. Consequently, the magnitude of these costs, their different forms —such as absenteeism, presenteeism, disability, and premature death—and their distribution across diseases, age and sex remain unclear. This study aims to quantify total production losses in Switzerland using a human capital approach for the years 2012, 2017, and 2022, examining the trends in their different forms and identifying the diseases driving these losses.

Methods: Our analysis followed a two-step approach: First, we calculated the total production losses by their different forms and aggregated them into their yearly totals. Second, we decomposed these losses by disease, age, and sex. We drew on multiple data sources, including national statistics on work volume, income, and causes of death, the Swiss Labor Force Survey, and a workforce panel survey covering working conditions, health issues, and the Work Productivity and Activity Impairment Questionnaire. Additionally, we accessed detailed data from the national disability insurance scheme. The data on production losses due to premature death and disability included diagnostic information, allowing clear attribution of these losses to specific diseases. In contrast, data for absenteeism and presenteeism were limited, covering only a selected subset of major diseases. To address this limitation, we applied a stepwise regression analysis, first attributing losses to uncoded diseases and then allocating the remaining losses to coded diseases.

Results (preliminary): Production losses amounted to 70.7 billion Swiss Francs (CHF, 1 CHF ≈ 1 USD in 2022), equivalent to 9% of Switzerland's GDP in 2022, representing a 15% increase compared to 2012. In 2022, presenteeism accounted for the largest share of production losses (48%), followed by absenteeism (26%), disability (18%), and premature death (8%). Musculoskeletal disorders (16%), mental disorders (15%), injuries (15%), and cardiovascular diseases (10%) were the leading causes of absenteeism, while 26% of absenteeism-related losses were attributed to uncoded diseases. Across all forms of production losses, mental disorders had the greatest impact, contributing 18% of total losses, with younger age groups being particularly affected.

Conclusions: In 2022, total production losses in Switzerland were only slightly lower than total health care spending (91.5 billion CHF). Combined, these costs represented over 20% of the country's GDP. Among the working-age population, production losses substantially exceeded health care expenditures. Production losses were primarily driven by high prevalence and often chronic conditions such as musculoskeletal and mental disorders. As labor shortages intensify and the population ages, understanding the factors contributing to various forms of production losses becomes increasingly vital. This knowledge is essential for developing effective policies to address their growing social and economic burden.

Ind-663 Estimating Lifetime Cost of Sexual Violence in the UK: An Analysis Using Administrative Data from Rape Crisis Services

PRESENTER: **Estela Capelas Barbosa**, City, University of London

Background: Sexual violence is a crime that has devastating consequences for its victims, including physical and mental health-related problems that result from trauma. In the UK, there is little evidence around the lifetime costs of sexual violence.

Methods: The aim of this study is to estimate the lifetime cost of sexual violence in Essex, UK and evidence return on investment for support services. There are three main methodological components to this study. First, a rapid review using a systematic approach was be conducted to identify relevant unit costs that may be attributable to child and adult sexual violence, which identified 26 relevant publications. Second, administrative data from three Rape Crisis centres was analysed, and regression predictions based on multiple imputation used to infer adjusted relative probabilities attributable to each victim of sexual violence and abuse. Administrative data was also be used to infer the duration of harm where relevant. Finally, an estimate of the cost of sexual violence and abuse was be calculated by cost component, differentiating between child sexual violence and adult sexual violence.

Results: The literature review enable the identification of relevant unit costs. Wherever possible, cost to public funds were preferred as a unit of measurement. We calculated the relative probability for the cost components, where the literature review did not identify a lifetime per victim cost. This enabled the relative probability to account for repetition, that is, when a victim appears in the dataset twice. We assumed that in this case, either there was multi-victimisation or that the abuse had not stopped after the first completion of support. Based on the fully imputed dataset, the likelihood of costs to education was 0.02 or 2%. This was only relevant for victims aged 16 and below. The adjusted probability of use of use of health services was 1.25 per victim. The adjusted probability of police involvement was 0.61 for cases of adult sexual abuse and 0.53 for cases of child sexual abuse (CSA). The lower probability for CSA is likely a result of the long lag between the incident(s) and reporting to the police in cases of CSA. Finally, the relative probability of QALY loss was estimated based on the disability weights for sexual violence

estimated by Global Burden of Disease Collaborative Network, 2018, and for productivity loss, relative proportion is the relative risk of unemployment, the unit cost is the ONS average salary in the UK and 37.4 years is the average work life. The estimated lifetime cost of child sexual abuse using administrative data from Rape Crisis centres in Essex is £472,048.53. In turn the estimated lifetime costs of adult sexual abuse using administrative data from Rape Crisis centres in Essex is £248,431.50.

Conclusions: Sexual abuse is more costly than previously estimated in other studies. While not directly comparable, our study reinforces the further need to make best possible use of administrative records to address gaps in knowledge. Further studies should focus on lifetime costs of victims with disabilities and other co-morbidities.

Ind-1962 Falling Behind: The Impact of Severe Mental Health Shocks on Prime-Age Workers' Labor Market Outcomes

PRESENTER: **Kamrul Islam**, NORCE Norwegian Research Centre & University of Bergen, Norway
AUTHOR: Egil Kjerstad

Background Working adults with severe mental disorders face significant challenges in the labor market, including reduced working hours, absenteeism, low wages, unemployment, and early exit from the workforce. Mental health shocks can impact labor market outcomes through multiple pathways. However, causal analysis of the relationship between mental health and labor market performance is complicated by the potential endogeneity of mental health shocks. Research needs to address these competing explanations in non-experimental settings. This study uses comprehensive registry data and advanced econometric techniques to examine the effects of severe mental health shocks on labor market outcomes, while also contributing to the understanding of ongoing research challenges in this field. **Data and Methods** Our data are obtained from different registry sources: health data come from the Norwegian Patient Register, socio-demographic, wage income, and disability pensioner (DP) data are gathered from Statistics Norway (SSB), and labor market participation data come from the FD-Trygd. We merged the datasets and organized the data as panel/longitudinal data. Our sample includes healthy individuals aged 24-45 who participated (n=892,991) in the labor market at baseline (2008/09). To analyze their labor market performance, we follow the cohort prospectively from 2010 to 2019 (N=5,725,949). We use a staggered difference-in-differences (DiD) design to estimate treatment effects, accounting for differential treatment effects across time and individuals. We define the treatment (event) as the first onset of an severe chronic mental health condition, such as schizophrenia, major depressive disorder, or bipolar disorder. To ensure the validity of the staggered DiD estimation, we rely on key assumptions, including staggered treatment adoption, which assumes that once individuals receive treatment, they remain treated throughout the observation period. Initially, we consider never-treated workers as the comparison group. To address potential endogeneity in treatment timing, we subsequently employ not-yet-treated groups and perform pre-treatment trend tests to validate the identification strategy. The average treatment effects on the treated (ATT) are estimated and aggregated within an event study framework. **Results** Our results show that, compared to never-treated workers, the treated workers' ATT is negative and significant: they are 11% less likely to be employed, and an increased probability of being on disability pension (7.7%) compared to never treated workers. Compared to not-yet-treated workers these probabilities are 7% and 3.8%, respectively. A similar negative impact is observed in the probability of earning lower wages (132%) and FTE (9.7%) compared to never treated workers. Compared to not-yet-treated these probabilities are 79.8% and 4.3%, respectively. Moreover, these negative effects vary notably by education level of the workers, highlighting the importance of accounting for heterogeneity across groups. Importantly, the identification strategy is supported by the absence of pre-tretment trends among not-yet-treated groups, whereas never-treated units exhibit inconsistent trends. **Conclusion** Our study concludes that severe mental disorders have a significant negative impact on various labor market outcomes. The magnitudes of the effects varies by education level, with lower-educated groups experiencing more negative impacts. These effects not only harm individuals directly affected by mental health issues but also have the potential to widen existing socioeconomic inequalities. Given the growing emphasis on work activation policies in many developed countries, it is crucial that future policy evaluations account for the specific challenges faced by individuals with mental disorders.

Ind-771 Patient Preferences for Long-Acting HIV Treatment among people with HIV in Kenya: A Preference Heterogeneity Assessment.

PRESENTER: **Enrique M Saldarriaga**, University of Washington
AUTHORS: John Kinuthia, Jacinda Tran, Douglas Barthold, Naum Jepkosgei, Brett Hauber, Susan Graham, Catherine Maina, Anne Kaggiah

Abstract

Background. Adherence to antiretroviral therapy (ART) remains an important barrier to achieving viral suppression in many sub-Saharan African countries, including Kenya, where approximately 1,4 million people were living with HIV in 2023. Long-acting ART (LA-ART) regimens are emerging alternatives to daily oral HIV treatment, designed to improve adherence. While LA-ART regimens are being rolled out in the United States as they become available, they are not yet available in most African settings. Understanding end-users' preferences for these therapies is crucial to increasing their uptake when rolled out.

Aim. We elicited preferences for LA-ART among people living with HIV in Kenya, explored heterogeneity in these preferences and investigated the association between preference heterogeneity and sociodemographic and psychosocial characteristics.

Methods. We designed a discrete choice experiment (DCE) to elicit preferences for LA-ART attributes. We recruited 700 participants from the Kenyatta National Hospital Comprehensive Care Clinic and two Sex Workers Outreach Program (SWOP) clinics in Nairobi, Kenya between January 2023 and February 2024. Each participant answered 17 choice-tasks, each with 2 hypothetical LA-ART alternatives and current daily oral therapy. Each LA-ART profile was defined by mode (long-acting oral pills, injections under the skin, injections into the muscle, and implants), pain, frequency, location of treatment, pre-treatment time undetectable, pre-treatment negative reaction testing, and late-dose leeway. Participants also answered demographic and psychosocial questions and provided consent to link their clinical data. We fitted a latent-class model to the DCE data and assigned class membership to each participant, then estimated a multinomial logit model to explore associations between class membership and participant characteristics.

Results. We found three classes in our DCE data. All classes preferred some form of LA-ART over their current daily oral therapy. Class 1 (38%) had a relatively high preference for injections (subcutaneous or intramuscular), Class 2 (21%) for LA-oral tablets, and Class 3 (41%) for implants. Classes 1 and 2 showed significant preference for "clinic" over "home" for treatment administration, while Class 3 was indifferent to this attribute. Compared to Class 2 participants, Class 1 and 3 participants had more experience with injections, were less likely to hate injections, and were less likely to be sex workers or men who have sex with men. Further, Class 1 was more likely to have private insurance, less likely to have a social support system, and less likely to be heterosexual. Conversely, Class 3 was more likely to have housing insecurity and less likely to be male.

Conclusions. Our findings show associations between heterogeneity in preferences for LA-ART options and demographic and psychosocial characteristics. These results provide a deeper understanding of the preference landscape for LA-ART. Preference heterogeneity can aid in the development of interventions better aligned to patients' needs, which may increase LA-ART acceptability, uptake and adherence.

Ind-131 Preferences of Cancer Survivors for Follow-up Care in China: Discrete Choice Experiment

PRESENTER: **Yiqi Xia**
AUTHOR: Ping He

Background: As cancer survival rates improve, follow-up care has become crucial for enhancing the quality of life among cancer patients. In China, where cancer incidence and survival rates are rapidly increasing, understanding the preferences of cancer survivors regarding follow-up care is essential. While previous studies have explored the preferences of cancer patients for follow-up care in developed countries, there is a lack of research on the perspectives of patients in China and other developing nations.

Objective: This study aims to elicit the preferences of cancer survivors in China concerning follow-up care using a discrete choice experiment (DCE) to inform healthcare strategies that enhance survivor satisfaction and health outcomes.

Methods: A discrete choice experiment was designed to investigate cancer survivors' preferences in China based on six key attributes of follow-up care, including care provider, thoroughness of follow-up contents, follow-up interval, delivery method, duration, and content of care. Data were collected from 192 participants online, and a mixed logit model was employed to analyze the results, allowing for the examination of heterogeneity in preferences. Additionally, latent class analysis was conducted to identify differences within the sample that exhibit distinct preferences.

Results: The care provider, follow-up interval, and delivery method were found to significantly influence cancer survivors' preferences for follow-up care in China ($p < 0.05$). Specifically, the study revealed strong preferences for follow-up care delivered by specialist doctors, at twice-a-month intervals, and online compared to the care provided by general practitioners, once three months and via telephone, respectively. The latent class analysis identified two distinct subgroups, highlighting variability in preferences based on demographic factors and cancer types. Class 1 favored consultations with specialist doctors, shorter intervals, WeChat communication, longer durations, and psychological support content, while Class 2 preferred follow-up with specialist nurses, longer intervals, telephone communication, shorter session durations, and advice on health management and complications. Simulated probabilities indicated a substantial increase in the likelihood of choosing follow-up care when delivered by preferred providers under optimal conditions. Notably, interactions with demographic factors such as age, marital status, and education revealed significant heterogeneity in preferences, emphasizing the impact of these characteristics on survivors' choices for follow-up care.

Conclusions: This study is novel to underscore the importance of tailoring follow-up care to the specific preferences of cancer survivors in China. The findings suggest that personalized follow-up strategies, particularly those involving specialist providers and preferred delivery methods, can significantly enhance patient engagement and satisfaction. Future healthcare policies should incorporate these preferences to improve the quality of follow-up care for cancer survivors.

Ind-1636 Preferences and Willingness to Pay for Pneumococcal Vaccines Among the Elderly in India: A Discrete Choice Experiment

PRESENTER: **Ramkrishna S L**
AUTHOR: Jeffrey Pradeep Raj

Introduction: Elderly people are at a high risk for severe illness from pneumococcal infections, such as meningitis and pneumonia. In order to device an effective immunization strategy, the preferences and willingness-to-pay (WTP) of elderly individuals in India for pneumococcal vaccines becomes important. The proportion of elderly in India is rising, and them being more susceptible to pneumococcal infections understanding their decision-making process is crucial. Utilizing a discrete choice experiment (DCE) framework, the study examines the trade-offs elderly are willing to make between key vaccine characteristics, such as efficacy, safety, and cost. *Methods*: The study is currently ongoing and is expected to be completed by Nov 2024 with a target sample size of 2000. A total of 843 participants were enrolled against a target of

2000. The study included consenting Indian citizens aged 60 years and older, regardless of biological sex. Participants were invited via an online link shared across various digital platforms. The questionnaire was divided into three sections: (1) socio-demographic details, (2) medical history and COVID-related information, and (3) a discrete choice experiment (DCE) presenting six pairs of hypothetical pneumococcal vaccines. Each vaccine was described using a fixed set of attributes such as effectiveness, side effects, cost, number of doses, duration of protection, and place of administration, with varying levels for each attribute in the paired comparisons. Responses that were incomplete or did not meet pre-defined quality standards were excluded from the analysis. *Results*: Of 941 respondents, 98 failed the trap question and 843 responses were finally analysed. The most important attributes were duration of protection followed by effectiveness. Respondents were willing to pay INR 4085 (48.41 USD), INR 3254 (38.56 USD), and INR 2898 (34.34 USD) per dose for vaccines offering lifelong, 10-year, and 5-year protection, respectively, compared to 1-year protection. Additionally, they were ready to pay INR 2277 (26.98 USD) for a vaccine with 70% effectiveness and INR 2042 (24.20 USD) for 90% effectiveness over a vaccine with 50% effectiveness. Vaccine hesitancy (to at least 3/6 vaccine pairs) was seen in 6.88% *Conclusions:* Duration of protection and effectiveness are key factors influencing pneumococcal vaccine preferences among the elderly in India. Before implementing a nationwide policy on pneumococcal vaccination for the elderly, it is crucial to understand their preferences, assess their affordability and willingness to pay, and address concerns about vaccine hesitancy.

Ind-524 Preference for Ambient-Assisted Living Services Among Older Chinese Adults: A Discrete Choice Experiment

PRESENTER: **Jin Liu**
AUTHORS: Anli Leng, Stephen Nicholas, Elizabeth Maitland, Jian Wang

Background: At the same time as China's aging population leads to a surge in demand for old-aged care, China faces a shortage of formal caregivers. One way to address the shortage of formal old-aged care, ambient-assisted living (AAL) services uses artificial intelligence (AI)—infused applications and platforms that promote independent living by utilizing assistive technologies to help older adults control age-related diseases, manage age-related health conditions and improve old-aged wellness. By promoting safe and independent aging in place, AAL can alleviate the care burden on family members, formal caregivers and the health system. Studies have confirmed the effectiveness of AAL services, indicating AAL's potential to address critical gaps in old-aged care. Surprisingly, there has been little research on older adults' decision-making towards emerging AAL services. This study investigates older Chinese adults' preferences and willingness-to-pay (WTP) for AAL services and explores the factors influencing AAL services decision-making.

Methods: Through stratified random sampling, a discrete choice experiment (DCE) was conducted with adults aged 60 and above across five cities in Shandong Province in August 2024. Each DCE scenario encompassed six attributes: service location, service function, difficulty, security, out-of-pocket payments and quality of life. Data were collected through face-to-face interviews using a structured questionnaire administered by trained investigators. Preferences, relative importance (RI) of attributes and the marginal WTP were estimated using a mixed logit model. Preference heterogeneity was examined by subgroups analysis.

Results: A DCE survey was completed by 235 older adults. All six attributes had a significant impact on older adults' preferences, with security, quality of life and service location identified as the most important factors. Participants preferred AAL services at home (vs nursing institutions, β=-0.454, $p<0.01$); focused on daily living assistance (vs psychiatric care, β=0.262, $p<0.05$); lower difficulty (vs high difficulty, β=0.327, $p<0.01$) and higher security (vs low security, β=0.736, $p<0.01$); enhanced quality of life (good vs poor quality of life, β=0.497, $p<0.01$); incurred lower out-of-pocket payments (β=-0.002, $p<0.01$); and with the maximum WTP of US$129.747 per month. The predicted uptake rate for the optimal AAL services scenario (home-based services, providing health management, low difficulty, high security, good quality of life and cost of US$14.04 per month) was 66.6%. Participants were willing to pay US$61.20 (95% CI: US$38.22, US$93.82) for improved security and US$41.36 (95% CI: $20.99—US$67.54) for a better quality of life. There was heterogeneity in the preferences of older adults with different gender, urban-rural residence, and health status characteristics.

Conclusions: This study revealed older adults' preferences to improve the design of effective AAL services. Policymakers should prioritize enhancing service security and improving quality of life to increase older adults' acceptance and satisfaction with AAL services. We recommend designing tailored AAL services solutions that address the diverse demands of older adults to improve old-aged care quality and older adults' overall well-being.

Ind-543 Examining Preferences for Public Healthcare Provision of Rural Residents in China: A Discrete Choice Experiment

PRESENTER: **rui liu**
AUTHORS: Xiaoying Zhu, Weidong Huang, Miao Miao

Abstract Background: The rural healthcare system plays a vital role in providing essential health service to rural population and contributing significantly to promoting health equity. However, the underutilization of rural healthcare services remains a persistent issue. The study aims on assessing the rural residents' preferences on public healthcare to provide evidence for policy makers in making rural healthcare service delivery more responsive to rural residents' health needs. Methods: A Discrete Choice Experiment (DCE) was conducted to assess preferences of the rural residents in Heilongjiang province, China. Drawing from the literature review, Anderson model, preference exercise, and Delphi method, six attributes were identified and included in the choice experiment questionnaire. The data collection was implemented between June and December 2021. Using stratified random sampling method, 13 cities in Heilongjiang Province were divided into three levels according to their economic development level. 4 rural areas were randomly selected for each level, and 52 rural residents were randomly recruited for each rural area. Mixed logit and latent class logit (LCL) models were used to analyze residents' preference. Results: A total of 536 participants completed the questionnaire, and the response rate is 85.8%. The attribute "Healthcare provider type" was found as the most significant factor influencing public healthcare services preference, followed by "Public medical institution type (PMI)", "Travel time", "Available diagnosis and treatments", and "out-of-pocket (OOP) payment". Preferred services included higher-level of hospitals, specialist, a broader range of diagnoses and treatments, closer distance and lower OOP expenses. For participants without chronic diseases, the type of PMI was the most influential

factor, while for those with chronic diseases, the healthcare provider type was the most important. The LCL model results suggested that the Class 1, labeled as "Quality Seekers," preferred healthcare services provided by specialized practitioners in large hospitals; the Class 2, labeled as "Positive Accessibility and Affordability," favored services located within 30 minutes of travel and with low OOP payments. Conclusions: Our findings provide valuable insights into public healthcare utilization preferences among rural residents. The results underscore the importance of healthcare provider quality, PMI type, travel time, and available diagnostic and treatment options in healthcare policy decision-making. **Keywords** Public healthcare provision; rural residents; preference; discrete choice experiment

Vaccination Costs

MODERATOR: **Brendan Kwesiga**, UNICEF

abs-os475 The State of the Evidence on Immunization Delivery Costs in Low- and Middle-Income Countries: Findings From a Systematic Review

PRESENTER: **Ms. Christina Banks**, ThinkWell
AUTHORS: Ms. Flavia Moi, Ms. Laura Boonstoppel, Syed Najibullah, Afroja Yesmin

Background: Evidence on immunization delivery costs is key to ensure that immunization programs are adequately funded and achieve their coverage targets. With 40 vaccines prequalified by WHO since 2020 and more essential vaccines about to enter the market, it is crucial that countries and donors understand the costs of delivering immunization services in LMICs, how costs differ across settings, antigens, and delivery strategies, and where evidence gaps remain. To this end, we conducted a systematic review to shed light on the state of the evidence on immunization delivery LMICs.

Methods: We conducted a systematic review of 4,853 resources published between March 2019 and December 2023. We included studies conducted in LMICs that reported immunization delivery unit costs, and excluded resources that only presented secondary data or modelled cost estimates. 607 unit costs as well as contextual information about the study setting (including vaccine delivered, delivery strategies, target population) and costing methodology were extracted from 51 publications matching the inclusion criteria, and compiled into a publicly available database—the Immunization Delivery Cost Catalogue (IDCC)—which presented results from a previous review. We then conducted a descriptive and evidence gap analysis of all unit costs in the IDCC and estimated the median, minimum, and maximum cost per dose across comparable datapoints.

Results: We found that immunization delivery cost evidence exists for 49 countries (36% of all LMICs). 73% of evidence is for routine delivery, 20% for supplementary immunization activities (SIAs) and 7% combine routine and SIAs. Only 16% of the studies reported unit costs for more than one delivery strategy. We identified evidence gaps on the cost of delivering through different strategies and to specific target populations (e.g. zero-dose children, out-of-school girls, the elderly), on specific types of SIAs (e.g. integrated campaigns, outbreak responses conducted during epidemics) and for new vaccines (e.g. mpox, dengue, HepB) for which currently there is none.

We found that with a median cost per dose of $1.34 (min-max: $0.11-$36.74) routine delivery is costlier than SIAs ($0.52, min-max: $0.17-$3.86) on a per dose basis. Outreach is the costliest delivery strategy ($3.73, min-max: $0.44-$27.27), while facility-based delivery is the least costly ($1.65, min-max: $0.08-$22.27). Targeting adults is more costly than reaching children, with COVID-19 priority populations being the costliest to reach ($2.85, min-max: $0.96-$5.34) and infants and children under 15 yo being the least costly target population (median: $0.63, min-max: $0.17-$3.51). Evidence for delivery of a single vaccine shows that vaccines targeting adolescents, adults, and priority groups are costlier to deliver per dose, with influenza (median: $3.75, min-max: $1.58-$5.85), HPV (median: $2.56, min-max: $0.39-$33.15), and TT/Td (median: $2.23, min-max: $1.57-$5.06) being the costliest on a per dose basis.

Conclusions: The cost evidence compiled by our review can be used for planning and budgeting at country level, and to inform resource mobilization and advocacy at regional and global levels. Moreover, our analysis provides a comprehensive overview of the existing evidence base on immunization delivery costs and highlights persisting evidence gaps, providing valuable insights on areas where further research is needed.

abs-os108 Approximating Reaching Zero-Dose Children With Standardized Country-Level Routine Outreach Vaccine Delivery Unit Cost Estimates

PRESENTER: **Allison Portnoy**
AUTHORS: Taylor Holroyd, Emma Clarke-Deelder, Dr. Tewodaj Mengistu, PhD

****Background**** The Immunization Agenda 2030 aims to reach all people with immunization services, including ‘zero-dose’ children—children who have not received any routine vaccine. To plan for the efforts to reach zero-dose children with needed vaccinations and make informed decisions to improve immunization coverage and equity, decision-makers need to know how much these efforts will cost. Without widely available primary data, there is a need for proxy estimates for the costs of extending vaccine delivery to zero-dose children who are typically part of disadvantaged and hard-to-reach populations. This project aims to approximate the costs of reaching zero-dose children with standardized country-level estimates of vaccine delivery unit costs for outreach delivery for low- and middle-income countries (LMICs).
****Methods**** We extracted estimates of the outreach delivery cost per dose for childhood immunization services from the 2024 update of the Immunization Delivery Cost Catalogue. We used these data to construct a prediction model for estimating standardized outreach vaccine

delivery unit costs. A meta-regression approach was used to incorporate factors expected to predict unit costs as a function of a set of country-level and study-level predictors (study year, economic or financial cost, routine or campaign delivery, full or incremental costing approach). The fitted prediction model, specified as a generalized linear regression model, assuming a Gamma distributed outcome and a log link function, was used to estimate outreach vaccine delivery costs per dose in 130 LMICs for the year 2023. ****Results**** We estimated the prediction model using results from 48 observations across 19 countries specific to outreach or mobile delivery of childhood vaccines. The best fit model with study-level predictors included reported diphtheria-tetanus-pertussis (DTP3) coverage and under-five population size. For 2023, the predicted mean economic cost per dose was $7.91 (95% uncertainty interval $2.44–20.14), averaged across all 130 LMICs. ****Conclusions**** Reaching zero-dose children is crucial for improving equity in global health, and estimates of the costs of doing so are needed to inform budgeting for immunization programs. Our study provides estimates produced via meta-regression analyses that can help countries to improve budgeting and planning for implementation of future interventions to reach zero-dose children.

Ind-1980 A Rapid Systematic Review of Costs, Cost-Effectiveness and Budget Impact of Measles, Malaria and Meningitis Vaccination Strategies in Africa

PRESENTER: **Charles C Ezenduka**
AUTHORS: Nkolika Uguru, Obinna Onwujekwe, Enyi Ifeoma Etiaba, Chibueze Anosike

Abstract

Background/objective:

The effectiveness of vaccines is critical to achieving the goal of disease control and elimination in mostly LMICs, constrained by limited resources and underfunding. In the face of dwindling resources and declining donor support, Africa remains mostly underserved with minimal coverage. We conducted a rapid review of published studies on the costs, cost-effectiveness, and budget impact analysis of priority vaccine delivery in Africa, to generate relevant information to strengthen evidence generation and inform policy for improved efficiency of vaccine coverage. The rapid review was necessary for faster decisions and further efforts at generating empirical evidence to inform vaccine policy for enhanced coverage in Africa.~~

Methods: We conducted a rapid systematic review of published literature on the costs, cost-effectiveness, and budget impact analysis of priority vaccine strategies to prevent measles, malaria, and meningitis in African countries, to synthesize information to achieve desired objectives. As a rapid review, we only searched reliable large electronic databases PubMed and HINARY using standard search terms and covering human studies published in English between 2004 and 2024. Our search also included reference tracing of selected studies. Following title and abstract screening, we appraised the quality of included studies in line with the standard guidelines to extract and report relevant data on costs, cost-effectiveness and budget impact of identified strategies. Where possible, incremental cost-effectiveness ratios (ICERs) were calculated to describe the efficiency of each intervention in increasing coverage.

Results: Our initial search yielded a total of 758 articles from which 49 which met inclusion criteria were selected following screening. A total of 23 of the 49 full text articles were finally appraised for quality and data extraction. Measles vaccine delivery was evaluated in ten (10) studies, closely followed by malaria vaccine, (9) and meningitis (4) studies. **S**trategies that increased immunization coverage and cost-effective were implemented alongside RI/EPI (16). No intervention accounted for the most common (8) comparator across studies. Transmission, mathematical, and Markov models were the predominant modeling tools (11). Costing measures varied significantly across studies, with implications on planning and budgeting. Majority (65%) of vaccination outcomes were measured in DALYs, with malaria accounting for 53%. Almost all malaria vaccination studies (8) included DALYs as an outcome measure, with ICER varying between seasons and countries, @$30 - $200 per DALY averted. For measles, ICER ranged between $1.5 and $861 per DALY averted. In 48% of the studies, vaccination outcomes reported cost savings - 7 in~~ measles, and 2 each in malaria and meningitis respectively.

Conclusion:

Our findings suggest very limited quantitative evidence on the costs, cost-effectiveness, and budget impact analysis of published vaccine strategies in Africa. Costing evidence needs more efforts for improvement and reporting to enhance more efficient allocation of resources in programs for improved coverage. Standardization of costing methods is highly recommended to enable the synthesis and use of cost data. Findings reveal scope for improved evaluation of strategies with comparable reliable methodological approaches to strengthen evidence generation for vaccine policy and planning for efficiency of service delivery and improved immunization coverage.

Ind-1409 Exploring the Cost Implications of Vaccine Regimen Changes: Evidence From Ethiopia's Switch to a Single-Dose Human Papillomavirus Vaccine Regimen

PRESENTER: **Mercy Mvundura**, PATH
AUTHORS: Belayneh Anteneh, Diriba Bedada, Rose Slavkovsky

Introduction

Based on a 2022 World Health Organization endorsement, countries have the option to implement a single- or two-dose human papillomavirus (HPV) vaccine regimen since a single dose of HPV vaccine was shown to have comparable efficacy and duration of protection as multiple doses. It may also offer program advantages including simplified logistics associated with delivering fewer doses, potential for improved vaccination coverage, and anticipated cost savings for vaccine procurement and delivery. However, the evidence on the cost implications of a single-dose HPV vaccine regimen is based on modeling. Our study aims to provide real-world evidence on the program cost implications and

operational context associated with a switch to a single-dose HPV vaccination regimen.

Methods

Ethiopia administered a single-dose HPV vaccine regimen to a cohort of 9- to 14-year-old girls during a November 2024 campaign. We will use ingredients-based micro-costing methods to collect data to estimate the financial and economic costs of the vaccination activities. Stratified random sampling was used to select 80 health facilities that provided HPV vaccination services during the campaign, representing four regional and 36 woreda (district) administrative offices. During data collection scheduled for January 2025, we will use structured costing questionnaires to interview health facility staff responsible for providing HPV vaccination services and program managers at the sub-national administrative levels in our sample and at the national level. For each HPV vaccination program activity conducted, financial costs will be estimated including costs for vaccine and supplies procurement, per diems, meetings, fuel, and vehicle rental. In addition, opportunity costs—such as the time costs for health and non-health workers involved in HPV vaccination program activities, as well as costs for capital (e.g., vehicles and vaccine storage equipment)—will be estimated. Numbers of vaccine doses administered and adolescents vaccinated (data from immunization program records) will be used as denominators in the costing analysis. The costing will be done from the health system perspective. All costs will be reported in 2024 USD.

Results

Results are pending, but we will estimate the financial and economic costs per facility, and per adolescent vaccinated under a single-dose regimen. These estimated costs will be compared to those reported when Ethiopia was using a two-dose regimen: economic costs of $23.47 per adolescent receiving the full regimen, of which $13.55 were financial costs and $9.92 were opportunity costs. Under the two-dose regimen, vaccine procurement costs were the largest share of the costs, and human resource time was the largest share of the opportunity costs. So, there is potential for large savings in these costs with a single-dose schedule. We will characterize program context including number of HPV vaccination sessions conducted, locations where sessions were conducted, and frequency and intensity with which program activities were conducted under a single-dose schedule.

Conclusions

The evidence generated will inform program planning and budgeting. It will also be useful for local stakeholders trying to make the HPV vaccination program more affordable and sustainable and as other countries seek evidence on the cost implications of the regimen switch.

Ind-2401 Optimising Scarce Resources to Improve Nutrition Outcomes in Low Resource Settings

PRESENTER: **Augustine Omodieke**

AUTHORS: Ibrahim Ibrahim, Yewande Ogundeji, Nduka Nelson, Godwin Onebunne

Background Nutrition and health outcomes in Nigeria have remained poor, with more than one-third of children under-5 stunted and at risk of death or impaired development. Despite the availability of cost-effective nutrition interventions which can address the drivers of poor nutrition outcomes, Nigeria has made very limited progress due to underinvestment and limited fiscal space for nutrition. In low resource settings (including Nigeria and many low- and middle-income countries), value for money through efficiency gains is a critical component for expanding fiscal space for implementing lifesaving interventions. Using Nigeria as a case study, we aimed to identify opportunities for more efficient resource allocation and spending for nutrition to accelerate improvements in nutrition outcomes within the context of constrained resources. **Methodology** A quantitative approach was utilized for this study aided by the Optima Nutrition tool. The tool contains a geospatial component to model and determine funding allocations that minimize stunting, wasting, anaemia and under-five mortality at both the national and regional levels. The model has a flexible intervention set that includes a variety of vitamin supplementation programs, infant and young child feeding education, treatment of severe acute malnutrition, treatment and prevention of diarrhoea, fortification of foods, and others. The study was conducted in four Nigerian states (Abia, Kaduna, Kano, and Oyo) to determine the best mix of cost-effective interventions to be prioritized and the investment requirement to accelerate nutrition results. In each state, a multisectoral Expert Working Group (EWG) was constituted, and trained on data requirements and conduct of optimization analysis. State specific databooks were completed (using national, state, and proxy data where applicable) and validated with specific objectives (targeting maternal and child outcomes) defined based on national targets, informing state specific optimization analysis. **Results** The optimization analysis showed that prioritizing (scaling up coverage levels), by reallocating more money to, a mix of interventions including Treatment of SAM, Micronutrient Powder, Iron and Folic Acid Supplementation (IFAS – at both health facility and community levels), Vitamin A Supplementation, as well as Infant and Young Child Feeding (IYCF 1,2,3) will collectively deliver greater gains in nutrition outcomes (including increased number of alive- and non-stunted, non-wasted, and non-iron deficient anemic children; and reduced child and maternal deaths) at the current spending level. Additionally, the analysis showed that with this intervention mix, these states could reduce prevalence of stunting, wasting, non-ID anemia in children and ID anemia in pregnant women by 1.8-9%, 3.2-50%, 2.2-12% and 10-18.25% respectively over a 5-year period by increasing their current annual investment in nutrition by up to (35%) Abia, (20%) Kano and Kaduna, and (30%) Oyo. **Conclusion** To achieve more nutrition for the money, it is crucial for nutrition financing to be optimized, and expenditure frugally planned. Many low- and middle-income countries with constrained fiscal space

can make remarkable progress towards achieving nutrition targets and consequently global targets utilizing the innovative Optima allocative efficiency analysis to determine the best intervention mix to be implemented (at both national and sub-national levels), and the incremental shift in annual nutrition investment required.

abs-os772 Assessing Fiscal Space for Health in Nigeria and Increasing Primary Health Care Facilities Spending

PRESENTER: **Stanley Chibuzor Ezenwa**

AUTHORS: Muhammed Muhammed, Aisha Aliyu, Joshua Elaigwu, Felix Abrahams Obi

The Nigeria Fiscal Space for Health initiative is a strategic endeavor aimed at significantly enhancing the financing of Primary Health Care (PHC) in three critical north central and northwest zones of Nigeria. This comprehensive study is being executed by the Health Financing Unit of the National Primary Health Care Development Agency (NPHCDA), with expert technical guidance from Results for Development (R4D), an organization renowned for its focus on improving health systems.

