DISCUSSANT: **John Ele-Ojo Ataguba**, University of Manitoba; **Manuela De Allegri**, University of Heidelberg; **Sally Stearns**, The University of North Carolina; **Nhung Nghiem**, "John Curtin School of Medical Research, Australian National University"; **Stirling Bryan**, University of British Columbia

Revising Benefit Package for Nepal's National Health Insurance: Challenges and Considerations

PRESENTER: **Suvekshya Tiwari**

Background: Health benefit package revision is a crucial component of ensuring equitable and cost-effective healthcare coverage, particularly in low- and middle-income countries (LMICs) like Nepal. The Health Insurance Board (HIB) of Nepal introduced its initial benefit package in 2017 using an input-based approach and a fee-for-service (FFS) payment model. A partial revision in 2021 updated the rates for 104 medical, surgical, and radiological services, along with 69 medicines. However, the system still faces major inefficiencies, prompting a full-scale revision initiated in May 2023.

Objectives: The study assesses challenges in revising Nepal's health insurance benefit package and guide the development of standardized, cost-effective and sustainable health services.

Data and methods: This study employs a mixed-methods approach, combining micro-costing analysis, claims data evaluation and stakeholder consultations to assess inefficiencies in Nepal's health insurance benefit package. Quantitative analysis will examine cost variations, utilization trends and financial sustainability while qualitative insights from policymakers, providers, and patients will identify challenges and improvement areas. Results The ongoing revision integrates an input-based and analytical approach, with service rates determined through a micro-costing methodology. The total cost for each surgical package now includes anesthesia, laboratory, radiology, physiotherapy, procedure, medicine, and consumable charges. Medicine pricing follows a market assessment, applying a 15% reduction to the mean maximum retail price (MRP), as recommended by the Department of Drug Administration (DDA). Additionally, a tiered benefit structure is under consideration, classifying healthcare facilities into five levels (primary care centers to super-specialized hospitals) and implementing a 10% co-payment for selected services. Despite these improvements, several challenges persist. The absence of standardized service rates leads to significant price variations across hospitals, with the cost of an Albumin test ranging from NPR 400 to NPR 1,200 in Kathmandu, highlighting inefficiencies in cost regulation. Resource constraints, both financial and human, have limited the ability to ensure comprehensive coverage of essential treatments and medicines. Additionally, the fee-for-service payment model, adopted without prior piloting, has resulted in inefficiencies and excessive reliance on provider-determined rates, making the system less cost-effective.

Conclusions: To overcome these challenges, several strategies have been proposed. Conducting regular assessments of the healthcare landscape will help monitor emerging medical technologies and cost trends, ensuring that the benefit package remains relevant. In-depth analysis of claims data, utilization patterns, and cost trends will enable the exploration of alternative payment models such as Diagnosis-Related Groups (DRG), capitation, or pay-for-performance (P4P). Implementing a tiered benefit structure will optimize resource allocation by differentiating coverage levels based on healthcare facility types. Additionally, performing cost-benefit analyses before incorporating new treatments will enhance financial sustainability. Establishing a continuous feedback loop involving service providers and insurers will further support ongoing improvements in the benefit package. This study highlights the need for a transparent, data-driven approach to benefit package revision to ensure cost-effectiveness, improve access to essential healthcare services, and enhance financial sustainability. The proposed reforms aim to strengthen Nepal's health insurance framework and contribute to achieving universal health coverage (UHC).

Health Facilities Financial Resilience amidst COVID-19: Insights from out-of-Pocket Payments Revenue Declines in Gabon

PRESENTER: **Olouyomi Scherif Adegnika**, CERMEL

Background: The recent COVID-19 pandemic strain on health systems all over the world was unprecedented, and low- and middle-income countries like Gabon faced unique challenges. With the aim of controlling the pandemic and safeguarding public health, the Gabonese government implemented a range of interventions which also resulted in significant socio-economic challenges. In Gabon, small health facilities from the public sector partially depend on patients' out-of-pocket payment for funding source. During the pandemic, restrictive measures, including recommendations to avoid health facility visits unless necessary, likely disrupted healthcare utilization and revenue streams. However, evidence on the extent and implications of these disruptions is scarce, particularly in smaller, resource-constrained facilities.

Objective: This study examines the impact of COVID-19 restrictions on healthcare utilization and associated revenue from out-of-pocket payments at the Isaac Dispensary in Lambaréné, Gabon. It aims to provide evidence for strengthening healthcare financing and building

resilience against future shocks.

Data and methods: A retrospective analysis using registry data from the Isaac Dispensary spanning 2019–2022 was conducted. A linear regression model was employed, with weekly visit numbers as the dependent variable, and weekly time period, average temperature, and average patient age as independent variables. The analysis compared healthcare utilization and relative revenue trends before, during, and after COVID-19 restrictions. Key events, including the 1st of April 2020 onset of the pandemic in Lambarene, and subsequent policy changes, were incorporated to assess temporal effects.

Results: The analysis revealed a significant drop in weekly visits and out-of-pocket revenue during the lockdown period compared to the pre-pandemic baseline. At the pandemic's onset, the dispensary experienced an average weekly decline of 23 visits, corresponding to a revenue reduction of 291,103 XAF, approximatively USD 579.00 . Notably, the drop was recovered by the subsequent increase in visits over the 25 weeks of observation as restrictions eased, suggesting partial resilience. Sensitivity analyses highlighted anticipatory effects, with declines in visits and revenue (33 visits weekly) starting mid-March 2020, coinciding with Gabon's first confirmed COVID-19 case in the capital city Libreville.

Conclusions: This study underscores the vulnerability of small health facilities in Gabon that rely heavily on out-of-pocket payments from patients for their revenue. The findings suggest significant financial strain on the Isaac Dispensary during the pandemic, highlighting the urgent need for diversified and sustainable healthcare financing mechanisms. Policies should prioritize strengthening the resilience of small health facilities to ensure continuous service delivery during future crises, mitigate disruptions, and maintain access to quality healthcare for vulnerable populations in Gabon and similar contexts.

Assessing the Value of Digital Health Technology Investments on the Management and Outcomes of Non-Communicable Diseases (NCDs) in Sub-Saharan Africa: Evidence from Service Delivery Indicators (SDIs)

PRESENTER: **Sharon Stella Musonza**

Background: In the face of emerging complex health challenges, digital health technologies have proven to be a game-changer on how we respond and approach public health. According to Arafa et al (2023), health technologies are rapidly evolving and transforming healthcare delivery. Efficient implementation of these technologies has potential to significantly improve accessibility and flexibility, even in Low- and Middle-Income Countries (LMICs) (Senbekov et all, 2020). However, little is known on the exact value of health technologies adoption in LMICs. In the face of dwindling external funding, 'choking debt' and limited fiscal space in LMICs who have already struggling health systems, now is the time to start thinking about optimal spending. Africa missed out on many gains because of lagging in adoption of technology, particularly in healthcare.

Aim: To carry out a 'Health Technology Assessment' that identifies the digital health technologies that gives the best value to support LIMCs-based policy making in priority setting in the management of NCDs.

Data sources: World Bank Service Delivery Indicators (SDIs) – already have access: World Health Organisation (WHO), observatory Demographic and Health Surveys (DHS), World Development Indicators (WDI)

Methods: 1. Assessing the Level of Digital Health Technology Adoption a. Literature review b. And trends in SDIs - commentaries 2. Analyse the impact of digital health technologies investment on NCDs outcomes (using Fixed Effects or Randoms methods) a. Quantify the effect of digital health technologies on NCDs outcomes eg reduced readmissions, improved treatment adherence and mortality rates b. Assess the differential impacts across socio economic groups, facilities settings/location and across countries 3. Evaluate the Cost effectiveness of digital health technology investments {using the Extended Cost-effective Analysis model and or/ propensity score matching (PSM)} a. Conduct an economic evaluation to estimate QALYs gained and DALYs averted resulting through digital health interventions for NCDs eg using ECEA, health technology assessment, health economic modelling to estimate the benefit cost ratios and net monetary benefits

Results: • Documenting the level of adoption of digital health technologies and assessing it versus global levels and international recommendations – read trends on factors influencing adopting certain technologies in a negative way or positive way • Paint the picture of the exact impact of digital health technologies on NCDs outcomes and general health system outcomes in terms of money invested over deaths rates, patient management and treatment compliance turnover • Quantify the real value of technology investment to readable format eg DALYs averted and QALYs gained and see what technologies matter the most in NCDs response.

Conclusion: This study adds insights into the role of health investments in technology in improving the management and outcomes of NCDs in LMICs. It measures the exact value and aids in prioritising needs in LMICs that have competing needs with limited fiscal space for health. It offers practical insights for policymakers to optimize health expenditure at a time they are forced to scale up digital health technologies in healthcare by complex health issues the most significant one being the COVID 19 pandemic.

Ripples in the Pond: The Impact of Parental Health Shocks on Children's Wellbeing

PRESENTER: **Maiken Skovrider Skovrider Aaskoven**, University of Southern Denmark

BACKGROUND: The onset of a major illness can have devastating effects, impacting not only the individual but also causing ripples through the entire household, particularly affecting children. If a parental health shock reduces investments in children, it may have profound implications for children's health and wellbeing, leading to poor outcomes later in life. Several theories propose returns on investments in children, but only few studies have so far assessed the intergenerational transmission of a health shock on the next generation's wellbeing.

OBJECTIVES: This study contributes to the literature by providing robust causal evidence of the effects of a parental health shock on children's wellbeing. Wellbeing is measured on a spectrum of severity, ranging from subjective wellbeing (SWB) to the use of medication and inpatient admissions for mental disorders. The study also identifies family-related characteristics that modify or accentuate the impact of

parental health shocks, and systematically investigates different trajectories of the health shock.

DATA AND METHODS: Children aged 6-16 living in Denmark (2015-2021) are linked to information on their (grand-) parents using nationwide Danish registers containing comprehensive information on health and social characteristics. To overcome the endogeneity of health, the first diagnosis of an acute and severe health shock, cancer, is used. To measure varying degrees of severity, wellbeing is measured on a spectrum. Child SWB is measured using data from the yearly national pupil wellbeing survey. Also school absence. Mild mental distress is measured as use of psychologists or talking therapy in the primary sector, moderate mental distress is measured as the use of anxiety or antidepression medication, while severe mental distress is measured as out- and inpatient health care services in the secondary sector for mental disorders. We employ a staggered difference-in-difference design to account for the endogeneity of a parental health shock, and adjust for various factors, e.g., the child's age and parents' socioeconomic position. We distinguish between fatal and non-fatal health shocks. We perform several robustness checks, e.g., considering non-lifestyle cancers.

RESULTS: Initial findings suggest that parental health shocks negatively impact the wellbeing of the next generation. Children affected by these shocks exhibit higher rates of school absences and mild mental distress, often requiring support such as talk therapy or psychological counselling. These effects are considerably more pronounced when the parental health shock is fatal. Interestingly, however, school wellbeing, use of psychotropic medications, and severe mental distress do not appear to be significantly impacted by parental health shocks.

CONCLUSIONS: The preliminary findings underscore the intergenerational impact of parental health shocks on children's wellbeing. While the effects generally manifest as increased school absences and mild mental distress rather than severe issues, these impacts are nonetheless significant, especially when the health shock is fatal. These results have important policy implications, emphasizing the need to improve children's access to psychotherapies and mental health care following traumatic household events. Recognising and addressing these broader familial impacts is essential in mitigating the long-term effects of health shocks on children's lives.

Exploring the Dynamic Effects of Income Inequality on Health Outcomes: A Longitudinal Empirical Analysis in the Australian Context

PRESENTER: **Han Cheng**

Background: Income inequality has emerged as a pressing socioeconomic issue with profound implications for population mental health. Australia presents a compelling case study, having experienced rising income inequality (Gini coefficient from 0.27 to 0.32, 1982-2018) alongside growing mental health concerns, with one in five adults experiencing mental disorders annually. The last major Australian investigation was conducted over a decade ago, creating a significant literature gap.

Objective: This research aims to examine the causal impact of income inequality on mental health outcomes in Australia using advanced methodological approaches. We seek to establish the causal effects of income inequality on mental health, analyze how different dimensions of inequality differentially affect mental health outcomes, and determine whether these effects vary across gender groups. The proposed dual methodological framework allows for the use of both traditional econometric methods and state-of-the-art machine learning techniques while ensuring that estimators remain unbiased and normally distributed asymptotically.

Methodology: We utilize longitudinal data from 22 waves (2001-2023) of the Household, Income and Labour Dynamics in Australia (HILDA) survey, comprising 433,102 observations from 24,857 unique individuals. Our dual framework combines individual fixed effects regression with double machine learning (Double ML) techniques using Random Forest and LASSO methods. Mental health is measured using the SF-36 mental health scale, with inequality calculated at local community level.

Results: Traditional fixed effects models show limited evidence for aggregate inequality effects, with only relative deprivation demonstrating significant negative associations (-12,889.49, $p<0.01$). In contrast, Double ML methods uncover significant effects previously undetected. The Theil index shows strong negative effects across both methods (-4.49 and -4.04, $p<0.01$), while Atkinson indices reveal that inequalities affecting lower-income groups have the strongest negative mental health implications. Gender-stratified analyses demonstrate that women show stronger responses to multiple inequality dimensions.

Conclusion: This study provides evidence that the inequality-mental health relationship is substantially more complex than previously understood, with traditional methods potentially underestimating these relationships. Our findings suggest that effective policy interventions require precision in measurement and targeting, with different inequality dimensions calling for different policy responses.

Causal Inference with Time-to-Event Outcomes: A Debiased Machine Learning Framework for Treatment Parameters

PRESENTER: **Meimei Chen**

Background: Causal inference is crucial in health econometrics for assessing the effectiveness and impact of health interventions. Traditionally, Randomised Controlled Trials are used to identify causal impact. However, advancements in data collection technologies, such as wearable devices and electronic health records, have significantly increased access to complex observational data, presenting new opportunities and challenges for health outcome evaluation. Concurrently, machine learning (ML) has gained recognition for its ability to handle and analyse large, complex datasets. This has led to the development of methods integrating ML with causal inference, including the notable approach of double machine learning (DML).

Objective: This research aims to adapt the DML framework for use with survival data, which are critical in health economics research for understanding survival and duration until events. The proposed method in this research allows for the use of a broad array of state-of-the-art ML methods while ensuring that the estimator remains unbiased and normally distributed asymptotically, which allows for the derivation of valid confidence intervals.

Methodology: This research develops a new framework for causal analysis with right-censored time-to-event data based on DML. In addition to the three fundamental assumptions of Rubin's potential outcome framework (i.e., exchangeability, consistency, and positivity), we assume that censoring is independent of the treatment assignment mechanisms, given all covariates. To remove bias introduced by ML methods, we provide a Neyman orthogonal score function for the parameters of interest, nuisance parameters, and censoring indicator. The Neyman orthogonality ensures that the estimator, which identifies our parameters of interest, is locally insensitive to the values of nuisance parameters. We also prove that estimators given in our research achieve a root-N rate of convergence and are approximately normally distributed.

Results: We used both simulated and real-world datasets to evaluate the accuracy and stability of our method. First, we showed that various state-of-the-art ML models, including random forests, gradient boosting machines, and neural networks, can be integrated into our method to estimate the nuisance parameters without compromising the consistency of our parameters of interest. Second, we compared the performance of our method with several conventional statistical methods on simulated datasets. We showed that as the number of nuisance parameters increases, our method remains stable. Third, we applied our method to a real-world dataset from the Linked Births and Infant Deaths Database (LBIDD). We compared our method to alternatives based on absolute bias, mean squared error, and standard deviation. Our method exhibited relatively smaller bias and lower variance.

Conclusion: Our research successfully extended the causal inference framework DML to incorporate time-to-event outcomes, showing robust performance on both simulated and real-world datasets. This method offers a powerful tool for health economists, enabling more accurate causal inference in studies involving survival data.

Ind-1107 Distributional Cost-Effectiveness Analysis: A Case Study of Dialysis in Thailand

PRESENTER: **Chittawan Poonsiri**

Introduction and Objectives End-stage renal disease (ESRD) presents a substantial economic burden on affected patients, their families, and healthcare systems, particularly when considering its inclusion in the benefit packages. Cost-effectiveness analysis (CEA) is commonly used to assess whether a treatment provides good value for money, as it evaluates the economic viability of treatments such as peritoneal dialysis (PD) and hemodialysis (HD). Previous CEA studies in Thailand indicated that neither PD nor HD were considered cost-effective. However, PD was deemed a relatively more economically efficient option than HD as an initial treatment, leading the Thai government to include PD in the benefit package. Traditional CEA, however, has some limitations. It focuses exclusively on cost and health outcomes, without accounting for health inequity, one of the critical issues in many countries. Distributional Cost-Effectiveness Analysis (DCEA) addresses this gap by integrating equity considerations, enabling evaluations that consider not only total health benefits but also their distribution across different population groups. The objective of this study is to apply DCEA to the case of renal dialysis in Thailand, examining the health and equity impacts of including PD and HD in the national health insurance scheme. **Methods** To conduct DCEA model, we divided our study into two phases. Phase 1 focused on estimating the baseline health distribution across Thai population and calculating an equity index, an essential step for incorporating equity metrics into the model. During this phase, two stakeholder meetings were conducted. In the first meeting, we introduced DCEA concepts to a diverse group of stakeholders, including policymakers, healthcare professionals, researchers, and patient representatives, providing them with foundational knowledge of the approach. The second meeting presented preliminary results from the baseline health distribution and health inequality aversion survey, allowing stakeholders to engage with and provide feedback on these findings. In Phase 2, we applied data and insights from Phase 1 to build the DCEA model. The first step was drafting “staircase of inequality,” which mapped disparities in health outcomes among ESRD patients, highlighting specific inequities within this patient population. Parameters from Phase 1, including baseline health distribution data and the derived equity index, were then integrated into a modified CEA framework for ESRD treatments. This model facilitated a comparative assessment of PD and HD based on both total health outcomes and reductions in health inequity. Using a social welfare index, we evaluated the trade-offs between maximizing total health benefits and minimizing health disparities, providing a comprehensive view of the interventions’ social and economic impacts. **Potential Impact** The findings of this study will provide crucial insights for policymakers in Thailand on how equity-focused economic evaluations could shape healthcare policy. By presenting a comprehensive analysis of both the health and equity impacts of dialysis treatments, this study serves as a potential model for integrating equity considerations into economic modeling. Additionally, the result from health inequality aversion survey can be used as a reference for future DCEA studies in Thailand

Ind-1729 Differential Health-Economic Outcomes of Anti-Amyloid Treatment for Alzheimer's Disease between Ethnoracial Groups in the United States

PRESENTER: **Adam Atherly**, Virginia Commonwealth University

AUTHORS: Eline M. van den Broek-Altenburg, Eric Ross

OBJECTIVES: There is concern that standard cost-effectiveness analyses can obscure important differences in outcomes across demographic groups. In this paper, we evaluate the effect of novel anti-amyloid treatments for Alzheimer’s disease (AD) on health-economic outcomes among ethnoracial groups in the United States.

METHODS: We used a previously validated mathematical model of Alzheimer’s disease treatment to project health and economic outcomes under usual care vs. with donanemab (an exemplar anti-amyloid antibody) for three ethnoracial groups: Hispanic, non-Hispanic Black, and non-Hispanic White. Key model inputs included the efficacy of donanemab (32% reduction in disease progression); price of donanemab ($26,500/year); relative medical care costs for Hispanic, Black, and White individuals (1.10, 1.22, 1.00); and likelihood of timely diagnosis for individuals with AD in the three ethnoracial groups (44%, 37%, and 61%). Outcomes include healthcare sector costs (in 2020 USD), quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratios (ICERs) at a lifetime horizon.

RESULTS: We project that a universal rollout of donanemab to eligible patients would result in a gain of 1.71 QALYs/100,000 patients with AD and increase healthcare sector cost by $389,000, yielding an ICER of $228,000/QALY. Relative to their share of the population with AD,

Hispanic individuals accrue 5% more QALY gains than expected, Black individuals 35% less, and White individuals 6% more. Sensitivity analysis with all groups assigned an equalized 61% likelihood of timely diagnosis alters the direction of these inequalities: Hispanic individuals accrue 24% more QALY gains than expected, Black individuals 5% more, and White individuals 5% less.

CONCLUSION: Based on current ethnoracial disparities in AD care, the benefits and costs of anti-amyloid treatment are likely to be unevenly distributed between ethnoracial groups, with Black individuals receiving a markedly lower share of the benefits. Efforts to improve timely diagnosis rates for Black patients would facilitate a more equitable distribution of benefits.

Ind-1990 Estimating the Distributional Impact of Improving Access to Snake Antivenom in Urban and Rural Lao PDR: An Extended Cost-Effectiveness Analysis

PRESENTER: **Chanthawat Patikorn**
AUTHORS: Jeong-Yeon Cho, Khamlub Senbounsou, Suthira Taychakhoonavudh, Thanapol Khuharatanachai, Nathorn Chaiyakunapruk, Mayfong Mayxay

Background: Lao PDR is affected by snakebite envenoming. Snakebite victims, especially in rural areas, primarily seek traditional healers to avoid the inadequate supply of antivenoms at hospitals and the financial burden of high out-of-pocket (OOP) expenditures, potentially posing health inequities between rural and urban Lao PDR.

Methods: An extended cost-effectiveness analysis (ECEA) was performed to evaluate the distributional impact of improving access to antivenom in urban and rural Lao PDR by comparing the “current access” with “full access” in which all victims received antivenom at conventional hospitals. Outcome estimates included disease burden (Disability-adjusted life years [DALYs], Case fatality rate [CFR], and mortality) and economic burden (% household OOP expenditures per monthly household income).

Results: In current access, rural areas compared to urban areas had higher deaths (+2.79 mortality rate per 100,000 population), and DALYs lost (+70.11 DALYs lost per 100,000 population), but lower household economic burden (-25% OOP expenditure per monthly household income). In the full access, rural areas compared to urban areas had higher deaths (+1.27 mortality rate per 100,000 population), DALYs lost (+32.14 DALYs lost per 100,000 population), and household economic burden (+39% OOP expenditure per monthly household income).

Conclusions and implications for policy and practice: Inequities existed in Lao PDR as rural areas had a higher disease burden than urban areas. Improving access to antivenom improved the gaps in disease burden but worsened the gaps in household economic burden. Strategies focusing on ensuring equitable access and providing financial assistance are needed.