The core objective of this assessment is to conduct an in-depth evaluation of the fiscal space dedicated to health at the Primary Health Centres (PHCs). To achieve this, we employed a descriptive cross-sectional methodology that combines qualitative and quantitative research approaches, ensuring a robust analysis. Our research instruments included carefully validated semi-structured questionnaires and Key Informant Interviews (KII) that explored a range of critical factors, such as community health needs, budgetary revenues and expenditures, and specific areas of inefficiency in the PHC framework. Data collection was carried out by a team of trained field assistants, who utilized the Open Data Kit (ODK) applications to capture information electronically.

The key findings from this assessment reveal significant challenges faced by PHCs, particularly concerning perceived inadequacies in budgetary allocations that directly impact the delivery of health services. It was identified that budget releases to PHCs consistently fall short of the amounts that were allocated from the national and state, which poses formidable obstacles to effective implementation of health programs. Moreover, there are growing concerns regarding the insufficient financial support from pivotal sources such as the Basic Health Care Provision Fund (BHCPF) and the National Health Insurance Agency (NHIA), despite some reports highlighting potential positive impacts of these funds. The team uncovered substantial financial management gaps, including inadequate record-keeping practices and a limited availability of skilled human resources within health facilities, which hinder operational efficiency and accountability.

In response to these identified challenges, we propose a series of targeted recommendations aimed at strengthening the fiscal framework and financial management within the PHC system. These include comprehensive capacity-building initiatives for healthcare staff, enhanced supervision and monitoring mechanisms, and active engagement with financial managers to foster better management practices and optimize resource allocation.

In conclusion, this assessment powerfully underscores the urgent need for carefully targeted interventions to improve the fiscal space and financial management strategies in Primary Health Care across all six geopolitical zones in Nigeria. Moreover, it highlights the potential for these improvements to serve as a model for similar initiatives beyond West Africa, ultimately contributing to better health outcomes for communities.

Ind-1901 Driving Efficiency and Strengthen Strategic Purchasing in Malawi's Public-Private Partnership with a Major Faith-Based Healthcare Provider

PRESENTER: **Christian Abraham Arega**

AUTHORS: Francis Zhuwao, Andrews Gunda, Moses Zuze, Dumisani Enricho Nkhoma, Gerald Manthalu, Emily Chirwa, Stephanie Heung, Mihereteab Teshome, Joe Zonda, Dominic Albert Nkhoma

Background

The Christian Health Association of Malawi (CHAM), the largest non-governmental healthcare provider, delivers 37% of healthcare services nationwide and 75% in rural areas through a Public-Private Partnership (PPP) with the Government of Malawi (GoM). Through Service-Level Agreements (SLAs), CHAM facilities are contracted to deliver pre-defined services under a fee-for-service (FFS) provider payment mechanism, alongside a healthcare worker salary block grant.

While this partnership has expanded access, questions have emerged about its value-for-money (VfM) and the efficacy of the FFS mechanism. This study was commissioned to inform the renewal of the Memorandum of Understanding (MoU) between CHAM and GoM.

Research Questions

The study answered three research questions. First, it examined whether the salary block grant supported efficient service delivery compared to public facilities. Second, it evaluated the cost savings to the government from contracting CHAM facilities. Lastly, it investigated the effectiveness of the FFS scheme in facilitating timely payments and explored whether alternative payment mechanisms might enhance service delivery.

Methods

Workforce modelling was used to investigate differences in service delivery output relative to the expected service volumes between 60 CHAM and GoM facilities. To achieve this, expected service volumes were calculated using cadre-level staffing data and time-motion estimates for 36 services. These estimates were then compared to actual service volumes from facility-level data available in DHIS2 and used to generate efficiency scores. Commodity and drug costs were compared between private sector, Central Medical Store Trust (CMST), and SLAs. Furthermore, to understand challenges of the FFS model, 26 qualitative interviews were conducted with stakeholders from Ministry of Health, Ministry of Finance (MoF), CHAM and development partners funding SLAs. Finally, a payment process map was created by tracking invoices from 12 CHAM facilities to pinpoint bottlenecks in the funding flow.

Key Findings

Findings indicate that for inpatient services, complicated deliveries, antenatal visits, and certain HIV services, CHAM facilities correlate with higher efficiency scores. This efficiency, along with cost savings from SLA contracts — 93% of SLA drug and commodity prices were lower than private sector equivalents and 60% below CMST — supports the continuation of the SLAs as they provide good VfM.

Despite the demonstrated VfM of contracting CHAM, the process mapping exercise highlighted delays of up to 90 days in FFS reimbursements frequently resulting in drug stockouts and reduced service volumes, which compromise care quality and accessibility. Nonetheless, majority of the CHAM facilities surveyed favoured the FFS model, if payments are timely and perceived risk of financial mismanagement with upfront payments. Hence, digitizing the payment system was identified as a priority to streamline invoice processing and ensure timely payments to facilities, thus improving liquidity and service continuity. In the future, a hybrid model with partial upfront payments and/or capitation may be considered to further mitigate solvency risks and introduce stronger cost-control measures.

Conclusions

The findings of this study have been used to inform the renewal of the MoU between CHAM and GoM, including efforts to address provider payment bottlenecks, as the CHAM SLAs have proven to confer strong VfM to the GoM.

Ind-2865 Mapping Health Financing Policies to Improve Spending Efficiencies and Financial Risk Protection in Middle Eastern and North African Countries.

PRESENTER: **Diana Kizza**

AUTHORS: Reem Hafez, Palwasha Anwari

Background: Health financing is pivotal to achieving Universal Health Coverage (UHC), ensuring equitable, efficient, and transparent resource allocation to improve population health. The Middle East and North Africa (MENA) region encompasses 20 countries with diverse economic, political, and demographic contexts that shape health financing systems. Despite these variations, UHC is a shared priority across the region, reflected in national development plans. However, challenges such as fragmented health spending, high out-of-pocket (OOP) payments, inefficiencies in public health finance, and limited financial protection persist, threatening progress toward UHC. This review maps and describes government health financing policy instruments across MENA to assess government intent to address health spending challenges and promote equitable access to financial protection for health service delivery. **Method:** Qualitative review of publicly available health financing policies, laws, and strategies in the MENA region, with analysis guided by WHO's health financing core functions framework, focusing on revenue generation, pooling of funds, and purchasing of services to evaluate policy intent, design, and alignment with UHC goals. Documents were sourced from government websites, international agency repositories, and academic databases. Inclusion criteria prioritized publicly accessible documents that explicitly or implicitly addressed health financing. Qualitative content analysis using a coding framework with a thematic focus on objectives of equity, efficiency, and financial risk protection was adopted to identify policy intent and implementation approaches. The study does not assess implementation fidelity or policy effectiveness, nor does it include unpublished documents. Ethical considerations were addressed by exclusively analyzing publicly available data. **Findings:** Eighteen countries embed the right to health in their constitutions, but only three (Egypt, Morocco, and Sudan) have dedicated health financing strategies. Thirteen countries have health policies or strategies that implicitly address health financing, while nine have health insurance laws or policies, with some implementing mandatory schemes. Persistent challenges highlighted in these policies include high OOP spending, affecting up to 13 million individuals annually, and limited insurance coverage exacerbating inequities, especially in middle-income countries. Protracted conflicts also strain health systems, necessitating the extension of unplanned provision of healthcare to migrants and refugees. Innovative responses vary by income status. High-income countries (six Gulf States) leverage oil revenues to provide free universal healthcare but face rising costs from non-communicable diseases and are exploring value-based mechanisms. The eleven Middle-income countries are expanding health insurance coverage, reforming policies to address inefficiencies, and refining strategic purchasing mechanisms, such as capitation, pooled procurement, and benefit package reviews, to improve resource allocation. **Conclusion:** Health financing reforms in MENA are evident in national policies, and reveal significant government intent to tackle spending inefficiencies, access inequities, and financial risks on households. This reflects governments' intent to address persistent barriers of technical and allocative inefficiencies and high proportions of OOP spending. Strengthening governance, expanding pre-payment mechanisms, and enhancing purchasing strategies will be vital to optimizing resource use and improving financial protection across the region. Further work is required to assess the implementation and effectiveness of these policies to achieve UHC goals; particularly in conflict-affected and middle-income countries with reduced fiscal space for health.

Ind-388 Strengthening Health Financing in Complex Humanitarian Contexts: Analysis From Northwest Syria and its Implications for Other Disrupted Contexts

PRESENTER: **Sophie Witter**, Queen Margaret University Edinburgh

AUTHORS: Abdulkarim Ekzayez, Ibrahim Bou-Orm, Fouad Fouad, Sumit Mazumdar

Background

WHO has developed clear norms for strong health financing systems to support progress towards Universal Health Coverage (UHC). These guidelines presuppose relatively stable settings with established governance arrangements. However, the world has seen a growing number of increasingly protracted crises, which have left many countries with disputed authorities in all of parts of their territories. These complex humanitarian crises represent major hurdles against progress towards global commitments of and ensuring equitable, affordable, and sustainable access to essential health services. What does this mean for how health financing systems are configured and do we need to adapt our guidance? In this study, we examine the case study of Northwest Syria, where successive periods of protracted war and forced displacement have led to shifting, fragile, and donor-dependent health systems. Our study aims to contribute to actionable evidence on the optimal use of scarce financial resources to reduce fragmentation, increase resilience, and build sustainability in the context of Northwest Syria and similar areas which lack unified state-led governance.

Research question

What are the challenges and potential opportunities to build resilience in relation to the health financing functions and their governance in Northwest Syria?

Methods

The study took a mixed methods case study approach, using data from (1) a desk review of key reports, agency publications, and relevant databases, (2) key informant interviews and (3) expert meeting(s), including drawing on the expertise of the research group. These were analysed thematically and used to develop causal loop diagrams that capture the complexities of financing in this setting. Findings were then compared with international health financing guidance to probe how fit this guidance is for disputed areas and protracted emergency settings.

Results

We present a diagnostic of financing arrangements in Northwest Syria, using the framework of the WHO Health Financing Progress Matrix (HFPM), highlighting specific financing bottlenecks, especially around coordination across the multiple actors, and propose interventions to support sustainable health financing and system recovery. We also propose areas of adaptation of the framework to make it more suitable to these disrupted settings.

Conclusions and implications

We highlight health financing challenges but also opportunities for system strengthening in northwest Syria. While specific, these challenges reflect features that are commonly found in other disrupted settings, so better understanding of their nature and how to address them is important for moving ahead with UHC globally. Suggested adaptations of the HFPM for complex emergency and disputed settings is also a contribution to the development of this important normative and measurement tool.

Ind-333 Payment Compliance of The Informal Sector Workers in Indonesian National Health Insurance: A Thorough Study on Ability and Willingness To Pay

PRESENTER: **Wan Aisyiah Baros**, BPJS Kesehatan
AUTHOR: Dedy Revelino Siregar

ABSTRACT

Background: Currently the Indonesian National health Insurance (JKN) has covered more than 90% of Indonesia population. Although around 18% of the enrolees were inactive related to the incompliance of their premium payment. The proportion of inactive enrolees were varied among the four types of membership within the three types of class. This situation could impede accessibility to health services and affect the overall health status.

Objective: aims to measure the ability to pay (ATP) and willingness to pay (WTP) between the informal sector workers enrolees (PBPU); and to determine the factors affecting their compliance and commitment to pay JKN premium regularly. In addition, this study will explore the alternative sources of funding to support the informal sector workers enrolees in order to comply the payment of the JKN.

Methodology:The study was a nation-wide survey that covered fifteen districts and 4059 respondents, which examined the ability (ATP) and willingness to pay (WTP) among informal sector workers under the JKN scheme. WTP was examined using bidding game, while ATP was calculated as 5% of disposable income by using household expenditure as a proxy for household income. Logistic regression was used to explore the compliance factor with variables of interest that includes household expenditure, JKN class, regional area, commitment (for compliance), risk aversion, and out of pocket, while for variables of control consist of demographic characteristics, family medical history, utilization, and satisfaction rate.

Result: The ATP were still below the existing premium, except for active enrolees in class three. The WTP of active enrolees were willing to pay 10% higher above the existing premium, while the WTP of inactive enrolees was 50% lower. In the case of catastrophic illness, WTP increased between 1-3%. Compliance to pay the premium was influenced by a number of factors, expenditure on tobacco and alcohol, willingness to pay, risk averse, catastrophic illness, healthcare utilization, size of household member and patient satisfaction. Surprisingly household member with childbearing and employment both have negative influence toward compliance. Other factors that have positive influence were expenditure on food and non-food, literacy on JKN and type of JKN class enrollment. In achieving an effective access, the gap between the existing premium and ATP WTP should be addressed. The limitation of government budget should lead to a finding alternative source of fund to meet the gap of informal sector financial burden.

Keywords: Ability to pay, willingness to pay, informal sector workers, National Health Insurance

Ind-2306 Exploring Political, Economic, and Social Drivers of Primary Health Care Financing in Indonesia: Challenges, Reforms, and Disparities in Fiscal Space

PRESENTER: **Ms. Likke Prawidya Putri**
AUTHORS: Dina Balabanova, Nouria Brikci, Kara Hanson, Adrianus Hendrawan

Background: Primary Health Care (PHC) in Indonesia has been critical for ensuring affordable healthcare access since the establishment of

Puskesmas in the 1960s. With over 20,000 PHC facilities today, PHC serves as the gatekeeper under the National Health Insurance (NHI) scheme. However, limited funding has hindered optimal PHC performance. Decentralized health governance has resulted in substantial variations in health system outcomes, compounded by disparities in resource distribution and fiscal space at the provincial and district levels. While national-to-local funding transfers exist, districts with low fiscal capacity continue to struggle in financing PHC services. This study explores how political, economic, and social factors have influenced PHC financing reforms and identifies challenges and opportunities for improving funding in districts with diverse fiscal capacities.

Method: This study employed qualitative case study method by systematically reviewing literature and regulations on PHC financing in the last 25 years and interviewing national and sub-national stakeholders. Three districts were included as the study locus, representing very low, low, and high fiscal capacity.

Results: Three key reforms took place that could have resulted in changes in PHC financing: the 2001 decentralization, the 2014 NHI, and the post-pandemic health sector transformation. These reforms directly influenced the funding for PHC through mechanisms such as the establishment of special allocation funds, which finance public PHC (Puskesmas) infrastructure development, or operational assistance fund (BOK) that fund promotional and preventative health strategies implemented by *Puskesmas*. Additionally, they indirectly influenced PHC by devolving authority, allowing PHC managers to innovate and increase budget availability. Political factors appeared to be more dominant compared to economic or social aspects in influencing PHC financing. Politically, the central government, despite decentralization, remains pivotal, contributing over 50% of PHC funding through policies and fiscal instruments. The role of transfers from national government played more significant role in those with very low fiscal capacity. Local political dynamics also shape PHC budgeting, with populist agendas like free healthcare and food supplementary program driving temporary funding increases. Advocacy by academics and civil society has led to long-term reforms, such as health operational assistance and national health insurance; yet, not much influence on local budget allocation. At sub-national level, efforts to achieve a good public finance management has led to an expanded Puskesmas' financial authority, leading to better use of PHC funding. From the economic aspect, the district with high fiscal capacity has more resources for health programs, allowing additional benefit package for its population. The presence of local private sector with a specific agenda could have influenced how PHC are financed at the district level.

Conclusion: This study identified the political, economic, and social factors influencing PHC financing in Indonesia. Despite decentralization, central government funding remains crucial, especially in low-fiscal-capacity districts. Key reforms have shaped financing, but disparities in fiscal space and resource allocation persist, challenging equitable healthcare access.

Ind-501 Factors Affecting Institutionalization of Economic Evidence and Cost-Effectiveness Threshold: A Qualitative Analysis of Policy Processes in Thailand

PRESENTER: **Pitsinee Supapol**
AUTHORS: Chittawan Poonsiri, Siobhan Botwright, Yot Teerawattananon, Nitichen Kittiratchakool, Ms. Wanrudee Isaranuwatchai

Background:

Financing health interventions under universal health coverage presents a significant challenge regarding best use of resources. Economic evaluation can identify interventions providing good value for money, with a cost-effectiveness threshold (CET) often used as a reference for system efficiency or willingness to pay. Institutionalization of economic evidence and a CET in decision-making is influenced by various factors unique to each context, particularly with respect to established formal rules and practice. These factors may evolve over time, with rotation of committee members or policymakers' growing knowledge and understanding of economic evidence and CET. While previous studies have examined factors influencing the institutionalization of Health Technology Assessment (HTA), there remains a gap in research specifically addressing the factors affecting the integration of economic evidence and CET, and many countries employing HTA, particularly in low-income settings, still do not fully integrate economic aspects into their decision processes.

Objective:

This study aims to investigate the factors influencing institutionalization of economic evidence and the CET to inform policymaking, and how this may change over time.

Methods:

This study adopts a qualitative process case study approach, as it enables an in-depth exploration of the complex, context-dependent process of institutionalizing economic evidence and the CET in health policy decision-making. Thailand, with a long history of applying economic evidence and CET in the Universal Coverage Benefit Package (UCBP) and the National List of Essential Medicines (NLEM), was chosen as the focus country to provide a rich longitudinal data, where having two institutional contexts as case studies improves generalizability of findings. Meeting minutes from sub-committee, board, and working group meetings from 2008 to 2023 served as the primary data source. Emerging themes and patterns were identified using thematic approach and iteratively tested for replication logic within-case and cross-case analysis. To improve validity, interviews were employed as a secondary data source, providing triangulation with the insights obtained from meeting minutes.

Results:

Preliminary findings from the review of UCBP meeting minutes indicate that, in the early years, the sub-committee, newly introduced to economic evidence and the CET for health intervention assessment, expressed significant concerns regarding the adaptability of these tools to Thailand's context, as well as the accuracy and completeness of data from economic evaluations. While the sub-committee initially appeared reluctant to rely on the CET, the chair played a pivotal role in encouraging its use. Eventually, the use of economic evaluation and CET has

clearly become an increasingly important aspect of Thailand's HTA process, with the sub-committee choosing to defer decisions when cost-effectiveness evidence was not adequately presented.

Conclusion:

These preliminary findings highlight that policymakers' familiarity with and understanding of economic evidence and the CET are important in institutionalizing these tools. The presence of advocates, including policymakers and pioneers in integrating economic evaluation into the HTA process, also strengthened the institutionalization. As a next step, comparing with experience in other settings will help uncover universally applicable factors that support the effective institutionalization of economic evidence and CET in decision-making.

Ind-843 Association of Multimorbidity on Medical Expenditures Among Older Adults With Cognitive Impairment: A Nationally Representative Study in China

PRESENTER: **ye zhang**, Renmin University

Background: Although the negative impact of cognitive impairment on health status and medical expenditures has been discussed previously, an increasing number of geriatric individuals with cognitive impairment are also suffering from multiple chronic diseases. However, there are limited estimates of medical expenditures for older Chinese adults with cognitive impairment and multimorbidity. This study uniquely contributed to the cognitive impairment literature by investigating mean medical expenditures associated with multimorbidity in total and out-of-pocket medical service categories. **Aim:** This study aimed to compare the medical expenditures of older Chinese adults with cognitive impairment, focusing on those with multimorbidity versus no multimorbidity. The study hypothesised that medical expenditures would be higher among those with both cognitive impairment and multimorbidity versus those without multimorbidity. **Methods**: Using data from the nationally representative Chinese Longitudinal Healthy Longevity Survey in 2018, this study included 3,036 participants aged 60 years and above with cognitive impairment. Cognitive impairment was assessed using the Chinese version of the Mini-Mental State Examination (MMSE). The score of MMSE ranged from 0 to 30, with higher scores indicating better cognitive function. Multimorbidity was defined as the presence of two or more chronic conditions. Nonparametric tests and a two-part model were applied to estimate group differences in total annual medical expenditures and the annual out-of-pocket medical expenditure. Three sensitivity analyses were conducted to assess the robustness of the results. **Results:** Descriptive analysis showed that multimorbidity was significantly associated with all personal characteristics ($p< 0.05$) except for the number of children ($p = 0.379$). Participants with multimorbidity had 122.2% greater total medical expenditures ($\beta = 0.80$, $p< 0.05$) and 90.3% greater out-of-pocket expenditures ($\beta = 0.64$, $p< 0.05$) compared with those without multimorbidity. All three sensitivity analysis proved the robustness of the results. Firstly, after excluding observations with 'unable to answer' on any MMSE items, medical expenditures were 134.0% and 99.3% greater in the multimorbidity group than in the no multimorbidity group for total and OOPE, respectively ($\beta = 0.85$, $p< 0.001$; $\beta = 0.69$, $p< 0.001$, respectively). Secondly, when using a stricter MMSE score to identify cognitive impairment, total medical expenditures increased by 154.8% ($\beta = 0.94$, $p< 0.001$), as was the case with OOPE increased by 122.6% ($\beta = 0.80$, $p< 0.001$). Thirdly, after imputing missing data on medical expenditures, total expenditures were 122.6% greater ($\beta = 0.80$, $p< 0.001$), and OOPE were 96.1% higher ($\beta = 0.67$, $p< 0.001$). **Conclusions:** This study found greater medical expenditures among older Chinese adults with cognitive impairment and multimorbidity, which captured the substantial financial burden of multiple chronic conditions in this population. This study highlights the need to design strategies and treatments for better chronic disease management in older population. **Keywords:** Cognitive impairment, Multimorbidity, Medical expenditure, Older adults

Ind-1570 Impacts of DRG Prospective Payment System on the Quality of Healthcare: Evidence From a Quasi-Experimental Analysis in Beijing, China

PRESENTER: **zhen cao**
AUTHORS: Zhongjun Guan, Moning Guo

Background： The DRG prospective payment system（DRG-PPS）is widely used around the world as an effective means of incentivizing healthcare providers to improve efficiency and control costs. However, previous studies have found uncertainty in the impact of DRG-PPS on healthcare quality. Chinese public hospitals derive their income mainly from health insurance funds, so they are vulnerable to the financial incentives created by payment reform. Moreover, high-quality empirical studies are concentrated in high-income countries. with limited evidence available for low- and middle-income countries. **Objective:** Exploring the impact of the DRG-PPS on the quality of healthcare, providing empirical evidence for the improvement of the payment system. **Methods:** Taking advantage of the exogenous shock of implementing the DRG-PPS based on the inpatient case home page and outpatient electronic medical record data of patients with neurological disorders in Beijing, we analyzed the impact of the DRG-PPS on the quality of healthcare by using the difference in difference method. We examined the trend of changes in healthcare quality indicators in the period before the policy implementation by utilizing the event analysis method. Given that the DRG-PPS might differentially affect patients undergoing various diagnosis and treatment methods, it is imperative to delve deeper into the variations in healthcare quality within surgery and internal medicine before and following the policy's implementation. Furthermore, an additional analysis was performed to examine the correlation between the decrease in medical resource consumption during the study and the propensity to admit patients with mild conditions identified. **Results:** DRG-PPS has had a positive impact on the improvement of the quality and efficiency of healthcare services, with a 12.6% decrease in the average hospitalization expenses and a 0.96-day reduction in the average length of stay, while at the same time, it has led to a significant decrease in the hospitalized mortality by 0.31 percentage points and a substantial reduction in the 30-day readmission rate by 3.04 percentage points. However, concurrently, the DRG-PPS has also occasioned a decline in the case-mix index across all disease group categories. Notably, there has been a specific decrease in the percentage of surgical patients within the surgical disease group. This observation partially substantiates the strategic behavior of hospitals, which may be engaging in patient selection following the payment reform. In addition, the DRG-PPS caused an increase in the 30-day post-discharge re-admission rate, and hospitals have a tendency to transfer the cost of healthcare to outpatient clinics. **Conclusion:** DRG-PPS demonstrates substantial effects in restraining cost escalation and enhancing quality. Nevertheless, caution must be exercised to mitigate potential issues such as patient selection bias and upcoding. **Keywords** DRG, prospective payment, Healthcare, Quality, China

Mental Health, Disability, Rehabilitation and the Care of Elderly

MODERATOR: **Matthew Franklin**, University of Sheffield

Ind-74 Stepped, Evidence-Based and Integrated Care for Severe Mental Illness: A Health Economic Evaluation of the RECOVER Trial for People with SMI

PRESENTER: **Léon Gerardo Kreis**, "University Medical Center Hamburg-Eppendorf, Department of Health Economics and Health Services Research"
AUTHORS: Anja Rohenkohl, Holger Schulz, Daniel Lüdecke, Hans-Helmut König, Christian Brettschneider, Jürgen Gallinat, Anne Karow, Antonia Zapf, Martin Lambert

Background: The goal of the stepped, evidence-based and integrated RECOVER care service model is to improve quality and efficiency of care for people with mental disorders by optimized cross-sector coordination, as well as systematic and evidence-based additions to the care system. One approach is to divide care services by illness severity, by which the RECOVER care model should allocate healthcare services adequately and efficiently, in order to achieve cost savings at care of equal or higher quality. This work focuses on people with a severe mental illness (SMI), representing levels 3 and 4 in the RECOVER model.

An SMI can cause serious functional impairments and significantly restrict important daily activities. The stepped interventions in RECOVER consisted of overarching programs (such as social work, supported employment, peer support) and additionally included case management, (group) psychotherapy, and pharmacotherapy (level 3), or Assertive Community Treatment including psychotherapy and pharmacotherapy (level 4). This work represents the health economic evaluation of the RECOVER care service model for persons with an SMI from a societal perspective.

Methods: Direct and indirect costs were determined based on the information provided by the trial participants on the uptake of healthcare services and productivity losses. Using this data, we compared costs between RECOVER and usual care during the 12-months follow-up, and assessed cost-effectiveness of RECOVER from a societal perspective.

Cost differences between RECOVER and usual care were estimated using GLM regressions with a log-link function, whereby a Poisson distribution was assumed. To analyze the cost-effectiveness, quality-adjusted life years (QALYs) were determined using the EQ-5D-5L. QALY differences between RECOVER and usual care were estimated using linear regressions. The incremental cost-effectiveness-ratio was calculated and uncertainty was assessed by estimating cost-effectiveness acceptability curves with net monetary benefit regressions. Scenario analyses considering a healthcare payer perspective and different patient-reported outcome measures were conducted.

Results: 506 patients with SMI (RECOVER: 252, usual care: 254) were included. Total societal costs over the 12-months follow-up period in RECOVER were significantly reduced compared to usual care (23,828€ vs. 30,443€, $p<0.001$). Cost savings were mainly attributable to lower inpatient costs (7,400€ vs. 13,782€, $p<0.001$), while costs for outpatient and psychotherapy services were significantly higher in the RECOVER model compared to usual care (4,650€ vs. 3,057€, $p<0.001$).

The cost-effectiveness analysis showed that the RECOVER interventions were associated with 0.02 QALY (n.s.) more than usual care, resulting in RECOVER dominating usual care. For all assumed willingness-to-pay thresholds between €0/QALY and €250,000/QALY, RECOVER yielded cost-effectiveness probabilities greater than 99%. Scenario analyses showed robustness of results.

Conclusion: The presented results of this study show considerable potential for increasing efficiency in the care of people with SMI, suggesting that the RECOVER service care model could be a cost-saving extension to usual care. These savings arise primarily from a shift in utilization from the inpatient to the outpatient sector, whereby the quality of life of those affected does not deteriorate.

Ind-792 Evaluating the Economic Costs of Common Mental Health Disorders in Ghana: A Case Study of Patients and Their Caregivers From two District Hospitals.

PRESENTER: **Mansoora Baidoo**
AUTHORS: Prince Boakye Frimpong, Jacob Novignon

Abstract

Introduction

About 2.3 million people in Ghana are estimated to be living with mental disorders (MDs), yet only 2% of them receive allopathic psychiatric treatment. The economic burden of MDs can be substantial given the reduced functionality associated with such conditions. Regrettably, these potentially extensive and long-lasting economic burdens are frequently disregarded. This study seeks to estimate the economic and financial costs of common MDs to patients and their main caregivers in two selected district hospitals in Ghana.

Methods

This study used a cost-of-illness approach to measure the economic and financial costs of MDs. Cross-sectional data was collected from 88

patients diagnosed with common MDs at the Ejisu and Effiduase district hospitals and their caregivers. Economic costs were divided into direct and indirect costs. Direct costs were further divided into medical and non-medical costs. Medical costs covered expenses on drugs, injections, diagnostic/laboratory tests, consultations, psychotherapy/counselling, and admission. Non-medical costs included the cost of food, transportation, accommodation, rituals/prayers, and miscellaneous. Indirect costs were estimated as the value of MD-related productive time losses for patients and their caregivers, using the human capital approach. These were calculated by multiplying the number of workdays a respondent is absent from work due to the condition by his/her reported wage rate, if employed, or by the national daily minimum wage, if unemployed. Additionally, intangible costs associated with MDs were assessed using a Likert's scale to rate the extent of the non-quantifiable welfare losses endured by patients and their caregivers under five themes: (i) stigmatisation, (ii) emotional distress, (iii) functional disability, (iv) loss of leisure, and (v) social relationship.

Results

The average annual cost of MDs in Ghana was valued at US$841.04 (GHS 9,259.85) per patient, with direct and indirect costs constituting US$323.09 (38.42%) and US$517.95 (61.58%), respectively. The highest direct cost components were drugs and injections with an average annual cost of US$141.85 (43.91%), followed by admission (22.71%), and transportation costs (13.43%). The value of patients' productive time lost due to unemployment was the greatest indirect cost component (38.08%), followed by the value of workdays lost to caregiving activities (17.54%). The average annual productive time lost by employed patients and caregivers was 41 and 32 workdays, respectively. The highest rated intangible cost for caregivers was emotional distress, while patients mostly reported stigmatisation and emotional distress as their key intangible costs.

Conclusion

These findings suggest that MDs have a high economic burden, with indirect costs accounting for a larger share of the total economic cost. They also highlight the need for interventions to lessen the burden on patients and their caregivers. These include improving and expanding mental healthcare resources, financial protection strategies to remove barriers to care, as well as raising awareness through anti-discrimination campaigns in Ghana.

Ind-614 Modelling Major Depressive Disorder Using the Validated SiMMDep Platform: Using Economic Analysis to Develop Clinical Pathways

PRESENTER: **Prof. Stirling Bryan**, University of British Columbia
AUTHORS: Shahzad Ghanbarian, Louisa Edwards

Background: Major depressive disorder (MDD) is a prevalent and recurrent condition associated with high levels of morbidity and substantial healthcare and societal costs. As a tool to support rapid evaluation of new treatments and interventions for MDD, we developed the Simulation Model of Major Depression (SiMMDep) platform, a validated individual-level simulation model of MDD care pathways in Canada.

Pharmacological therapy is often first-line treatment in MDD. However, most patients require multiple trials of medication to find one that is both effective and does not cause intolerable side effects. Pharmacogenomic (PGx) testing is a promising intervention that uses targeted genomic information to guide prescribing decisions, potentially reducing this trial-and-error process, improving patient outcomes and reducing care delivery costs.

Existing evidence points to the cost-effectiveness of PGx in the context of MDD, but the positioning of testing in the clinical pathway (e.g., testing at diagnosis or after "failing" one or more medications) has not been investigated. Our research addresses this question: For patients with MDD, where in the care pathway should PGx testing be positioned to maximize efficiency? This paper provides a rare example of model-based economic analysis to support the development of clinical care pathways, specifically focusing on the optimal positioning of a new test within the MDD treatment pathway.

Methods: We used the SiMMDep platform to conduct a probabilistic analysis assessing the effectiveness and cost-effectiveness of PGx testing for patients with a new moderate or severe MDD episode. This analysis was conducted from the public payer's perspective over a 20-year horizon. The model included a cohort (N = 194,149; mean age = 46 years) of both newly diagnosed and prevalent MDD patients. All clinical pathways modelled included use of PGx testing but varied in when testing was considered: 1) before first antidepressant, or 2) after "failing" one medication. The analysis estimated incremental costs, life-years (LYs), and quality-adjusted life-years (QALYs) for a representative MDD cohort in British Columbia (BC), Canada.

Results: We conducted a probabilistic analysis across selected variables, demonstrating that the pre-prescription strategy was cost-saving compared to the strategy of prescribing after "failing" one medication over a 20-year horizon. The pre-prescription approach resulted in an average incremental cost of $7.5 million, yielding 644 additional QALYs and 76 LYs.

Significant cost savings were identified for public healthcare payers, with $9.9 million saved on managing refractory MDD and $1.1 million saved on psychotherapy costs. These savings were driven by earlier access to more effective pharmacotherapy, which reduced reliance on more resource-intensive treatment options.

Conclusions: By re-using a robust and validated model, we were able rapidly to generate high-quality, evidence-based insights that support development of care delivery for patients with MDD in Canada. By providing PGx testing prior to initiating pharmacotherapy, we showed major cost-savings to the BC health system and improved patient benefits compared to waiting for one unsuccessful antidepressant trial. Exploring the broader implications of PGx testing using SiMMDep enables policymakers to evaluate its impact under different implementation strategies.

Ind-479 Effects of a Coordinated Post-Stroke Care Program (StroCare) on Healthcare Costs of Stroke Patients at 12-Months Follow-up

PRESENTER: **Andreas Beisel**

AUTHORS: Hans-Helmut König, Martin Härter, Lena Seibel, Stefan Boskamp, Michael Rosenkranz, Holger Schmidt, Götz Thomalla, Judith Dams

Introduction: Stroke is a leading cause of death and disability and imposes a high economic burden on public healthcare systems, largely due to expensive inpatient stays and post-stroke care. Although timely rehabilitation and interdisciplinary post-stroke care are essential for optimal recovery and cost reduction, many stroke patients in Germany face rehabilitation delays and barriers between healthcare sectors. The StroCare intervention provides a coordinated outpatient program to control risk factors after stroke. Moreover, it includes case managers and an electronic rehabilitation portal to improve interdisciplinary communication. The aim of this study was to evaluate whether StroCare reduces healthcare costs from the payer perspective.

Methods: Patients insured with the BARMER statutory health insurance were recruited from 01/2020 to 09/2022 in a multicenter trial in Germany. To assess health care utilization and costs, health insurance claims data were used to compare the intervention group with a usual care control group. Additionally, a historical control group was compiled from claims data. Inclusion was mainly based on stroke diagnosis and the absence of pre-existing dementia or disability. Adopting a German healthcare payer perspective, outcomes were inpatient hospital costs, care costs and total healthcare costs within a 12-month follow-up period after the initial hospitalization. Sensitivity analyses included winsorization and calculation of costs per day lived to account for cost outliers and mortality. As randomization was not possible, entropy balancing was applied to account for imbalances in sociodemographic and clinical parameters between groups. Weighted gamma and two-part models were applied. Significance was set at $p < 0.025$ with Bonferroni corrections.

Results: Compared to the usual care control group (n = 208), the intervention group (n = 186) caused 1799€ lower care costs (p = 0.006). Similarly, the intervention group caused 1897€ lower care costs than the historical control group (n = 2010; p = 0.000). No significant differences were observed for inpatient hospital costs and total healthcare costs. After calculating the costs per day lived, the difference between the intervention and usual care control group in terms of care costs was no longer significant.

Conclusion: Evidence suggests that StroCare was associated with lower care costs within 12 months after the initial stroke, although these results may be influenced by mortality. However, the long-term effects of StroCare beyond 12 months are not known yet and should be evaluated when data become available.

Ind-1216 Cost-Effectiveness Analysis of an Enhanced Recovery After Surgery (ERAS) Process After an Elective Minimally Invasive Heart Valve Surgery

PRESENTER: **Rebecca Thiel**

AUTHORS: Evaldas Girdauskas, Hans-Helmut König, Christian Brettschneider

Abstract

BACKGROUND:

Enhanced Recovery After Surgery (ERAS) programs are a multidisciplinary approach with the objective of optimizing the preoperative, intraoperative and postoperative recovery period. The implementation of ERAS demonstrated the ability to reduce hospital costs while concurrently improving health outcomes across various surgical specialties. Evaluations of ERAS in minimally invasive heart valve surgery are scarce. This study provides a cost-effectiveness analysis from a societal perspective.

METHODS:

This study is part of a bicentric cluster-randomized controlled trial, *INCREASE*, which was conducted in Germany. All participants underwent elective minimally invasive heart valve surgery, involving either the mitral or the aortic valve. The intervention group received the ERAS program, which included early extubation, intensive postoperative mobilization, and discharge approximately on the fifth postoperative day with rehabilitation scheduled thereafter. The control group received the standard of care.

Costs were assessed by hospital charges, additional costs associated with the intervention, health care utilization within one year postoperatively and the indirect costs resulting from productivity losses. The effect was analyzed in terms of quality-adjusted life years (QALYs). Both, costs and effects were valued using specific German value sets. An incremental cost-effectiveness ratio (ICER) and a cost-effectiveness acceptability curve (CEAC) were calculated by estimating a series of net-monetary benefit regressions.

RESULTS:

A total of 190 participants were recruited and analyzed, with 97 assigned to the control group and 93 to the intervention group. The intervention group exhibited higher costs (115€ (SE: 3237)) and additional effects (+ 0.017 QALY (SE: 0.02)) compared to the control group, these differences were not statistically significant. ERAS resulted in an ICER of 6,855 €/QALY. The intervention group had significant lower costs during the initial hospitalization (-2,937€ (SE:1,417) p-value:0.04). The CEAC indicated a 72% probability of cost-effectiveness at the 150,000€/QALY willingness-to-pay threshold.

DISCUSSION/ CONCLUSION

Although the ERAS program resulted in reduced costs for the initial surgery and hospitalization in comparison to the standard of care, the CEAC revealed that the probability of cost-effectiveness of ERAS-based elective minimal invasive heart valve surgery is moderate. Additional probabilistic sensitivity analyses demonstrated that the results were consistent across subgroups. Nevertheless, ERAS improved the quality of life while reducing hospital costs and length of hospitalization after valve surgery. The evidence is constrained by a small sample size, which was mostly male (74%). Therefore, further research is needed.

Ind-1401 An Economic Evaluation of Bimodal Cochlear Implantations Compared to Unilateral and Bilateral Cochlear Implantation among Adults in Australia

PRESENTER: **Mohammad Nure Alam**

AUTHORS: Bamini Gopinath, Yvonne Tran, Mutsa Mutowo, Kompal Sinha

Objective: Bimodal stimulation (BMS), combining a cochlear implant (CI) in one ear and a hearing aid (HA) in the contralateral ear, is increasingly used in adults with bilateral severe to profound sensorineural hearing loss (SNHL). Existing evaluations are limited by a lack of primary, patient-level utility data. This study tackles this knowledge gap by assessing the cost-effectiveness of bimodal stimulation versus unilateral cochlear implant and sequential bilateral cochlear implants using primary health utility data.

Methods: A Markov state-transition model was used to estimate costs and quality-adjusted life years (QALYs) over a lifetime horizon from the Australian healthcare system perspective. Utilities were assessed using the Health Utilities Index (HUI) Mark III. Resource utilization was based on expert-informed clinical pathways and costs sourced from the Medical Benefits Schedule (MBS) and Australian Refined Diagnosis Related Groups (AR-DRG) schedules.

Results: Total lifetime costs were $59,659 for unilateral cochlear implant, $64,691 for bimodal stimulation, and $116,684 for sequential bilateral cochlear implants. QALYs were 4.48 (unilateral cochlear implant), 4.63 (bimodal stimulation), and 4.72 (sequential bilateral cochlear implants). Compared with unilateral cochlear implant, bimodal stimulation yielded an incremental cost of $5,032 and a QALY gain of 0.15, resulting in an ICER of $34,753 per QALY. Bimodal stimulation was cost-saving versus unilateral cochlear implant. Scenario and sensitivity analyses confirmed the robustness of the findings.

Conclusion: Bimodal stimulation is a cost-effective strategy for adults with bilateral severe to profound sensorineural hearing loss who received hearing interventions and had residual hearing in the non-surgical ear.

Ind-2045 How Much Does It Cost to Care for Older Persons in Hong Kong? Estimation of Informal Caregivers' Time Costs, Out-of-Pocket Expenses, and Income Loss

PRESENTER: **Xingnan Yi**

AUTHORS: Xuechen Xiong, Vivian Lou, Jianchao Quan

Background With global aging accelerating, informal caregiving has become essential in meeting long-term care needs for older adults. In Hong Kong, the proportion of individuals aged 65 and above increased from 13.3% in 2011 to 19.6% in 2021, placing significant pressure on formal healthcare systems. Informal caregiving, provided by family members or friends without payments, addresses these gaps but imposes substantial burdens on caregivers. While previous research has often focused on psychological impacts on caregivers, financial and time costs remain underexplored. This study estimates both the direct and indirect costs of informal caregiving for older adults in Hong Kong, offering insights relevant to resource allocation in aging societies.

Methods We conducted a survey of 2,284 informal caregivers between December 2023 and June 2024. Eligible participants were Hong Kong residents providing at least six hours of care per week to a family member aged 60 or above. Of respondents, 61% were female, and 26% provided more than 44 hours of care weekly. Costs were reported across three categories: (1) time costs (opportunity costs of foregone activities); (2) out-of-pocket (OOP) expenses; and (3) income loss due to productivity impairment. Time costs were calculated via the opportunity cost method. Caregivers redistributed their weekly caregiving hours into paid work, unpaid work, and leisure (excluding sleep). These proportions were applied to their total caregiving hours to estimate forgone time. Paid work time was valued using median wage by gender and age. For those not formally employed, Hong Kong's statutory minimum wage (HKD 42/hour) was used. Time lost to unpaid work and leisure was valued at 35% of the assigned wage rate. OOP included spending on medical items, daily supplies, direct financial transfers to care recipients, and caregivers' own healthcare costs due to caregiving-related physical or psychological strain. Income loss was estimated by assessing productivity impairment. Caregivers rated how caregiving affected their work on a 0-10 scale, converted into a proportional work loss. This proportion was multiplied by weekly work hours and corresponding wage to estimate annual lost income.

Results The total annual cost of informal caregiving in Hong Kong is estimated at USD 4.72 billion (1.2% of 2024 GDP). Time costs comprised 43.8% of the total (USD 6,447 per caregiver/year), with the largest share from paid work (USD 3,190), followed by leisure (USD 3,053) and unpaid work (USD 204). On average, caregivers reported they would reallocate 62.9% of caregiving time to leisure, 32.9% to paid work, and 4.2% to unpaid work if caregiving duties were removed. OOP expenses made up 39.5% of total cost (USD 5,810 per caregiver/year). Among caregivers, 68% incurred caregiving-related spending (USD 3,614), while 36% reported health-related expenses due to caregiving (USD 2,196). Productivity impairment affected 43% of caregivers, leading to USD 2,454 per caregiver/year in lost income (16.7% of total cost).

Conclusions Informal caregiving imposes a substantial economic burden, primarily through unpaid time. These hidden costs warrant recognition in policy. Financial subsidies, workplace support, and accessible respite services could help ease caregiver strain. This study's comprehensive costing framework supports evidence-based decision-making in Hong Kong and other aging societies.

Ind-2714 Cost-Effectiveness of Hearing Aids in Supporting Cognitive Function in Older Adults at Risk of Dementia: An Economic Evaluation of The HearCog Trial

PRESENTER: **Marshall Makate**, Curtin University

Background and Motivation

Hearing loss is a major global health issue, currently the second leading cause of disability worldwide, affecting an estimated 1.5 billion individuals—90% of whom experience age-related hearing loss. The Lancet Commission on Dementia Prevention identifies hearing loss as a key modifiable risk factor, contributing to 8% of preventable dementia cases. Modelling studies suggest that delaying dementia onset by just two years could reduce its prevalence by 13%, significantly easing associated health and economic burdens. While epidemiological evidence has established an association between hearing loss and cognitive decline, trial-based evidence on the cost-effectiveness of hearing interventions remains limited. This study evaluates the cost-effectiveness of hearing aids in improving health-related quality of life (HRQoL) and reducing healthcare resource use, based on a randomised controlled trial (RCT) conducted in Western Australia involving older adults with mild cognitive impairment and hearing loss. The analysis is conducted from a health system perspective.

Data and Methods

A two-arm, parallel-group RCT was conducted with 180 participants aged 70 years and older, all with audiometrically confirmed hearing loss and mild cognitive impairment. Participants were randomised to receive either immediate hearing aid fitting (intervention) or delayed intervention after 12 months (control). HRQoL was assessed using the Short Form-12 (SF-12), with utility values derived via the SF-6D to estimate quality-adjusted life years (QALYs). Healthcare utilisation was captured via a validated patient-reported resource use questionnaire covering hospital admissions, medical consultations, medication use, procedures, and related costs. Changes in QALYs and healthcare use over time were analysed using multilevel mixed-effects models, accounting for within- and between-group variation.

Preliminary Results

At 12 months, participants in the intervention group demonstrated a mean QALY of 0.799 (95% CI: 0.780–0.819), up from a six-month baseline of 0.397 (95% CI: 0.388–0.407). In comparison, the control group (not yet treated) reported a 12-month mean QALY of 0.832 (95% CI: 0.815–0.850), up from 0.415 (95% CI: 0.406–0.423) at six months. These findings reflect the stepped-wedge design of the trial, where the control group had not yet received the intervention. Preliminary resource use data indicate that the intervention group reported fewer healthcare encounters related to cognitive and mental health, suggesting a potential reduction in health service demand.

Conclusion

Early findings suggest that hearing aid use may improve health-related quality of life and reduce healthcare utilisation among older adults with mild cognitive impairment. Preliminary cost-utility analysis supports the potential for hearing aids to form part of effective dementia prevention strategies. Further analysis will provide a more definitive assessment of cost-effectiveness from a health system perspective.

Ind-2062 A Global Systematic Review and Critique of Economic Evaluation Methods for Accessing Quality Post-Injury Care for Injured Persons

PRESENTER: **Francis Kwame Salman**

AUTHORS: Lungiswa Nkonki, Laura Bojke, Kathryn Chu, Janet Ncube, Justine Davies

Introduction Injuries are leading cause of mortality and rank among the top ten causes of Disability-Adjusted Life Years globally, particularly affecting adolescents aged 10–24 years. The associated economic losses are also significant, with estimates ranging from $245-261 billion in low to middle-income countries alone. Economic evaluations of injury care interventions can help policymakers make informed decisions on the most cost-effective interventions that reduce mortality, morbidity, and the associated costs and economic losses. **Research question and aim** Does the existing evidence of injury care meet healthcare decision-making requirements? We aim to identify and provide a narrative summary of the methods used in economic evaluations of injury care and assess whether the current evidence meets the needs of decision markers. **Methods** The systematic review was conducted and reported following the PRISMA guidelines, 2020. The protocol is registered with PROSPERO (CRD42022351978) and has received ethics exemption from the Stellenbosch University's Health Research Ethics Committee (X22/06/016). We searched the NHS EED, Cochrane, Paediatric Economic Evaluation Database, PubMed, the Cost-Effectiveness Analysis Registry and Scopus for full economic evaluation studies that met our inclusion criteria. We assessed whether the included studies were full economic evaluations that considered all available effectiveness evidence, estimated both costs and effects for various alternative interventions, and incorporate an appropriate time horizon. **Results** Our search strategy yielded 16 249 unique records that were independently screened. A total of 358 studies were assessed for eligibility through full text review and 259 studies were included in the systematic review. Most of the studies (92%) were conducted in high income countries and almost exclusively focused on receiving definitive care (93% vs 1% reaching care and 6% receiving long term rehabilitative care). We also found that only half of the included studies (51%) met the full set of criteria evaluated. Of the studies that fell short, 34% did not appropriately synthesize all available evidence, 2% failed to consider costs and outcomes over an appropriate time horizon and 14% of the studies failed to both synthesize effectiveness evidence and consider costs and outcomes over an appropriate time horizon. We also found that studies undertaken in low- and middle income countries were far less likely to meet the full criteria (75% did not meet the full criteria compared to 48% in high income countries). **Conclusion** Our review showed that half of the existing economic evidence on injury care falls short of the requirements needed to effectively inform policy and practice. Inadequate effectiveness evidence synthesis and inappropriate time horizons are the most common limitations. We believe that improving the methodological rigor of economic evaluations of injury care is essential to ensure that injury care is not only clinically effective but also offers good value for money - this is particularly the case for low- and middle-income countries and underrepresented phases of the injury care pathway.

Economic and Health Impact of Health Policies

MODERATOR: **Eva Pascoal**,

Ind-217 Uncover the Role of Early HTA in the Healthcare Innovation Ecosystem

PRESENTER: **Qi Gao**
AUTHORS: Yot Teerawattananon, Alec Morton, Yi Wang

Background

Early health technology assessment (eHTA) provides critical insights through comprehensive health and economic evaluations, informing development and investment strategies for innovative healthcare solutions. Despite positive qualitative feedback from stakeholders, empirical quantification of its long-term benefits and the mechanisms by which these benefits emerge is limited. This study addresses this gap by using mathematical modelling to evaluate the value of eHTA within healthcare innovation ecosystems.

Objectives

This work aims to (1) quantify the benefits of eHTA compared to its absence, (2) elucidate how eHTA impacts stakeholder interactions and decisions, and (3) evaluate its effects on ecosystem efficiency and societal welfare.

Methods

We developed an evolutionary game model based on the innovation ecosystem framework, involving three key stakeholders: healthcare payers, innovation funders, and innovators. These players make strategic decisions regarding further development of healthcare innovations, with two scenarios tested—one with eHTA information and one without. Healthcare payers decide whether to provide monetary incentives or policy benefit to funders; funders decide whether to invest in the technology; and innovators decide whether to continue or quit further development, with payoffs determined by the technology's health and commercial potential. We identified the evolutionary stable strategy (ESS) for each player under different scenarios. Numerical simulations were conducted to illustrate how eHTA affects stakeholders' decisions and ecosystem efficiency over time.

Results

Under the scenario where eHTA is absent, the game outcomes vary depending on the technology's value proposition. When commercial value is high, investment and development proceed consistently, while healthcare payers only provide incentives when health value is also high. When the commercial value of the product is low, all players choose not to proceed: healthcare payers withhold incentives, funders withdraw investment consideration, and innovators quit further development, regardless of health value. Economic value drives product development more strongly than health value, making innovations with high public health benefits but low commercial viability less likely to proceed. Although the involvement of eHTA does not alter equilibrium outcomes, it accelerates the convergence to stable strategies, enhancing ecosystem efficiency when equilibrium aligns with social optimality. The impact of eHTA on ecosystem efficiency increases when implemented in earlier R&D stages. However, when equilibrium diverges from social optimum, strategic disclosure of eHTA information becomes crucial for welfare enhancement. From a social welfare perspective, eHTA mitigates welfare loss through optimization of innovators' R&D strategies and process improvements for all players.

Conclusion

Integrating eHTA into product development cycle can benefit both enterprise growth and social development. This study underscores the need for frameworks that optimize eHTA timing and deployment, along with policies to incentivize health-oriented innovation. Further work is needed to explore stochastic elements and parameter uncertainty to refine these insights.

Ind-1915 Indonesia Health Systems Transformation: Impact on Health Equity and Way Forward

PRESENTER: **Tiara Marthias**, Universitas Gadjah Mada
AUTHORS: Sensa Gudya, Ms. Likke Prawidya Putri

While Indonesia is embarking on health systems transformation, there is a need to assess how these changes translate into more equitable access to quality health services, particularly at the primary care level and subsequently, referral services that are currently inequitably utilised only by the more privileged segments of the population. These include people living in urban areas, large cities with adequate access to secondary and tertiary health facilities, those with economic and social capital to utilise quality health services.

This research provides an overview of Indonesia's recent health system transformation, with a focus on the implementation of universal health coverage (UHC) through the **Jaminan Kesehatan Nasional (JKN)** initiative. Utilizing data from multi-year national surveys and claims data, this study evaluates progress toward equitable access to primary health services across the country.

A **difference-in-differences (DiD)** approach is applied to assess disparities in health service utilization before and after the introduction of

JKN, disaggregated by socioeconomic, geographic, and demographic factors. Additionally, **concentration indices** are used to measure and visualize the distribution of health care access, highlighting potential inequities across income groups, geographical areas, types of JKN membership, and other vulnerable population groups.

The findings reveal progress toward the attainment of UHC in Indonesia, with notable increases in primary and secondary care utilization among certain population groups. However, persistent inequities remain, disproportionately affecting rural populations, low-income families, and marginalized groups. Structural barriers, such as geographic inaccessibility, insufficient health workforce distribution, and administrative complexities within the JKN scheme, exacerbate these inequities.

Policy recommendations include the redesign of capitation-based payments to incentivize providers in underserved areas, investment in primary healthcare infrastructure, and targeted subsidies for the poorest households. Emphasis is also placed on addressing inefficiencies in service delivery to optimize resource use and improve health outcomes.

This study contributes to the growing body of evidence on the health equity impacts of UHC reforms in low- and middle-income countries, with insights from this research hoped to inform equitable health policy development in Indonesia and beyond.

Ind-2313 Macroeconomic Impacts of Sugar-Sweetened Beverage Taxation in Brazil: A Computable General Equilibrium Model Analysis

PRESENTER: **Larissa Barbosa Cardoso**, UNIVERSIDADE FEDERAL DE GOIAS
AUTHORS: Auberth Verson, Maria Victória Garcia Rosa, Kênia Barreiro de Souza, Flaviane Souza Santiago

Background: The consumption of sugar-sweetened beverages (SSBs) is on the rise globally, particularly in developing countries. While the health benefits of SSB taxation are well-documented, the macroeconomic implications of such policies warrant further exploration. Concerns over potential negative economic impacts, such as reduced production and employment, are often raised as objections. Existing studies frequently provide only partial analyses or overlook substitution effects in the economy. **Objectives**: This study aims to assess the economy-wide impacts of SSB taxation in Brazil over the short and long term, using a modeling approach. **Methods**: A national dynamic Computable General Equilibrium (CGE) model was employed, calibrated for the Brazilian economy using the 2015 input-output matrix from the Brazilian Institute of Geography and Statistics (IBGE). The analysis covered four taxation scenarios applied to the SSB sector for the period 2023–2032: Scenario 1 (SC1): Increase of 10 percentage points (p.p.) in the taxation of the sector from 2023; Scenario 2 (SC2): Increase of 20 p.p. in the taxation of the sector from 2023; Scenario 3 (SC3): Increase of 30 p.p. in the taxation of the sector from 2023; and Scenario 4 (SC4): Gradual increase from 10 to 30 p.p. in the taxation of the sector between the years 2023 and 2025. Each scenario was simulated under two assumptions: (i) no changes in government spending, and (ii) increased government spending in the Public Health sector, funded entirely by the revenue generated from SSB taxation. **Results**: With no changes in government spending, SSB prices increased across all scenarios (ranging from 7.61% in SC1 and 23.11% in SC3, respectively,), leading to a decline in household SSB consumption (from -3,74% in 2025 to -4,20% in 2032). The SSB sector experienced a decrease in economic activity, with reductions in production (-2.08% in SC1) and employment level (-4,32% in SC1). Negative macroeconomic effects were observed in the short term, including declines in employment (-0,08%), and GDP (-0,06%) in SC1. However, these effects were mitigated over time, with employment returning to positive levels by the end of the simulation period. When tax revenue was reinvested in the Public Health sector, the negative macroeconomic impacts were largely reversed, with minimal changes to the intended reductions in SSB consumption. Furthermore, the gradual implementation of tax increases (SC4) showed slightly less disruptive effects on economic indicators compared to immediate tax hikes, making it a potentially more favorable approach for minimizing short-term economic disruptions. **Conclusion:** The findings demonstrate the effectiveness of SSB taxation in achieving its primary goal of reducing consumption while highlighting manageable economic impacts. Reinvestment of tax revenues into public spending plays a key role in mitigating short-term macroeconomic drawbacks. A gradual tax increase strategy may offer additional advantages by balancing public health goals with economic stability.

Ind-2532 Evaluating the Impact of Health Workforce on Mortality : A Panel Data Analysis across Income Groups

PRESENTER: **Xinpeng Xu**
AUTHORS: Bangaman Akani, Ziwei He, Owen Fei, Yanfang Su, Novil Wijesekara, Wu Zeng, Huihui Wang

Abstract

Background: Reducing maternal mortality rates (MMR), under-five mortality rates (U5MR), and infant mortality rates (IMR) is pivotal for global health initiatives, notably the Sustainable Development Goals (SDGs). Investment in human resources for health (HRH) plays a crucial role in improving health outcomes. Despite previous studies exploring the impact of HRH on mortality rates, the potential for bias in prior cross-sectional analyses has been a concern. This study leverages panel data to reassess and explore potential heterogeneity in the relationship between HRH and mortality rates. **Methods:** We utilized panel data from 2013 and 2018 comprised of mortality rate outcomes, HRH density indicators, and control variables. Data were sourced from World Development Indicators and National Health Workforce Accounts. We applied fixed- and random-effect linear models with log transforms to examine impacts globally and by country income groups. **Findings:** Medical doctor (MD) density and Nurse density had varied impacts on mortality measures. For MMR, MD density and the MD/Nurse ratio had significant respective elasticities of -0.098 (P=0.016) and 0.075 (P=0.003) globally. Lower-middle income countries (LMIC) displayed the strongest impact, wherein if the MD/nurse ratio increased 50% the MMR would lower by 5.5%. For IMR, HRH measures were not statistically impactful, except for the MD/Nurse ratio in upper-middle income countries (UMIC), with an elasticity of 0.037 (**P=0.026**). For U5MR, total HRH density had significant impact in both LIC and LMIC, with MD density and the MD/Nurse ratio impactful in LIC and Nurse density impactful in LMIC. HIC data suggested an over-emphasis on MD vs. Nurse density. **Interpretation:** These findings underscore differentiated roles of MDs and nurses in addressing mortality, and imply context-specific strategies for investing in HRH. Investing in MDs would reduce

global MMR, with the largest gains in LMICs, and reduce U5MR in LICs. Investing in nurses could reduce IMR in UMICs and reduce U5MR in HICs.

Keywords: Human resources for health; Maternal mortality; Under-five mortality; Infant mortality; Panel data analysis.

Ind-2767 Income-Related Inequalities in ACSC Hospitalizations in Canada: Results from 2005-2019 Surveys linked with Hospitalization and Tax Data

PRESENTER: **M. Karen Campbell**, Western University
AUTHORS: Sisira Sarma, Nazire Begen

Background: Hospitalization due to ambulatory care sensitive conditions (ACSCs) represents inadequate access to primary healthcare, since effective management of chronic conditions in primary care settings prevents such hospitalizations. The objective of this study is to investigate socioeconomic related inequalities in ACSC hospitalizations in Canada's healthcare system. Although income-based disparities in healthcare access are documented in the literature, the degree of inequality and specific factors contributing to inequalities in ACSC hospitalizations remain unclear. To address this, we quantified income-related inequality in ACSC hospitalizations and employed the recentered influence function (RIF) decomposition approach. **Methods:** This study uses data from the Canadian Community Health Surveys 2005-2019 linked with the hospital Discharge Abstract Database and the T1 Family File (tax file) from nine Canadian provinces. We quantified income-related inequality in ACSC hospitalization using the Erreyger's Concentration Index (ECI) and RIF–Ordinary Least Squares (RIF-OLS) estimator to examine ACSC hospitalizations by demographic and socioeconomic subgroups. We also used Blinder-Oaxaca-RIF (BO-RIF)-regression to decompose group-specific differences in ACSC hospitalizations by sex, income, rurality, and age group. **Results:** The ECI results revealed persistent disparities in ACSC hospitalization over the 14-year study period, with small variations over time. The estimated ECI values range from −0.004 to −0.006 ($p < 0.01$). Our results consistently show that lower-income groups experience higher ACSC hospitalizations. The stratified analysis revealed that disparities are more pronounced among women, older adults, rural residents, and low-income individuals. For example, in 2019, older adults (66-74) had a higher ECI for hospitalizations (−0.0095, $p < 0.1$) than younger adults (≤65) (−0.0035, $p < 0.01$). Individuals from low-income households had higher disparities in ACSC hospitalizations (ECI: 0.0072, $p < 0.05$) compared to non-low-income households (−0.0048, $p < 0.01$). The RIF-OLS decomposition analysis highlights several socioeconomic factors contributing to ACSC hospitalizations. For example, age, immigrant status, employment status, chronic conditions (≥2), lack of a primary care provider, and rurality are important factors. The BO-RIF-regression decomposition in 2019 for ECI between age groups (18-65 vs. 66-74) showed a significant difference of −0.0111 ($p < 0.01$), driven mainly by an explained effect of −0.0092 ($p<0.01$). For rural versus urban areas, the gap was 0.0055 ($p<0.05$), with an unexplained effect of 0.0057 ($p<0.05$). The most considerable disparity was observed between the low- and high-income groups, marked by a gap of −0.0206 ($p<0.01$), driven by both an explained effect of −0.0981 ($p<0.05$) and an unexplained effect of 0.0775 ($p<0.1$). **Conclusions:** Our results indicate persistent income-related inequalities in ACSC hospitalizations in Canada. The RIF analysis identifies the main contributors to such disparities, including age, immigrant status, employment status, chronic conditions, lack of having a family doctor, and rural residency. The BO-RIF-regression decomposition results show significant gaps across age, rural-urban, and income groups. To reduce ACSC hospitalizations, targeted policy measures should focus on improving access to primary healthcare services, especially at-risk populations such as immigrants, individuals with chronic conditions, low-income household members, and those living in rural areas.

Ind-2542 Setting up The Threshold of Mandatory Health Spending: Is It Still Relevant?

PRESENTER: **Retno Pujisubekti**
AUTHORS: Ery Setiawan, Iko Safika, Gregorius Dimas Herlambang, Izza Maulana Rizqi, Trihono Trihono, Arisna Widianingsih, Novira Hasya, Farhan Kurniawan

Background: One of Indonesia's recent transformative approaches in public health financing has granted district greater financial autonomy by eliminating the minimum 10% mandatory local government spending on health sector. Removing the threshold, however, has raised an ongoing debate over its effect on national and sub-national health program achievements and sustainability. Under decentralisation system, this approach may lead to higher variability in budget allocation and expenditures for health across over 500 districts. This also may influence the local government spending on health priority programs, such as addressing child malnutrition. To assess the effectiveness of using the minimum 10% threshold, this study aims to measure the effect of local government spending on improving health programs, specifically for child malnutrition.

Methods: Secondary data analysis from multiple sources was used to assess local government expenditures on child malnutrition status. First, the Indonesia National Health Survey 2021-2023 measured malnutrition status, including stunting, wasting, and underweight prevalence. Second, the Ministry of Finance panel data for 2019-2021 was used to measure total expenditure by the local government on health programs. A two-year time lag was applied between predictors and outcome variables. A panel fixed-effect linear regression was used to assess the effect of the share of health expenditure on each malnutrition status prevalence. Unit analysis consisted of the district level, with 1,527 balanced observations in total. The health expenditures were analysed in two approaches: 1) the binary variable (above versus below 10% threshold; and 2) the continuous variable (percentage of health spending per total expenditure). We also adjusted several variables of interest, including poverty rate, urban-rural composition, smoking prevalence, and the availability of health facilities.

Result: The district's average share of health spending was around 11% in 2019 and 2020 and slightly decreased to 9.1% in 2022, with a maximum share of 31% and a minimum lower than 1% across year. However, only 51% of districts in 2019 and 2020 and 38% of districts in 2021 met the mandatory 10% threshold. Multivariate analysis reveals that the districts that fulfil 10% health spending did not significantly influence the reduction of malnutrition status prevalence compared to those that did not meet the threshold. This implies no significant difference in child malnutrition progress between district that spent above or below 10% on health program. Using the continuous measurement, the share of health spending by 1% significantly decreases about 0.07% of wasting prevalence [95% CI: 0.003 – 0.14]. However, this was not significant with stunting and underweight prevalence. It is worth noting that smoking prevalence and urban rural classification were found to be significant factors influencing malnutrition prevalence.

Conclusion: Using a financing scheme to boost health outcomes may be ineffective if it solely relies on setting up the mandatory threshold. With decentralisation in place, evaluating district level budget allocation alongside the development of incentive and disincentive financing schemes is worth considering. The local government should also consider controlling the risk factors of malnutrition.

abs-os714 Assessing Immunization Coverage Survey Costs

PRESENTER: **Logan Brenzel**

AUTHOR: Helen Saxenian

Coverage surveys are an important tool to measure immunization coverage changes, especially as countries work to vaccinate previously unreached children. There is limited information in the public domain on the costs of carrying out different types of surveys in different contexts. This study begins to fill this gap in addressing several questions: 1) What is the average and range of costs of immunization coverage surveys, by type of survey, by method, location, and level of precision and representativeness? 2) What are the major cost drivers in different contexts and how might they be modified to improve efficiency? 3) Who have been the major funders of immunization coverage surveys and in which countries?

This study used a mixed-method approach of primary and secondary data collection and 45 stakeholder interviews. Coverage survey costs were collected and analyzed to generate benchmarks on the costs of surveys in different contexts, and to identify key cost drivers. A database of 59 surveys from 27 countries conducted between 2011 and 2023 was developed on survey characteristics, survey design, implementation, and detailed budget/cost information. Two-thirds of the surveys were from African countries. Thirty percent of the surveys used the WHO Cluster methodology; 20% were Multi-Indicator Cluster Surveys (MICS). 30% of surveys were powered to the district level. Data were analyzed using Excel and all costs were converted to US$2023.

The median total cost of the surveys in the sample was $250,000, ranging from $15,000 to $2.4m. The median cost/cluster was $1300, the cost/household was $90, and the cost per person surveyed was $109. The median cost per household was highest in for sample surveys in Latin America ($430), compared with surveys in the Eastern Mediterranean ($47). Surveys using the WHO cluster survey method have highest costs per cluster, while Lot Quality Sampling Assessment (LQAS) surveys have the lowest cost. Post campaign coverage surveys (PCCS) have relatively lower total costs but the highest cost/household among survey types. The major cost drivers of nearly all surveys were personnel, transportation, and field work costs. However, technical support, particularly international technical support costs can represent a large share of total costs (30% on average).

Coverage survey financing is sometimes highly fragmented. This can impact timeliness, cost, and quality of survey results. Improved coordination of financing is needed. Several budget inputs were thought to be under-budgeted in surveys, including time for data processing and dissemination, airtime for communication during field work, community engagement, and security for field work. Innovations are underway or on the horizon that could potentially reduce costs, including those related to data collection and analysis.

The results of this work will help to provide a reference point for review of budget elements and costs; improve communication between funders and implementers of surveys in negotiating budgets for surveys; and raise issues related to budgeting and financing of surveys that can improve the overall efficiency and quality of immunization coverage surveys.

Ind-2274 Current Overview of Cost Management Implementation in the Family Health Strategy (ESF) in Brazil

PRESENTER: **Andréia de Freitas**, Minist rio da Sa de do Brasil

AUTHORS: Everton Nunes da Silva, Maciene Mendes da Silva, Clementina Corah Lucas Prado

Introduction: The National Cost Management Program (PNGC), an initiative by the Brazilian federal government to promote a culture of cost management in the public health system, offers a costing methodology to address the specificities of various types of health establishments. In the case of the Family Health Strategy (ESF), which mobilizes multidisciplinary teams to provide healthcare that ranges from health promotion to rehabilitation, the PNGC has defined cost centers for each professional class, as well as the physical structure. Given its emphasis on prevention, the ESF plays a crucial role in containing and reducing costs in the healthcare system, making it essential to understand the current landscape of ESF adherence to the PNGC. Methods: Qualitative, descriptive, and documentary research on the cost calculation and management through the PNGC in basic units of the Family Health Strategy, based on access to documents developed by the Ministry of Health. Results: The ESF, which operates in Basic Health Units (UBS), promotes health with a focus on prevention, reducing the need for more complex and emergency medical services, thus contributing to a reduction in healthcare spending in the long term. Understanding how much these units cost and their output is fundamental for efficient service management. Within the scope of the PNGC, the costing methodology was adapted, based on absorption costing, to specifically address the ESF, and made available for municipal health secretariats that voluntarily chose to join the Program and use the SUS Cost Calculation and Management System (APURASUS). By October 2024, 17 municipal health secretariats and the Federal District had adhered to the PNGC, corresponding to 682 UBSs engaged in cost calculation and management, distributed across all regions of the country: 168 in the Midwest, 81 in the Northeast, 3 in the North, 288 in the Southeast, and 142 in the South. These units can calculate the total cost of the UBS; the cost of various cost centers (community health agent, nurse, family doctor, nursing technician per team, specialty outpatient clinics, vaccination room, oral health, etc.), making it possible to calculate the cost per health team; and the average cost of services provided. Conclusion: In the face of the growing challenges faced by the healthcare sector, especially in terms of managing limited resources and ensuring effective service delivery, cost management becomes crucial. The Ministry of Health's initiative to provide a tool that facilitates cost management in Family Health Teams, combined with the commitment of local managers to get involved, highlights a desire to implement more efficient administration and make more informed decisions.