Ind-2558 Cost Consequence Analysis in the Real World: Making Difficult Decisions in Remote Australia

PRESENTER: **Jackie Roseleur**
AUTHORS: Narelle Campbell, Chris Hince, Chris Rissel, Kylie Stothers, Jonathan Karnon

Background Aboriginal and Torres Strait Islanders account for 3.8% of Australia's population, increasing from 1.9% in major cities to 32% in remote and very remote areas. These populations often travel long distances to access services in urban centres. Disability and rehabilitation services in remote Australia are limited by geographic isolation and scarce allied health professionals. A student-assisted service model, co-designed with community leaders, was piloted and expanded in a very remote location (Nhulunbuy, Northern Territory – population 3,267, distance to nearest major hospital 1,025km). Over 12 months, three rounds of four students each delivered eight-week services, supervised by an interprofessional team and local Aboriginal (Yolŋu) cultural consultants, with grant and university support. ## Aim The first aim of this study is to describe the costs and activities of a student-assisted service model and to model the costs of providing the same level of services via alternative service models (resident clinician and fly-in-fly-out). The second aim is to consider the broader effects of the student-assisted service, including improved cultural safety in service delivery and increased likelihood of students practicing in remote communities when qualified. Headroom analysis will be used to estimate the service’s maximum cost to be considered cost-effective. ## Methods Costs for the delivery of the same level of care provided by the student-assisted model were estimated for each service delivery model from a health system perspective. Quantitative and qualitative data were analysed to inform the broader effects of the student-assisted models in remote Australia. The headroom analysis considers stakeholder expectations regarding the program's benefits and overall value for money, while also identifying the types of evidence and effect sizes of the consequences of the student-assisted model that would be required to demonstrate value for money, including a more culturally responsive health service, community appreciation of the services, improvements in the quality of life associated with increased access to allied health services and increases in the future allied health workforce with a desire to work in remote communities. ## Key results Fifty clients participated in the student-assisted service model. Approximately half were female and 96% were Aboriginal and/or Torres Strait Islander. The total cost of the student-assisted service model was $118,141, with a cost per client of $2,363. For the resident clinician and the fly-in-fly-out models of care, the total cost of the service was $45,743 and $75,123, respectively, with a corresponding cost per client of $915 and $1,502, respectively. Key stakeholders from NT Health will be identified for input on headroom analysis. An information session will determine whether the available evidence to inform expected effects on clients, cultural safety and workforce justify the additional costs. ## Conclusions and implications This cost-consequence analysis underscores the need to balance financial costs against non-monetary benefits, including culturally responsive care and long-term workforce development in remote communities. Incorporating these multifaceted factors into decision-making frameworks is crucial for evaluating value in remote and Indigenous health contexts, enabling policymakers to assess whether broader positive impacts on health equity and access for Aboriginal and Torres Strait Islanders justify the additional costs.

Ind-1900 Cost-Effectiveness and Budget Impact Analysis of an Evidence Based Co-Designed Model of Cardiac Rehabilitation for Patients in Rural and Remote Areas

PRESENTER: **Norma Bulamu**, Flinders University
AUTHORS: Billingsley Kaambwa, Alline Beleigoli, Lemlem Gebremichael, Robyn Clark

Aim To assess the cost-effectiveness and budget impact of implementing a model of cardiac rehabilitation (CR) for patients in rural/remote areas which included a choice of face to face, telephone, web based, or primary care-based modes of delivery, the Country Health Attack Program (CHAP), compared to usual care (non-CHAP). ## **Methods** This was a prospective cohort study including all patients referred to CR in South Australia. Patients in CHAP were matched to non-CHAP by age, sex and Australian Refined Diagnosis-Related Groups (AR-DRG) in a 1:1 ratio. We evaluated 12-month attendance and completion of CR as the primary measure of effectiveness. Effectiveness data was obtained from a linked dataset of hospital admissions, CR referral and attendance. Costs were calculated based on the AR-DRG and length of stay. The analysis was conducted from a health system perspective with incremental cost-effectiveness ratios per CR attendance and completion calculated. A budget impact analysis estimated the financial benefit of implementing CHAP over five years for all individuals who attend CR in South Australia (30% of individuals eligible for CR). ## **Results** There were 1913 patients each in CHAP and non-CHAP. CR attendance through CHAP was more costly but more effective (costs: $6,205 vs $5,855; attendance: 24.1% vs 23.8%) and in terms of completions CHAP was superior: it was cheaper and more effective (costs: $6,542 vs $8,689; completions: 77.1% vs 57.5%). Subsequently, for both models of care it cost less per CR completion (CHAP =$8,494/completion, non-CHAP= $15,129/completion) than per attendance (CHAP=$25,668/attendance, non-CHAP=$24,551/attendance). The CHAP model had over 50% chance of being cost-effective in improving CR completion and attendance. Uptake of the CHAP model would result in a cost reduction ranging from $2,110,501 at 20% uptake to $10,010,777 if all patients referred attended and completed CR. ## **Conclusions** The CHAP model of care, which involved a combination of face-to-face, telephone and web-based delivery for CR provides a less costly and more effective alternative for completion of CR. Adapting the CHAP model results in significant savings to the health care system, however, they can only be realised if all individuals attending CR complete the program.

Ind-953 Understanding Chronic Kidney Disease in Western Australia: Cost, Prevalence and Equity

PRESENTER: **Suzanne Robinson**
AUTHORS: Delia Hendrie, Richard Varhol, Kanika Mehta, Elizabeth Thomas, James Boyd, Kevin Chai, Aron Chakera, Crystal Lee, Sean Randall

Background: Chronic kidney disease is a major public health issue, with substantial costs and impacts on healthcare systems worldwide. In Australia, CKD often progresses silently, contributing to increased morbidity until patients reach end-stage kidney disease where the economic burden dramatically increases. CKD disproportionately effects more vulnerable populations, particularly those in lower socioeconomic groups and remote areas where healthcare access is limited.

Aim: This study aimed to elucidate the prevalence and cost of CKD in Western Australia, examining disparities over time associated with socioeconomic status and remoteness, to inform targeted public health interventions and healthcare resource allocation.

Methods: This study utilised the CKD.WA dataset, consisting of linked public and private pathology data from all major pathology providers in WA, along with hospital and emergency admissions and death registrations. Individuals were included within the dataset if they had a recorded creatinine pathology test from any provider. This large dataset provided detailed unit-record level information for over 2.5 million individuals from Western Australia.

Individuals were identified with CKD based on two eGFRs values >90 days apart, or 2 uACR values >90 days apart. Individuals were classified by remoteness and socioeconomic status based on their recorded postcode. Costs components included hospital, emergency, dialysis, outpatient, medication, general practice and pathology costs. Medication, general practice and pathology costs were derived from a separate general practice database consisting of clinical records for 600,000 individuals.

Results: The study analysed data from 2.501,188 individuals aged ≥18 years, from between 2010 to 2020. Overall CKD prevalence increased from 2010 (3.5%) to 2020 (5.6%). CKD prevalence grew at a faster rate in both regional and remote areas as compared to major cities, with prevalence rate 13% higher in remote areas, and 25% higher in regional areas as compared with major cities. CKD prevalence was highly associated with greater socioeconomic disadvantage, with those in the most deprived quintiles having nearly three times CKD prevalence as compared to those in the least deprived. Average yearly costs attributable to CKD were $3,367 for Stage 1, $4,114 for Stage 2, $3,607 for Stage 3a, $6,572 for Stage 3b, $11,456 for Stage 4 and $62,558 for Stage 5. Non-dialysis hospital costs were the biggest contributor, followed by dialysis costs. The estimated total cost of CKD to Australia was $8.3 billion for 2019.

Conclusion: The study highlights significant growth and inequities in CKD across Western Australia. While CKD costs per individual are highest in later stages, the greater number of early-stage CKD cases means the majority of the cost burden is located among early-stage cases. Findings underscore the need for targeting health policies and interventions addressing the unique challenges faced by disadvantaged populations and those living in regional and remote areas.

Ind-367 Costs Associated with the Management of Wilms Tumor in Tanzania, A Narrow Societal Perspective.

PRESENTER: **Amosi Kilipamwambu**
AUTHORS: Rashid Mruma, Frida Ngalesoni, Lulu Chirande, Christopher Chambo
ABSTRACT

Background: Non-communicable diseases (NCDs) are a major global health concern, particularly impacting Low- and Middle-Income Countries (LMICs). Childhood cancer, notably Wilms tumour (WT), presents significant challenges in LMICs like Tanzania due to disparities

in healthcare access and resources. However, in Tanzania, managing WT is hindered by a lack of understanding of its financial implications. This study aims to address this gap by analysing the costs of WT management in major specialized hospitals in Tanzania to facilitate better resource allocation and cost-effective strategies.

Objective: To determine Costs associated with the management of Wilms Tumor at Muhimbili National Hospital (MNH) and Ocean Road Cancer Institute (ORCI) in Tanzania.

Methods: We utilized a cross-sectional costing study for Wilms tumor (WT) management, employing micro-costing with top-down and bottom-up approaches. A 'narrow' societal perspective approach, for the financial year 2021/22 was used to identify, quantify, and value resources used for WT Care after verification at the costing unit, with exit interviews with 52 caregivers, Data analysis was done through Excel and SPSS version 20 for both provider and patient perspective.

Results. From the patient perspective, 51 caregivers were female, averaging 32±5 years old, with 34.6% self-employed, 40.4% having primary education, and 78.8% uninsured. The annual unit cost for managing Wilms' tumor (WT) was 1,934,627 Tsh (737 USD) for early-stage and 3,230,604 Tsh (1,230 USD) for advanced-stage WT. From the provider's perspective, annual costs were 2,901,660 Tsh (1,105 USD) for early-stage and 8,744,835 Tsh (3,329 USD) for advanced-stage WT treatment.

Conclusion and Recommendations. Treating advanced-stage Wilms' tumor (WT) costs 2-3 times more annually than early-stage WT, highlighting the need for early diagnosis and treatment. Targeted interventions to enable early detection and care for children with WT will enhance cost-effectiveness.

Ind-611 Economic Evaluations of Stigma and Interventions Which Aim to Reduce Stigma: A Systematic Review.

PRESENTER: **Caroline Watts**, UNSW Sydney
AUTHORS: Elena Cama, Carla Treloar*, Virginia Wiseman*

Background There is growing recognition about the impacts of stigma on health, particularly the role of stigma in producing and reinforcing disparities in access to health care. Economic evaluations alongside interventions to reduce stigma are required to provide evidence of costs and effectiveness and support decision making and policy change. To date there has been no synthesis or appraisal of the methods used in economic evaluations which value stigma. **Aims** A systematic review was conducted with the aim to provide insights into types of interventions and populations targeted, methodologies applied and properties of the outcome measures used to value stigma. **Methods** Adhering to PRISMA guidelines, six electronic databases Embase PubMed, CINAHL, Scopus, PsychINfo, and Cost-Effectiveness Analysis (CEA) Registry were searched using the search terms; stigma, discrimination, cost effect* or cost benefit* or cost utility* or societal cost. The search was conducted from December 2023 with no limitations. Studies were included if they were a health economic evaluation of an intervention which aimed to reduce stigma or studies which defined and measured the cost of stigma as a study outcome. Two reviewers (CW, EC) completed the data extraction, and checks for reporting standards (Consolidated Health Economic Evaluation Reporting Standards (CHEERS)) and quality (Consensus on Health Economic Criteria (CHEC)) checklists. The review was registered on Prospero CRD42024597127 **Results** In total, 1378 articles were screened, 166 full text articles were reviewed, and 26 studies met the inclusion criteria of which the majority (24 studies) were from high income or upper-middle income countries and two studies were from lower-middle or low-income countries. The stigmatised conditions/populations included men who have sex with men, HIV, mental health, epilepsy, racism, ageism, and offending. The interventions were directed at people living with a stigmatised condition, health care workers, family, community members, work colleagues and the police. Evaluation types included thirteen full economic evaluations (nine cost-effectiveness analyses, three cost-benefit analyses, one cost consequence) and nine partial evaluations. Stigma measures used in ten studies were derived from questionnaires or interviews and thirteen studies used measures from validated instruments of which six studies used quality of life measures (QALYs, DALYS, Wellbeing) and three studies used generic measures of stigma related health or wellbeing outcomes. Stigma reduction strategies targeted the individual (18 studies), interpersonal (18 studies), community (11 studies), and structural (4 studies) of stigma. Reporting standards and quality for most studies were assessed as fair or adequate. **Conclusion** Cost of illness studies indicate there is a substantial cost burden due to stigma. Community level interventions showed mixed results with some studies having a range of outcome measures. There is a lack of consistency and clarity in both the conceptualisation and measurement of stigma in health economic evaluations. Generally, studies did not address wider issues such as the affordability, scalability, or sustainability of interventions. Inclusion of a measurement of stigma is important for evidence-based health practice to reduce prejudice and discrimination and support decision making.

abs-os27 Cost-Effectiveness of Epitope Compatibility in Kidney Allocation: A Canadian Discrete Event Simulation Study

PRESENTER: **Shahzad Ghanbarian**
AUTHORS: Steven Shechter, Matthew Kadatz, Anat Fisher, Louisa Edwards, Karen Sherwood, James Lan, Paul Keown, Prof. Stirling Bryan

Background: Kidney transplantation is the treatment of choice for patients with end-stage renal disease (ESRD), but these life-saving transplants may fail due to rejection. This has prompted development of advanced genomic technologies to reduce rejection risk. The use of epitope compatibility to guide deceased donor allocation is one promising approach. Greater epitope compatibility is likely associated with reduced graft loss, but some people will wait longer for a good match. We have developed a Discrete Event Simulation (DES) model to evaluate cost-effectiveness and equity implications of adding epitope compatibility to the current kidney allocation criteria in Canada.

Methods: A DES model was built using kidney transplant longitudinal data from British Columbia (BC). The model captures individual patient and donor characteristics, comorbidities, and clinical outcomes, simulating both pre- and post-transplant pathways, including waitlist dynamics, rejection, graft survival, and mortality. Patients and donors were sampled using bootstrapping to preserve correlations in the data. For our cost-effectiveness analysis, the base-case scenario applies existing BC organ allocation criteria, prioritizing patients primarily by wait time, with

additional prioritization for pediatric and immunologically sensitized patients. The intervention scenario sees the use of epitope-based matching in conjunction with these other priority criteria. Costs (CAD$ 2024) are estimated from a public payer perspective, and time-to-event outcomes are modeled using Cox proportional hazards. Incremental costs, life-years, and quality-adjusted life-years (QALYs) will be estimated, and sensitivity analyses performed to address key uncertainties.

Results: The model simulates a dynamic cohort of ESRD. Our observational cohort comprises all patients who joined the BC deceased donor waitlist for a kidney transplant between 2008 and 2018. A total of 2,148 patients (median age 55) joined the waitlist, with 1,245 (median age 55) receiving a transplant from a deceased donor. Based on cumulative incidence functions (CIFs) accounting for competing risks, 50% of patients received a deceased donor kidney within two years (median wait time: 671 days). During the same period, 3% died on the waiting list, 10% received a living donor transplant, and 3% were removed due to medical or other reasons. Our micro-costing analysis estimates the kidney rejection costs range from $2,121 to $24,714, depending on the type. Previous research suggests that better epitope matching of donor organ and recipient reduces transplant rejection, with potential for associated cost savings and improved post-transplant outcomes. However, epitope-based allocation comes with equity challenges: waiting times will increase for difficult-to-match patients. Our Canadian kidney transplant DES model is fully developed and currently in the model validation phase, to refine estimates and ensure robustness. Once validated, the model will predict the economic impact and health outcomes of epitope-based allocation and represent a powerful tool to undertake equity-focused analyses.

Conclusion: This DES model represents a novel tool for evaluating the cost-effectiveness of epitope-based kidney allocation and exploration of equity-efficiency trade-offs. Evidence-based support will be given to optimal design of organ allocation criteria reflecting both efficiency and equity considerations. While tailored for epitope mismatch evaluation, the model can adapt to allow rapid evaluation of other innovations in kidney transplantation.

Cancer Policy: National and Global Perspectives

MODERATOR: **Laksono Trisnantoro**, "Health Policy and Management Department, Faculty of Medicine, Public Health and Nursing, University of Gadjah Mada"

Ind-2744 ChemoGlobe: A Forecasting Model to Support the Planning and Procurement Needs of The Global Platform for Access to Childhood Cancer Medicines (GPACCM)

PRESENTER: **Nancy S. Bolous**
AUTHORS: Jennifer L. Pauley, Hannah Sauer, Nickhill Bhakta, Meenakshi Devidas, Yichen Chen

Background: Cytotoxic chemotherapy is essential for nearly all childhood cancers. Although many drugs used in the pediatric space are generic, pharmaceutical agents continue to drive a significant portion of the overall treatment cost due to market challenges such as small volume orders and complex registration barriers. To ensure equitable access, St. Jude Children's Research Hospital, the World Health Organization (WHO), and the United Nations International Children's Emergency Fund (UNICEF) partnered in 2022 to create GPACCM, a $200 million initiative. Like the Global Fund, GPACCM will purchase and distribute childhood cancer medicines at no cost to recipient countries. Six pilot countries (Ecuador, Jordan, Uzbekistan, Zambia, Mongolia and Nepal) were selected and will receive the first drugs in Q1-2025. To support strategic planning and drug procurement, our team developed a robust global forecasting model, then compared the findings to real-world data from the six pilot countries to identify opportunities to improve the model.

Methods: For initial planning, our base-case estimates were determined for 200 countries and territories, using three components: cancer burden estimates, medication quantification, and prices. To calculate burden, published modeled data were used to estimate childhood cancer incidence, diagnosis, and survival. Medication requirements were determined by calculating cumulative doses for 50 chemotherapy and supportive care agents, from 210 standard regimens across 47 cancer subtypes (as per the International Classification of Childhood Cancers, 3rd edition), stratified by risk and stage. Cost data were sourced from the International Medical Products Price Guide and IQVIA. For model validation, real-world burden and treatment protocol data collected from the six pilot countries were used to update the model. Outputs were then compared to local forecasting estimates, institution-level consumption data, and discussed with local stakeholders.

Results: All global base-case forecasting estimates for planning are publicly available on a cloud-based dynamic visualization platform (chemoglobe.stjude.org). This platform enables users to explore context-specific data visualizations, with estimates dynamically adjustable across several parameters.** Based on our analyses, the estimated cost of treating all newly diagnosed childhood cancer patients in 2024—assuming timely diagnosis, normal weight, and treatment with curative intent—totals $876,860,260. During the validation phase, several major challenges were identified. First, assuming vial sharing can have major implications on quantities and costs. Additionally, a universal assumption of 10% wastage was not appropriate for every drug. Finally, although hospitals claimed to use certain standard regimens, they often locally adapted treatment resulting in major procurement differences.

Conclusion: ChemoGlobe is a novel forecasting tool that supported the planning and early procurement needs of the GPACCM. Based on context-specific datasets, real-world data and input from local stakeholders, we are implementing several modifications such as, incorporating country-, age-, and gender-specific weight datasets; tailoring wastage assumptions for individual medications; generating outputs in vial sizes alongside absolute values; incorporating real-world data from additional countries; using prices negotiated by UNICEF and integrating these enhancements into the ChemoGlobe visualization platform. These changes will provide more reliable, rapid estimates for global partners and

help meet the GPACCM goal of expanding access to 50 countries over the next four years.

Ind-2126 Adapting HPV Screening Models for Populations Vulnerable to Cervical Cancer: Using Multiple Data Sources for Prediction

PRESENTER: **Haode Wang**
AUTHORS: Luke Vale, Li Sun, Paolo Rossi, Anna Foss, Anneli Uusküla, Rosa Legood

Introduction: We explore the use of calibration to adapt an existing human papillomavirus (HPV) screening model to populations highly vulnerable to cervical cancer (CC). To do this, we use Estonia as a case study, where HPV screening is the primary test for CC. However, the routine screening uptake rate is disproportionately low among women with heightened vulnerability to infection, including sex workers, women living with HIV (WLWH), women using injecting drugs and other underserved populations. To estimate the effect of tailoring HPV screening models for such populations, we report our modelling strategy that combines data from (i) a population-based case-control trial, (ii) calibration targets of age-specific absolute risk of CC, and (iii) local real-world data from each specific population. Unlike most prior cost-effectiveness research, the model is able to provide high flexibility for estimating the cost-effectiveness across different populations using a consistent model structure to facilitate comparisons.

Methods: We developed a Markov model with seven health states, reflecting the Estonia CBIG-SCREEN intervention protocol. The intervention encouraged WLWH aged 25-65 to participate in self-sampled mailing screening or community-based CC screening centres, while the control group followed the existing screening protocol. Data for the natural history states were derived from a UK study (ARTISTIC trial in England) for unvaccinated people and used a multiplier to better align to the situation in Estonia. We obtained relative risks (RRs) of WLWH using a literature review. The proportion of women with risk factors, corresponding uptake rate and cost data were collected by the local team. Model calibration involved varying the UK to Estonia alignment multiplier with range 1-3.5, determined by the literature, targeting a better fit with Estonia HPV prevalence, CC incidence and high-grade squamous intraepithelial lesions (HSIL) prevalence. Using the best-fit multiplier value, the HPV screening sensitivity and specificity were also then calibrated due to possible screening operation variance. Calibration was conducted with both Nelder-Mead simplex method and BOBYQA Method. Goodness of fit was calculated by simple sum of square function, with a log transformation to minimize the unit difference.

Results: Both calibration methods supported using a multiplier of 2.38 and achieved an error statistic of <0.005. The multiplier increased to 2.38 and sensitivity/specificity decreased after calibration. Our preliminary findings suggest that, comparing tailoring screening to standard screening with an expectation that tailored screening gave a 20% uptake rate increase, the total direct cost per case screened would decrease from €2412 to €2164, and the total cancer incidence would decrease from 6% to 5%. This predicted cost saving resulted from early identification of high-risk HPV (types 18/16), so preventing progression to cancer.

Conclusion: This study presents a method of using calibration to leverage multiple data sources across settings to model and estimate the impact of a screening intervention specific to a new setting. The evidence synthesis strategy introduced in this study emphasize the feasibility and potential for using multiple sources of data for innovative intervention modelling. This approach could be useful for other researchers adapting models to their local situation.

Ind-1323 Evaluative Frameworks for Tumour-Agnostic Precision Oncology: Machine Super Learning for Determining Survival Impact and Cost-Effectiveness

PRESENTER: **Emanuel Krebs**, Cancer Control Research, BC Cancer
AUTHORS: Ms. Deirdre Weymann, Mr. Dean A Regier

Introduction: Multi-gene panel sequencing streamlines the identification of therapeutic targets for personalized patient care. Adoption remains limited due to uncertain clinical and economic impacts. Evidence from randomized clinical trials (RCTs) is the standard for regulatory and reimbursement deliberations, yet is unavailable for many precision oncology interventions. We determined the effectiveness and cost-effectiveness of tumour-agnostic multi-gene panel sequencing compared to single-gene testing for advanced cancers, including advanced non-small cell lung cancer, melanoma, and colorectal cancer. **Methods:** Our population-based retrospective study followed the target trial emulation framework using patient-level linked administrative health databases. We considered adult British Columbia, Canada residents with an advanced cancer diagnosis who received multi-gene panel sequencing or single-gene *EGFR*/*BRAF*/*KRAS* tests between 2016-2018, emulating random assignment via genetic algorithm-based 1:1 matching. Our primary analysis included the same number of multi-gene panel patients and controls by tumour type. Our secondary analyses consider tumour-agnostic matching and stratified matching by tumour to understand the implications of tumour-specific versus tumour-agnostic evaluative frameworks. After matching, we estimated mean three-year survival time and costs (public healthcare payer perspective; 2021 CAD) and calculated the incremental net monetary benefit (INMB) for life-years gained (LYG) at $50,000/LYG using inverse probability of censoring weighted linear regression and nonparametric bootstrapping. **Results:** We matched 1,176 patients receiving multi-gene panel sequencing to single-gene controls, achieving good balance on all 21 covariates. Incremental costs in the primary analysis were $6,263 (95%CI: $43, $13,326) and incremental LYG were 0.16 (95%CI: 0.06, 0.24). The INMB at $50,000/LYG was $1,653 (95%CI: -$4,350, $7,010), with a 72.0% probability of being cost-effective. Findings were not sensitive to the evaluative framework based on secondary analyses. **Conclusions:** Implementation of a tumour-agnostic multi-gene panel for advanced cancers is likely cost-effective for health systems. This real-world evidence can inform best practices for tumour-agnostic evaluations and support policymakers in reimbursement deliberations for precision oncology interventions.

Ind-1187 Health, Financial Protection and Equity Impacts of Recent Breast Cancer Policy in the Philippines: An Extended Cost-Effectiveness Analysis

PRESENTER: **Stephen Jan**, The George Institute for Global Health
AUTHORS: Blake Angell, Corazon Ngelangel, Herdee Luna, Alex Chye, Nirmala Bhoo Pathy, Merel Kimman, Soledad Lim, Sanne Peters, Mark Woodward

Introduction

Women in the Philippines experience significant health and economic burdens of breast cancer. The Philippines has reformed financial protection for breast cancer but does not have a national early detection and treatment program. This study aims to evaluate the health and economic impacts of ACT NOW (breast cancer program that navigates women through free early detection to treatment) through an extended cost-effectiveness analysis.

Methods

A microsimulation decision tree model was used to model the ACT NOW intervention (including annual clinical breast examination (CBE); and biannual breast ultrasound (US) for women at high risk of breast cancer) over 5 years for healthy women 40-69 years old. Outcomes included health gains (breast cancer deaths saved), financial protection (financial catastrophes saved), and incremental cost-effectiveness ratios (ICER) (cost per DALY saved). Outcomes were stratified by income group. Probabilistic, one-way sensitivity and scenario analyses explored uncertainty.

Results

Over five years the ACT NOW intervention is cost-effective with an ICER of PHP11,813 (average incremental cost PHP145 [95% UI -156-304] and DALYs saved 0.01 [95% UI 0.01-0.02], below Philippines 2022 GDP per capita PHP178,751). Per 100,000 women, 57 deaths and eight financial catastrophes were saved. Cost-effectiveness did not vary significantly by income, but higher income groups incurred greater costs and lower DALYs. Results were sensitive to proportion of late-stage breast cancers, treatment adherence, intervention costs and downstaging effectiveness. Trade-offs are apparent between government contributions to financial protection and rates of financial catastrophe.

Conclusions

Early detection interventions (annual CBE, biannual breast US if at high risk of breast cancer) are likely to be highly cost-effective, reduce breast cancer related mortality through detection at earlier stages; and modestly effective in reducing the incidence of financial catastrophe. Further research is required to establish the best implementation model to pursue full implementation and ways of designing equity-based screening interventions.

Health and Wellbeing Impact of Elderly Care Programs

MODERATOR: **Audrey Laporte**,

Ind-419 The Golden Years' Dividend: Exploring the Effects of Old Age Allowances on Nursing Home Expenditures and Disability

PRESENTER: **Zining Liu**, Central University of Finance and Economics
AUTHORS: Xiao Han, Hong Liu

As the global population continues to age, the proportion of elderly individuals, particularly those aged 80 and older, is increasing rapidly in both developed and developing countries. In response, many nations have implemented welfare programs to support the elderly, including long-term care subsidies and non-contributory pensions. This paper examines the impact of a non-contributory old age allowance in China, which provides elderly individuals with a monthly cash transfer of 100 Yuan upon reaching the age of 80, regardless of their health status. Using administrative data on all elderly residents in nursing homes registered with the Beijing Municipal Civil Affairs Bureau (BMCAB) between 2021 and 2024, we employ a regression discontinuity (RD) design to exploit the age eligibility cutoff for receiving the allowance. This quasi-experimental approach enables us to estimate the causal effects of the old age allowance on two key outcomes: expenditures in nursing homes and changes in disability status. Our analysis reveals three primary findings. First, we find that receiving the old age allowance leads to an increase in nursing home expenditures of approximately 413 Yuan, or 6.1%, which is significantly higher than the 100 Yuan allowance amount. This effect is robust across various model specifications, including non-parametric estimations and alternative bandwidths. We also observe that this increase is more pronounced among certain subgroups, including men, individuals who lived with others prior to admission, those with a son as their guardian, and those with social health insurance. Second, we explore the mechanisms driving this increase in expenditures and find that elderly individuals receiving the allowance tend to choose more expensive accommodations. Instead of opting for higher levels of institutional care or increased spending on food and personal care, they prefer to invest in better living arrangements and select healthier companions who can provide peer-to-peer support. Third, we find that the old age allowance has a positive impact on health outcomes: it reduces the likelihood of disability deterioration by more than 10 percentage points among healthier elderly individuals. This effect remains

robust even after controlling for potential confounders, such as the length of stay in the institution and the potential manipulation of disability ratings. This study makes three important contributions to the literature. First, it provides new evidence on the effects of non-contributory cash allowances on expenditures in nursing homes, distinguishing it from previous studies that have focused on in-kind subsidies. Second, it examines the effects of such allowances on health outcomes, particularly disability ratings, offering insights into how relatively low-cost welfare programs can improve elderly health. Finally, the paper identifies potential mechanisms through which cash transfers may enhance health outcomes, such as changes in institutional care choices and the health status of co-residents. In conclusion, this research contributes to the growing body of literature on elderly welfare programs and offers valuable insights for policymakers seeking to balance healthcare expenditures while improving the well-being of an aging population.

Ind-1777 The Impact of the Victorian Healthy Homes Program on the Quality of Life in the Older Population: A Randomized Controlled Trial in Australia

PRESENTER: **Dan Liu**, University of Technology Sydney
AUTHORS: Patricia Kenny, Lutfun Hossain, Katie Page, Kees Van Gool, Rosalie Viney

Background: The relationship between the home environment and health outcomes has garnered significant attention, with a growing body of evidence underscores the pivotal role that the physical, social, and psychological aspects of the home play in influencing health and well-being. However, robust causal evidence linking the health and wellbeing benefits of home upgrades is lacking in the Australian setting. Results across countries may vary due to differences in climate, the quality of the housing stock and existing levels of energy efficiency. This is the first study to addresses this evidence gap. **Objectives**: The Victorian Healthy Homes Program (VHHP) is Australia's first randomized controlled trial (RCT) examining the impact of thermal home upgrades on health outcomes in vulnerable older adults. The program aimed to provide home upgrades for 1,000 households (1,300 individuals), offering up to $3,500 per household to improve thermal comfort and energy efficiency. This paper investigates the impacts of the VHHP on 22 outcome measures derived from three quality of life (QoL) instruments. **Methods**: The VHHP was implemented over three years using a staggered, parallel-group clustered RCT. Households were assigned to either an intervention group, receiving a home upgrade before winter (July – September) in 2018-2020, or a control group, receiving an upgrade after winter. Surveys collected data on demographics and QoL. Self-reported QoL was assessed using three established instruments. The 5-level EQ-5D version (EQ-5D-5L) measures health on five dimensions: mobility, personal care, usual activities, pain/discomfort and anxiety/depression. The 36-Item Short Form Health Survey (SF-36) measures health on eight dimensions: physical functioning, role functioning, bodily pain, general health, vitality, social functioning, role emotional and mental health. The Adult Social Care Outcomes Toolkit (ASCOT) measures individual's QoL that can be affected by social care, with eight dimensions measured by nine items: control over daily life, personal cleanliness/comfort, food and drink, personal safety, social participation, employment/occupation, accommodation cleanliness/comfort, and dignity (two items). We applied ordered logistic regression for categorical outcomes and Ordinary Least Squares (OLS) regression for continuous outcomes. Survey data were analyzed before and after winter, with adjustments for age, sex, location, and year fixed effects. **Results**: As a result of the home upgrade, overall QoL in the intervention group significantly improved during the winter period. Key drivers of these improvements, as measured by the SF-36, were changes in mental health and physical functioning. Additionally, the ASCOT measure revealed that accommodation had the greatest impact, with the intervention group reporting greater improvements in the cleanliness and comfort of their homes compared to the control group. **Conclusion**: This study shows that modest investments in housing improvements yield significant health and wellbeing benefits, particularly for vulnerable individuals. Enhanced mental health and QoL, especially in winter, are likely to persist due to the lasting nature of the upgrades. Large-scale, non-health-focused interventions can substantially improve wellbeing and should be prioritized by governments aiming to enhance public health. By recognizing the links between housing and health, policymakers, urban planners, and healthcare professionals can develop strategies to create healthier living environments.

Ind-2251 Effects of Medicare Advantage on Healthcare Use and Outcomes: Evidence from Public Retiree Health Benefits

PRESENTER: **Jose Escarce**, University of California-Los Angeles (UCLA)
AUTHORS: Victoria Shier, Rushil Zutshi, Peter Huckfeldt, Tyler Boese, Neeraj Sood, Helen Parsons

Medicare beneficiaries choose to receive coverage from traditional Medicare (TM) or through private Medicare Advantage (MA) plans. Starting in 2023, a majority (51%) of Medicare beneficiaries were enrolled in MA rather than TM. The Centers for Medicare and Medicaid Services (CMS) pays MA plans fixed monthly capitated payments to cover nearly all health care for enrollees. As MA plans keep the portion of payments not used on to provide health care (or lose money if spending is above the capitated payment), they have financial incentives to reduce health care use. In addition, MA plans have tools to reduce spending that are not present in traditional Medicare, such as establishing restricted provider networks and requiring prior authorization for services. However, financial incentives under capitation could lead to reductions in needed care. Prior research has found that MA enrollees have lower healthcare spending than TM enrollees, with fewer admissions for hospital and post-acute care but more preventive care visits, and mixed evidence on quality of care. However, recent research has been primarily cross-sectional and could be subject to selection bias, especially given that MA enrollees have been shown to be healthier than TM enrollees, even conditioning on observed health. ` `We investigate the causal effects of MA on healthcare use and patient outcomes utilizing a natural experiment. We studied 221,000 retired state employees in five states (AL, AZ, CO, CT, NJ) where retiree health benefits were shifted from state-sponsored supplemental "Medigap" plans (covering the extensive cost sharing in TM) to mandatory MA plans between 2017 and 2019. This natural experiment creates variation in MA enrollment that is independent of health status and thus avoids selection bias. State workforces include a diverse set of occupations and are broadly representative of older adults enrolled in Medicare. As a comparison group, we use retired state employees in ten states that continuously offered Medigap plans over this period. We estimate synthetic difference-in-difference models which assign weights to each comparison state to match the pre-policy trends of each "treatment" state. ` `After states shifted retiree health benefits from Medigap plans to MA, we find that 77% to 98% of retired state employees enrolled in MA across the 5 states in our sample. We find consistent evidence that MA enrollment led to higher rates of home evaluation visits and reductions in inpatient rehabilitation facility use. Other effects vary more across states: for example, MA enrollment increased annual wellness visits in two states but reduced them in two other states. We find mostly small and/or statistically insignificant effects for evaluation and management visits, hospital

admissions, and patient outcomes (institutional days and mortality) across states. Overall, our results show that MA increased use of certain outpatient services and reduced use of post-acute care without affecting the patient outcomes we observed, suggesting greater efficiency. However, future work should focus on outcome measures with greater sensitivity. The heterogeneous effects across states imply that no two MA plans are the same and that average effects may mask substantial variation.

Ind-2167 Evaluating an Integrated Care Model Targeted with Predictive Models to Reduce Readmission, Mortality, and Nursing Home Admission in Elderly Patients

PRESENTER: **April Yushan WU**
AUTHORS: Xia Nan, Eng-kiong Yeoh, Susan Zi-may Yau, Evora Hailin Zhu, Vivian Lou, Yingyao Chen

Introduction: As populations age and healthcare needs become more complex, health and social care systems are restructuring services to better accommodate patients with both poor functional status and significant healthcare needs. Hong Kong's public hospitals have introduced a territory-wide program called Integrated Care Management (ICM) to provide comprehensive medical-social care for discharged vulnerable elderly patients. This program encompasses thorough discharge planning, post-discharge rehabilitation, home support services, and caregiver training, all coordinated by link nurses and a multidisciplinary team. Additionally, a validated readmission risk prediction model is employed to identify high-risk patients and target them for the program. All elders aged 65 years and above with a risk score above 0.2, or those referred by clinicians, who are discharged from Hong Kong's public hospitals will be included in the program. **Objective:** To evaluate the association of ICM with hospital readmissions, emergency department (ED) visits, mortality, length of stay, and institutionalization in residential care homes among elderly patients post-discharge in Hong Kong. **Methods:** A population-based matched cohort study using propensity score matching was conducted to compare outcomes among community-dwelling patients aged 60 or above who received ICM services post-discharge from public hospitals in Hong Kong from 2012 to 2019.** Primary outcomes included post-discharge readmissions, mortality, and ED visits at 30-, 90-, and 180-days post-discharge. Secondary outcomes included the length of stay of index admissions and subsequent institutionalization in residential care homes. **Results:** A total of 47,190 ICM patients were matched with 1,182,129 non-ICM patients. The ICM program was associated with significant reductions in 30-day readmissions (adjusted OR = 0.45; 95% CI 0.43-0.46) and ED visits (adjusted OR = 0.53; 95% CI 0.51-0.55), but not in 30-day mortality (adjusted OR = 1.03; 95% CI 1.01-1.04). Significant reductions in mortality were observed at 90 days (adjusted OR = 0.87; 95% CI 0.82-0.92) and 180 days (adjusted OR = 0.84; 95% CI 0.80-0.87). The program also resulted in a slight increase in the length of stay (IRR = 1.03; 95% CI 1.01-1.04) and a lower incidence of institutionalization in residential care homes within six months post-discharge (adjusted OR = 0.73; 95% CI 0.71-0.75). Subgroup analyses indicated that mortality benefits were primarily observed in patients aged 80 and above. **Conclusions:** The medical-social integrated transitional care program was associated with reductions in healthcare utilization, institutionalization in nursing homes, and mortality within six months. The comprehensive design, involving coordinated social and health services and targeted interventions for high-risk patients, likely contributes to these outcomes. Further research with quasi-experimental design is warranted to further validate these findings, and compare the ability of healthcare professionals and predictive models in identifying the patients most in need.

Advancing Economic Evaluation for Health Policy and Implementation

MODERATOR: **Kavita Singh**,

Ind-2631 Unpacking Modular Payment Mechanism of Lead Maternity Carer Service in Aotearoa New Zealand: Qualitative Approach in a Realist Economic Evaluation

PRESENTER: **Olawale Joshua Oladimeji**, Obafemi Awolowo University
AUTHORS: Tim Tenbensel, Paula Lorgelly, Karen Bissell

Background

Payment mechanisms are critical to all stakeholders and have been applied to various healthcare services. Several payment mechanisms exist for maternal health services, and in most countries, there is more than one payment mechanism for funding maternity care. In New Zealand, the modular payment mechanism, a form of bundled payment, is applied to fund the Lead Maternity Carer (LMC) Service, which provides maternity services nationwide. Despite the growing body of knowledge on payment mechanisms, there is limited use of qualitative approach in economic evaluation and limited evidence from an economic lens on what works, how, why, and under what circumstances. In addition, in spite of its establishment almost thirty years ago, there is a paucity of evaluation of the LMC modular payment mechanism, and little is known about the effects of modular payment on service providers' workforce capacity. This study aims to apply a qualitative approach to explore how the economic-sensitive context and mechanisms of the modular payment system trigger outcomes and the effects of modular payment on workforce levels.

Method:

Realist economic evaluation (REE) provides the overarching approach for this research. A** sequential exploratory mixed method design is applied in this research. The research comprised three phases, and this study is phase one of the research. This phase includes thirty semi-structured interviews with Policy experts involved with the modular payment mechanism and LMC service providers. NVIVO was used for the data management and thematic analysis was applied to the qualitative data collected, identifying multiple themes and subthemes. Cost-sensitive

contexts and mechanisms of the modular payment system were identified, and economic program theories were developed.

The second phase would employ a quantitative method, including a Discrete Choice Experiment and an economic evaluation. The third phase will be integrating the results in phases one and two.

Findings: (Research ongoing)

Preliminary findings from phase one of the study show some effects of the modular payment mechanism on micro, meso, and macro-level maternity care service in New Zealand. At the micro level (LMC service provider), the effects of the payment system are influenced by the type of health professional, career level, location of practice, population group, and autonomy of practice. Some economic-sensitive contexts and mechanisms at the micro level were the number of clients, opportunity cost for autonomy, business model, payment rate and schedule, retention and recruitment, services paid for, and resources. At the meso level, the establishment and implementation of modular payment were influenced by professional organisations. The macro-level relates to the policymakers and government institutions involved with contracting and modular payment mechanisms. Economic program theories for the modular payment mechanism were developed along demand and supply frameworks.

Implications for policy and practice

Applying qualitative approach in economic evaluation and developing theory-informed economic evaluation can improve policymaking by generating evidence on how and why the cost and consequences differ in health interventions and the alternatives. Developing payment mechanism theories can promote efficiency and strengthen the health system.

Ind-2545 Environmental Impact in HTA: Input-Based Planetary Boundary Life Cycle Impact Assessment

PRESENTER: **Charlie Nederpelt**

Introduction Health systems are committed to provide optimal health and healthcare through access to and delivery of safe, high-quality health services. This introduces a pressure to diagnose, treat and care more and more. Healthcare resource use contributes to transgression of Earth's planetary boundaries (PB), negatively impacting future livability and health outcomes. While finite financial and human resource are explicitly considered, our finite planetary resources are largely omitted from health technology assessments (HTA) and resource allocation decisions. Lifecycle impact assessments (LCIAs) of whole healthcare sectors point to significant impacts. Reducing healthcare's ecological impact, however, occurs in trade-offs between specific interventions or inputs by healthcare providers in clinic, in guideline committees, by facility administrators, and in reimbursement decisions. To enable incorporation of PB impacts into these trade-offs, we present our estimation framework for PB-LCIA, in tandem with suggested reporting of impacts for health services. **Methodology** The LCIA framework captures all stages from production, transport, storage, preparation, use, to recycling and disposal for each service input. We used the Universal Health Coverage Compendium input structure, containing type and frequency of i) consults, ii) admissions, iii) procedures, iv) medicine, v) in vitro diagnostics and vi) consumables. The impact of facility- and system-level overheads is estimated based on LCIA of lighting, temperature control, ventilation, air-conditioning, IT consumption, and equipment use. For each ingredient, unit impact estimates are generated toward each of the PBs with thresholds and impact metrics: - Climate change (CO_2-emissions), - Biogeochemical flows (phosphorus, nitrogen and CO_2-emissions), - Atmospheric aerosol loading (aerosol emissions), - Stratospheric ozone depletion (ozone-depleting substance emissions), and - Freshwater change (H_2O consumption). External validity will be assessed crudely by comparing the alignment of PB-LCIA domains of essential healthcare services to previously published top-down, multi-regional input-output modelling estimates, primarily for CO_2-emissions, in the United States, United Kingdom, Canada, Australia, Japan, China and The Netherlands. **Conclusion** This study presents an initial ingredient-based lifecycle impact assessment framework for the impact of essential health services on planetary boundaries. Methods presented are an intended starting point for further contextualization using localized data. National and institutional health technology assessments, clinical guidelines, and reimbursement and resource allocation decisions urgently need to formally incorporate planetary impacts of healthcare.

Ind-165 Evaluating Task Shifting and the Role of Economic Evaluation

PRESENTER: **Peter Murphy**, University of York
AUTHORS: Simon Walker, Helen Fulbright, Susan Griffin

Introduction The realisation of universal health coverage is dependent on the adequate supply of trained health workers. Task shifting has often been proposed as a potential approach to address shortages of specific cadres of health worker by reallocating tasks (or care) to those workers with different, typically lower, levels of training. An increasing body of literature evaluates the effect of such task shifting, however, there is limited evidence on whether it represents value for money in the long run. A systematic review found a broad range of task shifting in LMICs resulted in immediate cost savings, yet the evaluations failed to account for the full range of costs and consequences of task shifting. To address limitations identified in the scope of these previous evaluative studies, we ask what are the key issues to consider when conducting an economic evaluation of task shifting in healthcare and how best to design studies to evaluate task shifting? **Methods** We first reviewed the literature describing the economic theory that underpins task shifting. This allowed us to develop a logic model describing the consequences of task shifting. The logic model was then refined through an expert workshop. Next, we conducted a rapid review of applied economic evaluations of task shifting using the principles of standard systematic reviewing. We searched 5 databases (Medline, Embase, EconLit, Social Sciences Citation Index and CEA Registry) for studies published between January 2014 to March 2024. Forwards and backwards citation searching was performed on included studies. We then considered the scope of the evaluations with respect to the ability to capture impacts of task shifting on key costs and outcomes. Results were then narratively synthesised. **Results** The logic model detailed the inputs, outputs and short-, intermediate- and long-term** outcomes which can occur as a result of task shifting but, in some cases, reflect the mechanisms to help capture the outcomes of interest. The outcomes are categorised into those that impact capacity, those that impact health workers, those that impact patients and wider effects. The rapid review identified 26 studies included in the synthesis covering 16 countries and 4 different approaches to economic evaluation although the majority were cost-effectiveness analyses (n = 23). The economic evaluations captured aspects included in the logic model such as patient health outcomes, staff costs and training costs but showed limited inclusion of aspects such as

change in capacity, access to care and health equity. **Conclusions** This research presents one of the first attempts to formalise the potential costs, consequences and mechanisms of task shifting. In doing so we highlight several that may ultimately impact population health and health equity and that have been routinely omitted in previous study designs and evaluations. It is hoped with this research that future economic evaluations of task shifting may more formally consider previously uncaptured aspects of task shifting relevant to economic evaluation to allow for the full consideration of the costs and consequences to inform decision making.

Ind-2504 Cost Estimation For Implementation And Maintenance of Oral Health Teams in The Brazilian Public Health System

PRESENTER: **Everton Nunes da Silva**, University of Brasilia
AUTHORS: Ana Carolina Esteves da Silva Pereira, MARIANA Marzullo M PEDREIRA, Alessandra Gaspar Sousa, Luis Eduardo Maciel dos Santos Ferreira, Gustavo Laine Araújo de Oliveira, Ivanessa Thaiane do Nascimento Cavalcanti, Harrison Floriano do Nascimento, Ms. Erika Aragao

Abstract: This study aimed to estimate the implementation and maintenance costs of Oral Health Teams (OHT) in Brazil's Unified Health System (SUS), considering different team types, weekly workloads, and regional variations. A microcosting methodology was applied using 18,466 valid procurement records from 2022 and 2023, covering 264 items including consumables, medications, and equipment. Additionally, 333 valid responses were collected from municipal health managers to estimate monthly quantities used by team type. The average investment required to implement a Type I OHT was USD 12,466.56, ranging from USD 11,821.52 in the Midwest to USD 12,819.10 in the South. This value includes one dental chair, estimated at USD 2,820.97, provided by the Ministry of Health. The national average monthly operating cost (COpM) was USD 1,495.51, with the highest observed in the North (USD 1,731.92) and the lowest in the Northeast (USD 1,411.62). Consumables represented the largest portion of COpM, followed by third-party services and medications. Human resources costs (CRH) varied widely across regions. The national average salary for a 40-hour-per-week dentist was USD 1,319.01, ranging from USD 846.95 (Northeast) to USD 1,905.49 (South). For oral health assistants, salaries ranged from USD 310.99 to USD 601.06, with a national average of USD 443.92. Total monthly costs (COpM + CRH) for Type I teams were USD 2,610.61 (20h), USD 2,908.03 (30h), and USD 3,259.56 (40h); for Type II teams (40h), the total was USD 4,355.38. The analysis indicated economies of scale, with reduced cost per hour in teams with longer weekly workloads, suggesting increased efficiency. Although equipment depreciation had limited monthly impact, long-term planning is required to ensure quality service continuity. Regarding federal funding, monthly transfers covered between 24.89% and 63.22% of the COpM, and between 14.26% and 30.09% of the total cost (COpM + CRH), depending on the team type and workload. At implementation, the federal contribution — composed of a BRL 14,000 transfer (USD 2,596.47) and donation of one or two chairs — covered 43.45% of implementation costs for Type I teams and 48.88% for Type II. Remaining investments must be provided by state and local governments. The findings indicate that maintaining OHTs involves significant and regionally variable costs, reflecting differences in input prices, salaries, and local infrastructure. Current federal transfers cover only part of actual costs, emphasizing the need for effective co-financing and coordinated planning among government levels to ensure sustainable and quality oral health services within the SUS.