Ind-1795 Application of Economic Criteria in Identifying and Prioritizing Emergency Preparedness and Response (EPR) Interventions in Africa

PRESENTER: **Dr Elias Asfaw Zegeye**

AUTHORS: Dr Joyce wamicwe, Justice Nonvignon, Dr Richmond Ensiwoyie, Dr Zana Somda, Brian Arwah, Osondu Ogbuoji, Dr Oyeldun Okunromade, Howard Nyika, Dr Kokou Nouwame Alinon, Carl Schutte, Dr Nicola Wiafe

Background The recent COVID-19 pandemic, the ongoing Mpox, Ebola and other epidemics in Africa have highlighted challenges that

countries on the continent face with optimal resource allocation, identifying and prioritizing interventions for effective emergency preparedness and response (EPR). To inform the development of a systematic and evidence-based process for priority setting and resource optimization, the five countries case studies conducted. **Method** We provide an overview of the approaches employed by African Union (AU) member states to identify and prioritize EPR interventions. The study is conducted through desk-based document review, key informant interviews with key stakeholders involved in EPR planning, and country visits in Uganda, Malawi, Nigeria, Burkina Faso and Morocco. **Result** The Five African Union Member states have used established tools such as Vulnerability Risk Assessment Mapping (VRAM) and WHO Strategic Tool for Assessing Risks (STAR) to prioritize pathogens of epidemic potential. They also adapt generic plans or plans from previous emergency responses to address new threats. Prioritisation of interventions is typically less structured. Decision makers consider factors such as health impact, socio-economic outcomes, ethical concerns, and equity when prioritising interventions. However, the consideration of these factors is not formalised and there is limited use of structured prioritisation processes which include consideration of economic criteria. Expert judgement and past experiences play a substantial role. Furthermore, review of data on the benefits and drawbacks of the different intervention options is not necessarily formalised, limiting decision makers' ability to assess the trade-offs of implementing one intervention option over another. The evidence co-production model used in the Nigeria COVID-19 response demonstrates how, even during the response phase, evidence can be generated to feed into decision-making. **Recommendation.** The assessment suggests that employing structured methods and processes for identifying and prioritizing interventions to implement in the context of EPR leads to more effective, fair, and equitable allocation of resources, resulting in improved health outcomes. Moreover, incorporating economic criteria approaches could encourage decision-makers to allocate more resources to EPR initiatives and enhance public trust in the decision process. Furthermore, incorporating economics criteria into these processes allows for optimization of limited resources

Ind-1961 Difference-in-Differences Analyses of Vaping and Smoking After E-Cigarette Flavor Bans: New Evidence from Canada

PRESENTER: **Shweta Mital**
AUTHOR: Hai Nguyen

Background: Flavors such as fruit, candy, and dessert ('youth-friendly' flavors) are common reasons for youths to start using e-cigarettes. Several jurisdictions in the US and Canada have banned these youth-friendly flavors in e-cigarettes to protect youths. However, these bans have been highly contentious. Recently, the Supreme Court of the United States was tasked with adjudicating whether the Food and Drug Administration's refusal to approve flavored e-cigarettes was unlawful. Similarly, three years since its first promise, nationwide bans on flavored e-cigarettes are currently on the table in Canada. Despite these ongoing debates, there is limited evidence on the effects of these bans. In particular, no study has examined the effects of the bans on use of flavored e-cigarettes. **Research Aims:** First, we study the effects of bans on use of youth-friendly flavors in e-cigarettes and overall e-cigarette use among both youth and adults. Next, we study possible substitution towards tobacco-flavored e-cigarettes and combustible cigarette use as a result of the bans. **Methods:** We use nationally representative, individual level survey data from all 10 Canadian provinces and difference-in-differences design to compare changes in outcomes in provinces that banned flavors in e-cigarettes with provinces that did not. Outcomes of interest include past 30-day use of youth-friendly flavored e-cigarettes, tobacco-flavored e-cigarettes, overall e-cigarettes and combustible cigarettes among youths and adults. **Results:** Among youths, the bans on flavored e-cigarettes were associated with 2.8 percentage points (p=0.02) reduction in past 30-day flavored e-cigarette use and 1.5 percentage points (p=0.04) reduction in overall e-cigarette use. We found no evidence of substitution towards tobacco flavored e-cigarettes or combustible cigarettes. There was also no effect of the bans on adults' use of flavored e-cigarettes or their overall use of e-cigarettes and combustible cigarettes. **Conclusions and Policy Implications**: Bans on flavored e-cigarettes are effective in reducing flavored e-cigarette use and overall cigarette use among youths. Furthermore, the null effects of the ban on combustible cigarette use alleviate concerns that the bans will promote combustible cigarette use among youths and adults.

MODERATOR: **Eduardo Gonzalez Pier**,

Ind-1867 Healthcare Workers' Preferences for Targeted Tuberculosis Interventions in Malawi: A Discrete Choice Experiment

PRESENTER: **Wala Kamchedzera**, Malawi Liverpool Wellcome Program
AUTHORS: Effita Fifi Masoamphambe, Wezi Msukwa-Panje, Patrick Msukwa, Augustine Choko, Rein Houben, Peter MacPherson, Nikita Arora

Background: Tuberculosis (TB) interventions that are not tailored to fit TB epidemics within settings are becoming less effective and efficient in eradicating the current TB disease burden. Interventions should be targeted to sub-populations that carry the highest TB burden as this is more cost-effective. In low-income countries like Malawi, limiting resource constraints makes decisions on resource allocation challenging. Choosing which population group to prioritise and how they should be targeted partly depends on practicability, and the health-system's capacity. Such dynamics are well understood by healthcare workers. This study aimed to measure healthcare workers' preferences for targeted TB case finding interventions in Malawi.

Methods: We designed and implemented a discrete choice experiment (DCE) to solicit healthcare workers' preferences for targeted TB case finding interventions. The DCE design was informed by literature and in-depth interviews. The study recruited 100 healthcare workers from one tertiary hospital and primary healthcare facilities across Blantyre, Malawi. Multinomial logit models were used to investigate preferences

for targeted TB interventions. We further estimated the marginal willingness to pay values for the different attribute levels.

Results: Overall, healthcare workers showed a preference for having any targeted TB case finding intervention over having no intervention at all (P<0.001). Healthcare workers were less likely to choose interventions that targeted at risk occupations (Odds Ratio [OR]: 0.79, 95% Confidence Interval [CI]: 0.64-0.97) and those that targeted males (OR: 0.54, 95% CI: 0.44-0.66) as compared to interventions that targeted geographical TB hotspots. They also preferred interventions that targeted all types of TB as compared to just targeting infectious TB (OR: 1.42, 95% CI: 1.19-1.69). They additionally showed a strong preference for interventions involving collaborating with community leaders as compared to no collaboration (0R: 1.54, 95% CI: 1.25-1.88). Healthcare workers also preferred interventions with non-financial (e.g: essential supplies, education and training) and financial benefits as opposed to none (P<0.001). Healthcare workers were indifferent to whether the intervention should focus on demand creation activities or TB diagnosis.

Conclusion: Our study provides insights on the value healthcare workers place on different characteristics of targeted TB interventions. The findings suggest that healthcare workers value targeted TB interventions and show strong preferences for those that target geographical hotspots whilst enabling collaboration with community leaders. However, these interventions need to be accompanied by incentives such as essential supplies for carrying out their work or financial staff benefits. Healthcare workers' preferences for interventions should be considered when designing new interventions. Understanding these preferences will ensure that interventions are context specific and are easily implemented by healthcare workers.

Ind-2422 Growth of Private Equity and Hospital Consolidation in Primary Care and Price Implications

PRESENTER: **Yashaswini Singh**
AUTHORS: Christopher Whaley, Nandita Radhakrishnan, Loren Adler

Research Objective: Consolidation of physician practices by hospitals and private equity (PE) firms has increased rapidly in the United States. This trend is of particular importance within primary care. Despite its significance, there is no systematic evidence on the emerging trends in ownership affiliation of primary care physicians (PCPs) and its association with prices paid for physician services. Using national data on insurer disclosed prices and PCP practice organization, this paper describes trends in hospital-affiliation and PE-affiliation in primary care and examines variation in negotiated prices paid by commercial insurers to hospital-affiliated, PE-affiliated, and independent PCPs.

Study Design: We used data from Pitchbook and IQVIA to examine hospital- and PE-affiliation of 198,097 PCPs. We linked PCPs and their affiliations to novel cross-sectional Transparency in Coverage (TiC) data. We analyzed 226.6 million negotiated prices for evaluation and management office visits (CPTs 99202-99205 and 99212-99215) across four national insurers (Aetna, BCBS, Cigna, United Healthcare). We used linear regressions to examine the association between hospital-affiliated, PE-affiliated, and independent PCPs and cross-sectional prices paid for physician services, with fixed effects for service, state, and insurers.

We examined the proportion of PCPs that are hospital-affiliated and PE-affiliated from 2009 to 2022. Using cross-sectional data from 2022, we also examined negotiated prices paid to physicians (physician professional fee) for office visits.

Principal Findings: PCPs affiliated with hospitals increased from 25.2% (28,216 of 111,793) in 2009 to 47.9% in 2022 (82,890 of 172,964). Over the same period, 1.5% (2,483 of 172,964) of PCPs became affiliated with PE firms. Relative to independent PCPs, negotiated prices for office visits are $18.28 or 11.5% higher for hospital-affiliated PCPs (CI: 6.5-16.80, $p < 0.01$) and $8.40 or 7.23% higher for PE-affiliated PCPs (CI: 1.13-10.24, $p < 0.01$).

Conclusion: The growing acquisitions of physician practices by hospitals and private equity firms is one of the most important recent trends in the organization of physician practices in the United States. As of 2022, nearly half of all primary care physicians are hospital-affiliated, while PE-affiliated PCPs are growing and concentrated in certain regional markets. Relative to PCPs in independent settings, hospital-affiliated PCPs and PE-affiliated PCPs have higher prices for the same services. Ownership and price transparency can uncover sources of price variation that will be important for policymakers to monitor. 2

Ind-2210 Testing the Norms Hypothesis Within-Physician Differences in Care by Insurance Type in U.S. Medicare

PRESENTER: **Eran Politzer**, Harvard University
AUTHORS: John Z. Ayanian, Bruce Landon, Vilsa E. Curto, Jeffrey Souza, Timothy S. Anderson
Background The "norms hypothesis" posits that physicians do not customize treatment decisions based on a patient's specific insurance reimbursement arrangements but instead adopt a relatively uniform treatment style that best conforms to the average or modal insurance coverage and reimbursement mechanisms across their patient population or within their geographic area. This study investigates the norms hypothesis in the context of the U.S. Medicare program by examining differences in care patterns for similar patients being cared for by the same primary care physician but enrolled in traditional Medicare (TM) or private Medicare Advantage (MA) plans. **Methods** Based on the universe of 2021 TM claims and MA encounter data, we identified primary care physicians (PCPs) who treated at least 25 patients from each program. We compared the annual utilization of services by similar MA and TM patients under each PCP using multivariable linear regressions, controlling for PCP fixed effects, patient demographic characteristics, and 30 chronic conditions identified using the Chronic Conditions Warehouse algorithms. Services analyzed include those largely at PCP discretion (e.g., number of PCP visits) and those likely requiring MA plan authorization. To address potential differences in MA coding practices, we excluded chronic conditions coded in chart reviews, and examined the sensitivity of the results to estimating a model that does not control for chronic conditions. **Results** We analyzed 80,093 PCPs, who each treated an average of 125.2 (SD: 108.8) MA patients and 175.9 (SD:136.7) TM patients. We found across the board lower utilization for PCPs' MA patients, compared to their similar TM patients. MA patients had 7% fewer annual PCP visits and 17% lower drug utilization. For services likely requiring prior authorization, MA patients had 25% lower utilization of radiology services, like CT scans and

MRIs and 42% lower utilization of musculoskeletal services, such as knee replacements. When controlling only for patients' demographic characteristics, within-PCP differences were smaller but utilization remained significantly lower for MA patients. **Conclusions** Our findings reveal substantial utilization differences between similar MA and TM patients under the care of the same PCP, with consistently lower service use among MA patients. The observed gaps, even for services typically under PCP discretion, challenge the norms hypothesis, and suggest possible differential treatment based on insurance type. These within-PCP gaps may contribute to the observed lower utilization of services in MA compared to TM. However, larger within-PCP utilization gaps in services that likely require prior authorization imply that MA care management tools play a significant role. Additionally, residual unmeasured selection effects may contribute to our estimated differences, for example, if MA enrollees are, in general, less prone to seek care.

Ind-2064 Rationing By Race

PRESENTER: **Manasvini Singh**
AUTHOR: Atheendar Venkataramani

Background

Decision-makers often allocate scarce resources using some mechanism based on social values (such as demonstrated need, lottery systems, wait lists etc). However, increasing scarcity can drive them to rely on implicit or explicit biases or heuristics when allocating resources. For instance, laboratory studies suggest that markers of group identity, such as race, unduly influence rationing decisions under scarcity. Thus, in this study, we provide causal evidence that resource scarcity exacerbates race-based disparities in healthcare, adversely impacting Black patients. This work bridges a critical gap in understanding how scarcity interacts with discrimination in real-world, high-stakes contexts.

Research Question

How does resource scarcity affect resource allocation – and ultimately outcomes -- for Black vs. White patients in hospital settings?

Methods

We analyze electronic health record data from 107,000 patient admissions from 2015–2018 across two hospitals in a large urban academic system in the southeastern United States. Informed by a conceptual framework linking resource scarcity to cognitive and systemic biases in the medical setting, we leverage plausibly exogenous variation in hourly hospital capacity strain as our measure of resource scarcity and examine how it affects rationing of hospital resources -- specifically beds and provider effort -- and mortality outcomes for Black vs. White patients. Machine learning and text analysis methods are applied to unstructured data from patient records to infer provider effort.

Results

We first show that in-hospital mortality rates rise disproportionately for Black patients as capacity strain increases. At the highest decile of strain, mortality increases approximately 15-17% more for Black patients than for White patients. As mechanisms, we show that discriminatory rationing of hospital beds can explain this widening disparity in mortality: Black patients experience larger increases in wait times for inpatient beds than White patients under strain. Notably, at all levels of strain, sick Black patients wait longer for beds than healthy White patients. In a more suggestive set of analyses, we show that Black patients receive less detailed and lower-quality clinical documentation than White patients, a disparity that widens under high strain. Reduced effort in record-keeping correlates with poorer care quality and worse health outcomes for Black patients.

Conclusion

This study uncovers a critical link between resource scarcity and discrimination, demonstrating how capacity strain exacerbates racial disparities in healthcare access and outcomes. These findings emphasize the importance of loosening resource constraints as a way to mitigate bias and promote equitable healthcare delivery. For instance, policies aimed at increasing hospital capacity or optimizing resource allocation could reduce discriminatory practices, even without explicitly targeting bias. This work has broader implications for understanding how scarcity shapes social inequities in other domains.

Ind-710 The Rise and Fall of Priority Setting in Mexico: Lessons from a Health Systems Perspective

PRESENTER: **Eduardo Gonzalez Pier**
AUTHORS: Mariana Barraza Llorens, Jaime Sepulveda Amor

Background: In 2004, Mexico launched Seguro Popular (SP), a significant policy intervention aimed at achieving universal health coverage (UHC) for the uninsured population through two targeted Health Benefits Packages (HBPs). SP employed an explicit priority-setting approach to optimize resource allocation, expanding access to essential services and high-cost interventions while attempting to mitigate catastrophic health expenditures. By 2020, SP had enrolled about half of the population (52 million individuals) and integrated 294 prioritized essential services and 66 high-cost interventions into its coverage portfolio. However, in 2020, SP was repealed, largely due to political and operational challenges, raising critical questions about the sustainability of priority-setting frameworks in health reform. This study (publication forthcoming) investigates SP's approach to priority setting, its impact on healthcare access, financial protection, and equity, and explores systemic factors that influence policy sustainability for priority setting.

Research Aim: This research aims to critically assess and proactively inform sustainable priority-setting practices in health policy.

Methods: The study utilizes a mixed-methods approach combining qualitative policy analysis with quantitative impact evaluation. Policy analysis was conducted on SP's HBP design and implementation strategies, examining policy documents, budgetary allocations, and regulatory

frameworks from 2004 to 2020. The quantitative analysis involved secondary data from national health accounts and household surveys in assessing SP's impact on key indicators: population coverage, the incidence of catastrophic health expenditures, and regional disparities in access. Analytic techniques included trend analysis and stratified comparisons across socioeconomic groups.

Key Results: Seguro Popular achieved substantial increases in healthcare access for uninsured populations and reductions in catastrophic health expenditures, demonstrating the potential of HBP to improve financial risk protection in a middle-income country context. However, persistent operational challenges undermined the program's political support, including constrained fiscal space, inter-regional inequities in service provision, and insufficient integration with the broader health system. Political vulnerabilities, such as unmet service quality expectations, reliance on discretionary budget allocations and shifts in policy priorities, ultimately contributed to SP's repeal, exposing the fragility of priority-setting reforms lacking institutional safeguards.

Conclusions and Implications: This study illustrates the critical role of explicit priority setting in advancing UHC but highlights the necessity of embedding these mechanisms within a resilient, depoliticized institutional framework. Sustainable health reforms must integrate adaptable funding strategies for middle-income countries, secure cross-party political support, and reinforce transparency in HBP development and resource distribution. Mexico's experience with SP provides valuable insights into designing politically robust, equity-focused, priority-setting processes to achieve and sustain UHC in dynamic policy environments.

Ind-1296 Setting Healthcare Priorities at the District Level in Malawi: A Qualitative Evaluation of Resource Allocation Processes.

PRESENTER: **Monica Patricia Malata**
AUTHORS: Fiammetta Bozzani, Jobiba Chinkhumba, Charlotte Ward, Wanangwa Chimwaza, Alinane Linda Nyondo-Mipando, Victor Mwapasa, Timothy Powell-Jackson, Catherine Goodman

Background

Priority setting and resource allocation (PSRA) processes are essential for optimising health system performance. These processes are especially critical in low- and middle-income countries (LMICs) like Malawi, where resources are severely constrained. With only 9% of government expenditure allocated to health and per capita health spending at $40—both below international benchmarks—Malawi, like many low resource settings, faces severe gaps between health needs and available resources, making effective resource allocation critical.

Resource allocation occurs at multiple levels, but in LMICs, sub-national processes have gained prominence due to decentralised health systems. There are several goals for resource allocation, such that processes might aim to efficiently, equitably, democratically, or justly distribute resources. Thus, evaluating priority setting processes from a multidimensional framework, encompassing both procedural and consequential aspects of priority setting processes, is critical.

Aim

To evaluate district level healthcare priority setting processes in Malawi.

Methods

We used a qualitative case study approach. Our study used the Priority Setting Evaluation Framework that assessed resource allocation using both consequential conditions (efficiency, equity, stakeholder satisfaction, stakeholder understanding, reallocation of resources, and implementation of decisions) and procedural conditions (stakeholder engagement, empowerment, transparency, use of evidence, community values, and mechanisms to reinforce decisions). Data were collected from February to May 2024 in two districts. Semi-structured interviews were conducted with 25 purposively selected health managers, service providers, and community stakeholders. We also observed district healthcare implementation planning meetings, to triangulate with interview data. All interviews were audio-recorded and transcribed. We used framework method for analysis, coding data using NVIVO 21 software.

Results

Districts made resource allocation decisions in the context of a highly constrained decision space. In terms of the consequentialist conditions, consideration of efficiency in decision-making was limited to the consideration of activity costs. Neither district considered equity in their decision making. In both districts, funding allocations remained relatively unchanged, as participants reported recycling of annual plans. Turning to the proceduralist conditions, district stakeholders drew on local epidemiological data to formulate plans, although the final decisions were not based on these data. In district 1, frontline workers had a better understanding of the planning processes, but in both districts, frontline workers and middle managers reported low satisfaction with the process. Regarding procedural fairness, health managers made decisions, with frontline workers only engaged in district 1, while community members were excluded in both districts. Development partners were reported to select their areas of focus without consideration of district priorities. The final decisions were not shared with frontline workers or middle managers. Overall, there were no mechanisms to ensure timely and standardised processes were followed.

Conclusion

The priority setting and resource allocation processes at the district level lacked stakeholder engagement, transparency, and adaptability. The limited decision-making space, exclusion of community voices, untimely planning, and poor communication with frontline workers and middle managers highlight systemic weaknesses that undermine the entire process. Districts need greater autonomy, standardised processes, and mechanisms that ensure transparency, equity, and stakeholder involvement in decision-making to improve their priority setting and resource allocation processes.

Ind-2606 Impact of the Family Doctor System on Healthcare Utilization and Medical Costs of Diabetics: Multistage Difference-in-Difference Analysis

PRESENTER: **Luying Zhang**
AUTHORS: Wen Chen, Xinyi Liu

Background: This study assessed the effectiveness of family doctor system in China on diabetics' healthcare services utilization and medical costs.

Methods: We conducted this study in an eastern Chinese city, an early adopter of the family doctor system in 2015. Our cohort included all diabetes patients registered in the city's official health management information system. Utilizing patient IDs, we merged individual-level data from the medical insurance claim database, encompassing demographic characteristics, healthcare utilization, and expenditures from 2014 to 2019. Given the phased implementation of the family doctor system, with annual enrollment of diabetics into the system, we applied a multi-stage difference-in-difference analysis to evaluate the program's impact over its various stages of deployment.

Findings: Our study included 62,365 diabetes patients (mean age 64.83 years; 43.71% male, 56.29% female). New registrants in the first stage experienced a 0.971 increase in annual outpatient visits and a 14.7% rise in outpatient expenses, notably with a 2.126 increase in community health center (CHC) visits and a 26.6% surge in CHC outpatient costs, while their visit frequency and cost of secondary/tertiary hospital and pharmacy significantly declined. Second-stage renewals exhibited no differences in annual visits but had a 1.949 reduction in pharmacy visits and a 144.0% decrease in pharmacy costs. Those newly registering in the second stage had a 2.545 increase in outpatient visits and a 28.0% rise in outpatient expenses, mainly from CHCs. Throughout, there was no significant change in the total medical expenses of diabetic patients, but their out-of-pocket expenses significantly decreased ($P<0.05$).

Interpretation: The family doctors, act as a soft gatekeeper in the healthcare system, successfully enhancing primary care utilization among diabetic patients while controlling patients' out-of-pocket expenses. This highlights the system's potential in enhancing chronic disease management, offering valuable insights for policymakers aiming to improve healthcare delivery and financial protection in similar contexts.

Ind-712 Somatic Comorbidities and Medical Expenses Among Patients with Severe Mental Disorders: Evidence From Community-Based Data in Beijing

PRESENTER: **Junli Zhu**

Background: Patients with severe mental disorders (SMD) often experience impaired social adaptability due to severe symptoms, placing them at a heightened risk of poverty. Although the government has implemented various policies to subsidize the mental health economic burden for this group, their high prevalence of somatic diseases continues to entrench many in poverty. Existing studies often rely on simple comorbidity counts or binary methods, which may overlook the varying impact of different disease types on healthcare expenses. Therefore, this study aims to assess the comorbidity status of patients with SMD by analyzing medical data from communities in Beijing and to explore the impact of various somatic comorbidity types on healthcare expenditures for SMD patients. **Method:** Data in this study include basic demographic characteristics and medical records of patients, covering healthcare utilization and expenses. Demographic information was collected through follow-up assessments and surveys conducted by community psychiatrists, while healthcare utilization and expense data were sourced from patients' medical records from 2019. The sample was obtained through stratified cluster sampling based on Beijing's administrative districts, yielding a final sample of 4,940 patients. Somatic diseases were classified according to ICD-11, and comorbidity counts were calculated. Chi-square, Z-tests, and the Kruskal-Wallis H test were used for group comparisons in the statistical analysis. A censored least absolute deviation (CLAD) model was applied to analyze factors influencing healthcare expenses, sequentially building three sequential models to examine the effects of various factors on total medical expenses. **Results:** The average total healthcare expenditure per patient was 16,456 RMB, with approximately 10,293 RMB attributed to mental disorders (63%) and 6,162 RMB to somatic conditions (37%). Significant differences in expense distribution were found between comorbid and non-comorbid groups across various disease categories. In terms of comorbidities, only 39.41% of patients had no somatic comorbidity. The most common comorbidities were circulatory diseases (36.6%), respiratory diseases (32.3%), digestive diseases (30.6%), and endocrine, nutritional, and metabolic diseases (29.8%). The regression analysis showed a significant positive correlation between the number of comorbidities and healthcare expenses ($p<0.001$). Comorbidities in ICD-11 chapters 2, 5, 7, 8, 9, 11, 13, 15, and 16 significantly influenced the expenses model ($p<0.05$). **Conclusions:** This study found that comorbidities are widespread in patients with SMD, and most of them lead to a significant increase in patients' medical expenses. Therefore, the treatment for SMD patients should address the prevention, management, and treatment of their somatic comorbidities to reduce the incidence and progression of these somatic comorbidities and, thereby alleviating the healthcare expenses burden on these patients. **Keywords:** Health Service Research; Community Mental Health; Psychotropic Drugs; Psychiatric Services; Expense Analysis

Ind-2832 Actuarial Challenges and Financial Sustainability of Indonesia's National Health Insurance (JKN): A Decade of Insights (2014-2024)

PRESENTER: **Fera Rusanti**
AUTHORS: Mr. Mahlil Ruby, Mr. Benjamin Saut Parulian Simanjuntak, Mr. M. Mizmara Alan Falihin

The premium setting for the National Health Insurance (JKN) program from 2014 to 2024 has shown a misalignment with actuarial practice standards, significantly impacting the program's sustainability. This study aims to examine the effects of non-actuarial-based premium policies on financial stability, the balance between revenue and benefit expenditures, and the sustainability of the Social Security Fund (DJS). Based on an analysis of premium trends, claim ratios, and related policies, it was found that the misalignment was caused by socio-political pressures, limited actuarial data, and government priorities in maintaining premium affordability. Since its inception in 2014, the Cost Per Member Per Month (CPMPM) has consistently exceeded the Premium Per Member Per Month (PPMPM) by 17-40%. Phenomena such as the golden cross

in 2019 and the death cross in 2023 illustrate the dynamics of financial imbalance within the program. To project medium-term financial conditions, actuarial risk analysis indicates that the growth rate of CPMPM will continue to outpace that of PPMPM. An actuarial loss ratio reaching 115% in 2024, with projections exceeding 150% by 2028, underscores the critical urgency of strengthening premium-setting policies to ensure financial stability and sustainability. This study recommends the consistent application of actuarial approaches in premium determination, risk-based adjustments, and enhanced cost control as solutions to ensure program sustainability. The findings of this study are expected to provide strategic input for the government in sustainably managing JKN. Keywords: JKN, premium determination, actuarial analysis, financial imbalance, loss ratio, program sustainability

Ind-99 Rural-Urban Migration and Substance use: A Temporal Causal Analysis Using Staggered Difference-in-Difference Regression

PRESENTER: **Adeola Oyenubi**, University of the Witwatersrand
AUTHOR: Umakrishnan Kollamparambil

Background and Contribution: While various risky behaviour outcomes of rural-urban migration have been explored in empirical literature, the relationship between substance use and migration has been largely studied in literature using cross-section data making it difficult to establish the causal effect of migration on substance use behaviour. Aside from exploring the causal effect of migration on the level of substance use using longitudinal data, this study is the first to examine the effect of migration on initiation of substance use and present post-migration temporal dynamics of substance use. **Research questions:** i) How does rural-urban migration impact substance use? ii) Does rural-urban migration influence the likelihood of initiating substance use? iii) Is there heterogeneity in the causal effect of migration on substance use across sex and age groups? **Data and Methods:** This study used five waves of a nationally representative longitudinal data over the period 2008-2017 to explore the causal effects of migration on substance use in the South African context. The outcome variable of substance use is constructed from three smoking and alcohol consumption behaviour variables using factor analysis. To explore heterogeneity in effect by demographic factors, the analysis is disaggregated by gender and age. The study is one of the first to use the heterogeneous robust difference-in-difference estimator introduced by de Chaisemartin and d'Haultfoeuille (2024) which allows for staggered treatment methodology to not only study the causal effect but also explore post-treatment temporal dynamics. **Results:** The analysis found that migration leads to increased substance use among men, but not among women. Moreover, this rise in substance use among men is not limited to the immediate post-migration period but persists in the medium term in subsequent years. The analysis also shows that the effect is stronger for individuals who are below the age of 35 when they migrated. Further, restricting the analysis to the population of those who report no substance use before migration, the study found that migration increased the likelihood of initiation for men, women and younger migrants significantly. The findings from the study remained consistent across various robustness checks including the use of equally weighted index, robustness to the assumption about initial condition and alternative estimation method. **Conclusion**: The gender differences found in increased substance use following migration can be explained by the variation in coping mechanisms typically adopted by men and women, whereby migrant men, more than women, are likely to externalize stress through behaviours such as substance abuse. The finding on initiation is important, particularly for women and young people. Given the serious individual and societal consequences of substance abuse, this study highlights the urgent need for preventative measures targeting new migrants, focussing especially on male and young migrants in urban centres. Additionally, the study findings suggest that interventions for addiction management should be made available to migrants who have settled in urban areas, helping to mitigate the long-term negative effects of migration on substance abuse.

Ind-1507 The Impact of Opioid Dependence Treatment on Employment, Government Service use, and Opioid-related Healthcare: Evidence From Physician Exits

PRESENTER: **Francis Graham**
AUTHORS: Dennis Petrie, Suzanne Nielsen, Sonja De New

Opioid dependence treatment the most effective treatment for managing opioid use disorder, yet little is known about the consequences of treatment disruption. Using Australian pharmaceutical claims linked to health, tax, and service records, we examine ODT patient outcomes following prescriber exit. Patients whose prescriber exits experience a 10 percentage point drop in retention 6 months after exit. They also experience shifts in healthcare use, including fragmented chronic disease management. Labour market outcomes remain stable, but decreased government service use raises concerns about increased economic insecurity. Our findings highlight the broader consequences of treatment disruption for patient well-being.

Ind-2011 Smoking Like a Hero? Media Regulation and Adolescents Smoking Behaviour in Mainland China

PRESENTER: **Liyuan Sun**

Background: Viewing movies or TV figures smoke particularly promotes adolescents' smoking initiation as they are prone to mimicking as reference points. When smoking is portrayed as normative, the role model effect of movie or TV characters might lead teenagers to overestimate smoking prevalence and hence smoke. Since no rating system for media content and the national minimum smoking or alcohol use age is not enforced in mainland China, the National Radio and Television Administration (NRTA) announced and implemented a first-ever

media regulation to restrict smoking scenes in movies and TV series in early 2011. This is to keep people, particularly adolescents, away from smoking content and tobacco. However, it is concerning that adolescent smoking prevalence still increases.

Objectives: We aim to answer whether the media regulation on smoking content on movies and TV influences adolescents' (i.e., age 10-19) smoking behaviour in mainland China and offer policy implications.

Methods: Based on wave 2015 of the China Health and Nutrition Survey (CHNS), this paper draws upon quasi-experimental evidence from the regulations on reducing smoking content in movies and TV series. We explore the probability of smoking and daily cigarette consumption of people from different birth cohorts using a unique cohort difference-in-differences (DiD) strategy. We treat respondents who were adolescents in the pre-policy period and watched media content as the treatment group. Respondents who were young adults (i.e., aged 20-24) before the policy or did not access media content serve as the control group. We plot the event study graph to show the effect on each birth cohort with socio-demographic controls and fixed effects. We also explore the heterogeneity between several key characteristics.

Results: Having satisfied the parallel trend assumption, the regulation of media smoking content reduces adolescents' probability of smoking by 23.5% and daily cigarette consumption by 0.52 standard deviations relative to young adult cohorts, but the effects fade when they become adults. Effects are mainly contributed by males, rural residents and provinces that haven't implemented indoor public space smoking bans. results are solid over the robustness check.

Discussions: the media regulation has achieved its aim of curbing adolescents' smoking behaviour. It is not surprising that it is mainly contributed by male adolescents since over 90% of the smoking population is male. Other countries with similar environments to China can learn from this policy, while policymakers should think of how to maintain the effect when adolescent becomes adult. Further studies can work on the mechanisms and explore other drivers of the increasing adolescent smoking prevalence.

Ind-2835 Perception of the Relative Harm of Electronic Cigarettes Compared to Combustible Cigarettes and its Correlates: Empirical Evidence from Indonesia

PRESENTER: **Puguh Prasetyoputra**
AUTHORS: Lazuradi Imran, Harris Siagian, Agus Syarip Hidayat, Alan Farandy, Felix Wisnu Handoyo
Abstract Title: Perception of the Relative Harm of Electronic Cigarettes Compared to Combustible Cigarettes and its Correlates: Empirical Evidence from Indonesia Electronic cigarettes (e-cigarettes) have gained significant popularity in recent years as alternatives to traditional combustible cigarettes (c-cigarettes). In Indonesia, the prevalence of e-cigarette use has increased tenfold, from 0.3% in 2011 to 3.0% in 2021, equivalent to 6.2 million adults. This rapid growth has sparked debate regarding the relative harm of e-cigarettes compared to combustible cigarettes. While some studies have suggested that e-cigarettes are less harmful, others have argued that they may be equally detrimental to health. Conflicting evidence has led to uncertainty among consumers and policymakers regarding the potential risks and benefits of using e-cigarettes.

Despite the growing body of research on e-cigarettes, there is limited evidence on how individuals perceive the relative harm of e-cigarettes compared to combustible cigarettes, particularly in low- and middle-income countries, such as Indonesia. Understanding these perceptions is crucial as they can significantly influence smoking behaviours and public health outcomes.

This study aimed to address this research gap by examining the perceived relative harm of e-cigarettes compared to c-cigarettes among Indonesian smokers. Additionally, we investigated the smoking-related, demographic, socioeconomic, and spatial correlates of these perceptions to provide a comprehensive understanding of the factors that influence harm perception.