Ind-1430 League Tables Based on Cost-Effectiveness Estimates of 132 Interventions in 204 Countries: A Meta-Regression Approach

PRESENTER: **Marcia Weaver**, University of Washington
AUTHORS: Fiona Silke, Jessica Klusty, Johnathan Hsu, Aishe Memetova, Lauren Earl, Esha Dwibedi

Background. The goal of cost-effectiveness analysis (CEA) is to rank interventions across diseases from the lowest to the highest incremental cost-effectiveness ratio (ICERs) within the context of a country's economy and health system. The rankings, referred to as league tables, can guide national decision-makers to allocate funding to the intervention with the lowest ICER first, and add interventions according to their rank and available funds. The goal is rarely achieved, because most researchers create CEA models for a single disease with a focus on a few interventions in a single location or a single intervention in multiple locations.

Research questions: Can we use meta-regression methods, which are used extensively to synthesize clinical evidence, to synthesize evidence from economic evaluations, predict country-specific ICERs for multiple interventions, and create country-specific league tables?

Methods. Data are from the Tufts University's cost-effectiveness registries through 2020 with health improvements measured in disability-adjusted life-years (DALYs) or quality-adjusted life-years. We included interventions with at least two published articles and three published ICERs. We grouped healthcare interventions into 17 broad categories such as medications to lower systolic blood pressure, and estimated 17 meta-regression models using a five-stage meta-regression framework. For each model, the dependent variable is the ICER, and the independent variables are country characteristics such as gross national product and cause-specific burden of disease, and intervention characteristics such as cost (for example drug price), and target group (for example medium to high cardio-vascular risk).

Then, we used the parameter estimates to predict country-specific ICERs for 204 countries. For each intervention, we predict median ICER, interquartile range (IQR), and 95% uncertainty interval in 2019 US dollars. We place ICERs in context of a league table and two measures of affordability: GDP per capita, and a country-specific opportunity cost from Pichon-Riviere et al (The Lancet Global Health, 2023).

Key Results. Parameter estimates from 17 models are used to predict country-specific ICERs for 132 interventions. League tables show that many interventions for non-communicable diseases have relatively low ICERs. For example, in India the median ICER for diuretics to lower systolic blood pressure for people with medium to high cardiovascular risk is $74 (IQR: 46, 122) per DALY averted, comparable to zinc and

iron biofortification of rice. The median ICER for ACE inhibitors and diuretics combined for that risk group is $222 (IQR: 157, 359) per DALY averted, comparable to rotovirus and measles vaccines. The country-specific opportunity cost is $523, and GDP per capita is $2093; the interventions are good options by multiple criteria. The median ICER for ACE inhibitors alone for that risk group is $448 (IQR: 282, 749) per DALY averted.

Conclusions. Meta-regression is a promising method to produce country-specific ICERs and league tables. Countries with respected health technology assessment agencies may want to use our estimated ICERs for interventions with many published CEA; they could focus their original research on newer interventions or those without published CEA. Countries that don't have health technology assessment agencies may want to use our estimates for ranking and selecting healthcare interventions.

Ind-1090 Cost-Effectiveness of On-Site Chlorine Production in Health Facilities of Ghana and Uganda:Strategies to Address Infection Prevention and Control Gaps

PRESENTER: **Teddy Naddumba**, PATH

Background: Use of chlorine as a disinfectant is recommended for hospital surfaces and medical instrument decontamination. Chlorine is efficacious in eliminating a wide variety of microbial pathogens that contribute to health care–associated infections (HAIs). However, chlorine access and availability remain a challenge in health care settings in low- and middle-income countries due to supply chain bottlenecks, low- or degraded-quality chlorine products available on the market, and knowledge gaps among health care staff on the correct dilution of chlorine to achieve the recommended concentration levels for medical equipment and surface disinfection. Health facility–level production of chlorine using the Aqua Research STREAM™ Disinfectant Generator (STREAM) can mitigate supply chain and quality issues. STREAM uses electrolysis processes to convert salt and water into a 5,000 mg/L chlorine solution, producing an adequate supply at the required 0.5% concentration to meet daily needs. Our study aimed to evaluate the potential cost-effectiveness of on-site chlorine production using the STREAM device in health facilities in Ghana and Uganda, compared to purchasing commercial chlorine. **Study design:** We used a static model to evaluate the benefits, cost, and cost-effectiveness of using STREAM-generated chlorine compared to commercial chlorine in health centers and primary and secondary hospitals in Ghana and Uganda. Published literature and STREAM evaluation data from both countries informed the development of a causal framework and statistical model on the effect of chlorine availability, chlorine quality, and effectiveness of disinfection practices on HAIs. Using primary data from ten health facilities in Ghana and Uganda respectively, we evaluated the benefits of on-site production, such as improved quality, elimination of chlorine stockout days, and impact on chlorine costs. We used secondary data to evaluate cost-effectiveness by modeling the potential reduction in HAIs, disability-adjusted life years (DALYs), and costs. Costs per DALY averted were estimated for two scenarios: (1) health facilities using commercial chlorine and (2) health facilities using the STREAM device to produce chlorine. Costs and outcomes were analyzed from the health system perspective over a one-year time horizon, and all costs were reported in 2023 US dollars. Incremental cost-effectiveness ratios were compared with willingness-to-pay thresholds based on gross domestic product per capita of $2,206 for Ghana and $934 for Uganda. **Results:** Our study showed that 50% infection prevention and control coverage using STREAM-generated chlorine could reduce HAIs by 5,365 in Ghana and 11,536 in Uganda and avert 103 and 56,280 DALYs in each country, respectively—resulting in treatment cost savings of an estimated $2,284,509 in Ghana and $3,883,885 in Uganda. **Conclusions:** These findings suggest that on-site chlorine production using the STREAM device has the potential to eliminate chlorine supply bottlenecks and quality issues, which inhibit the effectiveness of infection prevention and control practices at health facilities in LMICs, and consequently reduce the number of HAIs, DALYs, and associated treatment costs.

Ind-708 The Use of Cost-effectiveness Thresholds for Evaluating Vaccinations in LMICs and the Implications of Health-Opportunity Based Thresholds

PRESENTER: **Lynn Daryl Feliciano Villamater**
AUTHOR: Natalie Carvalho

Background Introducing new vaccines presents significant challenges for low- and middle-income countries (LMICs) with constrained resources and competing health priorities. In the absence of locally established cost-effectiveness thresholds (CETs), Gross Domestic Product (GDP) per capita has often been used in CEAs of health interventions. Recently, health opportunity cost-based have been proposed as more appropriate for budget-constrained health systems. However, their application and impact on vaccination CEAs in LMICs remain unexplored. While prior studies have examined CETs in health intervention CEAs broadly, none have focused specifically on vaccination CEAs or the adoption of opportunity cost-based CETs in LMICs. This study aims to: (1) identify commonly used CETs in vaccination CEAs in LMICs, (2) assess the impact of applying opportunity cost-based CETs, and (3) examine the association between country income levels and changes in cost-effectiveness conclusions using these newer CETs. **Methods** A literature review of vaccination CEAs from the Global Health Cost-effectiveness Analysis Registry published between May 15, 2017, and May 25, 2022, was conducted. The review was restricted to vaccine studies in LMICs reporting country-level incremental cost-effectiveness ratios (ICER), with explicit CET use and cost-effectiveness conclusions. Descriptive statistics summarized the study characteristics and the CET distribution by study, intervention and income levels. For the quantitative analyses, country-specific CETs were calculated by multiplying the GDP per capita by upper and lower bound CET estimates from studies by Woods et al., Ochalek et al., and Pichon-Riviere et al. Proportions of cost-effective conclusions were compared with proportion of conclusions using the newer estimates. Chi-square test and logistic regressions examined the relationship between income groups and changes in cost-effectiveness conclusions, and the differences between income groups, respectively. **Results** The review included 68 studies with a total of 413 interventions. 1-3x GDP was the most frequently (76%) used CET in vaccination studies. A large proportion of interventions (69%) referenced 3x GDP per capita, with the highest use observed in upper-middle-income countries. Low-income countries primarily used 1x GDP per capita (n=45). Vaccination CEAs started to reference opportunity-based thresholds in 2017, with a significant increase in 2020 and 2021. While 76% of interventions were initially deemed cost-effective, this declined to 45-48% and 21-39% after comparison to upper and lower opportunity-cost estimates, respectively. A significant association was observed between income level and changes in cost-effectiveness conclusions, with upper-middle-income countries having the highest likelihood of change compared to low-income countries. **Conclusion** GDP-based thresholds remain the most commonly used in vaccination CEAs despite their limitations. Health opportunity cost-based thresholds

have gained traction in recent years. Reliance on GDP-based thresholds may overestimate cost-effectiveness, potentially hindering vaccination program implementation in LMICs due to issues of affordability. This review highlights the need to reassess CET frameworks and adopt more contextually relevant thresholds in assessing cost-effectiveness of vaccination programs in LMICs. Decision-makers and researchers should consider alternatives to GDP-based thresholds to ensure accurate and effective CEA practices and optimize resource allocation in LMICs.

Ind-1921 Cost-Benefit Analysis of an Electronic Medical Record System in an Emergency unit based Private Practice in South Africa

PRESENTER: **Natasha Banda**

AUTHOR: Evelyn Thsehla

Background In South Africa, various electronic medical records systems (EMRS) have been implemented in both the private and public healthcare sectors. Currently, there is a lack of evidence on the economic consequences of adopting EMRS in the South African context. The aim of this study was to estimate the cost-benefit of adopting EMRS in an emergency unit setting. **Methods** A retrospective cost benefit analysis was conducted to ascertain the economic consequences of EMRS use compared to a Paper-based Medical Records System (PMRS) in a private medical practice which runs 25 emergency units in South Africa. The EMRS was implemented in these emergency units from 2019, with full implementation completed by end of 2021. Costs data was collected from existing records and from interviews with experts where data was not available. Costs for the EMRS included development costs, hardware costs, installation costs, training costs, software costs, personnel costs, and printing costs. Costs for the PMRS included costs for stationery, storage space, transportation and personnel. The measured amounts were discounted by the expected interest rate and inflationary adjustments made using the consumer price index (CPI), to calculate the net present value (NPV), benefit-cost ratio (BCR), and discounted payback period (DPP). The benefits included cost reductions after EMRS adoption. The time horizon used for the analysis was from 2017 to 2024. **Results** Out of the 25 emergency units currently being managed by the practice, 18 were identified to have been under the practice's management from January 2018 till June 2024 and were thus selected as part of the sample. Over the period 2018 to 2024, PMRS costs decreased by 85% from R2,868,554.60 (US$153,948.35) in 2018 to a predicted cost of R423,186.45 (US$22,711.39) in 2024. The total cost for the EMRS implementation and maintenance was estimated at R11,396,872.79 (US$611,642.45). From the start of implementation in 2019 till 2024, the total cost savings for the study sample were R6,668,580.76 (US$357,886.51). A NPV of -R4,728,292.02 (-US$253,755.94) and a BCR of 0.59 were estimated. The DPP was approximately 6.97 years. **Conclusion** Even though the adoption of the EMRS resulted in reduction of PMRS costs, the EMRS was shown not to be cost effective over the study period. Post-implementation, it is expected to take almost 7 years for the practice to breakeven with the EMRS intervention. Reducing EMRS costs and further reducing concurrent PMRS usage may potentially result in the intervention being more cost-effective.

Ind-555 A Systematic Review of Economic Evaluation Studies Assessing Regulatory Options For e-Cigarette Use

PRESENTER: **Louisa Collins**

AUTHORS: Daniel Lindsay, Tan Doan, Anita Lal, Joachim Schuz, Michelle Scollo, Michelle Jongenelis

Background: Governments around the world are considering regulating access to e-cigarettes containing nicotine to prevent uptake among youth. However, people that smoke tobacco may use e-cigarettes to assist with smoking cessation. Due to their relatively recent development, the actual long-term health and cost implications of regulating e-cigarette use among populations are unknown but have been explored in modelling studies. We systematically reviewed health economic evaluation and simulation modelling studies that assessed long-term health and economic consequences, interpreting their potential usefulness for key policy- and decision-makers.

Methods: We undertook a systematic review with an additional narrative synthesis. Six databases were searched for modelling studies evaluating population-level e-cigarette control policies or interventions restricting e-cigarette use versus more liberalized use. To be included in the review, studies were required to report the outcomes of life years, quality-adjusted life years (QALYs) and/or healthcare costs. The quality of the studies was assessed using two quality assessment tools, the Ten Rules of Credible Practice of Modeling and Simulation in Healthcare and the CHEERS checklist.

Results: In total, 15 studies were included with nine from the United States and one each from the United Kingdom, Italy, Australia, Singapore, Canada, and New Zealand. Most studies involved health state transition (or Markov) closed cohort models. Three studies included cost-utility analyses. The majority of studies had limitations with their model structures, data input quality and transparency, and insufficient analyses handling model uncertainty. Findings were mixed with 11 studies concluding that policies permitting e-cigarette use led to net benefits and 4 studies concluding net losses in life-years or QALYs and/or healthcare costs. Five studies had industry conflicts of interest, potentially influencing results.

Conclusions: While more studies reported net benefits than net harms, the significant limitations that we identified with many of the studies in this review make it uncertain whether countries can expect net population harms or benefits of restrictive versus unrestrictive e-cigarette policies. The generalizability of the findings were found to be limited for key policy- and decision-makers. In light of the deep uncertainty around the health and economic outcomes of e-cigarettes, future simulation modelling methods and uncertainty analyses should be strengthened.

abs-os421 Investigating the Intersection of Economic Evaluation and Implementation Science in Healthcare: a Conceptual Framework

PRESENTER: **Aleksandra Torbica**, Università Bocconi

AUTHORS: Kavita Singh, Ms. Manuela De Allegri

Exploring the link between economic evaluation and implementation science highlights a critical, emerging area that aims to bridge gaps between evidence-based practices and the realities of financial decision-making in real-world settings. Economic evaluation provides systematic methods to assess the value of interventions relative to their costs. Implementation science, on the other hand, focuses on studying

methods to promote the integration of research findings and evidence-based practices into healthcare, public health, and policy. When these fields are integrated, they create a robust framework for evaluating not only whether an intervention works but also how to make the intervention affordable, sustainable, and adaptable within different organizational contexts.

In this paper we propose a conceptual framework to foster the integration between the two fields. We argue that this integration is crucial for several reasons. Economic evaluation offers methods to quantify the value by comparing outcomes—such as improvements in health, quality of life, or productivity—with the costs of delivering and scaling them. However, these economic evaluations alone do not always consider the practical challenges of implementing interventions in complex, variable environments, particularly in resource constraint settings of LMICs. This is where implementation science contributes essential insights, by examining the context-specific barriers and facilitators to effective implementation. For instance, even if an intervention is found to be cost-effective in a clinical trial, real-world variables such as implementation factors e.g., inner setting and outer setting factors including availability of trained health workers, institutional culture, organizational leadership, political climate, and funding availability may impact its success or scalability.

Integrating and tailoring economic evaluation methods in implementation studies are pivotal to enhance the sustainability and scalability of proven effective healthcare interventions. However, policymakers and practitioners face the “real world” challenge of deciding not only which programs to fund but also how to allocate limited resources in ways that maximize impact while minimizing waste. An integrated approach enables a comprehensive understanding of both the financial implications and the practical feasibility of scaling up successful interventions. For example, interventions that show high cost-effectiveness in tightly controlled randomized trials may struggle in broader application due to unforeseen costs or operational hurdles. Implementation science, with its focus on adaptability and context and understanding theory of change model, can inform economic evaluations by identifying key factors—such as intervention characteristics, inner setting and outer setting, characteristics of individuals (implementing actors, end users) and implementation process, including local resource availability, stakeholder engagement, and long-term operational needs—that influence the likelihood of sustained success.

Furthermore, the combined approach contributes to equity by ensuring that interventions are evaluated with consideration of different populations and settings. Health disparities are often linked to socioeconomic factors, and the feasibility of implementing interventions greatly vary significantly across communities. A joint approach allows researchers and policymakers to examine whether an intervention is both economically and practically viable in underserved areas, ensuring that cost-effective solutions are accessible to those who need them most.

Beyond Treatment Costs: The Hidden Costs of Cancer, Mental Health, and Preterm Birth on Society

MODERATOR: **Philip Clarke**,

Ind-577 The Global Societal Cost of Cancer: Productivity Loss from Cancer Mortality and Morbidity

PRESENTER: **Yek-Ching Kong**

AUTHORS: Phuong Bich Tran, Jerome Vignat, Cindy L. Gauvreau, Alison Pearce, Marianna de Camargo Cancela, Marta Ortega, Nirmala Bhoo Pathy, Mr. Filip Meheus, Ms. Isabelle Soerjomataram

Background: Cancer is one of the most important causes of premature death and morbidity globally. The economic impact of cancer to society is measurable through productivity loss. We aimed to estimate the value of lost productivity from morbidity and premature mortality due to cancer for 36 cancer types in 185 countries. Methods: We estimated productivity loss from paid and unpaid activities due to cancer-related mortality and morbidity for individuals aged 15-64 in 2022. Data extracted include epidemiological data from the Global Cancer Observatory (GLOBOCAN), workforce statistics from the International Labour Organization (ILO) and governmental sources, estimates on absenteeism, presenteeism, and labour force shortfalls from literature review, and unpaid hours spent on care and domestic activities from the United Nations (UN) Women. Productivity loss from paid activities, valued using the human capital approach (HCA), was estimated from years of productive life lost (YPLL) for cancer mortality, and absenteeism, presenteeism and labour force shortfalls for cancer morbidity. Productivity loss from unpaid activities was valued using the opportunity cost method, wherein time use for unpaid activities was valued using the hourly wage of paid work. Results: The values of global productivity loss from cancer-related premature mortality and morbidity in 2022 were US$ 584 billion and US$ 87 billion, equivalent to 0.6% and 0.1% of the global GDP, respectively. Of the total productivity loss from cancer mortality, 53.8% (US$ 314 billion) was attributable to paid activities and 46.2% (US$ 270 billion) to unpaid activities. Meanwhile, 75.9% (US$ 66 billion) of lost productivity from cancer morbidity was from paid activities and 24.1% (US$ 21 billion) from unpaid activities. Regional variations in the relative proportion of productivity loss from paid and unpaid activities towards total productivity loss were observed. For cancer morbidity, more than half of the productivity loss from paid activities was due to labor force shorfalls (57.7%, US$ 38 billion), followed by absenteeism (34.9%, US$ 23 billion), and presenteeism (7.4%, US$ 5 billion). The ratio of paid to unpaid productivity loss differed between men and women; paid productivity loss was generally higher among men while unpaid productivity loss was higher among women. On an aggregate level, lost productivity from premature deaths was largest for lung cancer, followed by breast and liver cancers, whereas lost productivity from morbidity was largest for breast cancer, followed by colorectal and lung cancers. On a per capita basis, deaths from testicular cancer, skin melanoma, and brain and nervous system cancers led to the highest productivity loss on average, while morbidity from skin cancers, prostate cancer, and non-Hodgkin lymphoma resulted in the greatest productivity loss. Conclusion: Productivity loss from cancer-related premature mortality and morbidity is substantial. The sizeable value of productivity loss from unpaid activities reveals the often-overlooked burden borne by individuals outside the formal workforce, especially women, which emphasizes the importance of including both paid and unpaid activities to estimate societal burden more accurately. Continuous investments in cancer control efforts should be prioritized to save lives and minimize

the associated societal impact of cancer-related premature mortality and morbidity.

Ind-17 The Economic Implications of Non-communicable Diseases on Food Security and Resilience in Malawi.

PRESENTER: **Richard Moyo**
AUTHOR: Gowokani Chijere Chirwa

Background In the midst of multiple shocks, Malawi is also facing an increase in non-communicable diseases (Gowshall & Taylor-Robinson, 2018) and ongoing food insecurity(MVAC, 2024). Approximately 4.2 million people are expected to experience high levels of acute food insecurity, including 56,000 people in IPC Phase 4 (Emergency) and 4.1 million people who are in the crisis phase(MVAC, 2024). Additionally, NCDs are now the second leading cause of death among adults in Malawi, accounting for 16% of all fatalities, with a prevalence of 17% in males and 14% in females. Despite the increasing prevalence of NCDs, their specific impact on nutritional status within the context of food security remains inadequately understood.The complex interplay between non-communicable diseases (NCDs), nutrition, and food security reveals a compelling economic linkage. This interconnection manifests itself in several crucial ways. Initially, the financial burden of NCDs, including healthcare costs for diagnosis and treatment, competes with household expenditure on food, potentially limiting access to nutritious options(Nugent et al., 2018). Conversely, Wang et al., (2015) revealed that despite the anticipation of cost-free care at the point of service in Malawi, households in rural areas, particularly those grappling with severe poverty, face considerable financial strain. Additionally, NCDs can diminish individuals' productivity due to illness or disability, resulting in reduced income and constraining their capacity to procure diverse and high-quality foods(Kasambara et al., 2023) **Objective** We assessed the economic implications of non-communicable diseases on food security and resilience in Malawi by utilizing household dietary diversity, the food consumption score, and a reducing coping strategy index. **Methods** The study employed the propensity score matching model and analysed a sample of 11,443 households from the Malawi Household Integrated Survey (IHS5). **Results** The study revealed a multifaceted impact of NCDs on food security indicators. Households with NCD-affected members experienced challenges in accessing a balanced diet, with a decrease in the food consumption score of approximately -0.764 units compared with that of the nonaffected households. Additionally, these households demonstrated an increase in their rCSI score of approximately 1.162 units, suggesting a reliance on reducing coping strategies to address food insecurity. Finally, households affected by NCDs struggled to obtain nutritious meals, with a reduction in their household dietary diversity score of approximately -0.117 units. **Keywords:** Food Security; Noncommunicable Diseases; Propensity Score Matching; IHS5

Ind-580 Educational and Labour Market Trajectories in Adulthood for Very Preterm/Very Low Birth Weight Individuals:Evidence from a Multi-National Cohort Study

PRESENTER: **Hanifa Pilvar**
AUTHORS: Sungwook Kim, Mr. Stavros Petrou, Catia Nicodemo

Background Advances in neonatal care have improved survival rates for very preterm (VP) and very low birth weight (VLBW) infants, but understanding how early-life health disadvantages influence adult outcomes remains limited. While previous research has focused on childhood and adolescent outcomes, few studies have examined impacts in adulthood. This study addresses this gap by analysing the long-term effects of VP/VLBW on adult outcomes across six countries.

Research Aim

The aim of this study is to assess the impact of VP/VLBW status on adult outcomes, specifically focusing on mortality, educational attainment, economic activity, and working hours. Additionally, we examine the effects of each additional gestational week within the VP/VLBW group on adult outcomes.

Data We use data from the RECAP Preterm Project which collects longitudinal data on children born VPT/VLBW. We select a set of geographically diverse cohorts born in developed countries, namely Canada, Germany, the Netherlands, New Zealand, Norway, and the UK. Follow-up surveys were conducted when participants were 24-28 years old, allowing us to assess adulthood outcomes, including mortality, educational attainment, economic activity, and working hours.

Methods

To compare outcomes between VP/VLBW individuals and term-born controls, we apply coarsened exact matching (CEM) for balanced comparisons. For estimating the marginal effect of an additional week of gestational age within the VP/VLBW sample, we employ an instrumental variable (IV) approach using nulliparity as an instrument for gestational age to account for potential endogeneity.

Results

Coarsened Exact Matching (CEM):

Using CEM to compare VP/VLBW individuals with term-born controls, we find that VP/VLBW individuals have a 25 percentage point higher probability of mortality before adulthood. Among those who survive to adulthood, VP/VLBW individuals are 7.1 percentage points more likely to have lower educational attainment. We do not find significant differences in economic activity or working hours.

Instrumental Variable (IV):

The results of the IV method show that each additional gestational week reduces the probability of mortality by 6.8 percentage points, highlighting the critical role of gestational age in survival. However, we do not observe significant effects on other outcomes, such as educational attainment, economic activity, or working hours, in the main model.

Additionally, we explore the interaction between gestational age and the duration of assisted ventilation. This finding suggests that there is a positive impact of gestational age on educational attainment when accounting for the level of assisted ventilation received.

Conclusions These findings underscore that while extending gestational age can enhance survival, economic outcomes in adulthood are likely to depend on other factors, including neonatal care quality. Policymakers should consider holistic support strategies that address both survival and developmental needs of VPT/VLBW.

This research makes a unique contribution by utilizing an international sample of VPT/VLBW individuals from multiple countries. By examining long-term adulthood outcomes, including labour market indicators, we expand the literature beyond childhood and adolescence. Additionally, assessing both the levels of difference between VPT/VLBW and term-born individuals, as well as the marginal effect of each additional week of gestational age, provides a nuanced understanding of how preterm birth affects life outcomes.

Ind-757 Breast Cancer and Income Loss in Denmark: Heterogeneous Outcomes and Longitudinal Effects

PRESENTER: **Emily K Johnson**

AUTHORS: Angela Chang, Harsh Parikh, Liza Sopina, Kim Rose Olsen

0.1. Background

Income loss due to breast cancer is an important area of research, and prior causal studies in Denmark using register data have found modest loss in the working population within 5 years of diagnosis. However, the long-term effects and heterogeneous impacts of breast cancer on income across the population are understudied. The purpose of this study is to estimate the population-level, longitudinal effects of breast cancer on income in Denmark, and to identify socio-economic and demographic populations for whom income loss is the most disproportionate.

0.2. Methods

We use Danish register data to measure the effect of breast cancer on personal and household equivalized income in Denmark from 2000-2018. We adopt a cohort study design and match on age, baseline income, employment, baseline health, and other socio-demographic variables to investigate heterogeneous effects across sub-populations over a 10-year period. For validation, we also perform an event study difference-in-difference analysis which estimates income loss compared to a control population at each year following diagnosis. We additionally compare our estimates to those derived from matching methods along fewer matching variables, and we estimate personal income loss if mortality before retirement age is considered years of 0 income.

0.3. Findings

We measure personal income loss over 10 years amounting to €7138 (95% CI €6777 – €7498) per capita in the non-retired population and totaling €206.73 million across the population from 2000-2018. The working population, students, and individuals with comorbidities or high healthcare utilization experienced disproportionate loss. Household income losses are smaller at €1544 (€1233 – €1856) per capita, and annual losses recover within the period of observation. Event study difference-indifference results were consistent with the matching study indicating robustness to unobserved confounding in the primary estimates. Matching along fewer variables produced lower estimates of loss, indicating the potential presence of confounding when baseline socioeconomic status and health are not accounted for. Total mortality was higher in the breast cancer population than in the control, and accounting for premature mortality produced substantially higher estimates of income loss due to breast cancer.

0.4. Interpretation

Overall, the Danish economic protections are effective in mitigating long term economic impact of breast cancer on the population, and income losses are recoverable over time. However, there is room for improvement in protection of the most vulnerable groups including those early in their careers or in poor baseline health, who suffer substantial and persistent long-term economic impact.

Variation in Quality, Organization, and Efficiency of Care Delivery

MODERATOR: **Alistair McGuire**,

Ind-961 Exploring Change in Health Care Delivery System Value for 50 US States over Three Decades: 1991-2020

PRESENTER: **Maitreyi Sahu**, University of Washington

AUTHORS: Haley Kathryn Lescinsky, Kevin Schulman, Arnold Milstein, Joseph Dieleman

While the US as a whole spends more on healthcare per person than most peer countries, there is dramatic variation within the US. Moreover, health outcomes also vary dramatically, although they are only weakly correlated with healthcare spending. In this study, we leverage variation in healthcare spending and health outcomes to estimate state-level healthcare delivery system value after accounting for underlying differences

in population risk (ie age, obesity, smoking, etc). Then we examine trends in value over the last 30 years and identify key policies and characteristics associated with value following the enactment of the Affordable Care Act.

We extracted annual health condition-specific death and prevalence estimates for each US state from the Global Burden Disease 2020 Study for 1991 to 2020. We used state-level annual healthcare spending per person from the State Health Expenditure Accounts (SHEA) for 1991 to 2020. Using meta-stochastic frontier analysis, condition-specific mortality-prevalence ratios for 66 major treatable illnesses were regressed on per capita healthcare spending and key covariates including age, obesity rate, smoking rate, physical activity rate, and educational attainment. State- and year-specific inefficiency estimates were extracted for each health condition and combined to create a single estimate of healthcare delivery system value for each US state for 1991 through 2020. We also extracted data from the American Hospital Association to generate a state-specific measure of hospital market concentration. The association between changes in healthcare value and 30 key healthcare system characteristics and state health polices was measured using bivariate linear regression, with specific focus on market concentration for large, small, and individual group insurance plans, as well as hospital market concentration.

Across US states, delivery system value on average increased from 1991 to 2010, and then declined by 17% from 2011 to 2020. Over the three-decade span, the states with the most favorable value trajectories were California, New York, and Washington, and states with the most pronounced declines were South Dakota, Arkansas, and Mississippi. When looking at absolute healthcare value, New Hampshire, California, and Minnesota attained the highest scores in 2020. The percentage of state populations insured was strongly associated with value, while greater market concentration of insurers and hospitals were associated with worse healthcare value, as were increases in insurance premiums and hospital expenses. The net effect of increasing market consolidation among hospitals and insurers in the last decade, despite increasing insurance coverage, was a reduction in the national value score from 2011 to 2020.

In contrast to the prior two decades, a health care delivery system value score declined over the last decade. The decline was associated with reductions in hospital and payer market competition and partly mitigated by expanding insurance coverage. Policymakers should test interventions to increase competition in markets for health insurance and for hospital care, along with widening insurance coverage.

Ind-1024 The COVID-19 Lockdown Led to Undiagnosed Cancer Cases, with Impacts Varying by Age, Sex, and Cancer Stage

PRESENTER: **Li-Lin Liang**, National Yang Ming Chiao Tung University
AUTHORS: I-Hua Chen, CHANG-XI KUNG

BackgroundPrevious research has shown that cancer care was disrupted during the COVID-19 pandemic. However, the specific impact of lockdown measures on cancer burden at presentation remains underexplored, particularly in Asia. Moreover, studies examining non-cancer outcomes during lockdowns have shown disproportionate negative effects on subgroups such as women. To address these gaps, this study evaluated the impact of Taiwan's major lockdown measures—specifically the combined school and workplace closures—on the number of newly diagnosed cancer cases and tumor size at diagnosis, with a focus on subgroup differences. ***Methods*** This population-based study used data from the Taiwan Cancer Registry, National Health Insurance Research Databases, and the Oxford COVID-19 Government Response Tracker. The intervention period was defined as weeks 20–34 of 2021. Outcomes included weekly cancer incidence per 100,000 population and average tumor size at diagnosis. A multiple-group interrupted time series analysis (ITSA) estimated changes in cancer incidence, using 2018 and 2019 as historical controls. A difference-in-differences (DID) approach assessed changes in tumor size, using weeks 1–19 of 2021 as the pre-intervention period and 2015–2018 as the comparison group. Subgroup analyses were stratified by age, sex, socioeconomic status, AJCC stage, and cancer type. ***Results*** From January 2018 to December 2021, a total of 334,240 cancer cases were reported. During the lockdown period (May–August 2021), cancer incidence dropped by 39.3% ($P<0.01$) among females, with the decline disproportionately concentrated among those under 65, with Stage 0 and I cancers, and in colorectal, lung, and breast cancer cases. Among males, a decrease in incidence was observed only for Stage 0 (-37.7%) and Stage II (-38.8%) cancers. Average tumor size increased by 14.8% ($P<0.01$) in females and 11.2% ($P<0.001$) in males, with the largest increase (27.6%, $P<0.001$) seen in females under 50. Tumor size increased for lung cancer in both sexes (11–13%, $P<0.05$), for colorectal cancer in females (18.1%, $P<0.01$), and for oral cancer in males (12.6%, $P<0.05$).
ConclusionsTaiwan's school and workplace closures were associated with a substantial reduction in cancer diagnoses among women, but not men, and with increased tumor size at diagnosis, particularly among younger women. The more pronounced decline in early-stage cancers suggests potential stage migration. Concurrent decreases in incidence and increases in tumor size for female colorectal and lung cancers indicate delayed diagnoses. Tumor growth in colorectal cancer may be partly attributable to the invasive nature of diagnostic procedures such as colonoscopy, which may have deterred patients during the pandemic. Tumor growth in lung cancer may reflect healthcare system strain due to overlapping demands from COVID-19 and respiratory care. These findings highlight missed opportunities for curative treatment and emphasize the need for targeted policies to address the uneven impact of lockdowns on cancer care, especially among vulnerable subgroups.

Ind-2734 Contributions of Hospitals of Different Sizes to The Efficiency And Sustainability of The SUS: an Integrated Analysis With DEA And Malmquist

PRESENTER: **Ivan Augusto Cecilio e Silva**
AUTHORS: Ivanessa Thaiane do Nascimento Cavalcanti, Luis Eduardo Maciel dos Santos Ferreira, MARIANA Marzullo M PEDREIRA, Ana Carolina Esteves da Silva Pereira, Harrison Floriano do Nascimento, Alessandra Gaspar Sousa, Gustavo Laine Araújo de Oliveira, Ms. Erika Aragao

Background: Hospital efficiency is an essential metric for analyzing universal health systems, such as the Unified Health System (SUS) in Brazil. Based on the literature, efficiency tends to be relatively higher in large hospitals, which typically have greater technological and operational capacity. However, the contribution of smaller hospitals, crucial for ensuring access and equity, is often undervalued in efficiency analyses. **Objective:** The aim of this study is to analyze the performance of the hospital network in Brazil between 2019 and 2023, focusing on the provision of services to SUS. The research examines service production, investments in equipment and human resources, and hospital size, comparing and ranking health units in terms of technical efficiency (TE). **Methodology:** Data Envelopment Analysis (DEA) and the Malmquist

Index were used to measure changes in total factor productivity over the period from 2019 to 2023. The DEA model evaluates comparative efficiency among hospitals, while the Malmquist Index distinguishes the effects of technological progress and TE on productivity. **Results:** The analysis included 2,745 general hospitals that provide services to SUS, categorized by size (small, medium, large, and special) based on the National Register of Health Establishments (CNES). The results revealed an unequal distribution of efficiency, with large hospitals showing 11% efficiency, in contrast to 8% for special hospitals, 7% for medium hospitals and 3% for small hospitals. The Malmquist Index indicated that small hospitals had made more significant technological progress, while the others had greater difficulty in keeping up with innovations. However, these findings suggest that efficiency should not be analyzed solely through the lens of technological capacity and service volume. Smaller hospitals, although less efficient in terms of absolute productivity, play a crucial role in local access, promoting equity, and responding quickly to community health needs, particularly in areas more remote from large centers. **Conclusion:** Statistical findings point to disparities in TE according to hospital size, reinforcing the importance of a balanced hospital network in Brazil, where hospitals of different sizes complement each other in ensuring universal health access. The findings suggest that investment policies that strengthen management and technology in smaller hospitals could improve the efficiency and accessibility of SUS as a whole. To achieve this, it is essential to disseminate good practices observed in larger hospitals and adapt them to the realities of smaller hospitals, maximizing system efficiency without compromising the essential role of local hospitals. Differentiated investment strategies, such as technological support for smaller units and incentives for specialization in larger hospitals, have the potential to strengthen the sustainability and quality of health services in Brazil, serving as a model for health systems facing similar challenges. **Keywords:** Unified Health System, Hospital Care, Technical Efficiency, Hospital Size, Universal Coverage.

Ind-2320 Public Health System and Variation in Private Health Insurance Coverage

PRESENTER: **Ivan Prenhaca**
AUTHORS: Carolina Marinho, Sergio Firpo

This paper measures the impact of expanding universal public health on private insurance coverage. We employ a difference-in-differences framework and exploit the rollout of the Family Health Program (PSF) in Brazil, a community-based intervention focused on improving access to primary care. We find that the program decreased private coverage, with a stronger decline in more developed municipalities. We estimate an average crowding-out effect of the program on private health of about 32%, a magnitude similar to what is found in the US. We also present evidence of lower costs to small and micro firms as the program increases their share in the economy substantially. Our results suggest savings of 3.7 billion USD due to higher per capita costs in the private sector.

8:30 AM –10:00 AM MONDAY [Health, Its Valuation, Distribution And Economic Consequences]

Ind-401 Global Health and Related Economic Benefits of Urban Green Space

PRESENTER: **Tingting Ye**
AUTHORS: Ke Ju, Shanshan Li, Yuming Guo

Background While the health benefits of green space exposure are well documented, the economic benefits associated with reduced mortality have not been thoroughly quantified. This study estimates the global, regional, and national urban mortality burden preventable by long-term green space exposure, along with associated health-related economic benefits and spatiotemporal trends from 2000 to 2020. **Methods** Using high-resolution, validated data, we estimated preventable mortality linked to green space exposure across global urban areas from 2000 to 2020 at a 1 km × 1 km resolution. The normalized difference vegetation index (NDVI) served as a proxy for greenness. Age- and sex-specific population counts at the grid level were combined with country-level mortality rates from the Global Burden of Disease (GBD) database to analyze mortality by grid cell. Relative risks were derived from published meta-analyses of cohort studies that examined the causal relationship between NDVI and mortality. We adopted the value of statistical life (VSL) approach to estimate the country- and year- specific economic benefits from preventable mortalities All estimates were stratified by sex, age group, GBD regions, and World Bank income level groups. **Results** Long-term greenness exposure was associated with the prevention of approximately 1.17 million (95% CI: 0.70 – 1.67) all-cause deaths per year in urban areas from 2000 to 2020, equating to 9.24% (95% CI: 5.50 – 13.12) of total urban deaths or 89 (54 – 130) deaths per 100,000 population. Low- and middle-income countries (LMICs) accounted for over 76.9% of these preventable deaths, with the highest numbers in East Asia (0.29 million) and South Asia (0.22 million). Estimated economic benefits averaged $1,205 billion annually during 2000 – 2020, with the greatest benefits in China ($308 billion), the USA ($248 billion), Japan ($166 billion), the UK ($118 billion), and Germany ($106 billion). Globally, preventable deaths and associated economic benefits increased on average by 0.03 million deaths and $40 billion per year, respectively. In contrast, LMICs experienced an annual decrease in preventable deaths of 37 per 100,000 population. **Conclusion** Our findings highlight substantial global health and economic benefits of urban greenness, with the potential to avert significant mortality. These benefits underscore the need for policies to enhance green space accessibility, particularly in LMICs, to maximize health outcomes and promote environmental equity.

Ind-705 Accounting for Longevity: Assessing Cross-State Performance in India, 1981-2019

PRESENTER: **Pratyasha Acharya**
AUTHORS: Beverley Essue, Sumit Kane, Ajay Singh Mahal

Abstract

Background: India's real income per capita growth averaged 4.2% annually during 1981-2019, with considerable inter-state variation and no evidence of convergence. There were large interstate variations in health outcome gains over the same period, but policymaker focus has been on pure economic outcomes, neglecting the intrinsic value of health for social wellbeing. We incorporate longevity gains (to capture health gains) in a "full income measure" and assess cross-state gains in full income from 1981 to 2019, a period encompassing two key reform efforts: the 1980s and 1990s coincided with significant economic liberalization reforms; the 2000s were characterized by major health reforms, including investments in primary care and in publicly funded insurance.

Research Objectives: There were two main research questions: (1) Do Indian states exhibit convergence (or divergence) in growth in full income? (2) What are the implications for cross-state growth performance if the full-income measure were based on longevity gains among women, compared to if population-wide longevity gains were used?

Methodology: We followed Becker et al.'s (2005) approach that used the compensating variation method to measure the monetary value of longevity gains. State-level data on age-specific mortality rates from the Indian Bureau of the Census was used to construct survival functions using the Gompertz model. This was combined with income per capita data published by Reserve Bank of India to estimate the monetary value of improved survival from 1981 to 2019. Cross-state (real) per capita income changes were combined with monetary values of longevity gains to derive estimates of per-person growth in full income at the state level. Separately, the monetary value of survival gains among women was used to construct gender-adjusted rates of growth in full income. Cross-state and regional growth patterns in full income were assessed for convergence over time.

Key Results: Full income per person grew at an annual average rate of 5.8% compared to 4.4% for real income per capita during 1981-2019. The North region - which includes highly populous low-income states – experienced annual full income growth of 5.2%, while the relatively richer South and West regions grew at 6.3% and 6.5%, respectively, suggesting inter-regional divergence. Nonetheless, longevity gains contributed considerably more to full income growth (50.1%) than the Southern (38.8%) and Western (44%) regions. Moreover, the contribution of longevity to full income growth in poorer regions/states was especially marked during 1981 to 2001. Inter-regional full income performance based on the value of longevity gains among women is also divergent across states/regions, although disparities among states within regions narrowed. Nationally, the full income measure per person based on longevity gains among women was 7.4% more than when based on longevity gains among men, with the difference especially marked in the (poorer) North region.

Conclusion and Policy Implications: Trends in full income do not support the hypothesis of absolute convergence across Indian states. However, poorer regions have made significant strides in longevity gains among women and underline the instrumental role of accounting for health metrics in assessing economic growth patterns (and returns on health investments).

Ind-1306 Assessing the Effectiveness of Hospital Discharge Planning Synthesis of Empirical Evidence and Literature Findings

PRESENTER: **Lena Imhof**
AUTHORS: Jonas Schreyögg, Vera Winter, Robin Heber

Background/ research gap: Patient transitions between inpatient and outpatient settings represent a critical point in care, often associated with adverse events such as avoidable hospital readmissions or emergency department (ED) visits. Hospital discharge planning (DP) is a process designed to smooth the transition process and ensure continuity of care. Despite growing evidence on the effectiveness of DP practices, uncertainties remain regarding the specific interventions encompassed under the term "discharge planning". Furthermore, large-scale observational studies are limited and primarily focus on readmission rates, overlooking other meaningful patient and system-level outcomes. **Research question:** To address this gap, we conducted an umbrella review ("review of reviews") to categorize DP interventions and provide a comprehensive overview of studied outcomes, including their magnitude of effectiveness. We then used our literature findings to assess the effectiveness of DP on a variety of identified outcomes in a large-scale observational study. Our quantitative analysis particularly focuses on cardiovascular patients, a patient group often characterized by complex care needs and substantial healthcare utilization. **Methods:** For our umbrella review, we searched five databases. The methodological quality of each included review was determined using the AMSTAR 2 tool. DP interventions were summarized narratively and the strength of evidence was derived for all identified outcomes. In our quantitative analysis, we linked claims data from the largest German sickness fund with hospital quality data, which contain structural and quality-related metrics for all German hospitals. From this data, we derived hospital-level DP scores. We applied multilevel regression models with hospital random effects to assess associations between DP scores and outcomes such as readmission rates and length of stay. The models were adjusted for patient and hospital-level characteristics. **Results:** Our literature search yielded a total of 1,779 records of which n=34 reviews met our inclusion criteria. We identified 25 outcomes investigated by at least two reviews. Results indicate strong evidence that DP interventions reduce 180-day readmission and increase patient knowledge, moderate evidence for positively affecting quality of life and patient satisfaction, and low evidence for reducing mortality and ED-visits. Our data sample comprises 668,414 individual hospital cases between 2021 and 2024 with a cardiovascular diagnosis (ICD-10 I00-I99). Preliminary findings indicate a positive association between DP and several outcomes, but limited effects on other outcomes, such as mortality. Further subgroup analyses are planned to investigate whether the association between DP and outcomes differs across patient (e.g., disease type, case severity) and hospital (e.g., size, specialization) characteristics. The empirical findings align with the main results from our literature review. **Conclusion:** This study provides a comprehensive synthesis of the existing literature on hospital DP and presents new empirical evidence on the impact of DP on diverse patient outcomes. The findings offer valuable insights for researchers, policymakers, and professionals seeking to optimize care transitions and improve patient outcomes through strategic DP. The variability in effectiveness across outcomes highlights the need for tailored DP processes that align with patient and system priorities.

Ind-2778 The Causal Impact of Obesity on Labour Market Outcome: Evidence from Mendelian Randomisation Analyses Using UK Biobank Data.