We analysed data from a Discrete Choice Experiment (DCE) survey conducted in 2024. The survey included 627 Indonesian smokers aged 18 years and above. We fitted logit regression models to the data and used the average marginal effect (AME) as a measure of association. The results suggest that most respondents (41.57%) perceived e-cigarettes as equally harmful as cigarettes, 37.54% perceived e-cigarettes as more harmful, and only one in five (20.89%) perceived e-cigarettes as less harmful than c-cigarettes. Smokers who frequently use e-cigarettes, have no flavor preference, married or living together, and more educated were less likely to perceive e-cigarettes as equally or more harmful than combustible cigarettes. However, having children increases the probability of perceiving e-cigarettes as equally or more harmful.

These findings could inform regulatory decisions regarding e-cigarettes in Indonesia, potentially influencing policies on product labeling, marketing restrictions, and public health campaigns. However, it is crucial to balance accurate risk communication with measures to prevent youth initiation and non-smoker uptake of e-cigarettes. Future research should focus on the long-term health effects of e-cigarette use and the impact of different policy approaches on smoking behaviors and public health outcomes in Indonesia.

Ind-787 Using Machine Learning to Predict the Health Outcomes and Costs of Legalising Domestic Sale of Vaporised Nicotine Products

PRESENTER: **Jun Kiat Ng**, Australian National University

Background

There is increasing interest in advancing New Zealand's efforts to achieve its smoke-free goal. Traditionally, the impact of tobacco interventions on Quality Adjusted Life Years (QALYs) and associated Health System Costs (HSCs) is modelled using two approaches: (1) the Smoking and Vaping Life Table Model and (2) the Proportional Multistate Life Table Model. These models provide a structured framework to assess the potential health and economic outcomes of interventions in line with New Zealand's public health goals. Tobacco interventions that have been explored include: (1) Tobacco Tax Increase, (2) Tobacco Free Generation, (3) Outlet Reduction, (4) Sinking Lid, (5) Combination of multiple

interventions, amongst others.

Motivation

Studying the effects of legalising vape is compelling. On the one hand, it serves as a potential cessation tool for smokers. On the other hand, it could be an entry point for other smokers to eventually pick up smoking. A primary motivation for this research is to assess the impact of legalising vaping on these public health outcomes.

Research Aim

This research aims to leverage the findings of previous research papers to build a Machine Learning model that predicts the effects of legalising domestic sale of vaporised nicotine products, or vape for short, on (1) Quality Adjusted Life Years (QALYs), (2) Health System Costs, and (3) Māori/non-Māori health inequities.

Methods

To do this, we leveraged data from the Burden of Disease, Epidemiology, Equity and Cost-Effectiveness (BODE3) Health Intervention League Table, which compiles findings from multiple research studies modelling QALYs and HSCs. Prior to its integration into the machine learning models, each intervention is parameterised according to five key features: (1) Percentage of Tax Increase, (2) Percentage of Outlet Reduction, (3) Percentage Drop in Smoking Prevalence, (4) Percentage Decrease in Tobacco Supply, and (5) Percentage Decrease in Smoking Uptake. These parameters are intended to capture the essential characteristics of each intervention, providing a structured input for model training. The machine learning algorithms employed in this study include Random Forest and Extreme Gradient Boosting (XGBoost), alongside methodological techniques such as upsampling and cross-validation.

Preliminary Results

We have successfully trained machine learning models using data from previous studies to predict QALYs and HSCs. Moreover, we evaluated various algorithms and hyperparameter configurations to develop an optimal predictive model. Once refined, this model will be used to estimate the potential effects of legalising vape on these public health outcomes, including QALYs and HSCs. In addition, this study has enhanced input data extracted from the literature, which are often incomplete and disaggregated by only a subset of demographic groups, such as age, gender, and ethnicity, rather than comprehensively across all relevant categories.

Conclusions and Policy Implications

This study estimates health and cost outcomes of tobacco interventions with greater granularity, including distinctions by age, gender, and ethnicity. Given the novelty of this approach within the field, this study provides a methodological framework for future applications of machine learning for the prediction of critical public health outcomes to guide policies.

Economic Evaluations of Maternal and Child Health

MODERATOR: **Lungiswa Nkonki**,

Ind-432 Estimating Cost of School-Aged Population Screening in Integrated Primary Health Care for Non-Communicable Diseases in Indonesia

PRESENTER: **Gregorius Dimas Herlambang**
AUTHORS: Trihono Trihono, Ery Setiawan, Retno Pujisubekti, Anooj Pattnaik

Background: Indonesia's Ministry of Health (MoH) has introduced Integrated Primary Healthcare (ILP), transitioning from a program-based approach to a life cycle strategy in primary health care. As part of this shift, school-aged children (6–18 years old) are more comprehensive for non-communicable disease (NCD) screening. The screenings including anthropometry, vision and hearing, mental and dental health, and detection of anemia and diabetes. However, the current National President Quick Win Program named Free Health Screening (FHS) initiative under ILP does not include detailed cost assumptions and does not fully account for children in non-formal and out-of-school settings. This study estimates the cost and five-year budget implications of implementing nationwide school-based NCD screening to inform planning and support more effective resource alignment.

Methods: We used a provider perspective to estimate the cost per child screened, based on unit costs from the Ministry of Health's electronic procurement catalogue (e-catalogue) for consumables, medical devices, and human resources. Two screening packages were defined in accordance with ILP guidelines: a Basic Package consisting of anthropometry, vision and hearing, mental health, and dental/oral checks; and a Moderate Package that adds hemoglobin and blood sugar tests for anemia and diabetes detection. Population projections were developed using school participation rates from the National Socioeconomic Survey (SUSENAS) for 2012–2023 and Ministry of Education enrollment data from 2019–2023. Forecasts of school-aged population (2025–2029) included children in formal, non-formal, and out-of-school categories, using Auto-Regressive Integrated Moving Average (ARIMA) and linear regression models. Five-year budget projections assumed full annual coverage and 5% inflation.

Results: By 2025, the eligible school-aged population is projected to be 53.1 million children, 48.4 million in formal and non-formal education and 4.7 million out-of-school. Unit cost estimates are IDR 33,091 (USD 2.00) for the Basic Package and IDR 58,054 (USD 3.58) for the Moderate Package. This translates into an annual budget requirement of IDR 1.75 trillion (USD 107.9 million) for the Basic Package and IDR 3.08 trillion (USD 189.8 million) for the Moderate Package. Over five years, the projected cumulative budget is IDR 8.78 trillion (USD 541.9 million) for Basic and IDR 15.47 trillion (USD 954.4 million) for Moderate. Meanwhile, the current FHS budget allocates around USD 1.47 per child and mainly targets children in formal schools, leaving 28.4 million children outside the service scope and creating an estimated annual funding shortfall of USD 72.3 million. In addition, no secured five-year financing plan currently exists for this expanded service.

Conclusion: The findings highlight the need for more realistic and inclusive budget planning to support the expansion of school-based NCD screening under ILP. The Basic Package may offer a financially manageable starting point for broader implementation, while the Moderate Package could be considered where additional diagnostic benefits justify the higher cost. As a way forward, the Ministry of Health may consider updating unit cost assumptions and expanding the defined target population to include children in non-formal and out-of-school settings. To ensure sustainability, this effort would benefit from phased budgeting integrated into medium-term expenditure frameworks, along with stronger collaboration between the Ministry of Health, Ministry of Finance, and Ministry of Education to align financing, coverage data, and service delivery plans. This study offers a technical reference for anticipating fiscal requirements and planning toward more equitable screening coverage nationwide.

Ind-1395 Understanding the Potential Value of Adolescent Sexual and Reproductive Health Education in South Africa: A Cost Consequence Analysis

PRESENTER: **Funeka Bango**, University of Cape Town
AUTHORS: Sue Cleary, Linda-Gail Bekker

Background: Promoting the sexual and reproductive health (SRH) of adolescent girls remains central to enabling their health, education, and economic prospects. As endorsed by the United Nations agencies, school-based comprehensive SRH education (CSE) is a priority in many low and middle-income countries (LMICs), which are disproportionately affected by poor adolescent SRH outcomes. This is the case for South Africa, which faces an ongoing need for effective CSE programmes. While CSE is associated with improved sexual knowledge, attitudes and behaviours, implementing these interventions in most LMICs is inconsistent due to complex contextual factors. Consequently, the economic aspects of these interventions are underexplored, and little is known about their economic value. The objectives of this study were to estimate the costs and consequences of a within-trial afterschool CSE intervention targeted at adolescent girls in South Africa. While implementing the intervention faced significant challenges, resulting in failure of the trial to show impact on primary biological outcomes, rich variety of data were collected. This was critical for understanding the cost burden of poor SRH outcomes in a vulnerable population and exploring the economic aspects of CSE.

Methods: We conducted a within-trial cost analysis and a modelled cost-consequence analysis from a societal perspective, including a multisectoral provider (healthcare and education) and learner perspectives, using a Markov modelling approach. Our time horizon was the period of high school (5 years). The model was calibrated using trial and country-level data. The scope of costs included any changes in direct provider and learner costs. Provider costs included intervention costs and those associated SRH services. Learner costs were limited to the transport costs associated with accessing the intervention. Modelled intermediate outcomes included % pregnant, % giving birth and % time spent in school, and final outcomes included life years and quality-adjusted life years (QALYs). We conducted multiple one-way sensitivity analyses and scenario analyses to explore drivers of impact and potential value for money.

Results: Girls enrolled in the trial had a high need for SRH services. In our base case analysis, 24.3% were positive for sexually transmitted infections, 20.9% were using contraceptives, and 22.9% were modelled to fall pregnant over the course of high school. The estimated undiscounted healthcare provider cost per learner was $289.66, with contraceptives and obstetric services accounting for 48% and 47% respectively. The CSE intervention added $134.70 to the costs, and learner costs were estimated at $22.71. The total societal costs were $447.07, while the life years and QALYs were estimated at 4.9 and 4.4, respectively. Scenario analysis demonstrated key shifts in costs resulting from implementing an effective CSE intervention, specifically for the healthcare provider. Increasing levels of abstinence or contraceptives both improved biological outcomes, although the latter generated significantly higher costs.

Conclusion: Our results highlight the cost burden of poor SRH outcomes in adolescent girls in South Africa and demonstrate multisectoral provider costs changes and consequences in response to a CSE intervention. While further research is needed to explore ways to optimise CSE, our results can inform priority setting and resource allocation decisions.

Ind-1751 Empowering Emergency Response: A Comprehensive Costing Tool for Sexual and Reproductive Health Preparedness and Implementation

PRESENTER: **Frida Ngalesoni**, Muhimbili University of Health and Allied Sciences
AUTHOR: Patricia Mutai

The Minimum Initial Service Package (MISP) for Sexual and Reproductive Health (SRH) in Crisis Situations is a globally accepted set of priority objectives and essential SRH services designed to be implemented within 48 hours of an emergency's onset. Despite its integration into global health standards, many women and girls lack continued access to essential SRH services during crises due to fragmented emergency response efforts and insufficient budget planning for implementation of the MISP. PROPEL Adapt developed a MISP Costing Tool (the Tool) to support estimation of financial resources needed to implement the MISP to support stakeholders in planning and mobilizing financial resources for SRH services in crises thus enhancing preparedness and response efforts to ensure the continuity of essential SRH health services. The Tool's development process was collaborative, drawing on 11 key informant interviews with global experts as well as existing resources.

PROPEL Adapt gathered illustrative cost inputs from SRH in crisis stakeholders in both the Democratic Republic of the Congo and Ethiopia. The finalized Tool utilizes an activity-based costing approach to estimate the costs required for each of the 35 distinct sub-objectives and 72 activities within the MISP along with an additional area on MISP preparedness. The Tool is unique in its comprehensiveness as it covers all input costs associated with planning, coordination, and commodity logistics, storage and transportation, as well as preparedness actions such as policy development. While comprehensive, it maintains its simplicity, allowing for context adaptations in countries where previous preparedness work has already occurred. Lastly, the Tool estimates costs required to transition from crisis mode into providing comprehensive SRH services which are integrated into primary health care. In applying the Tool to the Ethiopian context, PROPEL Adapt estimated the total cost of implementing MISP at USD 1.41 million with the highest percentage of costs required to respond to the SRH needs of sexual violence survivors (28%). As expected, most of the commodities' related costs were associated with prevention of maternal and newborn mortality. In regards to resource requirements by cost category, running service delivery points - including health facilities, emergency camps, outreach and mobile clinics - accounted for 34% of the total costs. Once used, the Tool's cost estimates enable various stakeholders to assess the affordability, feasibility, and sustainability of the MISP while strengthening their preparedness and response efforts. The Tool can also support governments' stewardship and role in coordinating SRH in crisis response by equipping government decision makers with information to plan effectively and avoid duplication of activities. For instance, government stakeholders could use the individual MISP objective cost estimates to assign objectives to different implementing partners and provide them with budget envelopes. Similarly, the cost of health commodities outputs can be used to initiate discussions with the United Nations Population Fund or private sector entities regarding potential contributions to emergency SRH response efforts.

Ind-2646 Economic Evaluation of Trachomatous Trichiasis Surgery in Ethiopia

PRESENTER: **Amanuel Yigezu**

Background: Trachoma is the second most common cause of blindness in Ethiopia. Surgery to correct trachomatous trichiasis (TT) is a key intervention against trachoma. This study aims to estimate the costs and cost-effectiveness analysis (CEA) of TT surgery when compared to doing-nothing in Ethiopia in community settings. **Methods**: The costing was conducted from the healthcare provider's perspective. Micro-costing and top-down costing approaches were implemented to identify, measure, and value the resources used. Both capital and recurrent inputs were considered. Effectiveness was measured in Disability Adjusted Life Year (DALY). A Markov model, classified into five health states was built to estimate the incremental cost-effectiveness ratio (ICER). Both deterministic and probabilistic sensitivity analyses were performed by varying utilities and probabilities. All costs and effects were discounted by 3%. The willingness to pay threshold of Ethiopia's GDP per capita was used to evaluate the cost-effectiveness. **Results:** The cost of the TT surgery was US$ 31.90 per person. The ICER of TT surgery when compared to doing-nothing is US$ 12.73 per DALY averted from the healthcare provider perspective. A sensitivity analysis from a broader societal perspective indicated that the TT surgery costs less and averts more DALYs than the do-nothing scenario. Variability in other input parameters did not impact the overall cost-effectiveness of the intervention. **Conclusion:** TT surgery is a very cost-effective intervention in Ethiopia in community settings. **Keywords**: Blindness, Cost-Effectiveness Economic Evaluation, Trachoma, Trachomathous Trichiasis Surgery, Visual impairment

Ind-32 Cost-Effectiveness of Integrated Maternal HIV, Syphilis, and Hepatitis B Screening Opt-out Strategies in Nepal: a Modelling Study

PRESENTER: **Kasim Allel**, Centre for Global Health Economics, UCL
AUTHORS: Lucie Sabin, Hassan Haghparast-Bidgoli, Ghanshyam Gautam, Naomi Saville

Background and objective:

Every year, a significant number of infants are born with HIV, syphilis, and hepatitis B, transmitted by their mothers during pregnancy or childbirth. The World Health Organisation (WHO) developed a comprehensive framework encouraging an integrated and coordinated approach to achieve triple elimination of vertical transmission of HIV, syphilis, and hepatitis B in Asia. Integrated antenatal screening, which allows pregnant women to be screened for the three diseases during a single blood draw during the first antenatal care (ANC) visit offers a promising approach to enhance early diagnosis and timely treatment. However, evidence on the cost-effectiveness of integrated antenatal screening for HIV, syphilis and hepatitis B remains limited.

Although the prevalence is relatively low in Nepal, vertical transmission of these infections continues to be a critical public health concern. Current screening practices in Nepal show significantly lower coverage for syphilis and hepatitis B compared to HIV suggesting potential for integration. Given the constraints of limited resources and the need for prioritisation, determining the most cost-effective strategies for integrated antenatal screening is crucial. In this study, we aimed to model the cost-effectiveness of triple screening during antenatal care in Nepal.

Methods:

We modelled maternal HIV, hepatitis B and syphilis cascade of care and their corresponding disease states using disease-specific Markov models over a 20-year horizon with a cycle length of one year. We assumed screening occurred at the first antenatal care visit following an opt-out strategy, with subsequent treatment initiated promptly for disease-positive women. We compared dual integrated screening for HIV and syphilis and triple integrated screening for HIV, syphilis and hepatitis B with HIV screening only (status quo). Costs were estimated from a provider's perspective. Key indicators for effectiveness included number of new infections, number of disease-related adverse events, number of person-years living with the diseases and number of diseases-related deaths. Results were presented as cost per disability-adjusted life year (DALYs) averted. Deterministic and probabilistic sensitivity analyses were conducted.

Results:

Our modelling analysis of 752,506 pregnant women showed that integrated dual antenatal screening for HIV and syphilis was highly cost-effective, with an incremental cost effectiveness ratio (ICER) of $66 compared with the current strategy of screening for HIV only. Similarly, integrated triple screening was cost-effective, with an ICER of $150 compared to HIV screening only. However, when triple screening was compared to dual screening for HIV and syphilis, the ICER was $5,029, higher than Nepal's willingness-to-pay threshold. Nevertheless, 61% of the probabilistic sensitivity analysis estimates for triple screening were cost-effective.

Discussion:

Our results support WHO recommendations for the implementation of integrated triple prenatal screening in Nepal and Asia more broadly. The current development of integrated rapid screening kits for HIV, syphilis and hepatitis B will reinforce the feasibility and practicality of adopting this integrated approach. However, successful integration will require effective, high-quality ANC services supported with necessary human resources, facilities and supplies.

Ind-613 Estimating the Costs of Interventions to Reduce Anaemia in 193 Countries.

PRESENTER: **Tori Oliver**
AUTHORS: Yingying Wang, Robin Blythe, Natalie Carvalho, Sumie Leung, Clare Glover-Wright, Jacinta Holloway-Brown, Sant-Rayn Pasricha, Michael Bode

Background

Anaemia remains a significant public health issue impacting an estimated 1.92 billion people worldwide, with a disproportionate distribution of this burden falling on children and women of reproductive age. The past decade has brought only marginal gains towards addressing the global burden of anaemia, with no country on track to meet the Sustainable Development Goal target of a 50% reduction in anaemia prevalence in women of reproductive age by 2030. Prioritisation of cost-effective anaemia reduction strategies worldwide will be critical for making progress towards current and future targets and relies on robust estimates of the costs of available interventions. Published studies and tools estimating these costs typically focus on a single or limited number of interventions and country settings, with much variation in the methodological approach and types of costs included. This limits opportunities for global modelling of cost-effectiveness and total resourcing requirements using data that are comparable between interventions and country settings.

Research Aim

To develop a consistent methodology and complete set of data inputs for estimating country-specific unit costs for all interventions recommended by the World Health Organization (WHO) for reducing the burden of anaemia in women of reproductive age.

Detailed Methods

An Excel-based tool was developed to facilitate a micro-costing approach to estimating unit costs (per person receiving an intervention) for six WHO-recommended anaemia prevention and treatment interventions in 193 United Nations member states. A modified healthcare sector perspective and 1-year timeframe were adopted. Cost categories for each intervention included the commodity, supply chain, service delivery and administrative program costs. Quantities of resources for each cost category (e.g. number of tablets) were estimated based on WHO guidelines. The costs of each resource were estimated using secondary data sources. The impacts of uncertainty in parameter estimates were explored using one-way sensitivity analysis. Costs are presented in 2023 United States dollars (USD).

Key Results

In most countries, staple food fortification (rice and/or maize flour) was the lowest cost intervention, with a population-weighted average unit cost ranging from 0.41 USD in low-income countries to 1.48 USD in high-income countries per person per year. Multiple micronutrient supplements (MMS) generally had the highest unit cost, ranging from 9.58 USD (low-income countries) to 135.60 USD (high income countries). In high income countries, service delivery costs represented the largest component of unit costs for most interventions except for insecticide-treated bed nets and MMS (where commodity cost was the largest component). Program costs were the largest component of unit costs for several interventions in low-income countries. Uncertainty in commodity costs had the largest impact on overall unit costs for most interventions in most countries, followed by service delivery costs, particularly in high-income countries.

Conclusions and Implications

We developed a standardised methodology to estimate unit costs and understand cost drivers for WHO-recommended anaemia interventions in 193 countries. As the international community looks towards setting the next agenda for addressing anaemia, this work can help build a global evidence-base to guide investments in cost-effective interventions for reducing anaemia in women of reproductive age.

Ind-1034 Navigating Transition to Home: Resource Use and Cost Comparison of Nurse Navigator Support for Caregivers of High-Risk Infants Post-NICU

PRESENTER: **Myla Moretti**
AUTHORS: Julia Orkin, Kayla Esser, Wendy J Ungar, Jennifer Zwicker, Eyal Cohen, Vercancy Wu

Background: Infants in the neonatal intensive care unit (NICU) often require specialized post-discharge care involving primary care providers, medical sub-specialists, and allied health professionals, resulting in substantial healthcare resource utilization and costs. The Coached, Coordinated, Enhanced Neonatal Transition (CCENT) program is an innovative bundled intervention delivered by a nurse navigator to support caregivers of high-risk infants transitioning from the NICU to home, and during the first year of life.

Objective: The primary objective was to compare the frequency and associated costs of healthcare resource use between those high-risk infants and their caregivers who were assigned the CCENT intervention with those receiving standard care in the first year following NICU discharge.

Methods: This is an economic evaluation conducted alongside a randomized controlled trial conducted at seven Level III NICUs in Canada. Healthcare resource use and cost data were collected using a structured Resource Use Questionnaire (RUQ), administered to caregivers at 4 months (RUQ4) and 12 months (RUQ12) after discharge, post-randomization. Cost analysis involved estimating total and average costs per service provider type for each group, using summary statistics for counts and mean resource utilization.

Results: A total of 275 caregivers (290 infants) participated in the study. Resource use data were obtained from 202 caregivers who completed at least one RUQ, and cost analysis was conducted using data from 117 caregivers who completed both RUQs. Among those completing RUQ4, 91***% (n=** *68) of caregivers in the CCENT group reported one or more visits with a primary care provider compared to 95***% (n=79***) in the standard care group; at RUQ12, these figures were 89***% (n=**70) for CCENT and 90**% (n=**74) for standard care. For medical sub-specialist visits, 56**% (n=**42) of caregivers in the CCENT group reported visits at RUQ4 compared to 52**% (n=**43) in standard care; at RUQ12, these figures were 58**% (n=**46) for CCENT and 62**% (n=**51) for standard care. Similarly, visits to allied health professionals were reported by 52**% (n=**39) of caregivers in the CCENT group at RUQ4 compared to 37**% (n=**31) in standard care, with results for RUQ12 showing 37**% (n=***29) and 34%(n=28), respectively. Cost analysis for the intervention and standard care groups is in progress and will assess the economic implications of the CCENT program from both a healthcare system and family perspective.

Conclusions: This study is the first in Canada to provide a comparative analysis of healthcare resource use and costs for high-risk infants and their caregivers post-NICU discharge. High utilization across provider types in both groups underscores the complex medical needs and potential financial burden on caregivers. Although cost results are forthcoming, initial findings suggest that coordinated transitional care interventions like CCENT may help address these challenges. This research offers valuable insights for health policy aimed at supporting caregivers navigating medical needs for their high-risk neonatal population.

Ind-1287 Economic Evaluation of User Fee Exemption Policies: Evidence from a Cost-Effectiveness Analysis for Children Under Five in Burkina Faso

PRESENTER: **Thit Thit Aye**, Heidelberg Institute of Global Health, University Hospital and Medical Faculty, Heidelberg University
AUTHORS: Hoa Thi Nguyen, Laurène Petitfour, Valery Ridde, Aleksandra Torbica, Emmanuel Bonnet, Mariam Seynou, Mr. Joël Arthur Kiendrébéogo, Ali Sie, Ms. Manuela De Allegri

Background: Use fee exemption policies have emerged as a health financing strategy to improve financial access to essential healthcare services by eliminating direct payment at the point of care in Sub-Saharan Africa. While substantial research has investigated the effects of user fee exemption policies on service utilization, very few studies have assessed the relative costs and effects of these policies for children under five. This gap in economic evidence limits our understanding of the value of user fee exemption policies and our ability to make optimal decisions in resource allocation.

Aim: This study aimed to evaluate the cost-effectiveness of Burkina Faso's national free healthcare policy, which eliminated user fees for pregnant women and children under five as of 2016. Specifically, our analysis focused on common childhood illnesses of children under five and estimated the relative costs and effects of the policy compared to the baseline condition prior to its implementation.

Method: We developed a single decision tree model to assess the cost-effectiveness of the policy from its onset in 2016 until 2021 from a health system perspective. Inputs for model parameters were obtained from various data sources, including the model effect estimate on service utilization from own impact assessment, cost estimates from the Ministry of Health's reimbursement data and our micro-costing study, and disease parameters from peer-reviewed existing literature. We selected 2021 as the reference year and converted costs from the preceding years to the reference year. Given the acute nature of childhood illnesses and considering mortality constituted a major portion of the disease burden for children under five, we utilized Life Years Saved (LYs) as the primary outcome measure for the cost-effectiveness analysis. A standard annual discounting rate of 3% was applied to determine the effects. We conducted a deterministic analysis to determine the incremental cost-effectiveness ratio (ICER) per life-year saved. Additionally, we performed a series of one-way sensitivity analyses, a probabilistic sensitivity analysis (PSA), and scenario analyses to investigate the robustness of the results.

Result: The average service provision costs for a child were $6.91 without the policy and $8.94 with the policy. The service utilization had a cumulative average increase of 28.57%. Our preliminary analysis showed that the free healthcare policy was associated with an incremental cost of $2.03 and a discounted incremental effect of 0.019 life-years saved per child, compared to the baseline condition. These values resulted in an ICER of $108.72 per life-year saved, about 14% of the country's GDP per capita in 2021 (~$794).

Conclusion and Implications: Our deterministic findings suggest that user fee exemption policies for children under five are likely cost-effective. Yet, the result should be interpreted with caution, due to the context-specific uncertainties.

Ind-2395 Economic Evaluation of a Care Coordination Program for Families of Children with Medical Complexity

PRESENTER: **Myla Moretti**
AUTHORS: Samantha Quartarone, Londgi Fu, Nora Fayed, Sima Gandhi, Eyal Cohen

Background: Children with medical complexity (CMC), particularly those who are medically fragile and/or technology-dependent, often experience fragmented care and frequent hospitalizations. The Complex Care for Kids Ontario (CCKO) intervention aims to address these challenges through intensive care coordination delivered by a team led by a nurse practitioner.

Objective: This study evaluates the cost-effectiveness of the CCKO intervention compared to standard care in reducing emergency room visits from both health care system and societal perspectives.

Methods: A cost-effectiveness analysis was conducted alongside the clinical trial of CCKO, which used a waitlist variation of a randomized controlled design. A cohort model was constructed with parameter estimates, costs and ranges for sensitivity analyses derived from the clinical study. Incremental costs were compared to incremental changes in mean emergency room visits over a 12-month time horizon expressed as the incremental cost-effectiveness ratio (ICER).

Perspectives: This analysis will be performed from both a health care system and societal perspective.

Costs: Direct costs included the intervention itself and all health service use during a one-year follow-up period. Health system costs were obtained from administrative data sets (ICES). Additional health services use such as those covered by third-party payers and caregiver out-of-pocket expenses were obtained by direct interview with caregivers. Indirect costs, such as caregiver lost productivity were also recorded during caregiver interviews at multiple time points during the study period.

Outcome Measure: The primary effect measure of this economic evaluation was mean emergency room visits. Total inpatient days will be evaluated as a secondary effect measure.

Results: Intervention costs were $6500 per patient, derived from program budget, nurse practitioner case loads and total patient years accumulated during the trial. The preliminary analysis suggests there was no significant difference in mean emergency room visits over the 12-month time horizon, and as such, a cost-comparison approach was employed in this analysis. From a health system perspective, total costs in the intervention group were $73,384 CAD and in the waitlist control group $69,499, with an incremental cost of $3,885 higher in the intervention group. Incorporation of caregiver lost productivity costs is ongoing, as is sensitivity analysis to assess the robustness of these results. Further scenario analyses will also be performed to determine impacts of COVID-19 restrictions which may have limited health care utilization in the later part of the study time horizon.

Conclusion: Preliminary findings suggest that, although the CCKO intervention was not cost-saving over a short time horizon and did not appear to reduce emergency room visits, its costs may represent good value for money in addressing patient and family needs. The increasing complexity of care and burden on families suggests that a navigator may be a valuable resource, potentially leading to improved care coordination for these children and their caregivers. Further analyses over a longer time horizon are warranted to determine the intervention's potential impacts and benefits.

Ind-1203 Impact of National Health Mission on Maternal and Child Health Outcomes: An Interrupted Time Series Analysis Supplemented with Evidence of Inequity

PRESENTER: **Dr. Abinash Singh, PhD**
AUTHOR: Sukumar Vellakkal

India launched National Health Mission (NHM) in 2005 to reduce maternal and child mortality by providing equitable, affordable, and quality healthcare services. Studies assessing the impact of National Health Mission (NHM) were skewed towards the uptake of maternal and child health (MCH) services, with sparse evidence on related health outcomes at population level. Using annual time series data, we estimated the population level (intention-to-treat effect) impact of the NHM on MCH outcomes such as Infant Mortality Rate (IMR), stillbirth, Neonatal Mortality Rate (NMR), and Maternal Mortality Ratio (MMR). Our results exhibit a strong consensus of positive impact on IMR in the post-NHM period, with an additional annual decline of 0.49 deaths per 1000 livebirths in its rate and 0.3 deaths per 1000 livebirths in its regional differences. On the flip side, we find only a moderate impact on stillbirth and an insignificant impact on NMR and MMR. Further, a saturation effect in the impact with no significant change in the trend was observed after the targeted full implementation year of 2011-12, for all the MCH outcomes. Subsequently, using nationally representative individual sample data, we estimated the socioeconomic inequity in MCH outcomes in the pre- and post-NHM periods and found that the inequity disfavoring the poor still prevalent, however, there was considerable decline in the post-NHM period, where the highest decline was noticed for infant mortality: concentration index: -0.14, (P=0.000) in 2002-04 to concentration index: -0.082, (P=0.000) in 2019-21. Overall, NHM had a moderate impact on MCH outcomes with considerable variation across the states and MCH indicators. Our findings inform policy decisions for strengthening public health system to reduce pervasive socioeconomic inequity and amplify the positive gains on MCH outcomes.

Ind-141 Health Economic Evaluations of Immunotherapy and Biologics for Food Allergy Management: A Systematic Review

PRESENTER: **Dr. Andrew Fong, MD MHLM**
AUTHORS: Joshua Jacob, Jennifer Protudjer, Melanie Lloyd, Liz Thyer, Peter Hsu, Lei Si

Background: Food allergy is a significant public health concern with substantial economic costs, including the cost of treatment, healthcare service utilisation and carers' time. These economic costs of food allergy are borne by food allergic individuals, their families and the community more broadly. With the development of novel therapeutic approaches and evolving discussions around allergy management, there are multiple knowledge gaps on the cost-effectiveness of the various treatments available.

Methods: The aim of this systematic review was to identify and synthesise health economic evaluation studies on the use of immunotherapy and biologics in food allergy management. A comprehensive literature search was applied to databases including Medline, Cochrane Library and Scopus. Additional 'grey' literature was also reviewed. Studies undertaking an economic evaluation were included. Cost-effectiveness measures, including cost per quality-adjusted life year, incremental cost-effectiveness ratio (ICER) and net monetary benefit were extracted. The reporting quality of studies was assessed using the validated CHEERS checklist. Key outcomes and model inputs and design were collated, synthesised and reported descriptively.

Results: 2065 unique papers were identified. Independent screening by two researchers included 8 full text studies. 7 related to immunotherapy, and 1 reporting on biologics. Despite the heterogeneity of country of origin and thus health systems, most cost-effectiveness studies were modelled on a young child with peanut allergy. 5 studies were from the US context, with representation also from Australia, the UK and Canada.

Overall, commercial forms of oral immunotherapy and epicutaneous immunotherapy were shown to not be cost-effective in the US (ICER US$88,000/QALY gained & US$216,000/QALY gained respectively). In the UK, excluding the cost of clinician consultations, monitoring and follow-up associated with the administration of treatments, the UK National Institute for Health and Care Excellence (NICE) expressed that commercial peanut oral immunotherapy could be considered as acceptable for cost-effectiveness under the NHS. The preferred ICER following NICE assessment was £36,565/QALY.

In comparison, a non-commercial peanut oral immunotherapy for pre-school aged children using store-bought peanut flour was assessed as cost-effective in the US & Canadian contexts and was the dominant treatment option compared to avoidance. Similarly, an Australian study showed that a probiotic peanut oral immunotherapy is cost-effective compared to no treatment (ICER A$19,386/QALY gained).

For Omalizumab, in the base case and at current pricing, Omalizumab was not cost-effective as a sole food allergy treatment (family-level cohort ICER analysis $185,183/QALY gained). With sensitivity analysis, cost-effectiveness may be achieved at a lower retail price or when larger health utility shifts are apparent.

The reporting quality of these studies was appropriate and comparable between studies, although there was no discussion of the distributional effects and minimal engagement with the food allergy population.

Conclusions: These results conclude that the various commercial forms of immunotherapy available are generally not cost-effective, whilst non-commercial forms of oral immunotherapy have evidence for cost-effectiveness. At present, omalizumab is not currently cost-effective as a monotherapy for food allergy. We anticipate these findings will assist clinicians when prescribing immunotherapy and biologics and highlight areas of improvement for existing models of care.

Ind-698 Implementation of National Food Safety Standard Maximum Levels for Listeria Monocytogenes: Cost-benefit Analysis of a Public Sector Decision

PRESENTER: **Yi Li**
AUTHORS: Guoxiang Liu, Xin Zhang

Background Microbial contamination causes foodborne illness, and Listeria monocytogenes (L. monocytogenes) is the main foodborne pathogen. In 2021, China issued a new food safety standard that L. monocytogenes is prohibited in frozen drinks. This study aims to assist the national food safety department in formulating or changing regulations and policies, adjusting budgets, and guiding the development of the food industry. **Methods** We conducted a cost-benefit analysis for the implementation of food safety standard from societal perspective. The decision tree, willingness-to-pay, and value of statistical life were used to estimate health gains. Delphi technique, survey, and activity-based costing were used to estimate costs of government and enterprises. The outcome measure was Benefit-Cost Ratio (BCR). Costs and health outcomes were discounted to 2021. Parameters for one-way deterministic sensitivity analysis included the foodborne proportion of listeriosis in children under 5 years of age, pregnant women, and people aged 5-65 years and over 65 years, and etc. The data were driven from Chinese industrial enterprises database, field surveys, censuses, and etc. **Results** In 2021, there were about 3532 listeriosis cases in China, with health gains of

¥128,863,325.65 ($19,975,713.17). The compliance costs of government and enterprises were ¥9,163,833.75 ($1,420,529.18) and ¥22,877,454.88 ($3,546,342.41), respectively, and the BCR was 4.02. Sensitivity analysis showed that all parameters influenced little on the BCR, and the implementation was always cost beneficial. **Conclusion** In China, the health gains of implementation of national food safety standard maximum levels for L. monocytogenes in frozen drinks outweigh the compliance costs of government and enterprises. **Keywords** Listeria monocytogenes, Food safety regulation, China, cost-benefit analysis, decision tree model

Ind-1666 Equity Impacts and Cost-effectiveness of Salt Substitutes for Disease Prevention in Indonesia

PRESENTER: **Leopold Aminde**

AUTHORS: Nunik Kusumawardani, Wahyu Pudji Nugraheni, Santi Martini, Tety Rachmawati, Rofingatul Mubasyiroh, Febi Dwirahmadi, Mr. Lennert Veerman

Background: High blood pressure affects more than one in three Indonesians, and it is a major risk factor for heart disease, stroke and kidney disease. Growing evidence from pragmatic trials suggests that low-sodium potassium-enriched salt substitutes (LSSS) – containing 75% sodium chloride and 25% potassium chloride – are effective in lowering blood pressure (BP). However, there is limited research on the impacts of these LSSS in Indonesia. This study aimed to investigate the potential health impacts and cost-effectiveness of LSSS in Indonesia.

Methods: We developed a mathematical simulation model using the proportional multistate lifetable Markov framework to assess a government-led strategy that gradually switches the current regular salt (100% sodium chloride) consumed in the country to LSSS alternatives. BP distribution data were obtained from the Indonesian Basic Health Research Survey (RISKESDAS 2018), while baseline disease incidence, case fatality and disability rates were from the Global Burden of Disease 2019 study. The dose-response effects of LSSS on BP were derived from meta-analyses of randomized trials, while relative risk functions were used to estimate the effects of BP changes on incident disease. Changes in disease events and gains in life years, healthcare costs and policy implementation costs, and incremental cost-effectiveness ratios were estimated from a health system perspective. Outcomes were simulated for the population alive in 2019 overall, and by income quintiles. A discount rate of 3% was applied for health and economic outcomes. The relative concentration index was used to estimate health equity impacts. Uncertainty was assessed using probabilistic sensitivity analysis.

Results: A government policy to gradually replace regular salt with LSSS over a 10-year period could avert 1.5 million incident cardiovascular disease events and 643,000 new cases of chronic kidney disease in Indonesia. In addition, over 200,000 CVD and CKD deaths could be postponed. Over the lifetime of the Indonesian population, this could result in 24.6 million health-adjusted life years (HALYs) gained. This salt switch is predicted to reduce cardiovascular-related health inequalities (concentration index, -0.075, 95%CI: -0.088 to -0.062). The projected policy implementation salt reformulation costs (US$ 1.2 billion [Indonesian Rupiah (IDR) 17.2 trillion], as of July 2019) were outweighed by the net savings in health expenditure (~US$ 2 billion [IDR 27.7 trillion]) due to reduced disease cases. After accounting for healthcare expenditures from added years of life due to the intervention, LSSS were dominant (cost-saving) over the lifetime, and very cost-effective even with a high LSSS price.

Conclusion: This analysis demonstrates that a switch from regular salt to LSSS alternatives could be a cost-saving strategy to prevent chronic disease and reduce health inequalities in Indonesia.

Ind-2843 Estimating The Relationship Between Knowledge of The Negative Externalities of Antibiotic Consumption and Willingness to Pay For Antibiotic-Free Food

PRESENTER: **Melisa Williams Higgins**

Background

The widespread use of antibiotics in food–producing animals, particularly those deemed medically important to humans, is one of the mechanisms for increased resistance in humans. This is more concerning given recent evidence of a direct causal link between antibiotic consumption in animals and resistance in humans. Individuals aware of this should have an increased demand, that is higher willingness to pay (WTP), for foods produced with appropriate antibiotic methods compared to other foods.

Research aims

This paper aims to estimate respondents' WTP to forgo antibiotic use in the foods they consume and identify if this WTP is affected by their knowledge of antibiotic consumption and resistance. This is the first study to investigate whether knowledge has a causal impact on WTP for antibiotic-free food.

Methodology

I conducted a survey in October 2019 with 523 UK residents to collect primary data. The survey included a choice experiment, using the sequential bid contingent valuation method, from which I calculated the individual's willingness to pay for the antibiotic–free option for the most-purchased and least-purchased good (of chicken, seafood, and legumes). I assumed that each respondent has a single willingness to pay value, and that the responses in the experiment were driven by this single value. The intervals are completely exogenously determined as only the interval bounds containing the respondent's true WTP is observed.

For each respondent, I calculated a knowledge index by summing the number of correct responses to the knowledge questions which tested the respondents' awareness of resistance, and knowledge of antibiotic use in humans and food production. To ensure robustness of the results, knowledge is also measured using a subset of the questions including the use of antibiotics in food production, and a Principal Component Analysis which reports the most important knowledge variable for each respondent.

For the estimation I use interval regression, as the data is censored, and linear regression using the WTP interval midpoint as a proxy for the true WTP.

Results

On average the WTP for the antibiotic–free option (compared to the regular option) is 57% higher for the most–purchased protein and 52% higher for the least–purchased protein. Additionally, knowledge has a positive and significant effect on WTP for the most–purchased protein, which is robust to different specifications, and positive but non–significant effect for the least–purchased. The interval regression estimates suggest that the WTP for the most–purchased antibiotic–free good increases by approximately £0.085 (a 5% increase relative to the mean) for each one standard deviation increase in the knowledge index (OLS results are very similar).

Conclusion

The findings suggest that consumer WTP for antibiotic avoidance is non–trivial, the WTP is over 50% higher than the price of the regular option even for the least-purchased protein and may justify government regulation over the use of antibiotics in food production. The knowledge index calculated was low (less than 50% in most cases) suggesting that even with low levels of knowledge, respondents would still prefer foods produced without antibiotics.

Ind-110 Utilization of Inpatient Health Services for DM Patients of JKN Participants in Referral Health Facility in Indonesia

PRESENTER: **Erfan Chandra Nugraha**
AUTHORS: Pujiyanto Pujiyanto, Vetty Yulianty

The number of participants suffering from diabetes mellitus (DM) in Indonesia continues to increase and is becoming a burden in financing the National Health Insurance (JKN) program. Access to health services by DM patients participating in JKN at Advanced Level Referral Health Facilities (FKRTL) is seen as only being utilized by certain membership segments. Apart from that, various factors influence access to health services at secondary-level referral health facilities. This study aims to analyze the use of health services by DM patients participating in JKN based on membership type and examine the determinants of health service use at the inpatient level. This research uses secondary data in the form of 2022 DM contextual BPJS Kesehatan sample data. The data was analyzed univariately, bivariately, and multivariately with the Zero Inflated Negative Binomial regression model. The results of statistical tests show that the level of hospitalization, age, treatment class and province of participants significantly differ in the use of health services. in inpatient care based on predisposing factors, namely age and enabling factors, namely treatment class and participant provincial/regional variables which are significantly related to service utilization, Lampung Province is the region with the largest inpatient utilization 1.1 times compared to Aceh Province, meanwhile type Participation in the JKN program does not have a significant effect on inpatient services. Keywords: Utilization of health services, inpatient care, national health insurance participants, diabetes mellitus, sample data

Ind-240 Health Service Utilization Equity in Less Developed Areas of China: Evidence from Gansu Province

PRESENTER: **Jiaxian Zhou**
AUTHORS: Jie Lu, Jianmiao Li, Xin Gao, Shuyi Li, Xiaobin Hu, Shengxin Tao, Xi Chen, Xuhong Pu, Ningwen Mao

Objective Equity is a key issue in the utilization of health services. All countries in the world are constantly exploring the reform of health system to promote the equality of residents' utilization of health services. However, previous studies have shown that there are still great inequities in the utilization of health services among different residents, especially in some economically underdeveloped areas. The purpose of this study is to explore the equity of health service utilization and its influencing factors among residents of less developed regions, and to provide reference and policy recommendations for the effectiveness of the new round of health care system reform in China. **Mathods** Taking the data of the 7th National Health Service Survey in Gansu Province as an example, based on Anderson model, the equity of health service utilization and its influencing factors were evaluated by using the centralized index (CI) and its decomposition method. On this basis, it screened out patients who had used outpatient or inpatient services from the survey subjects, and extracted their out-of-pocket payments (OOPs) incurred by using the above services. Recentered influence functions (RIF) regression and its decomposition method were used to analyze the equity difference of health service utilization level between urban and rural residents, and the contributing factors were discussed. **Result** The CI of outpatient service utilization (two-week visit rate) was 0.0422 and -0.0268, and the CI of inpatient service utilization (hospitalization rate) was 0.1462 and -0.1294, respectively. The utilization of both outpatient and inpatient services tends to be high income residents in cities, while in rural areas, the lower the economic level of residents, the higher the utilization rate. Further analysis of the level of health service utilization showed that the Gini coefficients of OOPs for urban and rural patients were 0.703 and 0.748, respectively, indicating a large inequality. RIF regression and its decomposition results show that rural patients have greater inequality than urban patients in OOPs for out-patient and in-patientcare, and there is discrimination effect. **Conclusion** At present, there are still inequities in the utilization of health

services in less developed areas of China, especially in the utilization of hospitalization services, but the degree of inequity is reduced compared with previous studies. In terms of the fairness of health service utilization level, the inequality degree of rural residents is greater than that of urban residents, and there is a greater discrimination effect. This finding suggests that it needs to develop and implement health equity policies for rural residents to ensure that they are not discriminated against in their access to health services. Equity in the utilization of health services is also monitored and evaluated to ensure the effectiveness of the policies and equal treatment in their implementation. **Keywords**** Less developed areas, Utilization of health service, Anderson Model, Concentration index, Gini coefficient, RIF regression

Ind-1538 Climate Extremes and Antenatal Care Utilization: an Interrupted Time Series Analysis of the 2010 Palmares Floods

PRESENTER: **Ivan Augusto Cecilio e Silva**
AUTHORS: Cassia Favoretto, Letícia Xander, Everton Nunes da Silva, Giacomo Balbinotto, Josephine Borghi

Background: Floods severely disrupt healthcare systems, damaging infrastructure, interrupting utility services, and affecting healthcare workers' availability. These disruptions hinder essential services, including antenatal care (ANC), often used as a proxy for overall healthcare accessibility. Simultaneously, floods can reduce healthcare demand, as families prioritize immediate needs like shelter and food. Economic losses further diminish the capacity to afford healthcare, even in theoretically free systems. Despite growing awareness, the impact of floods on maternal and child healthcare (MCH) systems, particularly in lower-middle-income countries (LMICs), remains understudied. **Objective:** This study investigates the immediate and long-term effects of the June 2010 floods in Palmares, Pernambuco, Brazil, on MCH systems, focusing on ANC utilization patterns. It aims to fill a research gap by providing empirical evidence on flood-induced disruptions in healthcare services in a middle-income setting in South America. **Methods:** Using an interrupted time-series analysis, we examined 90,337 individual birth records from the Information System on Live Births (SINASC) between 2000 and 2019. ANC data were classified into three categories: ≥1, ≥4, and ≥7 visits during pregnancy. Records with incomplete ANC data (0.34%) were excluded. The intervention period began the week following the flood (June 20, 2010). We integrated disaster data from the Integrated System of Information on Disasters (S2iD) to link environmental events with healthcare metrics. Data were aggregated weekly, capturing consistent trends. **Results:** The floods caused significant disruptions to ANC utilization, with the most pronounced decline observed in the highest frequency category (ANC ≥7). Post-flood, utilization rates gradually recovered. However, trends varied: while ANC ≥1 and ≥4 showed slower recovery rates, ANC ≥7 demonstrated a faster rebound with a positive trend shift. These findings highlight both the vulnerability and resilience of ANC systems under disaster conditions. **Conclusion:** Floods significantly disrupt ANC utilization, with varying recovery trajectories across care levels. These findings emphasize the need for integrating disaster preparedness into healthcare policy, particularly in LMICs prone to environmental shocks. Policymakers must prioritize adaptive measures to mitigate healthcare disruptions and enhance system resilience, ensuring equitable access to MCH services during and after disasters.

Ind-564 Weathering the Storm: Primary Care Delivery and Telehealth Utilization under Climate Shocks

PRESENTER: **Chunfeng Zhang**
AUTHORS: Ling Li, Xiang LI

This study explores the behavioral dynamics of primary care utilization in the context of climate change. By analyzing daily weather observations at the county level and approximately 20 million telehealth service records in 2023, we find that the impact of temperature shocks on primary care utilization exhibits a U-shaped curve, suggesting the presence of an optimal temperature zone. In contrast, the effect of precipitation shocks follows a J-shaped curve, indicating that the influence intensifies with increasing precipitation levels. The telehealth platform not only enhances accessibility to primary care but also fortifies its resilience, as waiting times remain relatively stable despite increased service volumes. We identify three mechanisms that underpin the resilience of the telehealth platform: the mobilization of available workforce across geographic regions, professional titles, and varying levels of affiliated hospitals. Telehealth platform functions as a form of quasi-insurance that can effectively pool and manage weather-related risks across different regions, leading to pareto improvements.
Keywords: Primary care, climate, weather, telehealth platform **JEL classification:** Q54, I10, L00 1

Ind-1085 Improving Access to Family Planning Services through Voucher Schemes in Punjab, Pakistan: Case Study from Rahim Yar Khan District

PRESENTER: **Dr Shabana Haider**
AUTHORS: Amna Akhsheed, Rahema Hasan

Background: Punjab province in Pakistan is home to 52% of the country's total population. With an estimated 127 million residents, it ranks as the 11th most populous region globally, surpassing nations like Germany (85 million), Japan (112 million), and Malaysia (34 million). The province's population is growing at a rapid rate of 2.53%, projected to reach 150 million by 2030. Efforts toward population control have plateaued over the past decade, with an unmet family planning need of 16%, particularly among marginalized populations and the lowest wealth quintiles in Pakistan. Amongst these women, 22.5% in the lowest wealth quintile have an unmet need for family planning, compared to 13.7% in the highest wealth quintile. Global and local evidence suggests that voucher programs can effectively expand contraceptive choices, overcome method-specific barriers, and make private healthcare providers accessible to disadvantaged clients who face constraints. This research study explores using vouchers as a tool for promoting family planning by the government in the district Rahim Yar Khan. The voucher scheme offered recipients free family planning services at designated public and private healthcare facilities, along with reimbursement for transportation costs, reducing financial, physical barriers and minimizing out-of-pocket costs.

Research Question: How did the implementation of the voucher scheme increase access to and uptake of family planning services in Rahim Yar Khan District, Punjab? What lessons can be learned from this scheme for scaling it up in other areas of Punjab?

Methodology: Our approach combines quantitative and qualitative assessments of secondary data related to provision of family planning services in the district Rahim Yar Khan between 2019 and 2021. We conducted a comprehensive literature review on the use of vouchers for family planning services. Project-related data, which included financial data, was obtained from the implementing agency, the Punjab Population Innovation Fund (PPIF). A rapid assessment of data collected during the implementation of the voucher scheme was conducted, which was then triangulated to draw inferences and conclusions.

Results and conclusion: The Government of Punjab financed the voucher scheme at a cost of PKR 85 million (USD 500,000)[^1], implementing it through a public-private partnership model. The scheme targeted 80,000 marginalized women registered in the national safety net institution in Rahim Yar Khan, of whom over 21,000 (add percentage here) availed free family planning services. The cost per beneficiary was PKR 4,500 (USD 26). The study results showed a 9.9% increase in the contraceptive prevalence rate (CPR) and a 4% reduction in the unmet need for family planning in Rahim Yar Khan district. Additionally, by the end of the project, 35% of individuals in the area who had never used contraceptives reported doing so. These findings demonstrate that vouchers can be an effective tool for improving access to and uptake of family planning services among poor and marginalized populations in Punjab and Pakistan overall. This research provides valuable insights into how enhancing access to free services and reducing financial barriers can drive higher demand for and utilization of health services.

[^1]: 1 USD = 170 PKR (average for 2020-21)

Ind-1363 Wealth-related Inequality in Antenatal Care Service Utilization: Evidence From Nepal Multiple Indictor Cluster Surveys 2014 and 2019

PRESENTER: **Suman Sapkota**
AUTHORS: Bipin Thapa, Amrita Gyawali, Yifei Hu

Antenatal care (ANC) is essential for improving maternal and neonatal health outcomes and its utilization can be affected by socioeconomic status. This study aims to assess the association between wealth-related inequality and ANC service utilization among Nepalese women using data from the nationally representative Nepal Multiple Indicator Cluster Survey (MICS) 2014 and MICS 2019. The analysis included 2,045 women from the MICS 2014 and 2,518 women from the MICS 2019 who gave birth to a child two years preceding the survey. The main outcome variables were receipt of recommended ANC visits, a binary variable, and total number of ANC visits, a count variable. Household wealth index was the independent variable, while women's sociodemographic, household, and settlement characteristics were the covariates. Using individual survey datasets from 2014 and 2019, along with pooled dataset of both surveys, we assessed the association of ANC service utilization with household wealth index using logistic regression and negative binomial regression models. We measured wealth-related inequality using concentration curves and concentration indices (CIx). The Erreygers-corrected method was used to calculate the concentration index for receipt of recommended ANC visits, whereas the generalized concentration index proposed by Wagstaff et al. was used to determine the CIx for the number of ANC visits. The proportion of women who received at least one ANC visit increased from 87.7% in 2014 to 95.5% in 2019. However, women in the highest wealth quintile were 4.78 [95% confidence interval (CI): 2·52, 9·04] times, 3.69 (95% CI: 1·76, 7·72) times and 4.52 (95% CI: 2.80, 7.29) times more likely to receive recommended ANC visits compared to those in the lowest quintile in 2014, 2019 and pooled analysis, respectively. Similarly, compared to being in the lowest wealth quintile, being in the highest wealth quintile increased the expected number of ANC visits by 63% (95% CI: 43%, 87%) in 2014, 41% (28%, 54%) in 2019, and 52% (95% CI: 1.4,1.65) in pooled analysis. Concentration curves revealed a decline in pro-rich inequality in both the receipt of recommended ANC visits and the number of ANC visits from 2014 to 2019, when there was a decline in the national multidimensional poverty index from 30.1% to 17.4%. Despite the decline in pro-rich inequality, the concentration curves and CIx showed that inequality persisted for over five years. The results indicated that for 2014 and 2019, the CIx values for receipt of recommended ANC visits were 0.352 and 0.175, respectively. Similarly, the CIx values for the number of ANC visits in 2014 and 2019 were 0.145 and 0.091, respectively. Our findings reveal wealth-related inequality in ANC service utilization among Nepalese women, with women from higher socioeconomic statuses having higher odds of receiving recommended ANC visits and a higher number of ANC visits. These findings underscore the need for concerted and continued efforts by stakeholders to improve access to and utilization of ANC services among disadvantaged populations in Nepal, particularly those from lower wealth quintiles.

Ind-688 Inequality in Health Service Utilization Among Middle-Aged and Elderly Hypertension Patients in Cold Region of China

PRESENTER: **Haofei Li**
AUTHORS: Lan Zhou, Weidong Huang

【**Objective**】The issue of inequality in the utilization of healthcare services remains a significant topic in the field of health. This study aims to investigate inequality in outpatient and inpatient service utilization among middle-aged and elderly hypertensive patients in cold regions of China, using Heilongjiang Province as an example, and to explore the driving factors behind this inequality. 【**Methods**】Based on the latest round of health service survey data from 2023, hypertensive patients aged ≥45 years in Heilongjiang Province were selected as the study population. The outpatient visit rate within two weeks and the annual hospitalization rate were used as indicators to describe their health service utilization status. The concentration index was used to measure the degree of inequality in outpatient and inpatient service utilization, and a logit model was further employed to decompose the concentration index, identifying key influencing factors behind the inequality. 【**Results**】The two-week outpatient visit rate and the annual hospitalization rate of middle-aged and elderly hypertensive patients in Heilongjiang Province were 16.45% and 18.66%, respectively. The concentration indices for outpatient and inpatient service utilization were 0.0055 and 0.0537, respectively, indicating pro-rich inequality. Household economic status (Percentage contribution:150.45% and 61.71%), multimorbidity (Percentage contribution:131.48% and 57.75%), and family size (Percentage contribution:18.63% and 1.23%) were the main factors driving inequality in outpatient and inpatient service utilization. Patient age had a positive effect on outpatient utilization inequality, with a contribution rate of 55.89%. Additionally, participation in basic medical insurance (Percentage contribution: -3.18% and -8.09%), employment (Percentage

contribution: -191.67% and -0.56%), and education level (Percentage contribution: -39.32% and -17.77%) alleviated pro-rich inequality in outpatient and inpatient service utilization to varying degrees. 【**Conclusion**】There is pro-rich inequality in health service utilization among hypertensive patients in cold regions of China, particularly in inpatient services. Therefore, efforts should be made to further improve the social security system to ensure that the healthcare needs of low-income groups are fully met. 【**Keywords**】Hypertension, Health service utilization, Inequality, Cold regions

Ind-1353 Poverty and Intersecting Inequities in Health Service Access and Utilization in Nepal: Insights From Nationally Representative Surveys

PRESENTER: **Achyut Raj Pandey**
AUTHORS: Suman Sapkota, Kjell Arne Johansson, Krishna Kumar Aryal, Shiva Raj Adhikari

Background: Physical accessibility to health facilities significantly impacts healthcare utilization, particularly in countries like Nepal with sparse distribution of facilities, difficult geographical terrain and limited access to means of transportation. Inequitable facility expansion exacerbates disparities, especially among those facing poverty, rural residence, and challenging terrains. These inequities deepen with overlapping or multiple deprivation thus challenging the health system goal of equitable access to and utilization of health services. In this context, this study analyses intersecting inequities in healthcare access, and utilization which could provide insights in equitable expansion of health infrastructures. **Methods**: We analyzed data from the nationally representative Living Standard Survey 2023 (9,600 households) and the Demographic and Health Survey 2022 (14,845 households). Participants in both surveys were selected using a multi-stage random sampling process. Accounting for the complex survey design, we assessed the intersections of poverty, province, and urban/rural settings. We examined inequities in physical access to health facilities by analyzing travel time and distance to health facility, and utilization by self-reported adequacy of health service utilization. Descriptive bivariate analysis and logistic regression were performed using R programming software. **Findings**: Poor individuals face greater barriers to healthcare access compared to non-poor populations. The median distance to the nearest health facility was 3.61 km for the poor, compared to 2.74 km for the non-poor. Rural residents travel an average of 4.2 km, nearly double the distance of urban residents (2.33 km). Only 26.8% of poor individuals can reach a government hospital within 30 minutes, compared to 47.3% of the non-poor. This disparity increase in magnitude when poverty status intersects with urban rural setting: 11.7% of poor rural residents access a hospital within 30 minutes, versus 58.8% of non-poor urban residents. The disparities are even more pronounced with intersection of three variables: poverty, urban rural setting and province. In Lumbini province, 67% of non-poor urban residents can reach a hospital within 30 minutes, while none of the poor rural residents in Bagmati province can. Access to basic health facilities ranges from 32% among poor rural residents in Bagmati to 88.8% among non-poor urban residents in Lumbini. Among those who faced challenge in accessing care, distance to health facilities was a barrier for 12.6% of the poorest and 65.6% of richest segment of population. In regression analysis, statistically significant association was noted with 92% lower odds for Karnali poor rural residents, 87% lower for Bagmati poor rural residents and 72% lower for Gandaki poor rural residents demonstrating stark inequities in access to care. **Conclusions and implications for policy:** Current practice of establishing health facilities solely based on administrative structures perpetuates inequitable access. Government should consider the other factors like area and population size of the administrative region, difficulties in geographical terrain, economic status of residents and access to means of transportation in establishing and expanding health infrastructures to ensure equitable access to and utilization of the health services.

Ind-818 The Impact of Long-term Prescription Policy on Primary Care Utilization and Costs among Hypertensive Patients in China: A Six-year Longitudinal Study

PRESENTER: **Chunlu Yu**
AUTHORS: Lei Zhang, Luying Zhang, Wen Chen

Background: To strengthen the chronic disease management, China has recently implemented the long-term prescription policy as a component of the family doctor system. This study evaluated the net policy impact on healthcare utilization and costs at community health centers (CHCs) among hypertensive patients. **Methods:** The study population included 164,857 hypertensive patients from a provincial capital city in Eastern China. Their healthcare utilization and costs from January 1, 2014 to December 31, 2019 were collected from the medical insurance claims database. Long-term prescription policy, implemented from 2018, allowing patients who registered with family doctors to obtain up to 3-month prescriptions. The multi-stage difference-in-differences model was applied to examine the policy impact, comparing healthcare utilization and costs between those eligible for the long-term prescription policy and those not. **Results:** The average age of the sample population was 69.93 years old, with 24.45% of the patients having hypertension-related comorbidities. By 2018, 155,258 patients had registered with a family doctor and were influenced by the long-term prescription policy, while additional 9599 patients were not influenced. The average annual number of outpatient visits at CHCs was 19.82 in 2017, with growth rate of 27.79% from 2014, while decreased to 16.10 in 2019. The interval of prescriptions at CHCs was 24.50 days in 2017, with decrease rate of 18.55% from 2014, whilst prolonged to 29.72 days in 2019. The average annual outpatient costs were USD 1,006.74 and USD 990.48 in 2017 and 2019, respectively. The average annual number of hospitalizations increased from 0.28 in 2017 to 0.45 in 2019. The long-term prescription policy significantly reduced hypertensive patients' annual outpatient visits by 2.47 at CHCs ($p<0.001$) and 0.18 at pharmacies ($p=0.018$), prolonged the interval of prescriptions by 3.10 days at CHCs ($p<0.001$). Furthermore, the policy decreased the annual drug costs at pharmacies by 47% ($p<0.001$), though it had no significant effect on the annual outpatient costs at CHCs ($p=0.240$). Additionally, this study didn't observe impact of the long-term prescription policy on patients' annual number of hospitalizations ($p=0.147$). **Conclusions:** The long-term prescription policy mainly affected patients' healthcare utilization at CHCs, and did facilitate patients with chronic diseases to refill drugs conveniently. The policy impact on patient health outcomes needs to be further observed and more attention should be given to the factors that may influence family doctors' behavior in delivering the long-term prescription service.

Ind-1642 Exploring Gender-Specific Unmet Needs and Affordability Barriers in Assistive Technology Access in Uganda: Insights From Uganda's 2023 rATA Survey

PRESENTER: **Md Zabir Hasan**, Johns Hopkins University
AUTHORS: Gerald Okello, Abdul Bachani, Wesley Pryor

Background: The global demand for assistive technology (AT) is increasing due to rising noncommunicable diseases and aging populations. However, access to AT in low- and middle-income countries remains limited, with financial barriers as the major drivers of inequities. In Uganda, where an estimated 7 million people need AT, gender differences in unmet needs and financial barriers remain poorly understood, deterring efforts to design equitable, gender-sensitive policies.

Objective: This study aimed to measure gender-specific unmet needs and financial barriers to accessing AT using data from the 2023 Uganda "rapid Assistive Technology Assessment (rATA)" survey.

Methods: This study included a representative sample of 16,733 individuals aged ⩾5 years from 3,188 households using multi-stage cluster random sampling, spanning 301 enumeration areas across 50 districts in 15 sub-regions of Uganda. Exploratory analyses were conducted to compare the proportions of unmet needs and financial barriers between genders. Multilevel mixed-effects logistic models were used to estimate gender-specific effects, accounting for clustering at the household and enumeration area levels. The adjusted models included covariates such as age, type and levels of functional limitations, and other demographic factors.

Results:

Only 4.5% (n = 758) of the respondents currently use AT products, while 21.0% (n = 3,515) reported unmet AT needs. Significant gender disparities were observed, with women accounting for 56.7% of those with unmet needs compared to men (43.3%, $p < 0.001$). Women with communication ($p = 0.002$) and memory-related ($p = 0.028$) functional limitations reported significantly higher needs than men. Financial affordability was the most frequently reported barrier, cited by 86.8% (n = 3,051) of respondents with unmet needs, with women disproportionately affected (57.7% vs. 42.4% for men, $p = 0.003$). Women with mobility ($p = 0.044$), hearing ($p = 0.007$), and memory-related ($p = 0.004$) limitations also reported significantly higher affordability challenges compared to men. In the unadjusted model, women had 1.22 times higher odds (95%CI: 1.12–1.32, $p < 0.001$) of reporting unmet needs than men. However, this association was no longer significant after adjusting for covariates (OR = 0.94, 95%CI: 0.82–1.09, $p = 0.431$). In contrast, women consistently had higher odds of reporting affordability barrier, both in the unadjusted (OR = 1.43, 95%CI: 1.12–1.83, $p = 0.005$) and adjusted models (OR = 1.36, 95%CI: 1.05–1.75, $p = 0.021$). Clustering effects were stronger in the affordability model than the unmet need model, with intraclass correlation coefficients of 18.4% vs. 12.3% at the enumeration area level and 48.6% vs. 41.2% at the household level, respectively.

Conclusions:

The findings reveal significant gender disparities in AT access in Uganda, with women facing higher unmet needs and financial barriers, particularly for mobility, hearing, and memory-related limitations. Policymakers must prioritize gender-sensitive strategies (e.g., subsidies, public financing, and insurance coverage) to address affordability concerns. Tailored programs for women with specific functional limitations, community-based distribution, and integration of AT services into broader health systems can reduce inequities. Incorporating these insights into Uganda's National Rehabilitation and Assistive Technology Strategic Plan will ensure equitable, inclusive access and improved quality of life.

abs-os15 Adolescent Mental Health Services in West Africa: A Comparative Analysis of Burkina Faso Ghana, and Niger.

PRESENTER: **Ludovic Deo Gracias Tapsoba**
AUTHORS: Ama Pokuaa Fenny, Michel Adurayi Amenah, Jacob Novignon, Roxane Borges Silva, Tim Ensor, Irene Agyepong, Ibrahlm Nasslrou

Background: Adolescent mental health (AMH) is a critical issue worldwide, particularly in West Africa, where it is intensified by socio-economic, cultural, and security challenges. Insecurity and the presence of mining sites expose adolescents to hazardous environments, substance abuse, and adulterated alcohol, further aggravating their mental health. Despite these severe issues, research on AMH in this region remains limited. This study aims to analyze the provision of AMH services in Burkina Faso, Ghana, and Niger, highlighting the unique challenges these countries face within the broader West African healthcare context.

Methods: The study adopted a multi-stage, stratified sampling design to collect data from primary healthcare centers (PHCs) in the three countries. Using STATA.17, Descriptive analysis was conducted on the data related to availability of AMH services, types of mental health disorders treated, resources available, and OPD attendance rates. The analysis also incorporated factors such as the rural-urban divide and the presence of national guidelines for AMH services.

Results: The findings reveal a significant shortfall in the provision of AMH services across the region, with less than 30% of PHCs across all the countries offering these services. The study also highlights a pronounced rural-urban disparity in AMH service availability, a general absence of national guidelines for AMH care, and low OPD attendance rates.

Conclusion: The study highlights the urgent need for comprehensive policy reform and targeted interventions to enhance AMH services in West Africa. Key policy reforms should include the development and implementation of national guidelines for AMH care and integration of

adolescent mental health services into primary healthcare. Additionally, efforts should focus on capacity building through the training of mental health professionals, increasing public awareness to reduce stigma, and ensuring equitable resource allocation across rural and urban areas. Improving AMH care is essential not only for the well-being of adolescents but also for driving broader socio-economic development in the region.

Ind-6 Climate Vulnerability and Health Facility Performance in the Republic of Congo

PRESENTER: **Soazic Elise WANG Sonne**, The World Bank
AUTHORS: Tanmayn Vivek Kshirsagar, Sudhanshu Deshpande

Despite the fact that the Republic of Congo's (RoC) contribution to greenhouse gas (GHG) emissions is negligible, the country has recently faced a sharp increase in temperature and climate risks. Temperature projections, under the scenario of high emissions, indicate an increase in: (i) approximately 1.5°C by 2040 and (ii) 2°C to 3.5°C by 2070.Consequently, the Republic of Congo is ranked 106th out of 191 countries by the Inform Risk 2023 Risk Index, which measures exposure to climate risks. Climate change is likely to have serious consequences for human health. Climate change is already making the RoC hotter, with more erratic rainfall, and these changes are likely to accelerate in the coming decades, triggering more challenges for the health sector (Congo CCDR, 2023). The increased incidence of infectious diseases, such as malaria, cholera, typhoid fever, and tuberculosis, is a direct consequence of climate change in the RoC (GAVI,2022). Climate change-induced flooding due to heavy rainfall and heat stress exacerbates demand-side constraints by reducing access to health facilities and supply side constraints, damaging infrastructure and medical equipment and disrupting the availability of essential medicines and commodities. In this study, we provide a clear identification of where facilities, communities, and districts stand on the climate change vulnerability risk scale using unique geo-coded primary data from the latest 2023 general evaluation of health facilities in the country. Much specifically, we provide a map of which health facilities are facing the dual challenges of low health system performance due to lack of basic infrastructure and increasing vulnerability to climate change and environmental hazards. We also provide an empirical assessment of the relationship between extreme weather events and health facility performance using machine learning models and OLS modelling, controlling for human resources for health and financial resources. We found that climate change negatively impacts health facility performance after controlling human and financial resources.