PRESENTER: **Aharon Katz**

Obesity is one of the most pressing public health challenges of our time, with widespread implications for individual well-being, healthcare systems, and economic productivity. Its prevalence has risen dramatically in recent decades, accompanied by increasing evidence of its adverse impact on labour market outcomes such as employment probabilities, wages, and absenteeism. However, establishing a causal relationship between obesity and labour market performance is challenging due to confounding factors, reverse causality, and measurement biases. This study explores the causal impact of obesity on labour market outcomes using data from the UK Biobank, a comprehensive dataset combining genetic, health, and socioeconomic information. We apply a Mendelian randomisation (MR) approach, using a genetic risk score (GRS) for higher body mass index (BMI) as an instrumental variable. This method leverages genetic predispositions determined at conception, enabling us to isolate the exogenous variation in obesity while addressing key endogeneity concerns, such as omitted variable bias and reverse causation. To account for the heterogeneity in obesity's impact across diverse demographic and socioeconomic subgroups, we apply a combination of IV techniques and the person-centered treatment effect (PeT) framework. This methodological approach extends beyond traditional average treatment effect estimations, uncovering nuanced, subgroup-specific impacts that reflect the complex relationship between obesity and employment probabilities. Our findings consistently demonstrate a significant and negative causal effect of obesity on employment across all methods included. Furthermore, the marginal effect of obesity on employment probability varies notably by the approach applied and by sex, age, and socioeconomic status. These results highlight the broader economic burden of obesity, revealing its impact not only on healthcare costs but also on labour market performance and the deepening of economic inequalities. This research makes several key contributions. It enhances the methodological robustness of causal inference in the obesity-labour market literature by integrating genetic instruments and advanced econometric techniques. It also provides actionable insights for policymakers and public health stakeholders, emphasising the need for targeted interventions to mitigate the economic and social consequences of obesity. Policies promoting healthy weight management could have far-reaching effects, not only improving public health but also enhancing workforce productivity and reducing economic disparities. By drawing on the rich UK Biobank data and applying innovative analytical approaches, this study offers a comprehensive examination of the intersection between obesity and labour market outcomes, bridging gaps in existing research and contributing to a deeper understanding of the economic ramifications of obesity.

Behavioral and Systemic Drivers of COVID-19 Vaccine Uptake and Healthcare Utilization

MODERATOR: **Laura Boonstoppel**,

Ind-1840 Medium-Term Effects of the Covid-19 Pandemic on Healthcare Utilisation in Europe: Changes in Behaviours or in Characteristics?

PRESENTER: **Florence Jusot**, Université Paris Dauphine

AUTHORS: Justine Bondoux, Louis Arnault

Background The COVID-19 pandemic has significantly altered health and healthcare use of many individuals, all over Europe. Healthcare rationing was severe during epidemic peaks, due to postponed treatments or elective surgeries and to a contraction of demand induced by fear of contamination. Recent literature has mainly studied this decline at both the demand and supply levels. It also has focused on individuals' determinants of unmet care needs and their short-term effect on health. However, the medium and long run impact of the COVID pandemic on health care utilisation has not been studied. **Research question and aim** This study explores the medium-term effects of the COVID-19 pandemic on healthcare utilisation of people aged 50 or more in Europe. It analyses whether unmet needs that occurred during the pandemic induced a subsequent increase in health care utilisation, or whether healthcare needs may still not have been met after the pandemic. We aim to identify the mechanisms behind these potential evolutions, by distinguishing between the role of changes in healthcare-seeking behaviours, and of shifts in individuals' needs and resources. This differentiation offers a new approach to documenting the mid-term consequences of COVID-19. **Data and Methods** We use a balanced panel of over 37,000 respondents from waves 8 and 9 of SHARE, aged 50 or over and living in private households across 28 countries. Oaxaca-Blinder decompositions are applied to various curative and preventive care variables to compare the determinants of healthcare utilisation before and after the pandemic. This method helps to disentangle how changes in characteristics (e.g., health needs, socio-economic variables, etc.) and behaviours (i.e., shifts in the effects of these characteristics) have contributed to differences in healthcare use. **Results** The findings indicate a decrease in the probability of doctor visits (both general practitioners and specialists) and preventive care utilisation (eye exams, mammograms, and colon cancer screenings), except for flu vaccinations. The reduced number of visits can be attributed to changes in healthcare-seeking behaviours induced by the pandemic, despite health deterioration that would typically lead to increased healthcare utilisation. Notably, older individuals are less likely to undergo screenings and medical consultations post-pandemic. Individuals with chronic conditions tend to have fewer doctor visits, women are less likely to have at least one contact with a specialist, and the influence of financial stability and income on eye exam utilisation has diminished. **Policy Implications** Understanding the extent to which healthcare utilisation has fallen short enables policymakers to adapt public policies to ensure that individuals receive care that aligns with their needs (to safeguard their health and that of their relatives) and is delivered at the right time (to prevent future healthcare costs). Additionally, analysing the mechanisms driving these changes can inform the development of tailored public policies, adapted to specific national contexts or target population groups, thereby promoting greater equity in healthcare utilisation.

Ind-2376 COVID-19 in Adults With Disabilities: Disparities in Health Care Utilization And Employment Outcomes

PRESENTER: **Prof. Zoe McLaren, Ph.D.**, University of Maryland Baltimore County
AUTHORS: Mir Usman Ali, Nancy Miller, Zach Starr

Objective

The Covid-19 pandemic has disproportionately impacted individuals with disabilities continuing long-standing inequities in access and use of health care. In the United States (U.S) adults with disabilities were more than twice as likely to have experienced Covid-19 and twice as likely to report a negative health impact from Covid-19 than those without disabilities. This disparate impact has been attributed to two key factors: a higher risk of poor health outcomes and decreased access to routine care. Post-Covid condition (i.e. long Covid) is defined as having one or more of a broad range of symptoms develop during or after Covid-19 and continue for at least 2 months and has been considered a disability in the U.S. since July 2021.

To assess the short- and longer-term health impacts of Covid-19 for adults with disabilities, we will use nationally representative data from the United States National Health Interview Survey (NHIS) to estimate the impact of post-Covid conditions on disability status, health care utilization and employment outcomes. We examine how these impacts are moderated by differences in disability status, race and household income.

Data and Methods

We will use nationally representative in-person interview data from repeated cross-sectional panel data in the NHIS of approximately 27,000 adults annually from 2019 through 2023. The data includes information on health (including sensory, physical and mental impairments, Covid infection and post-Covid condition) as well as sociodemographic groups, health insurance, health behaviors, health care utilization, and employment. Our analysis uses linear probability regressions of binary outcomes on our set of explanatory variables and a standard set of control variables.

Results

Individuals with post-Covid condition are a statistically significant 1 percentage point more likely to report having a disability, a statistically significant 7 percentage points more likely to report delaying accessing health care due to travel time and a statistically significant 6.4 percentage points more likely to report delaying accessing health care due to limited insurance coverage. They are no more likely to report being employed. Among individuals with post-Covid condition, greater household wealth is associated with a lower likelihood of being disabled or reporting barriers to health care. We find no evidence that race confers greater disadvantage to those with post-Covid condition in the areas of health care access or employment. However, underlying racial disparities in access to health care may hinder non-white populations from being diagnosed with post-Covid condition in the first place. Our results are robust to several measures of disability status.

Conclusions

Given that Covid-19 continues to circulate widely in the U.S., a large population is therefore at potential risk for post-Covid condition. Policy is urgently needed, not only in the U.S. but also around the world, to mitigate the negative short-term and long-term impacts of post-Covid condition and the associated impairments that limit access to health care.

Ind-349 The Effects of Individual Perceptions of COVID-19 on Vaccine Acceptance Among Korean Employees: Focusing on Work and Family

PRESENTER: **Na-Young Yoon**
AUTHORS: Juhyeon Moon, Dongkyu Lee, Soonman Kwon

[Introduction] During the COVID-19 pandemic, South Korea relied on extensive testing, contact tracing, and social distancing rather than lockdown. Although temporary work policies allowed flexible work arrangements, most Korean employees continued on-site work due to company policies. Each employee faced their own circumstances within their families, leading them to respond to the pandemic with different perceptions. These perceptions of COVID-19 could impact their acceptance of preventive health measures, particularly vaccination. COVID-19 vaccine acceptance was complex, considering both the government and individuals' insufficient information about potential side effects. Consequently, understanding employees' perceptions of COVID-19, considering their personal contexts, is important for explaining their vaccination behaviors. This study aims to analyze the impact of individual perceptions of COVID-19—including risk perception, and satisfaction with the government's COVID-19 response—on employees' vaccine acceptance.

[Methods] The data were obtained from the 2021-2022 Korea Labor and Income Panel Survey. The study focused on low-risk subjects aged 18 to 49 who could voluntarily choose to be vaccinated. A total of 2,009 respondents were analyzed, excluding those vaccinated before August 2021—when mass vaccination for the low-risk general population began—and unvaccinated for medical reasons. To identify factors influencing vaccine acceptance, survival analysis using Cox regression was conducted. The time from August 2021 until the completion of the first and second vaccine dose were calculated using survey data indicating the vaccination year and month. Covariates were grouped into four categories: 'Perception factors' (risk perception, satisfaction with the government's COVID-19 response)', 'Family environments' (household size, living with seniors aged 60+, presence of young children), 'Working conditions' (employment status, job classification, work schedule, experience of flexible work arrangement), and 'Socio-economic factors' (sex, age, education, residence, marital status, income, health status, risk preference, resilience).

[Results] Among the 2,009 respondents, 94.03% had received at least one dose of a COVID-19 vaccine, while 5.97% remained unvaccinated.

Risk perception of COVID-19 was significantly associated with earlier initiation of partial vaccination (first dose only) (HR=1.10, 95% CI: 1.03-1.17). In contrast, satisfaction with the government's COVID-19 response was significantly associated with earlier completion of full vaccination (both doses) (HR=1.04, 95% CI: 1.02-1.07).

When the interaction between individual perceptions and personal context was examined, only the effect of COVID-19 risk perception on vaccination timing varied across family environments, not across working conditions. In larger households—specifically those with four or more members—higher risk perception was significantly associated with earlier uptake of both partial and complete vaccinations (interaction term: Partial, HR=1.20, 95% CI: 1.02-1.41; Complete, HR=1.25, 95% CI: 1.05-1.48). Similarly, among individuals living with senior household members aged 60 or older, higher risk perception was also significantly associated with earlier uptake (interaction term: Partial, HR=1.25, 95% CI: 1.05–1.49; Complete, HR=1.20, 95% CI: 1.00–1.43). In contrast, satisfaction with the government's COVID-19 response did not exhibit any significant variation across either family contexts or working conditions.

[Conclusion] Our findings suggest that increased concerns about infecting family members are key factors in understanding how employees' individual perceptions affect their vaccine acceptance. In these circumstances, they may be more risk-sensitive, and decide to get vaccinated earlier due to perceived positive externalities for both themselves and their close contacts. To promote compliance with preventive health policies among employees, the government should design risk communication strategies that are more tailored to their family circumstances.

Ind-957 A Qualitative Inquiry on Drivers of COVID-19 Vaccine Hesitancy Among Adults in Kenya

PRESENTER: **Stacey Orangi**, Kemri-Wellcome Trust Research Programme
AUTHORS: Daniel Waweru Mbuthia, Evelyn Kabia, Elwyn Chondo, Carol Ngunu, John Ojal, Edwine Barasa

Background: COVID-19 vaccination rates have been low among adults in Kenya (36.7% as of late March 2023) with vaccine hesitancy posing a threat to the COVID-19 vaccination program. This study sought to examine facilitators and barriers to COVID-19 vaccinations in Kenya.

Methods: We conducted a qualitative cross-sectional study in two purposively selected counties in Kenya. We collected data through 8 focus group discussions with 80 community members and 8 in-depth interviews with health care managers and providers. The data was analyzed using a framework approach focusing on determinants of vaccine hesitancy and their influence on psychological constructs.

Results: Barriers to COVID-19 vaccine uptake were related to individual characteristics (males, younger age, perceived health status, belief in herbal medicine, and the lack of autonomy in decision making among women - especially in rural settings), contextual influences (lifting of bans, myths, medical mistrust, cultural and religious beliefs), and COVID-19 vaccine related factors (fear of unknown consequences, side-effects, lack of understanding on how vaccines work and rationale for boosters). However, community health volunteers, trusted leaders, mandates, financial and geographic access influenced COVID-19 vaccine uptake. These drivers of hesitancy mainly related to psychological constructs including confidence, complacency, and constraints.

Conclusion: Vaccine hesitancy in Kenya is driven by multiple interconnected factors. These factors are likely to inform evidence-based targeted strategies that are built on trust to address vaccine hesitancy. These strategies could include gender responsive immunization programs, appropriate messaging and consistent communication that target fear, safety concerns, misconceptions and information gaps in line with community concerns. There is need to ensure that the strategies are tested in the local setting and incorporate a multisectoral approach including community health volunteers, religious leaders and community leaders.

Air Quality and Health: Economic and Social Impacts of Pollution and Policy Interventions

MODERATOR: **Aparnaa Somanathan**,

Ind-447 Cardiovascular Health and Economic Outcomes Under Improved Air Quality in China: A Modelling Study

PRESENTER: **Siyuan Wang**
AUTHORS: Sarah Lewis, Mingsheng Chen, Lei Si, Gian Luca Di Tanna, Laura Downey, Yawen Jiang, Stephen Jan, Zhiwei Xu

Introduction: China faces the dual challenge of elevated air pollution and an increasing burden of cardiovascular disease (CVD). Estimates suggest that approximately 5.09 million CVD related deaths occurred in 2019, of which 1.42 million deaths were attributable to exposure to particulate matter (PM). Annual average PM2.5 concentrations in 49 cities were above 50 μg/m3 in 2020, surpassing national regulatory guidelines, and more than 10 times above the WHO suggested guidelines of 5 μg/m3. Few studies have projected the potential cardiovascular, quality of life and economic benefits of improved future air quality scenarios. To model these benefits associated with lowering PM2.5 concentrations and guide future national air policies, we estimated the healthcare cost savings associated with CVD and the quality-adjusted life years (QALY) gained under scenarios of improved air quality in China. **Methods:** A health prediction model was developed to estimate 10-year CVD-related costs and QALY associated with PM2.5 levels in 2015, as well as two hypothetical improved air quality scenarios: 1) the China national PM2.5 target of 35 μg/m³, and 2) the WHO's PM2.5 guideline of 5 μg/m³. 10-year age-and sex- specific integrated atherosclerotic cardiovascular disease (ASCVD) risks were estimated from the 2015 China Health and Retirement Longitudinal Study. Relative risks from

WHO's integrated response functions were subsequently applied to baseline cardiovascular risks to predict ten-year ischemic stroke and coronary heart disease (CHD) event probabilities for individuals aged 45 to 85 years under the three air quality scenarios. Further, probabilities were extrapolated to the national population, where we sourced baseline population data and survival probabilities from the UN population prospects database for all individuals between 45-85 years. Baseline survival probabilities were adjusted to account for improvements in air quality. On a yearly basis, we predicted national 10-year estimates of ischemic stroke and CHD incidences, total healthcare costs and accrued QALYs at a 5% discount rate for individuals aged 45 to 85 years under the modeled scenarios. **Results:** Under PM2.5 levels in 2015, we estimated a cumulative 10-year incidence of 35.40 million CVD events, resulting in healthcare costs of US$96.12 billion and 4.44 billion QALYs. Under the national target of 35 μg/m³, the projected 10-year CVD incidence was 31.92 million cases, resulting in cost savings of US$9.29 billion and 3.43 million QALY gains compared to 2015 levels. If PM2.5 concentration levels meet the WHO's guideline of 5 μg/m³, the projected number of CVD events would decrease to 24.18 million, translating to cost savings of approximately US$30.10 billion and gains of 11.29 million QALYs. **Conclusion:** Our findings show that achieving the WHO recommended PM2.5 concentration level of 5 μg/m³ could lead to over threefold greater health and economic benefits than those achievable under national standards of 35 μg/m³. This underscores the potential need for stricter future national PM2.5 standards. Our findings also inform other LMICs in establishing effective long-term PM2.5 targets.

Ind-451 Health and Economic Benefits Associated With the 14th Five-year Clean Air Action Plan in China: A Modeling Study

PRESENTER: **Siyuan Wang**
AUTHORS: Zhiwei Xu, Mingsheng Chen, Lei Si, Stephen Jan, Laura Downey, Gian Luca Di Tanna

Introduction: Air pollution poses a significant health and economic challenge in China. The national 14th Five-Year Action Plan has committed to reducing PM2.5 levels by an additional 10% by 2025, relative to 2020 levels and establishing a national target of 25 μg/m³ by 2030 for 337 prefecture-level cities. To assess the health and economic impacts of these policies, we modeled the attributable health and economic outcomes associated with achieving the latest national regulations from 2021 to 2030, as well as the additional benefits associated with reaching the more stringent WHO target of 5 μg/m³ over the same period. **Methods:** Using 2020 ground-level PM2.5 measurements as the baseline, we projected cause-specific mortality and morbidity outcomes for all 337 prefectural-level cities in China from 2020 to 2030 under two policy scenarios: 1) the 14th Five-Year Action Plan (i.e. a 10% PM2.5 reduction by 2025, with a target of 25 μg/m³ by 2030), and 2) the WHO target of 5 μg/m³ by 2030. Mortality estimates for non-communicable diseases (NCD), lower respiratory infection (LRI), stroke, ischemic heart disease (IHD), lung cancer (LC), and chronic obstructive pulmonary disease (COPD) were calculated using the Global Exposure Mortality Model. Hospitalizations were projected using log-linear models based on national epidemiological evidence from China. We applied the value of statistical life (VSL) method to estimate economic benefits from reduced mortality and the cost-of-illness (COI) method for benefits from reduced hospitalizations. Baseline demographic data from the 2020 census were projected according to the Shared Socioeconomic Pathways (SSPs). Cause-specific mortality rates were sourced from national death registries and projected annually, assuming continuous trends in risk factors. Cause-specific hospitalization rates and associated healthcare costs for cardiovascular and respiratory diseases were sourced from national statistical yearbooks and projected using joinpoint regression. **Results:** Under the SSP2 scenario ("middle of the road"), we estimated an average annual reduction of 166,314 (95% CI: 136,363 to 180,823) in PM2.5-attributable premature deaths across 337 cities. This included average annual reductions of 50,825 premature deaths from IHD, 59,240 from stroke, 14,517 from COPD, 4,683 from LRT, and 22,669 from LC. Annual average reductions in hospitalizations were estimated at 19,683 for cardiovascular diseases and 24,391 for respiratory diseases. Subsequently, economic benefits from reductions in mortality and morbidity across 337 cities amounted to US$23.8 billion annually over the policy period, including US$23.4 billion in mortality benefits using a VSL of US$230,421. Further, achieving the WHO's target of 5 μg/m³ is projected to result in an additional average reduction of 459,843 premature deaths annually, along with a decrease of 42,462 cardiovascular hospitalizations and 52,681 respiratory hospitalizations each year, corresponding to an additional annual economic benefit of US$65.18 billion. **Conclusion:** Our findings highlight the health and economic benefits of the clean air action plan across 337 cities in China and underscores the need for more ambitious air quality targets, given the additional benefits achievable at the 5 μg/m³ threshold.

Ind-1174 Beyond Diagnosis: The Hidden Health Burden of Long-term PM2.5 Exposure on Hypertension, Diabetes, and Kidney Disease Through Biomarkers

PRESENTER: **Akshar Saxena**, Nanyang Technological University
AUTHORS: Mingxuan Fan, Zhuoru Ma

Background: Long-term exposure to PM2.5 has been linked to elevated risks of various chronic diseases. However, existing studies primarily rely on self-reported ever-diagnosed data, overlooking the potential of biomarkers to assess the early health impacts of air pollution. This gap may lead to an underestimation of PM2.5's true health burden. Evidence suggests that PM2.5 induces systemic inflammation and oxidative stress, impairing vascular endothelial function, insulin sensitivity, glucose metabolism, and glomerular filtration, thereby altering biomarkers associated with early health risks. These biomarkers are not only predictive of early health damage but are also strongly correlated with risks of hypertension, diabetes and impaired kidney function. **Aim:** This study aims to investigate the causal relationship between long-term PM2.5 exposure and the risks of hypertension, diabetes, and kidney disease, with a focus on the sensitivity of biomarkers in detecting early health risks compared to traditional clinical diagnoses. This approach addresses gaps in existing research and provides new insights into the mechanisms of PM2.5-related health impacts. **Methods:** We conducted analyses using data from the China Health and Retirement Longitudinal Study (CHARLS), National Aeronautics and Space Administration (NASA), and the China City Statistical Yearbook. The study employs a three-year average PM2.5 exposure as the independent variable and applies a two-stage least squares (2SLS) approach to address endogeneity in causal identification. A key innovation lies in the construction of the wind direction variation instrument, which captures inter-city differences in air pollution driven by changes in wind patterns. This refined instrument significantly enhances the validity and precision of the instrumental variable. Robustness checks included using alternative exposure periods (2 and 1 years), a substitute instrumental variable (thermal inversion days), and a one-year lagged diagnosis analysis. **Results:** The 2SLS results show that each unit increase in PM2.5 exposure raises the risk of

hypertension, diabetes, and kidney disease by approximately 4.87%, 15.87%, and 9.26%, respectively, as detected through biomarkers. In contrast, PM2.5's impact on traditional self-reported diagnoses by clinician for these conditions was not significant. This discrepancy indicates that biomarkers are more sensitive in capturing early health impacts of PM2.5 exposure, while clinical diagnoses may underestimate the true health burden. Robustness checks confirmed these findings across different exposure periods and instrumental variables, and the lagged one-year diagnostic analysis further underscores the limitations of clinical diagnoses in detecting disease risks, while highlighting the superior capability of biomarkers in assessing early-stage health risks. **Conclusions:** This study demonstrates that long-term PM2.5 exposure significantly increases the risk of hypertension, diabetes, and kidney disease by affecting biomarkers. These findings deepen our understanding of air pollution's health effects and underscore the critical role of biomarkers in early disease detection. Policymakers should consider stricter air pollution control measures and incorporate biomarker-based assessments into public health monitoring systems to identify and intervene in high-risk populations sooner.

Ind-1317 Maternal and Child Health Impacts of Pollution: Evidence from a Quasi-Experiment, the Low Emission Zones in England.

PRESENTER: **Eleonora Fichera**
AUTHORS: Habtamu Beshir, Stephanie von Hinke

Background: This paper extends our [BLIND REF] research on the impact of air pollution on physical health and wellbeing to UK hospital records on maternal and child health outcomes. Conceptual frameworks from human and health capital theory by Becker and Grossman, and self-productivity and dynamic complementarities (Heckman) highlight the importance of focusing on this population group because of the long term-effects on later life outcomes. However, establishing the causal impact of pollution on health is hindered by location sorting and avoidance behaviour generating a spurious correlation. This article contributes to this gap using hospital records, a quasi-experimental design and accounting for confounders with mother fixed effects. *Objectives*: In this paper, we exploit a quasi-experiment with the introduction of Greater London's Low Emission Zone (LEZ) and Central London's Ultra-Low Emission Zone (ULEZ) to estimate the causal impact of pollution on maternal and child health outcomes. LEZ was launched in 2008 over most of Greater London. ULEZ, implemented in Central London since early 2019, imposes stricter emission standards such as: Euro 4 for petrol cars and vans; Euro 6 for diesel cars; Euro 6 for diesel vans; and Euro 6 for lorries, buses, and coaches. *Data and Methods*: We have used Freedom of Information requests on postcode level data from Transport for London (TfL) to identify the areas under LEZ ad ULEZ. Using this information and with the help of the NHS digital team, we have constructed individual level exposure/treatment to LEZ and ULEZ based on the patient's postcode in the Hospital Episode Statistics (HES) dataset. Our outcome measures are hospital records on mother and child health outcomes: infant prematurity (< 38 weeks), birthweight, stillbirths and gestational age, type of delivery, gestational hypertension. Moreover, we have used Lower Super Output Area socioeconomic data from the ONS and weather data from the Met Office - MIDAS Land Surface Stations to account for area level differences. We then use difference-in-differences, and event study analyses exploiting the time of introduction of LEZ and ULEZ and comparing exposed areas in Greater London and Central London to comparable unexposed areas in England. *Results*: We find that exposure to LEZ and ULEZ significantly improves maternal and child health outcomes. Specifically, LEZ and ULEZ policies lead to a reduction in stillbirths, increase in birthweight and reductions of C-section deliveries. This impact is stronger for those living in relatively more deprived areas. *Policy implications*: The negative impact of air quality on key measures of child health, given the literature on dynamic complementarities over the life cycle, suggests that clean air transport policy may also have positive impacts later in life.

Ind-1421 Air Quality and Suicide

PRESENTER: **Claudia Persico**
AUTHOR: Dave Marcotte

Suicide is among the world's leading causes of death, claiming the lives of more than 800,000 annually (WHO, 2014). Following a period of decline, suicide rates are on the rise in the United States. While much work has focused on the roles of economic conditions and substance abuse on suicide, exposure to pollutants has received almost no attention as a risk factor. Pollution has been shown to increase depressive symptoms, affect health more generally, and increase the likelihood risky behavior leading to misbehavior in school and criminal activity, yet we know little about the effects of pollution on self-harm. Nevertheless, there is evidence that pollution could affect suicidality through increasing inflammation in the body, leading to worse symptoms of depression.

In this paper, we conduct the first-ever large-scale study of pollution and suicide, relying on data for all deaths in the U.S. over eight years. We estimate the impacts of individual pollutants on suicides throughout the U.S. using daily data on suicide counts by state-county matched to daily air quality data from the Center for Disease Control (CDC), daily weather data from the National Oceanic and Atmospheric Administration (NOAA), daily pollution data from the Environmental Protection Agency and CDC, and demographic data between 2003-2010. Using a difference in differences design controlling for weather, population, holidays, day of the week, and county, state-month and month-year fixed effects, we first estimate whether days in the same month, year and county with elevated levels of pollution lead to atypical increases in suicide. We then use variation in wind direction as an instrument for pollution, to limit attenuation bias that results from measuring exposure to pollution within a county-day using fixed monitoring sites. We find that a 1 μg/m3 increase in daily Particulate Matter 2.5 (PM2.5), also known as fine particulate matter, is associated with a 0.49 percent increase in daily suicides (a 0.5 percent increase above the mean). In addition, we find that a 1 μg/m3 increase in PM2.5 is associated with a 0.3577 percent increase in all daily deaths, which is an increase of 0.4% above the mean. We also find that a 1 μg/m3 increase in monthly PM2.5 is associated with 0.171 more suicide-related hospitalizations (a 50.5% increase above the mean), as well as evidence that pollution affects self-reported mood more broadly. We also investigate the timing of exposure through event studies.

This work has important implications for suicide prevention. Our work could add insight into an additional mechanism for policy makers working to reduce suicide mortality. If we know that certain places are more likely to experience increases in suicides on certain days, policymakers and practitioners will be better able to target resources to those places. In addition, this work has implications for understanding

the full costs of airborne pollutants. If certain types of pollution increase the risk of suicide, then targeted regulatory efforts might decrease the suicide rate.

Mental Health: Causes and Consequences

MODERATOR: **Andrew Briggs**,

Ind-295 Global Distribution and Economic Burden of Depressive Disorder: Equity and Socioeconomic Determinants in Middle- and Lower-Middle-Income Countries

PRESENTER: **Yan Xu**
AUTHORS: Shang Gao, Liangwen Ning, Xihe Yu

Background Depressive disorder is a leading global public health issue and a significant contributor to disability and reduced quality of life. The economic burden of depression, particularly in middle- and lower-middle-income countries, is compounded by social and economic determinants such as gender, education, income, employment, and poverty. These factors often exacerbate health disparities, leading to unequal access to mental health resources and services, which reinforces the cyclical relationship between poverty and poor mental health.

Methods

Data for this study were sourced from the 2019 Global Burden of Disease (GBD) study, encompassing depressive disorder incidence and burden data from 1990 to 2019 across 204 countries and territories. An age-period-cohort (APC) model was applied to assess trends in depressive disorder incidence across different SDI groups. This model captures the nuanced effects of age, period, and cohort, enabling detailed analysis of incidence trends and economic burden across all countries. Using the sociodemographic index (SDI), which includes per capita income, education, and fertility rate, countries were divided into five levels from high to low development. This study focused on middle- and lower-middle-income countries, and age-standardized incidence rates (ASIR) were applied to adjust for age distribution, offering clearer insights into depressive disorder trends across socioeconomic contexts.

Results From 1990 to 2019, the global incidence of depressive disorder saw a slight decline, with an age-standardized net drift of -0.24% (95% CI: -0.29, -0.18). Yet, trends varied significantly across SDI regions, revealing stark inequities in mental health outcomes. In high SDI regions, the incidence of depression rose notably among younger populations but decreased among the elderly, reflecting perhaps both high pressures among youth and effective support for older age groups. In contrast, middle and lower-middle SDI regions demonstrated a reverse trend, where the incidence declined in younger populations and increased in older cohorts. These findings suggest that social determinants, including limited access to education, low income, and inadequate employment opportunities, may play a significant role in shaping these trends in lower-income countries. Additionally, the APC model showed that lower-middle SDI countries had the largest decline in incidence, with a net drift of -0.46% (95% CI: -0.56, -0.37), while low SDI regions showed a notable but smaller reduction.

Conclusion The disparities in depressive disorder incidence and burden underscore the influence of social and economic factors on health outcomes, particularly in middle- and lower-middle-income countries. Economic strain, limited healthcare infrastructure, and restricted social safety nets intensify the burden of depression in these regions. High SDI regions benefit from more robust healthcare systems, though the rising incidence among younger individuals signals a need for mental health interventions that address the unique pressures faced by youth. In contrast, middle and lower-middle SDI countries require more substantial investment in social determinants of health—such as poverty reduction, education, and equitable healthcare access—to alleviate the disproportionate economic burden of depressive disorder. Policy actions should focus on enhancing mental health resources and addressing the socioeconomic barriers that drive disparities, ultimately fostering greater equity in mental health outcomes worldwide.

Ind-301 Mass Layoffs and Mental Health Care Use

PRESENTER: **Anam Bilgrami**, Macquarie University
AUTHORS: Rohan Best, Noura Saba, Yuanyuan Gu, My Tran, Dandan Yu, Marco Bertoni

Background: Approximately 44% of Australians aged 16–85 experience a mental disorder in their lifetime. Mental ill health imposes national economic costs of over $43 billion annually, and amongst developed countries, Australia ranks second on lost wellbeing attributable to mental ill health. Income is strongly interconnected with mental wellbeing. The most disadvantaged population quintile is two times as likely to have high psychological distress compared to the most advantaged. Past studies have also causally linked income ‘shocks’ to mental health. Compared with other chronic conditions, people with mental ill health are more likely to skip treatments, which may worsen psychological distress, and increase treatment costs from more severe future illness. Deferring health care is also more likely under financial stress. Recent data reveal that 70% of Australians under financial stress deferred seeing a doctor or getting prescriptions, with females and singles with children most likely to do so. Despite the implications of financial stress for mental health and health care use, there is no robust, causal evidence on whether Australians adjust mental health care use when facing income shocks, and whether income shocks contribute to disparities across population groups. This research will therefore explore whether and how Australians adjust their mental health care use in response to negative income ‘shocks’ created by ‘exogenous’ job displacement from mass layoffs, and whether impacts vary across population groups.
Research Aim: Our aim in this study is to look at the mental health care use impacts (medical services and pharmaceuticals) of job

displacements from mass layoffs in Australia over the period 2014-2016. **Methods:** We will estimate impacts using a difference-in-difference strategy to compare mental health care use outcomes in long-tenure Australian workers displaced by mass layoffs over 2014-2016 to those who were not displaced. We will draw a sample of workers from whole-of-Australia population data over 2011-2019 linked to administrative data on employment, firm-level data on mass layoff frequency and health care use data (medical and pharmaceutical). Heterogeneity analyses will explore whether impacts vary across different population groups, including those who received welfare payments to cushion income losses, males versus females, those in high versus low socioeconomic regions, regional remoteness and individuals with and without dependent children. **Results**: The estimations are currently ongoing, and all results and descriptive statistics are under strict confidentiality obligations. They will be finalised and vetted by the Data Integrating Authority and Australian Bureau of Statistics and released before the conference, ready for presentation. **Conclusions and expected policy implications:** The research has strong potential to improve living standards by informing policy on access to mental health care across Australian population groups by need, including potential barriers that need to be addressed. The research will generate policy suggestions on welfare and income support policies targeted to people experiencing job displacements, and ensuring adequate support and access to health care in the face of income shocks created.

Ind-1917 Working Longer, Feeling Worse? How Job Quality Shapes the Mental Health Toll of Delayed Retirement

PRESENTER: **Michele Belloni**
AUTHORS: Alexandra Lugova, Bérangère Legendre, Jérémy Tanguy

The ageing population in the EU is placing significant pressure on pension systems, prompting reforms aimed at extending working lives to reduce financial strain. However, these changes may have unintended consequences on the mental health of senior workers, particularly those in demanding jobs, leading to increased healthcare costs and reduced productivity. While previous research suggests a general decline in mental health following delayed retirement, few studies have examined how job characteristics influence these outcomes. This paper explores how different occupational characteristics modulate the mental health effects of pension reforms, highlighting the importance of considering working conditions when designing policies to extend working life. We focus on pension reforms that delayed the retirement age between 2011 and 2015 across 14 European countries, assessing their impact on late-career depression, which we measure with the Euro-D scale that shows the number of depression symptoms on a 12-point scale. Using individual demographic and health data from the Survey of Health, Ageing, and Retirement in Europe (SHARE), combined with occupation-level data on working conditions from the European Working Conditions Survey (EWCS), we employ a staggered difference-in-differences design to estimate the effects of these reforms. Specifically, we examine how changes in the work horizon (*i.e.* the number of years a worker must remain employed before becoming eligible for retirement) affect depression prevalence among senior workers, with a focus on how job characteristics - such as skills and discretion, working time quality, physical environment, social environment, job intensity, and career prospects - moderate these effects. We show that, overall, extending the work horizon worsens mental health among older workers. A 1-year increase in the work horizon leads to a 0.041 increase in depression symptoms, while reforms extending the work horizon by more than a year result in a 0.273 increase in depression symptoms, corresponding to 2% and 26% of the control group mean, respectively. However, this effect is not uniform across occupations. Workers in low-skilled, high-intensity, insecure jobs with poor career prospects and unsupportive social environments experience significantly worse outcomes – doubling and tripling the baseline estimates, depending on the job quality dimension. In contrast, we find reversed effects for workers in supportive, high-quality work environments with stable jobs offering good career prospects, who show strong improvements in mental health, with reductions in depression symptoms doubling the baseline estimates in amplitude. We ensure that these results are robust to different threats that may affect the identification of these causal relationships. These findings suggest that policies extending working lives should incorporate targeted support, such as gradual, partial, and flexible retirement schemes, for workers in precarious jobs, where mental health risks are higher. At the same time, interventions aimed at improving workplace social support and promoting lifelong learning may help mitigate the adverse effects of delayed retirement at the organizational level.

Ind-2006 Evaluating the Influence of Taxation and Social Security Policies on Psychological Distress: A Microsimulation Study

PRESENTER: **Daniel Kopasker**, University of Glasgow
AUTHORS: Rachel Thomson, Petra Meier, Srinivasa Vittal Katikireddi, Matteo Richiardi, Peter Craig, Clare Bambra, Patryk Bronka, Nik Lomax, Alison Heppenstall

Background

Economic determinants are important for population health. Tax and social security policies directly influence these economic determinants and could be harnessed to improve health outcomes and reduce inequalities, but actionable evidence of how policies can utilise these pathways remains scarce. Microsimulation is a promising method to support evidence-based policymaking when empirical evaluations are either unavailable or may take many years to emerge. This study employs an open-source microsimulation framework to evaluate the effects of taxation and social security policies on population mental health. The UK economic crisis caused by the COVID-19 pandemic provides an informative context involving an economic shock accompanied by one of the strongest discretionary fiscal responses amongst OECD countries.

Methods

The analytical setup involves a dynamic, stochastic, discrete-time microsimulation model (SimPaths) projecting changes in psychological distress given predicted economic outcomes from a static tax-benefit microsimulation model (UKMOD) based on different policy scenarios. We contrast projections of psychological distress for the UK working-age population from 2017 to 2025 given the observed policy environment against a counterfactual scenario where pre-crisis policies remained in place. Levels of psychological distress and potential cases of common

mental disorders (CMDs) were assessed with the 12-item General Health Questionnaire (GHQ-12). The main hypothesis tested is that the policy response limited increases in psychological distress and CMDs during the economic crisis by influencing economic determinants of mental health. Support for this hypothesis will provide initial evidence for the scale and nature of changes required for tax and social security policies to improve population mental health more generally. While the focus is on the UK, the analysis can inform the structure of policy responses to economic crises in other countries with well-developed tax and social security systems.

Results

The UK policy response to the economic crisis is estimated to have prevented a substantial fall (over 12 percentage points, %pt) in the employment rate in 2020 and 2021. In 2020, projected psychological distress increased substantially (CMD prevalence increase >10%pt) under both the observed and the counterfactual policy scenarios. Through economic pathways, the policy response is estimated to have prevented a further 3.4%pt [95%UI 2.8%pt, 4.0%pt] increase in the prevalence of CMDs, approximately 1.2 million cases. Beyond 2021, as employment levels rapidly recovered, psychological distress returned to the pre-pandemic trend. Sustained preventative effects on poverty are estimated, with projected levels 2.1%pt [95%UI 1.8%pt, 2.5%pt] lower in 2025 than in the absence of the observed policy response.

Conclusion

The study shows that policies protecting employment during an economic crisis are effective in preventing short-term mental health losses and have lasting effects on poverty levels. This preventative effect has substantial public health benefits. Microsimulation has the potential to overcome barriers that have limited the evidence base for governments to improve population health using a range of policy areas.

Ind-172 Long-term Sustainability of National Essential Medicines Policy in Primary Care System in Rural China from 2012-2017

PRESENTER: **Xuechen Xiong**
AUTHORS: Zhaohua Huo, Li Luo, Jianchao Quan

Background: The implementation of National Essential Medicines Policy (NEMP) in China since 2009 was effective in curbing exploding drug prices and expenditures; however, evidence on its long-term sustainability is lacking, especially in rural and remote areas. This study evaluated the long-term impacts of NEMP on drug availability and affordability in a deprived rural county in southwestern China from 2012-2017. **Methods:** A quasi-experimental design with pre-post-comparison was used to analyse 108,111 purchase records on 475 medicine types, extracted from 7 township health centres (THCs) and 76 village clinics from 2012-2017. Pharmaceutical data were analysed quarterly. Availability of medicine was measured by the number of medicine types prescribed for patients; affordability was measured by the price index, based on the cost changes to obtain a fixed basket of medicines since 2012. For statistical analysis, interrupted time-series analyses were used to examine sustained trends of outcomes during the 1st-stage NEMP (2012-2015) and the immediate and sustained changes after the 2nd-stage NEMP (2016-2017). **Results:** Overall, the number of medicines in rural primary care kept increasing during the 1st-stage NEMP (+5.1 per quarter) but encountered significant and sustained drop after the 2nd stage NEMP. Drug price index has kept increasing during the 1st-stage NEMP as well as after 2nd-stage NEMP (+0.2% per quarter), while the overall medicine sales remained steady over the observation course of NEMP. By medicine types, availability of traditional Chinese medicines improved and surpassed that of western (chemical or biological) medicines. In contrast, rises in price of western medicines outstrip those of TCMs, especially after 2nd-stage NEMP. By facility levels, village clinics encountered continuous drops in both the availability and sales of western medicines, while facing the edging up prices. In THCs, drug prices and sales presented milder rises, especially in western medicine and after 2nd-stage NEMP. **Conclusions:** Availability of medicines improved in the longer run of NEMP in rural primary care, mainly attributed to TCMs. Nevertheless, challenges remained alongside the policy promotion, especially in the provision of western medicines under the uprising price trends. Village clinics as health gatekeepers are facing severer challenges in this context and require further attentions. **Keywords**: essential medicine; accessibility; affordability; price; rural; primary care

Ind-1088 Effectiveness of Strengthening Primary Care Management on Chronic Conditions Through Waiving Pharmaceutical Copayment: a Pilot in Rural China

PRESENTER: **Weijia Lu**
AUTHORS: Timothy Powell-Jackson, Anne Mills, Qianchen Wei, Hanyi Xu, Beibei Yuan, Ping He, Qingyue Meng, Jin Xu

Introduction

The underutilization of primary care (PC) presents a substantial challenge in enhancing the people-centeredness, quality, and efficiency of health services for patients with chronic diseases. User fees, particularly for medicines, have been considered a key barrier to patient access in low- and middle-income countries (LMICs). As pharmaceutical copayment constitutes the largest proportion of household health expenditure for NCDs in LMICs, reducing such copayment is a potential strategy to encourage PC use and improve health system performance regarding

NCDs.

However, there has been a lack of research exploring PC-targeted expansion of pharmaceutical benefits in China and other LMICs. To evaluate this potentially useful policy intervention, this study evaluated the effects on healthcare utilization and expenditures for patients of a pilot in rural China that waived copayment for essential pharmaceuticals at PC facilities (i.e. township health centers) only. The study also sought to explore whether free medication might reduce disease-related hospitalizations.

Methods

The impact of PC-targeted removal of pharmaceutical user fees on health service utilization and expenditures was analyzed through a synthetic difference-in-differences (SDID) approach using claims data from the New Cooperative Medical Scheme. Our sample included a total of 39790 patients with hypertension and/or diabetes, including 9115 patients from 11 townships in County L where the policy change was introduced, and 30675 patients from 86 townships from the other 9 counties in the same municipality. Considering that policy was managed at the level of the township and that the claims data were not decomposable to a level below year, we used township-year as the unit of analysis. Claims data for 2010-2017 were used, including 4 years prior to and the 3 years after the start of the policy change.

Results

The policy led to a significant increase of 0.69 in the number of PC visits per patient per year (95%CI: 0.46 to 0.91), equivalent to a rise of 44.1%. Annual spending per person on outpatients at PC facilities increased significantly due to the policy, by 58 yuan (95%CI: 36 to 80), equivalent to a rise of 40.5%. As for outpatient visits at hospitals, there was a 25.8% significant reduction in the number of visits per year (-0.56; 95%CI: -0.95 to -0.16) and a nonsignificant increase in spending (45 yuan; 95%CI: -111 to 21). The annual number of admissions and spending on inpatients per person in all facilities remained stable.

Conclusion

PC-oriented removal of outpatient pharmaceutical copayment, like other policies that increase PC benefits, incentivizes patients to seek outpatient care at the primary level rather than at higher-level institutions. However, without additional efforts to strengthen the quality of PC, waving pharmaceutical copayment alone may not be a sufficient effect in achieving improved health outcomes and therefore avoid expensive inpatient care, if patients obtain medication without receiving necessary medical assessments and treatment. A more synergistic approach that combines financial incentives with professional support for PC may be needed to achieve meaningful and sustainable PC strengthening and health improvement.

Ind-542 The Influence of Cost-Effectiveness and Other Factors on Pharmaceutical Benefits Advisory Committee (PBAC) Recommendations in Australia

PRESENTER: **Yingying Wang**
AUTHORS: Ms. Marie-Anne Boujaoude, Yi-shin Yang, Cate Bailey, Kim Dalziel, Nancy Devlin, Natalie Carvalho

Objectives: In Australia, the Pharmaceutical Benefits Advisory Committee (PBAC) advises the Minister for Health and Aged Care on the listing of medications on the Pharmaceutical Benefits Scheme (PBS). Although summaries of PBAC decisions are published, it is not always clear what role cost-effectiveness and other factors, including clinical evidence and equity considerations, have on decisions. This study aims to explore how cost-effectiveness, in the form of incremental cost-effectiveness ratio (ICER) and other factors, including clinical evidence and equity considerations, influence the PBAC's recommendations. **Methods:** We acquired all public summary documents (PSDs) spanning November 2019 to May 2024 from the PBAC website. The eligibility criteria included PSDs reporting cost-utility analysis (CUA) and where PBAC recommendations were based on CUA results. The extracted information included: intervention, PBAC recommendation, incremental cost-effectiveness ratio (ICER) ranges for the base case and sensitivity analysis, population characteristics, disease area, comparator, efficacy and safety claims, budget impact, uncertainties in clinical and economic evidence, equity considerations, price negotiations, and consumer comments. A binomial logistic regression model was developed to explore the association between PBAC recommendations as binary outcome (recommended, rejected) and the identified factors. **Results:** Of 767 PSDs spanning the relevant time period, a total of 263 eligible PSDs were included in the analysis. Outcomes included 122 recommendations, 132 rejections and 20 other outcomes. 46.4% of submissions were related to cancer and other neoplasms, and 23.6% included indications for paediatric use. The median base case ICER range midpoint was similar across outcomes: and was stated as $65,000/QALY, though the mean varied from a stated $148,420/QALY for rejected submissions to a stated $106,077/QALY for recommended submissions. The median budget impact (over six years) midpoint was stated as $87.5 million for recommended submissions and $150 million for rejected submissions. Preliminary logistic regression analysis revealed several factors influencing the likelihood of a positive outcome. Submissions from 2021 ($p = 0.014$) and 2022 ($p = 0.021$) were associated with lower odds of a positive outcome compared to 2019. Higher budget impact midpoint was negatively associated with a positive outcome ($p = 0.004$). Submissions with fair (cost-effective with price reduction) or good (cost-effective and robust) economic evidence significantly increased the likelihood of a positive outcome ($p = 0.002$ and 0.003, respectively), and a similar trend was observed for good clinical evidence ($p = 0.087$). The stated ICERs (both the range in the base case, and from sensitivity analysis) were not found to be significant predictors of PBAC outcomes to recommend or reject based on publicly reported data. **Conclusions:** Preliminary findings suggest that PBAC recommendations are based on a range of factors extending beyond stated publicly reported cost-effectiveness. We did not observe a statistically significant association between outcomes and claimed ICERs; rather, the overall quality of cost-effectiveness estimates matters. Further investigation will be conducted by including more factors in the logistic model to better understand the determinants of PBAC recommendations.