Ind-2574 Exposure to Violence and Food and Mental Health Insecurity in the Occupied Palestinian Territories

PRESENTER: **Tracy Lin**

The detrimental effects of violent and non-violent political events on food insecurity, and separately, on mental health, are well documented in fragile and conflict-affected settings (FCAS). Concomitantly, the relationship between food insecurity and mental health is abundant. However, little is known about the differential and cumulative impact of repeated political events – ranging from violent events (e.g., military assaults) to less extreme non-violent events (e.g., international agreements) – on the relationship between food insecurity and mental health in FCAS. To address these gaps, we leverage a longitudinal, geo-location political events dataset (The Armed Conflict Location & Event Data (ACLED)) and three waves of repeated cross-sectional, representative household and individual survey datasets (Socio-Economic and Food Security Household Surveys (SefSec)) from a protracted conflict setting, the occupied Palestinian territories (oPt); together, these data are uniquely positioned to permit examination of the relationships between political events, food insecurity, mental health, and their intervening pathways. The time frame of this study is from 2016 to 2020.* We include three waves of bi-annual survey datasets (from 2016, 2018, and 2020) from oPt and geo-merged to an event-based, geo-location dataset of all violent and non-violent political events that occurred in oPt during the time frame. We tested whether increased frequency of political events (both violent and non-violent) will reduce food diversity (lower food consumption score), increase food insecurity (higher FIES), and increase level of distress (higher GHQ score).* Following previous approaches examining mental distress measured using GHQ-12, we begin the analysis with descriptive statistics and bivariate analysis, including t-test and ANOVA. To estimate the association between political events on food diversity, food insecurity, and mental distress in a multivariate analysis *(Aim 1a, 1b, 1c)*, we use a two-level random mixed-effects model that is expressed as follows: $Zitj = b0 + b1Pitj + b2Xitj + qj + mt + eit$ where *Zitj* is an indicator for a given outcome (i.e., food consumption score, food insecurity experience score, GHQ 12 score) for individual I at time *t* in district *j; Pitj* captures whether a political event type or the frequency of political event type occurred in the individual's district of residence; *Xi* represents a series of individual and household-level observable characteristics (e.g. economic status); θi represents a vector of district fixed effects; and μt controls for survey wave year. Preliminary findings suggest that increased frequency of political events (both violent and non-violent) reduced food diversity, increased food insecurity, and increased level of mental distress. The proportion of unacceptable food consumption scores increased from 0.8% in 2014 to 4% in 2020 ($p<0.05$) and the GHQ score increased from the mean of 9.06 (SD=5.01) in 2016 to 10.11 (SD=4.99) in 2018, underscoring a significant and worsening health condition in oPt, even before the most recent conflict escalation and resulting famine. Heterogeneous effects of exposure to political events are associated with residential military zones (Area A, B, or C) and economic status.

Ind-635 Dietary Diversity and Aspirations of Youth. Evidence from India

PRESENTER: **Deepthi Sara Anil**

1.Relevance of the study India faces persistent undernutrition and micronutrient deficiencies despite economic growth. Studies show no notable gender differences in stunting or anemia among children under five, though girls may be breastfed for shorter periods. Gender biases in food allocation for younger children are mixed; some studies show a pro-boy bias, especially among children of illiterate mothers, while others report no significant gender disparity in dietary intake at later ages. However, disparities become more evident in adulthood, as women aged 15–49 are less likely to consume nutrient-rich foods and face higher anaemia rates. Indian social norms, like women eating leftover food, can lead to internalized lower priority, affecting broader life aspirations (Ghatak et al., 2024). This study examines the link between dietary diversity and aspirations among children and adolescents in Andhra Pradesh and Telangana using data from the Young Lives project. Addressing nutritional disparities during this transition period is essential given India's significant gender gap in the labour force. **2. Data** Data come from the Young Lives project in Andhra Pradesh, focusing on two groups: the Younger Cohort (born 2001–02) and the Older Cohort (born 1994–95). A multi-stage sampling method targeted disadvantaged areas, selecting 20 clusters per country. Each cluster included 100 households with younger children (6-18 months) and 50 with older children (7-8 years). While not nationally representative, the sample aligns closely with India's population variability. Analysis spans survey Rounds 2, 3, and 4 (2006, 2009, and 2013). Dietary diversity data from these rounds measure the variety of food groups consumed over 24 hours, based on caregiver reports for younger children and self-reports for older ones. An index from 0 to 7 indicates the number of food groups consumed. Although dietary diversity was generally low, with about four groups on average, variation existed across food types like animal-source foods, fruits, and legumes. Aspirations are measured by expectations regarding education, employment, and belief in achieving these goals. **3. Empirical Strategy** To analyse the relationship dietary diversity and aspiration measures, we use the following model specification: $Yijt=\beta0+\beta1Diyt+\beta2Xijt+\delta j+\epsilon ijt$ In this model Yijt denotes the aspiration outcome for individual i in household j at time t, while ϵijt represents the individual-specific error term, which is unique to each person. The focus is on the parameter $\beta1$ which quantify the effects of dietary groups on aspirations. These parameters represent the average impact of consuming these foods on the outcomes. The model includes controls for age, gender, household size, BMI, marital status, education, employment, region, and income. Initially, Ordinary Least Squares (OLS) regression estimates dietary diversity's impact, with household-clustered standard errors. Additional estimates use household fixed effects to account for unobserved traits, though shared household factors may obscure dietary diversity's influence. The study also examines if effects vary by gender, age, religion, and BMI, with interaction terms identifying differences. Analyses of specific foods, like fruits, vegetables, and proteins, reveal which items most favourably impact aspirations.

Ind-2061 Examining the Relationships between Household Food Insecurity, Child Behaviour and Parent Mental Health Using Data from the Born in Bradford Study

PRESENTER: **Sarah Abraham**

AUTHORS: Penny Breeze, Hannah Lambie-Mumford, Laura Gray

Background Household food insecurity (HFI) refers to a situation where there is inadequate, unreliable access to adequate and nutritious food, at the household-level. The Department of Work and Pensions found that in 2023, 17% of children in the UK were living in food insecure households. Previous US-based studies have reported an association between HFI and poor child behaviour and mental health. These studies have identified the role of parent mental health as a mediator between HFI and child behaviour. No UK-based studies have explored this relationship, which is critical for evaluating the effectiveness and cost-effectiveness of interventions targeting HFI and its impacts on child health in UK child populations. Aim This study aims to examine whether HFI is associated with child behaviour in school-age children aged 7-11 years, and whether the relationship is mediated by parent mental health. Method We used datasets from the Born in Bradford (BiB) and BiB1000 sub-study at the Growing Up follow-up when children were aged 7-11 years. HFI was parent-reported using the six-item United States Department of Agriculture Household Food Security Survey module, between 2017-2020. Between 2017-2022, parents were invited to complete the Strengths and Difficulties Questionnaire (SDQ), a validated tool used to measure child emotional symptoms, conduct problems, hyperactivity, peer-problems and prosocial behaviour. A parent survey measured sociodemographic characteristics, self-reported symptoms of anxiety using the generalised anxiety disorder questionnaire (GAD-7) and depression using the Parent Health Questionnaire (PHQ-8). Complete cases were analysed. Confirmatory factor analyses (CFA) were estimated to test factor structures for child behaviour and parent mental health. A structural equation model (SEM) was estimated to test the direct and indirect pathways between HFI and child behaviour, and parent mental health. Child ethnicity, gender, household occupational status, parent age and free-school meal eligibility status were added as covariates for HFI and child behaviour pathways. While household size was a predictor of parent depression and anxiety. In secondary analysis, parent subjective financial insecurity was added as a covariate, to the HFI and parent mental health pathway. Results The total sample consisted of n=1763 and a large proportion of data were missing. Among complete cases (n=290), 90% children were food secure. CFA identified a three-factor model for child behaviour (internalising, externalising and prosocial), while parent mental health was represented by parent mental health latent factor, with subcomponents depression and anxiety. HFI did not have a statistically significant direct relationship with all three child behaviours. An indirect relationship between HFI and internalising ($\beta=0.12$, $p=<0.01$), externalising ($\beta=0.29$, $p<0.01$) and prosocial behaviour ($\beta=-0.10$, $p=0.03$), via parental mental health was observed. Conclusions This study found that HFI was not directly associated with child behavioural difficulties (internalising and externalising) or prosocial behaviours. However, findings suggest that HFI may adversely affect child behaviour through its impact on parent mental health. The study highlights the importance of considering parent-child dynamics when evaluating interventions aimed at tackling the health implications of HFI in children.

Ind-2237 Synergistic Effect of Nutrition-Specific and Nutrition-Sensitive Intervention to Combat Anemia: Evidence from an Indian Cohort Data

PRESENTER: **Disha Bajaj**

AUTHOR: Sukumar Vellakkal

Despite concerted efforts to combat anemia, it is the most common nutritional deficiency affecting over 72 million adolescents in India. In this regard, the Indian government has launched various interventions to overcome the prevalence of anemia among adolescents which are broadly categorized into access to health services and awareness programs. Wherein, Anemia Free India (2018), aims to improve compliance with Iron-Folic acid (IFA) supplementation and deworming; whereas, Adolescent Health and Wellness Day aims at disseminate useful information regarding health needs to school students, parents, and other key stakeholders. Interestingly, studies demonstrated mixed effectiveness of the

above-mentioned interventions due to ineffective coverage, consumption adherence, and frequency of IFA distribution. Past Research focused on the impact of specific and standalone health interventions on countering anemia, whereas synergistic effects of multiple national interventions were not entirely understood. **Objective:** In the study, we evaluate the impact of combined participation in nutrition-specific intervention (Weekly Iron-Folic Acid Supplementation -WIFS) and a nutrition sensitive intervention (Free from child marriage and dowry awareness program) on prevalence of anemia in adolescents aged 10-19 years. **Methods:** We exploited the comprehensive longitudinal data - Understanding the lives of young adults and adolescents (UDAYA) conducted in 2015 and 2018 with a total sample size of 16292 adolescents recruited from Bihar, India and Uttar Pradesh, India. In addressing the self-selection issues arising from voluntary nature of the program we employed the semi-parametric difference-in-difference and difference-in-difference with fixed effect, accounting for observed and unobserved heterogeneity to estimate average treatment effect. **Findings:** We found that simultaneous participation in programs increases the hemoglobin levels by 0.31 g/dl ($p<0.05$) and reduces the stunting by 9 percentage points ($p<0.05$) among the adolescents. We separately analyze the impact of individual interventions, WIFS was not able to improve Hb levels significantly ($p>0.10$), whereas free from child marriage and dowry awareness program increases the Hb levels by 0.25g/dl ($p<0.05$), which was lesser than the combined impact. In analysis of stunting, the impact of combined participation reduced the stunting of adolescent girls by 16 percentage points ($p<0.01$) and in boys stunting got reduced to 8 percentage points ($p<0.10$). In contrast, sub-group analysis found unchanged Hb levels among unmarried and married adolescent girls, whereas Hb levels were significantly increased by 0.35gm/dl ($p<0.05$) in adolescent boys. We conjecture that gender equality, education advancement etc., are few outcomes serves as the potential mechanism causing the discussed effect. **Discussions:** Our results suggest that to overcome the ineffectiveness of individual interventions it is required to establish the convergence for the better management of health and non-health related interventions. United Nations, 2018, explains that social policies can operate in holistic and integrated way when more focus is given to conceptualization and operationalization of interlinkages of sustainable development goals. Synergy of interventions has many other benefits, including cost-effectiveness, better reachability, targeting on larger group, and overall well-being of the society.

Ind-2341 The Effects of Food Security on Labor Productivity in Indonesia: Investigating the Mediating Effect of Stunting

PRESENTER: **Maman Saputra**
AUTHOR: Nicholas Goodwin

Abstract

Food security plays a crucial role in shaping human capital and labor productivity, particularly in developing countries like Indonesia. While prior studies highlight the impacts of malnutrition and food access on economic outcomes, limited evidence exists on the mediating role of stunting—a chronic form of malnutrition—in this relationship. This study addresses this gap by examining how food security dimensions influence labor productivity, mediated by stunting, using provincial-level data in Indonesia. The study employs panel data from the Central Bureau of Statistics and the National Labor Force Survey (2018–2023), analyzing relationships between food security dimensions, stunting prevalence, and labor productivity using a Fixed Effects regression model. The results show that a 1% increase in food access is associated with a 0.052 million IDR rise in labor productivity per worker ($p < 0.05$), while poor food utilization reduces productivity by 0.082 million IDR per worker ($p < 0.01$). Stunting significantly mediates this relationship, with a 1% rise in stunting prevalence linked to a 0.241 million IDR reduction in productivity per worker ($p < 0.05$). The Fixed Effects model explains 7.8% of productivity variation, indicating the importance of other factors such as education and healthcare. These findings highlight the economic costs of food insecurity and stunting, emphasizing the need for integrated nutrition and food security policies to enhance labor productivity. Addressing stunting through targeted nutrition interventions could yield substantial economic benefits by strengthening Indonesia's human capital.

Keywords: food security, labor productivity, stunting, human capital, economic valuation

Ind-2701 The Consumption of Sugar-Sweetened Beverages in Kenya and Its Association with Household Expenditure Allocation (Crowding-out Effect)

PRESENTER: **Mr. Senzo Mthembu**
AUTHOR: Hassan Haghparast-Bidgoli

There is a growing concern worldwide about the rising rates of overweight and obesity and their consequential healthcare and societal costs. In particular, Sugar-Sweetened Beverages (SSBs) have been linked to adverse health outcomes for individuals and communities, and their consumption can lead to significant costs at both the family and national levels. Moreover, if SSB expenditures displace expenditures on other essential goods and services, such as education and healthcare, this "crowding-out" effect could have long-term detrimental consequences. This ongoing paper aims to estimate the statistical association between spending on SSB products and budget allocation in Kenya. To achieve this, the paper draws on data from the Kenya Integrated Household and Budget Surveys (KIHBS) of 2015/2016, Demographic Health Surveys (DHS), and Euromonitor survey datasets. Furthermore, the paper uses a Generalized Ordered Probit model to estimate and examine the relationship between key socioeconomic variables and the decision to purchase SSBs. In addition, the paper utilizes a Seemingly Unrelated Regression Equations (SURE) methodology to investigate the association between the decision to buy SSBs and budget allocation on other goods and services. Specifically, we analyze the relationship between SSB expenditures and the allocation of budgets for other essential goods and services, such as education and healthcare. Our preliminary results reveal that households in Kenya allocate a substantial portion of their budget to SSBs, with a mean monthly expenditure of KES 100 ($0.76). We find that households with higher income and education levels are more likely to consume SSBs and allocate a more significant proportion of their budget to them. Finally, our analysis indicates that the "crowding-out" effect of SSB expenditures is present in Kenya, with a significant negative association between SSB expenditures and budget allocation on other essential goods and services. Our findings highlight the need for targeted policies and interventions to reduce SSB consumption in Kenya and promote healthier dietary choices, particularly among households with lower socio-economic status. Such interventions could include taxation policies, regulations on marketing and availability of SSBs, and educational campaigns on healthy dietary practices. Ultimately, addressing the issue of SSB consumption in Kenya could improve public health outcomes and reduce the burden of non-

communicable diseases while safeguarding the allocation of resources to other essential goods and services.

abs-os295 A Mixed-Methods Study to Determine the Validity of the EQ-HWB for Parents of Children with Health Conditions

PRESENTER: **Cate Bailey**, The University of Melbourne
AUTHORS: Kim Dalziel, Tessa Peasgood

Background: The EQ-HWB is a new, generic measure that aims to assess health, social care, and carer-related quality-of-life (QoL). There is emerging evidence on the EQ-HWB's performance for informal caregivers. Here, we present a mixed-methods study on the validity of the EQ-HWB (25-items) and EQ-HWB-S (9-items) in parents of children with health conditions, using qualitative and quantitative methods.

Aims: We aimed to investigate the psychometric properties of the EQ-HWB instruments compared to the Carer Qol-7D and EQ-5D and assess them in terms of the COSMIN attributes of relevance, comprehension and comprehensibility.

Methods: An online survey of parents with children with health conditions was developed that included demographic questions, informal care-related questions, and other QoL measures suitable for validation analyses (CarerQol-7D and EQ-5D-5D) as well as the EQ-HWB (25 items). The sample frame was participants from the Paediatric Multi-instrument Comparison Study who elected to be involved in further research. Analysis was conducted at the EQ-HWB (25 items) item, sum-score, and EQ-HWB-S (9 items) utility (pilot UK value-set) levels. We investigated response distribution by item, convergent and known-group validity with a priori expectations (Spearman's r, t-tests and one-way ANOVAs) and effect sizes (Cohen's d and eta-squared) compared to the other QoL measures. A short follow-up survey was administered 2-days later to investigate test-retest validity.

Twenty-one semi-structured, think-aloud interviews were conducted with a subset of parents. We used content analysis to investigate relevance and comprehension by item. Comprehensiveness was assessed by investigating participants thoughts on the choice of the 9 items for the EQ-HWB-S, and whether three caregiving concepts included in the CarerQol should be considered for inclusion in the EQ-HWB.

Key results: Data from baseline (n=230) and follow-up surveys (n=190) were obtained. The EQ-HWB item responses had a wide distribution over all items except the 5 physical items of seeing, hearing, mobility, activities, and self-care, where few problems were reported. Correlations were consistent with a priori hypotheses in convergent validity analyses. The EQ-HWB instruments performed well on a wide range of known groups specific to caregivers such as caregiver intensity, finances, ability to work while caregiving, as well as child factors such as child's mental health and QoL. Test-retest results were promising.

While most items were relevant for participants in this population, seeing and hearing were less relevant. Feeling unsafe was only found in a subset of participants, but these had high levels of problems. The items were well understood by participants, though some participants based their answers on whether they used the aids mentioned in the examples in the seeing, hearing and mobility questions. Participants found the items chosen for the EQ-HWB-S to be comprehensive. Participants preferred the fulfilment from caregiving and finance questions but were ambivalent about including a question about caregiver/care-recipient relationships.

Conclusions and implications: The EQ-HWB instruments performed consistently well in psychometric analyses and compared to other QoL instruments. The EQ-HWB instruments should be of high value in future health economic assessments with a need for an Australian value-set to facilitate scoring for our context.

abs-os293 A Theoretical and Methodological Framework for Extending the Health-Related Quality Adjusted Life Year by Combining Instruments

PRESENTER: **Rosalie Viney**, The University of Technology Sydney
AUTHORS: Brendan Mulhern, Deborah Street, Richard Norman, Rosalie Viney

Recently, there have been a number of calls in the literature to extend the focus of the quality adjusted life year (QALY) beyond a narrow focus on health-related quality of life (HRQoL), arguing that extending what is measured and valued will improve the allocation of scarce resources. A number of initiatives have developed broader instruments 'de novo', including the EQ-HWB, and psychosocial bolt-on dimensions for the EQ-5D-5L. Instruments have also been developed to measure broader areas of quality of life (QoL) such as social care using the Adult Social Care Outcomes Toolkit (ASCOT) and capabilities using the ICEpop CAPability measure for Adults (ICECAP). Much work has also focused on developing condition specific preference-based measures to complement generic instruments.

Another approach to extending the health focused QALY is to combine descriptive systems into a single instrument. This extends the measurement and valuation framework into a broader conceptualisation of QoL. The aim of this paper is to describe this approach, and outline the methodological process for generating broader descriptive systems. This will use the EQ-5D-5L and ASCOT as an example.

The presentation is divided into two sections. The first section explains the conceptual basis for combining existing instruments into a broader descriptive system, and discuss the advantages and disadvantages. Advantages include increasing measurement sensitivity to the wider QoL impacts of many interventions, and developing value sets encompassing preferences that are a result of trading off between diverse concepts of QoL. This enables values informed by impacts on broader QoL concepts with relevance across diverse health conditions, populations and interventions, to be used. Disadvantages include theoretical limitations linked to the constructs of generic or condition specific QoL the extended instrument could include, and practical difficulties in combining instruments into a combined system that is amenable to valuation.

The second section of the presentation describes the methodological process for generating combined descriptive systems. This includes a description of the process for identifying which constructs of QoL (or which instruments) should be included, and how different generic and condition specific constructs can be conceptualised in this approach. This is followed by an outline of both the qualitative and quantitative work required to generate a descriptive system that is psychometrically valid, and appropriate for valuation. Qualitative work includes cognitive interviews to assess the descriptive system, and possible framings of the dimensions as overall items and in a valuation task setting. Quantitative work includes conducting psychometric analysis to assess the relationship between the dimensions, and the dimension structure.

In conclusion, combining constructs of QoL from existing instruments offers a way to extend the QALY that differs to developing instruments de novo. This presentation will outline the framework for this approach, the advantages and disadvantages, and outline a research agenda.

abs-os297 Assessing the Dimensionality of Diverse Measures of Quality of Life using Factor Analysis

PRESENTER: **Mina Bahrampour**
AUTHORS: Akanksha Akanksha, Deborah Street, Rosalie Viney, Brendan Mulhern

Background: Various instruments have been developed to measure different aspects of quality of life (QoL). The EQ-5D-5L assesses health-related QoL, while the EQ Health and Wellbeing instrument (EQ-HWB) captures a broader concept of wellbeing that extends beyond health. The Quality of Life-Aged Care Consumers (QOL-ACC) focuses specifically on the QoL of older adults in aged care, and the Adult Social Care Outcomes Toolkit (ASCOT) assesses social care-related QoL. Although these instruments target distinct aspects of QoL, there is both overlap and divergence in the QoL constructs that are measured. Some evidence exists on the overlap and divergence between instruments, and this has been used to understand in which contexts instruments may be most appropriately used, and where instruments could be extended (e.g. with bolt-ons), or combined. However this work is dataset and measure specific and doesn't include newer instruments such as the EQ-HWB or QoL-ACC. This study aims to investigate the dimensionality of multiple QoL instruments (EQ-5D-5L, EQ-HWB, QoL-ACC and ASCOT) to reveal the primary domains and structures they measure, particularly in older populations. Understanding these differences will support the development of more comprehensive and integrated QoL assessments, inform where each instrument should be used, and guide further work exploring how to combine instruments in a broader measurement and valuation framework.

Method: Data were derived from a longitudinal online survey in Australia. Overall, 1505 respondents completed the survey, of which 453 participants were older than 65 and completed all four instruments. Exploratory Factor Analysis (EFA) was conducted to identify the underlying domain structure by pooling items from these instruments. Factors were selected based on eigenvalues greater than one, but a wider range of models including 3 – 8 factors were explored . A correlation cut-off of 0.32 was applied to determine item loading on a given factor. Both oblique (assuming correlations between factors) and orthogonal (assuming uncorrelated factors) models were explored.

Results: Comparisons of four, five, six, and seven factor models showed that the five-factor oblique model provided a better fit, model parsimony and interpretable with improved differentiation of items. The five factors identified represent key domains; emotional functioning; self care and usual activities; enjoyment of activities; cognition and senses; and pain. All factors incliuded items from at least three instrument Five items from the ASCOT and two items from HWB did not load on any factor

Conclusion: This study provides evidence on the dimensions of QoL assessed by health focused and broader instruments in an older adult population. The results inform the ongoing development of the EQ-HWB, and support the justification for, and conceptualisation and development of broader instruments.

abs-os300 Extending Quality of Life Measurement by Combining instruments: A Qualitative Exploration

PRESENTER: **Akanksha Akanksha**
AUTHORS: Carrie-Anne Ng, Richard Norman, Deborah Street, Mina Bahrampour, Katie Page, Brendan Mulhern, Rosalie Viney

BACKGROUND

Recent research has aimed to expand the scope of quality-adjusted life years (QALY) beyond a narrow health-related quality of life (HRQoL) focus to improve the equitable allocation of scarce resources. A novel approach to extend the health focused QALY is to combine existing descriptive systems into a single comprehensive instrument (for example combining HRQoL (measured by the EQ-5D-5L) with social care-related quality of life (SCRQoL) (measured by the Adult Social Care Outcomes Toolkit, ASCOT-SCT4). However, understanding how the distinct domains of these instruments overlap and diverge, and also how to frame and word the dimensions for respondent completion and valuation, is an important step in the development of a coherent combined tool. This qualitative study seeks to understand how respondents perceive the dimensions of each instrument, and the interactions between them, and also the preferred approach to wording and presenting the dimensions for valuation in a Discrete Choice Experiment (DCE).

METHODS

An adult Australian sample (n=15) was recruited to ensure a balanced age and gender distribution reflective of the general population. A think aloud interview with follow up prompts was used. To explore dimension perception and overlap, participants engaged in a 'card sorting' exercise, where they were shown all 14 dimensions from EQ-5D-5L and ASCOT and asked to group items they perceived as similar. For each grouping, participants provided a theme and rationale. To explore dimension wording and valuation format we tested modified versions of the ASCOT dimensions related to control, social contact, cleanliness, and dignity. Shortened descriptors and frequency-based response options were tested. Participants then completed four DCEs designed to evaluate the impact of presentation format and different wordings. Thematic analysis followed a deductive approach, utilizing an initial coding framework, with additional codes generated as new themes emerged.

RESULTS

Thematic analysis indicated that while respondents generally perceived the shortened ASCOT response options as similar to the originals, frequency-based options were often seen as distinct. Notably, for the control and dignity dimensions, the frequency-based wording sometimes influenced respondents' choice of response. Many respondents found frequency-based options easy to interpret, though a preference for the original ASCOT wording persisted among some. A three-column DCE layout (including overall dimension information as well as profile descriptors was widely favoured for its readability and ease of comparison, allowing respondents to better visualize their choices. Most respondents displayed consistency across the DCE tasks. The card sorting exercise revealed that participants often grouped items in ways that aligned with established EQ-5D-5L and ASCOT constructs, while some new themes emerged, such as 'assistance' and 'domestic violence,' pointing to unique interpretations of quality-of-life domains within an integrated measure.

CONCLUSION

Findings support the potential of a combined instrument combining EQ-5D-5L and ASCOT to measure and value broader QoL. The results provide further insight into conceptual overlaps, guiding the tool's refinement to better reflect integrated health and social care outcomes, and also inform the design of upcoming valuation studies to generate an Australian value set for the combined instrument for use in healthcare decision making.

Harmful Social Practices and Violence Against Women and Children: Intervention Effectiveness, Value for Money and Methodological Considerations

MODERATOR: **Giulia Ferrari**, London School of Economics & Political Science

abs-os400 (Digital) Cash Transfers and Intimate Partner Violence: Evidence from Uganda

PRESENTER: **Ms. Giulia Greco, PhD**, London school of hygiene and tropical medicine
AUTHORS: Pallavi Prabhakar, Selim Gulesci, Munshi Sulaiman

Abstract

Cash transfer programs are a key social safety net in many countries and one of the most used social protection measures in response to humanitarian crises.

More than 70% of countries in sub-Saharan Africa had some form of cash transfer programming. Cash transfers provide financial assistance to vulnerable households. However, evidence on the effects of cash transfers on women's empowerment and intimate partner violence (IPV) is mixed. Privacy of information is mentioned as a potential mechanism for why using digital financial services to transfer cash may lead to better outcomes for women, but evidence on this is suggestive at best.

We study whether mobile money has a differential impact compared to cash on women's economic outcomes and IPV. We present evidence from a cluster randomized controlled trial with over 2000 women from 250 communities in Uganda. Study participants were married women, aged 20-45 years, living with their spouses in refugee and host communities in Kyegegwa and Kiryandongo districts. They owned a mobile phone and had a mobile money account registered under their name.

Participants were randomly divided into four treatment arms and a control group. Two treatment groups received cash transfers, while the remaining two received mobile money transfers. Within each transfer modality, information about the cash transfers was either privately provided to the beneficiary, or shared with both the beneficiary and her spouse.

We find that the mode of cash transfers affect women's economic empowerment.

In particular, transfers paid in cash increase women's engagement in income-generating activities that they conduct jointly with their spouse. On the other hand, transfers paid into their mobile money accounts enable women to engage in their own, independent income generating activities. Women who receive mobile money transfers increase their independent, individual earnings by 31%. Women who receive mobile money experience a 0.17 SD increase in their control over labour market participation, children's schooling and health, household financial decision

and family planning. We do not find significant differences in terms of the privacy of information.

Transfers in cash are more effective in reducing IPV compared to digital payments, especially when women's partners are informed about the transfer. Women who received their transfers in cash and whose husbands were informed about the intervention were 12ppt less likely to report having experienced any type of IPV during the past year. This is driven by a decrease on all types of IPV, including an 8.4ppt for physical and 4.1ppt for sexual forms of IPV. None of the other treatment arms have a significant effect on IPV and we can reject null of equality between the effect of the joint cash treatment with all other arms.

These findings suggest that the public nature of cash transfers can be most effective in reducing IPV. Importantly, they demonstrate a trade-off between improving the effectiveness of cash transfers in terms of women's economic empowerment and reducing IPV: while digital payments can be more effective in empowering women, cash-based payments with public information can achieve greater impact in terms of IPV prevention.

abs-os467 Estimating the Prevalence of Child Labour in the Cocoa Industry Via Indirect Elicitation Methods: A Mixed-Methods Study

PRESENTER: **Aurelia Lepine**
AUTHORS: Henry Cust, Ariane Ndjore, Selina Binder, Megan Passey, Carole Treibich, Laurent Foubert

Abstract

Background

Child labour in Côte d'Ivoire's cocoa industry is a significant concern, with data from children indicating a prevalence of 38%. While child surveys may reduce sensitivity biases like social desirability bias, they pose ethical challenges and may still involve other reporting biases. This makes obtaining accurate estimates of child labour particularly challenging.

Research Aim

The study aimed to determine whether data collected from parents using indirect survey methods could provide more accurate estimates of child labour prevalence compared to direct questioning and child-reported data.

Method

Data were collected from 1,741 cocoa producers in Côte d'Ivoire. Researchers employed three approaches: direct questioning, a list experiment, and a novel non-verbal method known as the "colorbox." Qualitative in-depth interviews were also conducted to explore motivations behind reporting behaviours.

Results

Indirect elicitation methods revealed higher prevalence rates of child labour compared to direct questioning but yielded lower rates than child-reported surveys. Qualitative interviews highlighted parental underreporting due to fear of legal consequences and mistrust of stakeholders.

Conclusion

Indirect methods, while useful, are insufficient to fully address underreporting when collecting data from parents. To achieve more accurate estimates, future research should prioritize direct data collection from children while addressing the associated ethical concerns.

abs-os451 Social Norms Interventions to Prevent Child Marriage: Effectiveness and Cost-Effectiveness of CARE's Tipping Point Initiative in Pirgacha, Bangladesh

PRESENTER: **Ms. Giulia Ferrari**, London School of Economics and Political Science
AUTHORS: Shehrin Shaila Mahmood, Mahfuz Al-Mamun, Sultan Mahmud, Ruchira Tabassum Naved, Md. Golam Rabbani, Orin Akter

Background Child marriage (CM) is one of the main challenges to child development in Bangladesh, with 50% of girls being child brides. CM heightens health risks and lowers educational attainment and economic power. It remains a stubborn challenge rooted in harmful social practices. The Tipping Point Initiative (TPI) is social norms change intervention involving girls, parents and boys to eliminate CM developed by CARE. At 10 months post-intervention, TPI had no effect on child marriage. Social practices change slowly, yet evidence on the medium-term impact and cost-effectiveness of CM prevention through social norms change is lacking. *Aims* To report on the medium-term impact and cost-effectiveness of TPI by determining effectiveness and cost-effectiveness of - TPP+ versus the status quo - TPP versus the status quo - TPP+ versus TPP. *Methods* We report on the effectiveness and cost-effectiveness of TPP using primary data from a three-arm cluster-randomised control trial (cRCT) and accompanying costing study. A three-arm cRCT evaluated the impact of the intervention on girls' past-year CM: arm 1 received the Tipping Point Program, to empower girls (TPP); arm 2 received TPP and a social-norms change component (TPP+); arm 3 was a pure control arm (status quo). We determine effectiveness using linear multilevel models. We compute the economic costs of TPI from a provider perspective in USD 2022 prices, at 3% discount rate, in a research setting using bottom-up micro-costing. We compute the interventions' impact on girls' mental and sexual and reproductive health, and the incremental cost per Disability-Adjusted Life Year (DALY) averted by each programme compared to the other and to the status quo. Univariate sensitivity analyses show how uncertainty in cost

drivers impacts programmes' cost-effectiveness. A probabilistic sensitivity analysis computes the probability of cost-effectiveness for each comparison, given Bangladesh's budget constraints. *Key Results* Girls in TPP+ villages report a reduction in CM among at five years post baseline (adjusted risk difference: -0.01 (95% CI: -0.03, 0.24; NS). This result is not statistically significant. It cannot be generalised to the population. TPP has no impact on CM compared to the status quo and TPP+ reduces CM, in-sample, compared to TPP. We find similar patterns for girls' education and economic outcomes. TPP+ reduces depression compared to the status quo (adjusted risk difference: -.47 (95% CI: -.90, -.04; p<.05)) and averts .02 DALYs (95% CI: -.03, .002; p<.10). The incremental per capita cost of TPP+ versus control is USD 26, with a 12% probability of cost-effectiveness at Bangladesh's USD 186 willingness-to-pay threshold. *Conclusions* Girls' empowerment with community-wide social norms change (TPP+) improves girls' mental health and shows promise for the reduction of CM five years post baseline. The cost-effectiveness of TPP+ is promising. *Implications* Policy makers, donors and implementers should consider adding social norms change components to girls' empowerment programmes. Researchers should measure health impacts consistently and produce medium- to long-term impact estimates to assess the impact CM prevention.

Integrating Equity into Decision-Making: Methods and Applications for Equity Informative Economic Evaluations

CONVENER: **Shan Jiang**, Macquarie University

DISCUSSANT: **Stéphane Verguet**, Harvard University

abs-os429 A Case Study of the Health Inequality Impact Calculator for Socioeconomic Groups in Australia

PRESENTER: **Anita Lal**, Deakin University
AUTHORS: Stephanie Moriarty, Gunjeet Kaur, Richard Cookson, Suzanne Robinson

Objectives

To evaluate the technical feasibility of routine distributional analyses of health care interventions in Australia, by developing a Health Inequality Impact Calculator for Queensland. Building on methodologies established in a previous study conducted in England, the calculator compares the magnitude of health inequality impact across interventions for different diseases.

Methods

The calculator was adapted for Queensland adults and Socio-Economic Indexes for Areas (SEIFA), an Australian measure of socioeconomic status. SEIFA specific data inputs included population estimates from the Australian Bureau of Statistics, hospital admissions by ICD-10 3-digit level in 2023 from Queensland Health, and quality-adjusted life expectancy. A targeted review was conducted to select a suitable cost-effectiveness study to demonstrate the calculator with i) a high health inequality gap, and ii) reported the health benefits in quality adjusted life years, and iii) reported incremental costs and benefits. The calculator determined the distributional cost-effectiveness analysis outputs, according to SEIFA quintiles and the health inequality benefit of the interventions based on the slope index of inequality in quality adjusted life years (QALYs).

Results

The case study chosen contained two interventions for screening of diabetes and hypertension, and three treatment interventions for the management of chronic kidney disease. The calculator demonstrated that all interventions would reduce health inequality. Population screening for diabetes had the greatest impact on reducing health inequality by 8,562 QALYs. Of the treatment interventions, intensive blood pressure control had the greatest impact on health inequality, with a benefit of 514 QALYS.

Conclusions

This study successfully adapted and demonstrated the feasibility of the health equity calculator for estimating the health inequality impacts of interventions in Queensland. The findings suggest that developing an Australian-wide version would be technically feasible for identifying when equity outcomes are relevant to policy decisions within the Australian healthcare system.

abs-os453 Equity-Informed Economic Evaluation of Next-Generation Nets for Malaria Prevention in Uganda: A Comprehensive Application of Multiple Equity Methods

PRESENTER: **Catherine Pitt**, London School of Hygeine and Tropical Medicine
AUTHORS: Katherine Snyman, Adrienne Eepstein, Sarah Staedke, Samuel Gonahasa

Background: Equity considerations are becoming increasingly important in economic evaluations, yet the best methods for incorporating equity remain uncertain. This case study explores the application of various equity-informative economic evaluation methods to assess the cost-effectiveness of screening for malaria prevention in Uganda, a low- and middle-income country (LMIC). Given that malaria disproportionately affects poor and rural populations, addressing the intersection of equity and efficiency is crucial in evaluating interventions that aim to reduce both the health and economic burdens of the disease.

Aims: This study assesses the cost-effectiveness and equity impacts of screening for malaria prevention within the context of the Uganda Housing Modification trial, a cluster-randomized study. The trial compares the impact of screening in two districts in Eastern Uganda.

Methods: We estimated the financial and economic costs of screening homes, from a disaggregated societal perspective. Intervention coverage and sociodemographic information was collected via cross-sectional community surveys. Cohort results in children 0-5 years was used to estimate the cumulative effects on malaria incidence over one year post-modification. A 3% discount rate and a five-year time horizon for costs and effects were applied, with malaria death effects modeled beyond this period. Incremental costs per malaria case and per DALY averted were calculated, and variations in cost, incidence, and cost-effectiveness across SES and house type were assessed. Uncertainty was examined using deterministic and probabilistic sensitivity analyses. Equity was assessed using multiple equity-informative economic evaluation methods including extended-cost effectiveness analysis, direct equity weighting and distributional cost-effectiveness analysis.

Results: Screening cost $8.13 per malaria case averted and $453 per DALY averted over five years, which is not cost-effective by any plausible threshold. Stratifying by wealth quintile, ICERs showed a clear trend as they were lowest in poorest quintile (Q1: $255/DALY averted) and highest in the least poor quintile ($1,535/DALY averted). There was no difference in financial risk protection across any of the quintiles. Using direct weighting with a social welfare function and the Uganda-specific inequality aversion parameter, the ICER decreased to <$1 /DALY averted. Distributional cost-effectiveness analyses will be completed in June.

Conclusion: Screening all homes in our study area was not cost-effective by conventional thresholds. However, cost-effectiveness improved substantially in the poorest households, highlighting the value of equity-informed approaches in economic evaluations. These analyses were only possible because the trial was designed to collect detailed sociodemographic and outcome data, underscoring the importance of planning for equity analysis in study design. We did not observe an equity-efficiency trade-off; rather, targeting poorer households appears to enhance both equity and efficiency. While the implementation pathway for housing modifications remains unclear—particularly regarding who bears the cost (households, government, or donors)—our findings suggest that targeted delivery could reduce health and economic disparities. This case study illustrates how incorporating equity into economic evaluation can generate policy-relevant insights for LMICs, especially for interventions like malaria prevention where disease burden is unequally distributed.

abs-os448 Evaluating Cost-Effectiveness and Distributional Impact of Population-wide BRCA Screening in Australia: A Model Incorporating Patient Preferences

PRESENTER: **Shan Jiang**
AUTHORS: Yuanyuan Gu, Bonny Parkinson

Background: Hereditary breast and ovarian cancer (HBOC), commonly associated with BRCA gene mutations, is a prevalent genetic disorder worldwide. In Australia, breast cancer is among the most common cancers, and ovarian cancer has a high mortality rate, highlighting the potential public health impact of effective screening. While cost-effectiveness analysis (CEA) is routinely used by Australian health authorities to inform policy decisions, the distributional impacts of interventions on health inequalities between socioeconomic groups remain underexplored, leaving a gap regarding the cost-effectiveness and equity implications of population-wide BRCA screening in Australia.

Aims: This study evaluates the cost-effectiveness of population-wide BRCA screening in Australia and its impact on health inequalities, aiming to inform policies that reduce disease burden and promote health equity.

Methods: A CEA was conducted comparing population-wide BRCA screening to family history-based testing among Australian women aged 30, 35, 40, 45, and 50. The analysis used a lifetime horizon from the Australian healthcare system perspective, with outcomes measured in quality-adjusted life years (QALYs) and 2024 AUD costs, discounted at 5%.

A decision-analytic model, comprising a decision tree and two Markov models, simulated screening outcomes. The first Markov model represented BRCA carriers undergoing annual mammography and MRI for intensive surveillance. The second model included carriers using mammography alone and non-carriers undergoing routine mammography. Transition probabilities included carriers opting for risk-reducing mastectomy or salpingo-oophorectomy if aware of their status. Model inputs were derived from Australian Bureau of Statistics (ABS) data and empirical studies.

Distributional impacts were assessed using net health benefits (NHB) and Equally Distributed Equivalent Health (EDEH) calculated with the Atkinson inequality index. Socioeconomic quintiles were defined using Socio-Economic Indexes for Areas (SEIFA). Opportunity costs were estimated using UK data as a proxy. The ICER threshold was set at AUD $50,000 per QALY.

Results: The ICER of BRCA screening varied by age. Screening at age 30 was cost-saving (ICER: AUD -8,331 per QALY). Screening at ages 35 and 40 was cost-effective, with ICERs of AUD 28,231 and AUD 40,086 per QALY, respectively, both below the threshold. Screening at ages 45 and 50 exceeded the threshold (ICERs: AUD 78,666 and AUD 155,937 per QALY). Distributional analysis showed that screening at age 30 increased both average QALE and EDEH, indicating overall health gains and a reduction in health inequality between socioeconomic groups. As the screening age increased to 35 and above, both QALE and EDEH decreased, suggesting diminished benefits and worsening health inequality.

Policy Implications: Population-wide BRCA screening is cost-effective for Australian women when initiated at younger ages, particularly at age 30, and contributes to reducing health inequalities between socioeconomic groups. Policymakers should consider implementing BRCA screening programs targeting younger women to achieve both economic efficiency and equity objectives. Early screening could lead to significant reductions in the disease burden and mortality associated with HBOC, while also addressing disparities in health outcomes across different socioeconomic strata. Strategies to enhance access and uptake among disadvantaged groups may further amplify these benefits, promoting a more equitable healthcare system.

abs-os458 Shall We Pay More for Rare Disease Drugs? Assessing Decision-Makers Preferences by A Sequential Discrete Choice Experiment Approach

PRESENTER: **Yuanyuan Gu**, Macquarie University
AUTHORS: Shunping Li, Shan Jiang, haiyin Wang

Background: Countries worldwide face the challenge of prioritizing the allocation of scarce health resources. Economic evaluation has become the preferred approach to inform policymaking, with the quality-adjusted life year (QALY) serving as the most widely used measure of healthcare treatment value. However, research and health technology assessment practices indicate that QALY gains alone may not fully reflect the value of interventions. For instance, QALY gains from treating rare diseases are often viewed as more valuable than those from treating common diseases. Nevertheless, empirical evidence on such value judgments remains limited, particularly from the perspective of decision-makers, and it remains unclear whether rarity itself generates additional value.

Aim: This study aims to investigate whether health insurance decision-makers in China assign higher value to rare disease treatments and, if so, to quantify this value.

Methods: We conducted two sequential discrete choice experiments (DCEs). The first DCE, labeled, compared a common disease drug with a rare disease drug and included five attributes: disease severity, childhood onset, potential for catastrophic expenditure, absence of alternative treatments (novelty), and clinical benefit. This experiment sought to identify the specific conditions under which decision-makers prioritize rare disease coverage. The second DCE, unlabeled, compared two rare disease scenarios within each choice task. It retained three attributes from the first DCE and introduced two quantitative attributes: average QALY gained per treatment beneficiary and the projected annual increment in social insurance premiums. These additions facilitated the estimation of willingness to pay per QALY, which was subsequently converted into incremental cost-effectiveness ratio (ICER) thresholds. A D-efficiency design was used, generating 16 and 20 choice sets for the first and second DCEs, respectively, each of which was blocked into two versions. In 2023, invitations were sent to all 120 decision-makers involved in the negotiation and development of the National Reimbursement Drug List. Data collection was conducted online through face-to-face interviews. Data analysis employed the conditional logit model, exploring various utility functions to capture decision-makers' preferences.

Results: In total, 101 eligible decision makers provided complete responses and were included in the analysis. Nearly half of the respondents were female (47.5%), with 58.4% having over ten years of professional experience. Many participants had expertise in health insurance system research (48.5%) and pharmacoeconomics (77.2%). Estimates from the first DCE suggest that decision-makers do not perceive rarity itself as adding value but place higher importance on disease severity, drug innovation, and health benefits, particularly the first two factors. The second DCE indicated that the ICER threshold for treating rare diseases, incorporating equity considerations, would be 1.9 times the GDP per capita—approximately three times the baseline ICER threshold currently used in China.

Policy Implications: Chinese decision-makers demonstrate a willingness to assign higher value to rare disease treatments, particularly when considering severity and novelty. This study provides empirical evidence that supports higher ICER thresholds for rare disease treatments to account for equity considerations. The findings offer valuable insights for policymakers seeking to refine health insurance reimbursement strategies and ensure a more equitable allocation of resources.

abs-os581 High-Frequency Measurement of Health Out-of-Pocket Expenditure

PRESENTER: **Patrick Hoang-vu Eozenou**
AUTHORS: Mr. Gil Shapira, Asiyeh Abbasi

Designing more effective policies to improve financial protection in health requires a granular understanding of patterns of out-of-pocket (OOP) health spending. Typically, measures of financial protection are derived from infrequent, cross-section, nationally representative multitopic household expenditure surveys, collecting information on health OOP and on total consumption expenditure. To reduce recall bias, health expenditure modules usually collect data on expenditure on outpatient care and medicines during a short period preceding the survey interview (e.g. 4 weeks). The implicit annualization assumption used to construct household budget shares for health expenditure may often be wrong, particularly in contexts where seasonal variations in health expenditure are prevalent or where health spending is driven by large infrequent spending events. In this study, we analyze panel data collected at infra-annual frequency through phone surveys in 5 sub-Saharan African countries between February 2022 and April 2024 to assess how the use of more frequent data would change inference on who is spending and how much they spend. To do this, we compare the annualized distribution of OOP per capita and its composition across 3 different annualization estimation approaches: (1) panel data approach, (2) pooled cross-sectional estimation, and (3) single independent cross-sectional estimation. We treat the panel data approach as our benchmark and report the average difference with the other two estimation methods to

distinguish between the role of high-frequency data collection from the role of collecting longitudinal information at household level.

abs-os566 Towards Universal Health Coverage: A Unified Tracking of Financial Hardship in 153 Economies

PRESENTER: **Gabriela Flores**, World Health Organization
AUTHORS: Asiyeh Abbasi, Marc-Francois Smitz, Paatrick-Hoang-vu Eozenou, Mr. Gil Shapira, Catherine Korachais, Vladimir Sergeevich Gordeev

Background Financial hardship is a key consequence of inadequate financial risk protection mechanisms, hindering progress toward Universal Health Coverage (UHC). The Sustainable Development Indicator 3.8.2 is intended to track financial hardship due to out-of-pocket (OOP) health spending. This is currently done with a focus on large household expenditure on health as a proportion of total household expenditure or income. After six years of tracking SDG 3.8.2, the evidence emerging from global, regional and country data is clear. The current definition doesn't capture much of the financial hardship experienced by poorer people and lower-income countries. Of the latest estimated 1 billion people with household expenditures on health exceeding 10% of household total expenditure or income for 2019, only 9% were living in extreme poverty and only 13% were living in relative poverty. Within countries, health expenditures exceeding more than 10% of household budget are mostly concentrated among the better off. This paper proposes a globally policy relevant indicator that classifies both large and impoverishing OOP health spending as financial hardship while recognizing that the cost of basic needs increase as countries become richer. **Method** Drawing on previous methodological work to develop metrics based on household's discretionary budget, also called capacity-to-pay approaches, and the social poverty line, this paper proposes to identify the proportion of the population with positive out-of-pocket household expenditure on health exceeding 40% of household discretionary budget to monitor financial hardship. The overall population rate can be decomposed into those facing only large OOP health spending or both large and impoverishing OOP health spending. We produced population rates for 153 economies accounting for 95% of the world's population in 2019, using data from 808 surveys. **Results** The concentration index of the proposed definition points to a greater financial hardship experienced by the worse-off in 97% of the economies; the median gradient across quintiles of both consumption and income is systematically negative; trends over time within countries are not sensitive to the choice of the threshold value (10%, 25%, 40% or 100% of the discretionary budget); using the 40% threshold, median rates in low-income countries are 2.7 times higher than in high-income ones. In all countries, the level of financial hardship is higher than the rate of both, those incurring catastrophic OOP health spending as tracked by SDG 3.8.2 indicator and impoverishing OOP health spending, but it is lower than their simple sum. The global trend of the proposed indicator points to a reduction financial hardship driven by a reduction in the population rate experiencing impoverishing OOP health spending. But in terms of number of people facing financial hardship, the reduction is marginal (2.02 billion in 2019 versus 2.04 billion in 2000). **Conclusions** The proposed definition is globally applicable and policy relevant and provides a robust assessment of financial hardship over time, within and between countries. The proposed definition aligns better with the Sustainable Development Goals objective to leave no one behind and reduce inequalities.

abs-os582 Validating Out-of-Pocket Health Spending Data Collection: Computer-Assisted Mobile Phone Survey Vs. Face-to-Face Survey

PRESENTER: **Idrissa Ouili**
AUTHORS: Abdramane Soura, Souleymane Sanogo, Gabriela Flores

Background Household surveys are the main data source for estimating financial hardship due to household out-of-pocket payments (OOPs) and the primary source of information in national health accounts, especially in developing countries. However, these surveys are expensive to conduct every year, resulting in irregular data. The use of mobile phones as a means of data collection can reduce costs and time. To date, the validity of mobile phone-based data for assessing OOPs has not been sufficiently investigated. This field experimental study conducted in Burkina Faso aimed to investigate the agreement between provider records and household reported OOPs via a computer assisted face-to-face survey (CAPI) and a computer assisted mobile phone (CATI) survey. **Method** We used provider sampling approaches with prospective data collection for outpatient and drug item validation and retrospective data collection for inpatient item validation. Households were randomly assigned to the two data collection methods (CAPI versus CATI) within two sampling groups. The sample sizes are 140 (CAPI) and 124 (CATI) for the prospective data collection and 113 (CAPI) and 131 (CATI) for the retrospective data collection. Using data from provider records as the gold standard, we compared the mean OOPs and estimated the mean ratio and variability in the ratio of household expenditures to provider data using the Bland-Altman method of assessing agreement. **Results** Overall, for both data collection methods (CATI and CAPI), household OOPs tend to be higher for outpatient and inpatient services than for the corresponding provider OOPs, and lower for medicines. The ratio of means outpatient OOPs (households/providers) is 58.65 for CATI compared to 19.31 for CAPI, and the ratio for inpatient OOPs is 5.26 for CATI versus 4.88 for CAPI. These values are 0.39 for CATI versus 1.01 for CAPI for OOPs on medicines. The mean bias is higher for mobile phone surveys than for face-to-face surveys for outpatient OOPs (CATI=23.16 versus CAPI=2.70) and medicines (CATI=0.26 versus CAPI=0.56), but lower for inpatient OOPs (CATI=2.00 versus CAPI=4.17). The variability, measured by the 95% limits of agreement, also varied by type of spending and was especially wide for outpatient OOPs. We find evidence of an effect of the data collection method on outpatient OOPs. The average health expenditure derived from CATI increases by 2.14 times (p=0,000) as the average health expenditure derived from CAPI increases. There was no evidence of a differential effect between the two methods in estimating OOPs for inpatient care and medicines. **Conclusions** The study suggested that CATI is as reliable than CAPI to collect data on OOPs for inpatient care and medicines at the household level.

abs-os632 Validation of Self-Reported Information on Financial Hardship

PRESENTER: **Rocio Garcia-Diaz**
AUTHORS: Gabriela Flores, Vladimir Sergeevich Gordeev, Rouselle Flores Lavado

Background People suffer financial hardship when their out-of-pocket (OOP) health spending threatens their living standards or compromises access to essential goods such as food, shelter, clothing, or education. Traditional measures of catastrophic and impoverishing OOP health

spending capture this concern by comparing household's out-of-pocket health spending to their total consumption expenditure or income. However, this requires collecting data on a battery of questions through lengthy, resource-intensive, and detailed face-to-face household surveys, limiting the availability of timely data at global, regional, and country levels, especially in low-resource settings. Failure to produce recent and frequent information limits the evidence base of policy recommendations and the possibility of evaluating recent policy efforts. This paper examines the reliability of a simplified, self-reported measure of financial hardship, where respondents are asked whether anyone in the household had to reduce spending on necessities (such as food, housing, or utilities) because of OOP health spending. Such self-reported information was piloted in Facebook and mobile phone surveys in 2021 and 2022. However, this is the first time that a self-reported financial hardship question was collected alongside a comprehensive consumption module, which would allow for its validation. **Methods** Using data from Cambodia, we assess the reliability of this self-reported measure compared to traditional, quantitatively derived indicators of financial hardship. First, we evaluate the agreement between the self-reported and quantitatively derived indicators using Bland-Altman analysis. Second, we assess the predictive validity of both measures in identifying reductions in consumption of necessities through fractional logit regression. Third, we explore the association between both measures and self-reported anxiety about future household finances due to healthcare costs, serving as an indirect indicator of economic stress. To understand the drivers of discrepancies, we examine how household characteristics – sex and age of the household head, age composition, household size, and income quintile – affect the variation in financial hardship reports and identify which subgroups show the greatest differences between self-reported and quantitative measures. **Preliminary Results** Preliminary analysis shows that self-reported financial hardship is higher than quantitatively derived indicators. However, we expect the two measures to exhibit reasonable agreement overall. We anticipate that discrepancies will vary systematically by household type, with larger and lower-income households – who may experience greater financial strain – more likely to report financial hardship, while smaller and higher-income households may underreport due to the framing of the question. Preliminary analysis suggests that self-reported measures of financial hardship can identify people dedicating on average a smaller share of their budget to food. We further expect that both measures of financial hardship will correlate strongly with anxiety about future household finances, reinforcing their validity as indicators of financial stress. **Conclusions** If the self-reported measure aligns reasonably well with the more detailed quantitative indicator, it could provide a practical, though less precise, alternative for monitoring financial hardship with in low-resource settings, in shorter but more frequent surveys or full-scale surveys that cannot accommodate a lengthy questionnaire on consumption.

abs-os435 Valuing Volunteer Time in Community-Led Interventions: Insights from Cost Analyses of Student- and FSW-Led Programs in Zimbabwe

PRESENTER: **Collin Mangenah**

AUTHORS: Ms. Fern Terris-Prestholt, Oppah Kuguyo, Primrose Matambanadzo, Jane Kalweo, Karin Hatzold, Liz Corbett, Lindiwe Mancitshana, Frances M Cowan, Euphemia L Sibanda

Background Excluding volunteer time in cost estimates can lead to underfunding and unsustainable programming, while overestimating its value can tie up limited community resources. We evaluate alternative methods of valuing volunteer time in three Zimbabwe community-led interventions: FSW-led self-help groups (SHG), student-led HIV self-testing, and student-led distribution of a self-care packages for pregnancy and HIV. **Methods** Three interventions were implemented between October 2022 and February 2024. In the FSW-led SHG intervention, 10 groups nominated representatives to an empowerment resource group for training as peer trainers and crisis responders, integrating income-generating activities to make members both users and providers. The tertiary student-led interventions supported peer-led distribution of HIVST kits and self-care products (HIVST, post-exposure prophylaxis, emergency contraception, and condoms) to their peers. We analysed total and unit financial and economic costs, using expenditure records, on-site observations, and detailed self-reported time logs. Volunteer time was valued using financial cost ($50/month) and their opportunity costs (minimum hourly wage of $1.03 for FSW and student intern rate of $1.21). Costs were adjusted to 2024 USD. **Results** Across 10 SHGs, 70 members were supported at a financial cost of $229 ($220-$258) per member when volunteer time was valued at $50 monthly reimbursement. Economic costs, including volunteer time contributions (mean: 14 hours; range:<1 to 48 hours per member) valued at $14.59 (cross SHG group range: <$1-$49.61), resulted in $307 ($253-$415) per member. For HIVST distribution, the economic cost per student exposed to the programme was higher ($1.85) in peer-led distribution than in control ($0.91). Average financial cost per HIVST kit distributed was US$8.28 (cross institution range: $4.65-$17.47) and US$10.23 (cross institution range: $8.13 - $24.61) across the two arms. Economic cost per HIVST kit distributed (including valuation of distributor-time based on the average of the peer self-recorded distribution time, the mean medical staff ($2.50) and Zimbabwe student internship rates ($1.25) were US$8.45 and US$10.40 per HIVST kit distributed respectively. For the self-care intervention, the financial cost per student reached was $7.72 (cross institution range: $4.84-$13.39) when valuing distributor-time at the $50 incentive rate, and $7.75 (cross institution range: $4.85-$13.44) when valued on the average of the peer self-recorded distribution time and the mean Zimbabwe student internship rate ($1.25 per hour). **Conclusion** The results of the three studies show wide variation in the self-reported number of hours worked and in unit costs (financial versus economic), underscoring challenges in designing fair pay systems and valuing donated time equitably. These findings highlight the importance of balancing equity and real-world cost considerations in community-led interventions to ensure sustainable programming and fair compensation.

abs-os408 Costing the Breadth of Community-Led HIV Services: a Participatory Study in Sierra Leone

PRESENTER: **Kathleen Victoire McGee**
AUTHORS: Wilbourne Showers, Consortium of Community-led Representatives, Emmanuel Koroma, Abdul Rahman Sessay, Amara Lebbie, Isaac Ahemesah, Ms. Fern Terris-Prestholt

Background Community-led organizations (CLOs), led by and for key populations, are pivotal in delivering HIV services to their communities. Health services are rarely delivered in silos but are integrated into larger packages of care tailored to community needs. However, the economic costs of these activities remain poorly understood, limiting efforts to scale and sustain them. This study assessed the financial and economic value of resources used by five CLOs delivering HIV services from June 2022 to June 2023. **Methods** The five CLOs provided integrated services including HIV testing, care linkage, ART adherence support, socio-economic assistance, and support for gender-based violence and stigma reduction. Services were delivered to people and children living with HIV, female sex workers, and men who have sex with men. Financial costs were derived from expenditures, while economic costs included communities' donated goods and volunteer time. Financial data were supplemented by interviews, field observations, and timesheets documenting resource allocation per intervention. Costs were adjusted to 2024 US Dollars ($). A participatory approach was employed, involving collaboration between CLOs and health economists. **Results** CLOs delivered complex health and social interventions that often overlapped. Costed interventions and units of outcomes were defined by the CLOs based on available output and outcome data, prioritizing unit costs that were relevant and actionable for their programming. Annual costs across the five CLOs ranged from $103,038 to $432,674. Prevention-focused CLOs allocated 30%-44% of costs to sensitization and HIV testing, and 14%-23% to community engagement and stigma reduction. ART adherence-focused CLOs directed 26%-30% of costs to adherence support, with 42%-69% supported broader services like community engagement and socio-economic assistance. During the study period, the CLOs tested between 149 and 27,222 individuals, yielding positivity rates from 1.63% to 14.77%. Financial costs per person tested ranged from $4.14 to $25.70, and per positive case from $76.59 to $521.30. Economic costs per person tested were $4.56 to $26.64, and per positive case $84.32 to $525.36. ART adherence support costs ranged from f $9.75 to $15.41 per client (financial) and $15.64 to $20.65 (economic). Non-health services included skills training and livelihood support ($14.53-$33.20 financial; $21.20-$33.49 economic per person), educational support ($10.67 financial; $11.83 economic per person), gender-based violence support ($17.40–$36.39 per case), stigma reduction activities ($66.69 per activity), and community engagement events ($791.07–$1,335.63 financial; $939.59–$1,518.60 economic per event). **Conclusion** CLOs deliver a holistic package of care, integrating HIV and non-health services to address community needs comprehensively. Volunteer contributions and non-health services enhance outreach and reduce unit costs for HIV testing and adherence support, but failure to account for the full spectrum of activities risks underfunding CLOs and their communities. The participatory approach was instrumental in breaking down complex, overlapping interventions into defined and actionable unit costs, ensuring findings are relevant to CLOs. Comprehensive costing of these integrated services is essential for effective resource allocation and policy planning to strengthen community-led HIV responses.

abs-os200 Guideline for Costing and Budgeting the Community-led Response

PRESENTER: **Pitchaya Peach Indravudh**
AUTHORS: Kathleen Victoire McGee, Sedona Sweeney, Charity Nagemi, Mitzy Gafos, Ms. Fern Terris-Prestholt

Introduction Global HIV targets aim to expand the role of community-led organisations (CLO) in delivering interventions for testing, treatment, prevention, and addressing societal enablers. Complete cost estimation of the community-led response (CLR) is important to guide planning, investment, and resource mobilisation. While standardised guidelines and tools for costing and budgeting health interventions exist, they lack sufficient focus on issues specific to CLRs, including measuring and valuing donated time and resources. Without such methodological guidance, there is a risk of underestimating costs. Additionally, most guidelines are designed for technical audiences, underscoring the need for tools CLOs can use to estimate their own costs and project future costs. **Methods** We conducted literature reviews and expert consultations to inform the development of the costing and budgeting guideline for CLRs. Literature reviews included 15 guidelines addressing costing and budgeting across health areas, assessing principles, methodologies, and reporting standards. Quality of guidelines was evaluated using an adapted framework based on standard costing principles. Expert consultations convened a technical advisory group of 15 experts, including CLO members, to build consensus on the proposed guidance, with monthly meetings over 12 months. Topics focused on defining CLO needs in producing and using costs and understanding contexts for cost estimation. **Results** We developed guidance on costing and budgeting of CLRs with CLOs as the primary audience. The first section establishes a conceptual and methodological foundation for CLOs. Chapter 1 introduces the guideline, while Chapter 2 defines CLRs, describes core response areas, and identifies key resources contributing to costs. Chapter 3 provides guidance on defining the purpose and scope of the exercise. Key concepts covered include the purpose of cost estimation for CLOs, including to support advocacy and resource mobilisation; perspectives, including CLOs as both providers and users; time horizons relevant for CLRs; types of costs, particularly economic costs of donated time and resources; and types of inputs and outputs, including those related to non-service delivery interventions (e.g., advocacy). Chapter 4 summarises methods and data sources for costing and budgeting, highlighting approaches for measuring and valuing in-kind contributions. The second section applies these concepts and methods and includes tools to aid CLOs in data collection and analysis. Chapters 5 and 6 offer guidance for planning, collecting, and analysing observed costs, while also addressing constraints experienced in costing CLRs. Chapter 7 includes instruction for planning and projecting costs based on observed and modelled costs. Throughout the guideline, case studies, worked examples, and presentation slides are included to facilitate learning. **Conclusion** This guideline provides a comprehensive framework for costing and budgeting CLRs and addresses an important gap in practice for CLOs. By addressing key issues relevant to CLRs, this guideline can enable more complete estimations of observed and projected costs. Applications of this guideline will enhance the quality of cost data and therefore their usefulness for informing decision-making for programme and policy in the context of the CLR. Piloting is underway to further refine the relevance of the guideline based on their practical applications.

abs-os590 Government Subsidy, Hospital Expansion, and Patient Expenditures: Evidence from Public Hospitals in East China

PRESENTER: **Mr. Wei Jiang**
AUTHORS: Lina Song, Qiulin Chen, Xuyan Lou, Mr. Zhuo Chen

The growing health expenditures raised great concerns worldwide, and China is no exception. Most existing studies focused on specific policies related to medical price regulation and hospital expansion. However, we have limited knowledge of how government subsidy affects hospital management and performance. Our research provides new evidence on the causal relationship between government resource allocation and hospital management. Using a unique administrative dataset with hospital-level information, we conducted a series of empirical analyses to explore how government subsidies were determined for public hospitals and the impact of subsidy on patients' medical expenses. To remediate the biases associated with omitted variables and unobservable individual heterogeneity, we use a dynamic panel regression model to estimate the impact of government subsidy on patients' medical expenditures. The benchmark results present a positive effect of subsidies on drug expenditures and medical service expenditures. In contrast, inpatient services are less affected by subsidies. In addition, this study conducts non-linear regression model to investigate how subsidy influences patients' expenditures under different scenarios of hospital management strategies. For hospitals in the stage of expansion, government subsidies are positively associated with patients' expenditures. We conclude that government subsidies do affect hospital-level outcomes but more research is needed to determine if the subsidies achieve the policy objective and are cost-effective. Keywords: Government subsidy, Hospital management, China, Dynamic panel regression

abs-os583 Public Trust in Physicians and the Role of Healthcare Utilization: Evidence from China

PRESENTER: **Yang Li**
AUTHORS: Lefan Liu, Mr. Zhuo Chen

A growing body of literature realizes the importance of public trust in physicians in shaping the patient-physician relationship in the healthcare system of most countries, particularly in China. Using China Family Panel Studies (CFPS), a nationally representative data, this paper examines the effects of healthcare utilization on patients' trust in physicians in China. We measure respondents' healthcare utilization from three dimensions: any use of health- care services, medical cost, and primary health care utilization. Our analyses suggest that consumption of healthcare services in the past year, either inpatient or outpatient care, is significantly associated with an increase in one's trust in physicians, indicating the effect of dynamic learning from past health utilization experience. However, the share of out-of-pocket expenditure has a significantly negative impact on one's trust in physicians. The choice of health providers also matters: using primary facilities has a negative impact on respondents' trust in physicians compared with those who seek healthcare from higher-tier hospitals. Our heterogeneous analyses further show that this negative effect of using primary facilities tends to be statistically significant among urban residents and the older group, which can be explained by patients' perceptions and ratings of health providers. We provide two policy implications. First, the current healthcare reform, aiming to reduce the financial burden of residents in using healthcare, including more generous insurance coverage and less incentive for physicians to over-prescribe, is likely to improve public trust in physicians. Second, efforts should be made to strengthen the quality of primary health care facilities, which can help to enhance patients' trust in physicians and thus to incentivize patients to use primary health care.

abs-os600 Reflections and Insights on the Modernization of Chinese Health Governance

PRESENTER: **Ms. Cheng Xu**
AUTHOR: Yao Xiong

Health governance is a critical issue that requires attention worldwide, and it is also a significant measure to promote the implementation of the Healthy China strategy. This study, based on the concept of systems thinking and governance framework, analyzes literature and conducts expert interviews to summarize the characteristics of health governance systems in different dynasties and identify the core elements that influence the development and evolution of health governance systems in China. The research found that the health governance system in China originated in the Western Zhou Dynasty and continued to evolve during the Qin and Han dynasties. During the Sui and Tang dynasties, the medical education system underwent significant development. In the Song Dynasty, a health governance system led by the government with the support of social forces began to take shape. In the Yuan Dynasty, under the exchange and integration of multi-ethnic medical cultures, a top-down, network-radiating governance system was formed. In the Ming Dynasty, not only did the development of formula science accelerate, but a relatively complete medical security system was also established. In the Qing Dynasty, the public health system was further improved. In addition to the changes in political structure, economic development level, and external system environment such as epidemics and wars, which played an important role in the evolution of the health governance system, people's perception of health and its determinants, especially the perception and preferences of successive rulers, as well as the development of medical concepts and diagnostic and treatment technologies, also had a decisive influence on the objective functions, organizational structures, and governance tools of the health governance system. This study provides a new perspective for understanding the health governance systems of different dynasties in ancient China, which can help further

explore the theoretical framework of health governance systems and mechanisms. It also provides valuable references for exploring the modernization of Chinese-style health governance and global health governance practices. Keywords: Health governance, Medical Security and Policy Development, Chinese-style, Historical reflection, Global health governance

abs-os587 Road to an Age-Friendly Society: A Performance Evaluation Framework for Healthy City Strategies in China

PRESENTER: **Yao Xiong**
AUTHORS: Yuexia Gao, Ms. Cheng Xu

With the acceleration of global population aging, developing age-friendly societies has become in high demand as a response to demographic aging. This study explores how healthy cities influence the development of age-friendly societies and the key challenges and opportunities. The construction of the assessment framework begins with an analysis of the definition and core dimensions of an age-friendly society, integrating guidelines from the World Health Organization (WHO) and other sources. Existing evaluation methods and indicator systems are identified and integrated. A multi-dimensional assessment framework is constructed, including social security, health and elderly care services, livable environments, and social participation, with 12 secondary and 28 tertiary assessment indicators defined. Data collection involves the development of questionnaires and interview guides, designed to capture the nuances of age-friendly society constructs. The selection of cities and communities is based on a stratified random sampling method, ensuring representation from various geographical, socioeconomic, and demographic profiles. The survey includes a mixed-methods approach, combining quantitative data with qualitative analyses. Surveys are administered to a random sample of older adults and community leaders, while interviews are conducted with key informants, such as healthcare providers, urban planners, and social service coordinators. Statistical methods are applied to the collected data to validate the assessment indicators and the reliability of the assessment model. Factor analysis is used to identify underlying patterns and groupings within the data, which helps in refining the dimensionality of the assessment framework. Reliability analysis, specifically Cronbach's alpha, is employed to ensure the internal consistency and stability of the survey instruments. Data Envelopment Analysis (DEA) is utilized to evaluate the relative efficiency of different age-friendly initiatives across the selected cities and communities, providing insights into best practices and areas for improvement. Multiple regression analysis is conducted to explore the relationships between the various dimensions of the assessment framework and key outcomes, such as health outcomes and quality of life indicators. Factor analysis confirmed the validity of the assessment indicators, while reliability analysis showed that our questionnaires and assessment tools have a high degree of internal consistency. Data Envelopment Analysis (DEA) revealed efficiency differences in the construction of age-friendly societies across different cities and communities, identifying best practice cases and areas for improvement. Multiple regression analysis found that the accessibility and quality of health services, the adaptation of housing for older adults, and the participation in community activities are key factors affecting the quality of life of older adults. The study also pointed out that insufficient funding, uneven policy implementation, and low community participation are the main challenges faced in the construction of age-friendly societies, while technological progress, increased social awareness, and policy innovation provide opportunities. Therefore, we conclude that the constructed assessment framework can effectively evaluate and monitor the construction process of age-friendly societies, providing a scientific basis for policy formulation and resource allocation.