Ind-1438 Efficiency Analysis of the Ethiopian Pharmaceutical Supply Chain System

PRESENTER: **Samuel Abera Zewdie**
AUTHORS: Ermias Dessie, Tesfaye Mesele Mekonnen, Dominic Albert Nkhoma, Tewodros Tebekew Admasu

Pharmaceutical supply chain (PSC) management is the backbone of healthcare delivery as the availability of pharmaceuticals and other medical goods at the right time and in the right quantities is crucial for the proper management of patients. Hence, an efficient supply chain is essential for assuring access to medicines, medical supplies, and equipment and minimizing wastage, thus bringing positive health outcomes. The PSC system in Ethiopia faces numerous challenges that hinder access to drugs. These challenges include inadequate storage facilities, unreliable transportation infrastructure, and inefficient distribution networks. Additionally, stockouts, counterfeit drugs, and poor-quality control are significant issues. The study attempts to understand the levels and sources of inefficiencies in the Ethiopian pharmaceutical supply chain, examining the procurement, warehousing, distribution, and utilization stages. It primarily explores inefficiencies in different supply chain stages to identify possible cost-savings and efficiency improvements. The study used a mixed-method approach involving quantitative and qualitative data collection and analysis focusing on pricing, order fulfilment cycle time, wastage of medicine, and stock-out rate. The results showed strong performance in some key measures while revealing gaps that should be addressed. On average, framework agreements (FAs) appear to offer better value for money in procurement, although there was wide variation in their expensiveness relative to non-FA. Stronger contract negotiation and management capacity could likely improve FA outcomes, especially if coupled with a strong market-shaping system, price monitoring, and international benchmarking system. Comparatively, the study has shown that EPSS' purchasing prices are lower than Uganda's NMS but higher than Kenya's KEMSA, suggesting that there is still room for further improvements. The study found that levels of preventable pharmaceutical wastage at EPSS warehouses were relatively low, but some savings could be made. The main causes of the expiry of pharmaceutical products include weak data management systems, and poor planning and forecasting, with 84% of drugs expiring over 30 days after arriving at the facilities. The average stockout rate across regular drugs was 27% and it takes 11.3 days for a customer to access the pharmaceutical commodity once an order is made from EPSS. To reduce inefficiencies, the study recommends investment in IT infrastructure to strengthen the coverage of e-LMIS across the health system. This would improve and promote end-to-end visibility and accountability in the PSC, enable wider use of efficiency metrics, and better support for informed decision-making in the PSC. In addition, reviewing and strengthening the implementation of the stock transfer policy across health facilities without compromising the quality, and strengthening policy on the donation of medicines by enforcing minimum shelf-life rules to reduce wastage and adhere to existing standards.

Ind-2104 Consumer Concentration and Digital Technology Adoption in Pharmaceutical Innovation: Insights from US Medicare Part D

PRESENTER: **Chuanzi Yue**, University of Bristol

This study examines the impact of consumer concentration on the adoption of digital technology in pharmaceutical innovation, leveraging the introduction of Medicare Part D as a natural experiment. Announced in 2004, Medicare Part D provided publicly subsidized prescription drug insurance to U.S. citizens aged 65 and older who previously lacked coverage. The program led to a substantial reduction in drug prices, driven by concentrated negotiations conducted by Part D insurance providers on behalf of the newly insured senior population. Using a difference-in-differences design that leverages exogenous variation in drug spending exposure across diseases among this demographic, I analyze pharmaceutical trial data from ClinicalTrials.gov over the study period. Specifically, I compare the adoption of digital technology in trials targeting diseases with a high versus low spending share on prescription medications by Medicare Part D beneficiaries. The findings reveal that a 10% increase in exposure to Medicare Part D is associated with a 1.4% decline in the adoption rate of digital technology in pharmaceutical trials. Notably, this effect is concentrated among new trials initiated after the program's announcement, rather than those already underway. Furthermore, competition in the same disease area exacerbates this effect; each additional trial in a disease area prior to the announcement decreases the likelihood of digital technology adoption by 0.7%. In contrast, no significant reduction in adoption is observed in areas without competitive pressures. States implementing stricter biometric data laws experienced a more pronounced decrease in technology adoption following Medicare Part D exposure. These findings align with existing theoretical frameworks, emphasizing the trade-offs faced by forward-looking agents between the marginal benefits and costs of adopting new technology. The anticipated revenue from pharmaceutical innovations —dampened by consumer concentration through market competition—reduces the rate of adoption by lowering the perceived value of digital technology utilization. Furthermore, factors affecting the cost of adoption shape the elasticity of this response.

Ind-216 Occupational Mobility of Healthcare Workers over Business Cycles

PRESENTER: **Takuya Hasebe**, Sophia University
AUTHOR: Koyo Miyoshi

Abstract

Objectives: Securing a stable labor supply of healthcare workers is an important policy goal. Previous studies have found counter-cyclical patterns in health outcomes, with recent research suggesting that healthcare worker turnover contributes to these fluctuations. Therefore, understanding the occupational mobility of healthcare workers over business cycles is important. However, little is known about how and which types of healthcare workers response to changes in economic conditions. To fill this research gap, we examine the impacts of economic fluctuations on the likelihood a healthcare worker remains in their current occupation, switches to a different occupation, or stops working, and whether the impacts vary by the characteristics of a worker. Among healthcare occupations, this study focuses and compares on occupational

choices of registered nurses and nursing aides in the United States, with the former requiring more skills than the latter. Other healthcare occupations, such as physicians and pharmacists, are excluded due to either low occupational mobility or insufficient observations.

Methods: We use the basic monthly Current Population Survey (CPS) and its panel structure to estimate a multinomial logit model, with a monthly state-level unemployment rate as a key explanatory variable that proxies local economic conditions. We categorize occupational switches into two groups: health-related and non-health-related occupations. Thus, our logit model has four outcome categories: remaining in the current occupation, stopping work, switching to health-related occupations, and switching to non-health related occupations. Our sample covers the 20 years preceding the Covid-19 pandemic, from December 2000 to February 2020, ensuring sufficient sample sizes of the healthcare workers and ample variation in economic conditions. To investigate which types of workers are more responsive to changes in unemployment rates, we examine heterogenous impacts across educational attainment, wage distribution, and age.

Results: The procyclicality of the outflow in the healthcare workforce is observed only among skilled workers. When the unemployment rate is lower, registered nurses are more likely to switch to non-health-related occupations, especially those who are more educated, higher paid, and older. Conversely, less educated nurses are more likely to switch to other health-related occupations when the unemployment rate is lower. In contrast, nursing aides show little responsiveness to changes in unemployment rates, despite having a higher baseline occupational mobility than registered nurses.

Discussion: Our results suggest that the skill composition of the healthcare workforce likely fluctuates over business cycles. Given these fluctuations, healthcare quality is likely to be counter-cyclical, aligning with findings in the literature. However, this study does not yet uncover the mechanism by which the mobility of skilled healthcare workers responds to economic conditions. Understanding the mechanism is essential for designing policies that stabilize healthcare quality.

Ind-2258 Self-Sufficiency in the Healthcare Workforce: A System Dynamics Model of the Domestic and Foreign Educated Nursing and Midwifery Workforce in Ireland

PRESENTER: **John Cullinan**, NUI Galway
AUTHORS: Paul Caulfield, Peter O'Connor, Terence Hynes

ABSTRACT

Background

World Health Organisation (WHO) projections point to an increasing global demand for nurses and midwives, leading to shortages in many countries, particularly in less developed regions. Ireland, the context of this paper, currently relies heavily on foreign educated nurses and midwives to meet its demand, with Government policy now shifting towards a domestic recruitment model. This paper aims to identify the optimal nursing and midwifery annual recruitment requirement for supply to meet demand in the Irish health and care system in the long-term. It also seeks to highlight policy considerations for countries aiming to comply with the WHO Global Code of Practice on the International Recruitment of Health Personnel.

Methods

This paper develops and applies a system dynamics model of the domestic and foreign educated workforce supply by age and gender and is based on regulatory data on stocks and flows from the national professional regulator for nurses and midwives in Ireland. The model scope and design was informed by a problem statement developed in a series of workshops with officials of the Chief Nurses Office in Ireland. A range of reform scenarios and sensitivity analyses are also undertaken.

Results

The results confirm that Ireland is currently significantly undersupplying domestic nursing and midwifery graduates. The recruitment requirement in whole time equivalents (WTEs) in 2021 was 3,019, which would have required 3,495 graduates or 3,965 student places (4 years earlier) to meet this demand. This represents 152% of the 1,570 student places that were available in 2017 and suggests significant increases in nursing and midwifery student intake are urgently needed if Ireland is to reach self-sufficiency in a timely manner. The reform scenarios identify that by between 2034 and 2044, Ireland will need between 3,729-4,143 graduates in terms of WTEs a year. The sensitivity analysis suggests that the outer bound may be approximately 3% above or below the recruitment requirement by the end of the projection period. This would require between 4,895 and 5,439 students over the period 2030 and 2044.

Conclusions

The analysis suggests that Ireland requires a significant increase in nursing and midwifery student places to achieve self-sufficiency and that this will take time to achieve. Moreover, in addition to a sufficient domestic supply of nurses and midwives, self-sufficiency will also depend on managing demand volatility. Finally, countries anticipating an older society in the future should ensure they have sufficient health and care student places in place before the demographic transition.

Ind-1063 Assessing Allied Health Professional Preferences for Rural Workforce Training: A Discrete Choice Experiment

PRESENTER: **Rachel Milte**, Flinders University
AUTHORS: Jenny Cleland, Diana Khanna, Chris Brebner, Ali Dymmott, Stacey George

Background: People living in rural and remote areas experience higher rates of death, injuries, disease and hospitalisation than those living in metropolitan areas. Rural and remote Australians have significantly reduced access to health professionals who can support them to manage their health, including Allied Health Professionals (AHP). The search for workforce strategies to improve recruitment and retention of health professionals to rural and remote areas where they are needed continues. The Allied Health Rural Generalist Pathway (AHRGP) has been developed as a potential strategy to address workforce maldistribution. The program allows AHP to undertake formal education in rural generalist practice alongside dedicated supervision, quarantined study time at work and work-integrated learning opportunities. However, the importance of different components of the program to increase uptake among AHP and their managers has not been extensively investigated to date.

Methods: This study used a Discrete Choice Experiment (DCE) to evaluate participant preferences for an AHRGP via an online survey. In the DCE, the participants were presented with a series of hypothetical choices between two hypothetical AHRGP program options across six key attributes.** The six attributes provided variation in the level of costs covered, flexibility of the formal study program, recognition of training, expected increase in earnings, and broader professional development available. The DCE was provided to both AHP currently working in their disciplines, as well as Managers of AHP to understand any differences in preferences for design of the AHRGP between these two groups. Analysis was undertaken using Stata using a range of models including the conditional logit (as a widely-used model for analysis of such data) and mixed logit (to account for heterogeneity in preferences between individuals)

Results: 85 participants completed the Discrete Choice Experiment (DCE) survey. Participants significantly favoured options with flexible study options (0.49, $p<0.001$), and recognition of prior experience (0.37, $p=0.002$). Additionally, participants preferred formal recognition with a qualification at the completion of the program as compared to continuing professional development points (0.38, $p=0.001$). When comparing responses from AHP themselves vs their managers, managers showed a significant aversion to no cost coverage for the program (-1.66, $p<0.036$), but this was not significant for the AHP themselves. A greater range of attributes were statistically significant determinants of choice for the AHP compared to the managers, including the recognition of prior education in the program, and provision of a formal qualification upon program completion. Offering broader professional development online to staff of the practice more broadly was not a significant determinant of preferences.

Conclusions: This study provides for the first time preferences via a DCE approach for the design of workforce support programs to improve recruitment and retention of AHP to rural and remote areas. Overall, participants prioritised options that provided financial support, flexibility in the formal study program, formal recognition via a qualification for participation in the program, and recognition of prior learning towards their qualification. This study provides crucial information for the Australian government as they re-design supports offered for AHP working in rural and remote areas.

Ind-1455 Junior Doctors' Preferences for Clinical Practice in South Korea: A Discrete Choice Experiment

PRESENTER: **Young Kyung Do**
AUTHORS: Eunhye Hyun, Moo Hyuk Lee

Geographic and sectoral imbalances in physician distribution have long been a policy challenge not only in low- and middle-income countries but also in high-income countries. While these imbalances are observed at the aggregate level, they ultimately reflect individual physicians' preferences for clinical practice. This issue became particularly prominent in South Korea in February 2024, when the government announced a 65% increase in medical school admissions to address shortages in underserved areas and in certain "essential" specialties, such as emergency medicine. In protest of this policy, most junior physicians have walked off their jobs, resulting in severe disruptions to the healthcare system that continue to this day.

While theoretical and empirical research suggests that salary, leisure, location, and disutility from inducement are key factors affecting physicians' utility, preferences for clinical practice may vary substantially across healthcare systems, both in terms of the relative importance of these factors and the presence of other context-specific influences. This study investigates junior doctors' stated preferences for clinical practice in South Korea amidst the ongoing healthcare crisis. Using a discrete choice experiment (DCE), we aim to assess whether, and to what extent, non-pecuniary factors influence junior doctors' preferences for clinical practice.

To design the DCE, we conducted qualitative interviews with junior doctors using a semi-structured questionnaire informed by a review of relevant literature. Six key attributes were identified: salary, location, legal liability and lawsuit risk, pressure for hospital revenue, workload, and professional job satisfaction. These attributes, each with specified levels, were combined in an efficient design, allowing participants to repeatedly choose between two hypothetical healthcare institutions. The DCE survey was conducted in August 2024 and involved a total of 324 trainee doctors and specialists, proportionally allocated by region. A conditional logit model was used to estimate willingness-to-accept (WTA) values, quantifying the relative importance of each attribute level and the trade-offs between them. We also conducted subgroup analyses to explore potential heterogeneity based on respondents' characteristics, including hometown, medical school location, and residency training region.

Our results indicated that the six attributes were consistent with the predicted directions. The WTA estimates showed that junior doctors would require an additional $10,546 per month to practice in a non-SCA province, $20,339 to offset 'high' legal liability and lawsuit risk, $3,477 for 'high' pressure to generate hospital revenue, and $4,262 for a 'high' workload. Conversely, they were willing to accept a $4,112 monthly salary reduction for 'high' professional job satisfaction. Subgroup analysis also revealed that doctors from non-SCA provinces would require less compensation for working in such areas, compared to those from the SCA.

These findings underscore the significant role of non-pecuniary factors, such as legal liability and professional job satisfaction, in shaping junior doctors' preferences for clinical practice in South Korea. Current policy efforts to direct more junior doctors into rural provinces and "essential" specialties should take these factors into account. This includes addressing physicians' legal liability concerns at the national,

community, and institutional levels, as well as ensuring professional job satisfaction in both “essential” specialties and rural areas.

Ind-189 Estimating the Cost of Attracting Medical Graduates to Primary Health Care Positions in China: A Discrete Choice Experiment

PRESENTER: **Dan Wang**
AUTHORS: Hongbin Wu, Yu Yang

Background:

The development of primary health care is crucial for achieving universal health coverage. However, positions in primary health care, especially in rural areas, are often not the first choice for medical students. Enhancing the attractiveness of these positions to secure high-quality talent is of great significance.

Objective:

To understand the trade-offs and considerations in medical students' employment choices, calculate the cost of attracting them to primary health care settings, particularly in rural areas, and analyze the correlation between attraction cost and students' performance.

Methodology:

A discrete choice experiment was conducted as part of the 2024 China Medical Student Survey (CMSS). The study involved 11,618 final-year clinical medicine students. The experiment explored students' preferences and willingness to pay (WTP) for job characteristics including hospital level, cash incentives, career development support, years of service, and staffing status. Using a specific regression analysis method, we calculated the WTP for each job characteristic in terms of annual salary. By combining these findings with the actual employment destinations of medical students, we estimated the cost required to attract students with different employment preferences. Furthermore, we analyzed the correlation between the cost of attraction and students' performance.

Results:

All selected job attributes significantly influenced medical students' career choices. Students exhibited a high willingness to pay for staffing status (WTP = 44,820 RMB). Under equivalent conditions, township health centers need to offer an additional annual salary of 38,840 RMB to be as attractive as urban primary health service centers; an additional 35,030 RMB to match the attractiveness of secondary hospitals; and an additional 63,420 RMB to be as attractive as tertiary hospitals. Compared to students from urban areas, students from rural areas had higher preferences for cash incentives, transfer support, and staffing status. For these students, township health centers can offer relatively lower salaries to achieve the same attractiveness as urban hospitals. The cost of attracting medical students to primary health care positions, especially in rural areas, was positively correlated with their performance.

Conclusions and Implications:

Understanding medical students' preferences and willingness to pay for job characteristics can help policymakers design more effective incentives to attract high-quality medical graduates to primary health care positions, particularly in rural areas. The comprehensive application of these methods can positively impact the increase of human resources in primary health care, thereby promoting its development and contributing to universal health coverage.

Ind-2740 Motivating Social Workers for Smoking Cessation: A Discrete Choice Experiment in Urban China

PRESENTER: **Fengyi Sun**
AUTHORS: Zhan Zhao, Can Wang, Jixuan Wang, Jialong Tan, Jian Wang

Background Motivating social workers supporting smoking cessation is critical to enhancing the effectiveness of interventions aimed at reducing smoking prevalence and preventing relapse. Social workers, many of whom are volunteers, are instrumental in providing social support to disadvantaged groups, who often exhibit higher smoking rates and face significant barriers to quitting. Their role extends beyond traditional healthcare interventions, as they act as vital links between communities and public health initiatives. Despite their importance, China currently lacks sufficient grassroots smoking cessation programs and robust mechanisms to support social workers in this field. Existing programs are often fragmented, underfunded, and fail to provide the necessary incentives to sustain social worker engagement. This gap hinders the potential impact of community-based interventions and underscores the urgent need for strategies to effectively incentivize and empower social workers supporting smoking cessation. - **Objectives and Methods** This study aims to identify the key motivational factors influencing the participation of smoking cessation social workers in volunteer activities. A discrete choice experiment (DCE) was conducted among 227 smoking cessation social workers in District F of City B, China. Participants ranged in age from 18 to 68 years and represented diverse backgrounds, including students, healthcare physicians, retirees, and others. Using a validated smoking cessation knowledge questionnaire, we assessed their knowledge of smoking cessation, attitudes toward social work activities, and perceived self-efficacy. During the experiment, each social worker completed nine choice tasks, selecting between two hypothetical activities characterized by differing incentive structures, including monetary and non-monetary incentives, activity requirements, and location flexibility. These attributes were determined through literature research and expert interviews. Data were analyzed using mixed logit model and latent class model to understand preferences and heterogeneity among participants. - **Results** The mixed logit (MXL) analysis revealed that non-monetary incentives, such as *honorary recognition* and *opportunities for personal development*, were the most valued motivational factors. These incentives were as attractive as providing a transportation subsidy of approximately RMB 30 (USD 4.2) per activity. Conversely, mandatory participation requirements, such as minimum quotas for persuading smokers, significantly reduced willingness to engage. Activities held at flexible locations, including outdoor settings, were particularly appealing. Surprisingly, financial bonuses did not have a statistically significant effect on participation. Furthermore,

the latent class model (LCM) indicated that social workers with positive attitudes toward smoking cessation and higher self-efficacy preferred activities emphasizing recognition and skill development opportunities. - **Conclusions** The findings highlight the importance of leveraging non-monetary incentives, such as recognition and learning opportunities, to attract and retain social workers from the urban communities. These strategies align with the intrinsic motivations of social workers and foster a sustainable approach to strengthening smoking cessation interventions. Policymakers should prioritize designing programs that not only enhance social workers' skills and sense of accomplishment but also address structural barriers to their participation. By addressing these motivational needs, this approach provides a practical pathway for reducing smoking rates and improving public health outcomes in China.

Ind-1792 Preferences of Public Sector Doctors, Nurses and Rehabilitation Therapists for Multiple Job Holding Regulation: a Discrete Choice Experiment.

PRESENTER: **Busisiwe Matiwane**, University of the Witwatersrand
AUTHORS: Duane Blaauw, Laetitia Rispel

Background: Multiple job holding (MJH), or dual practice, of health professionals can impact healthcare both positively and negatively. This has resulted in a range of regulatory approaches in different countries, from having no restrictions to an outright ban. In South Africa, MJH is legally permissible, albeit with clear stipulations. The effectiveness of MJH regulation depends on the behavioural responses of different groups of health professionals but little is known about their preferences and likely reactions. **Aim:** Investigate the preferences of public sector doctors, nurses, and rehabilitation therapists in two South African provinces for different MJH regulations. **Methods:** We developed a novel discrete choice experiment (DCE) to evaluate the preferences of health professionals for jobs with varying MJH policy interventions. The DCE attributes included *restrictive* regulations (banning MJH) versus *reward-oriented* policies (increased public sector salaries, expanded overtime, well-resourced clinical practice environment, and better management). We produced an unlabelled DCE using an efficient design and administered it to doctors, nurses and rehabilitation therapists in public sector hospitals in two South African provinces. Each participant completed nine choice tasks, selecting between two hypothetical public sector jobs, offering different combinations of MJH incentives and restrictions. Generalized multinomial logit (G-MNL) models were used for analysis. Preference heterogeneity between professional groups and by MJH status were tested in interaction models. **Results:** Overall, 1387 participants from 29 public sector hospitals across two provinces completed the DCE in 2022, comprising 484 doctors (34.9%), 565 nurses (40.7%), and 338 rehabilitation therapists (24.4%). Doctors, nurses, and rehabilitation therapists were strongly opposed to banning MJH, requiring salary increases of 45.7%, 20.0%, and 42.8%, respectively, to accept a ban. Increased public sector salaries significantly improved retention. Non-financial incentives were also influential, with doctors, nurses, and rehabilitation therapists willing to forgo 57.9%, 54.8%, and 38.9% of their salaries, respectively, for an improved clinical practice environment. Competent hospital management was slightly less important. The DCE suggests that a ban on MJH could be offset by increased salaries or a well-resourced clinical environment, though overtime or better hospital management would need to be combined with other incentives. Some preference heterogeneity was confirmed; nurses had significantly different preferences compared to doctors and rehabilitation therapists, being less interested in part-time work and overtime and instead prioritising salary increases and the clinical practice environment. Health professionals engaged in MJH were more opposed to a ban and placed less importance on salary increases and the clinical environment compared to their non-MJH counterparts. **Conclusions:** The study confirms the preferences of three health professional groups for MJH regulatory interventions and the role of non-financial factors in MJH decision-making. Improving public sector working conditions and hospital management could boost retention, even if MJH is restricted. Such information is useful in the design and tailoring of MJH regulation, particularly in low- and middle-income countries (LMICs). The findings can guide the revision of MJH legislation in South Africa and inform MJH regulation design in other LMICs.

Ind-2769 How Does Heat Impact Healthcare Workers Performance and Quality of Care in Labour and Delivery Units? A Cross-Country Study Using Time-Motion

PRESENTER: **Nasser Fardousi**
AUTHORS: Elizabeth Dangaiso, Thabani Muronzie, Shobna Sawry, Veronique Filipi, Nondumiso Mbatha, Isabelle Lange, Giorgia Gon, Mbalenhle Mvundla, Bongani Mutimutema

Background:

Healthcare workers (HCWs) experiencing elevated temperatures in healthcare settings often suffer from thirst, excessive sweating, and fatigue, which can impair their focus. In resource-limited settings, healthcare is often underprepared for extreme heat events. Assessing the performance of HCWs under heat stress is crucial for improving service delivery and enhancing healthcare systems' resilience to climate change. This study aims to evaluate the effects of heat on midwives' performance and quality of care in labour wards in two hospitals in Zimbabwe and South Africa.

Method:

In both countries, we collected data on HCWs' performance during hot and cold seasons. We developed a specialised time-motion data collection tool to capture tasks performed by midwives and the time required to complete them during labour and childbirth. Data collection occurred in labour wards in Mt Darwin Hospital in Zimbabwe between Oct-2023 and Jul-2024, while data from South Africa were collected between Feb-2024 and Sep-2024 in Mamelodi Hospital.

To investigate the quality of care, we used guidance from the World Health Organisation on the quality of maternal care to define our indicators. More specifically, we measured performance indicators covering the provision of evidence-based practices(e.g. occurrence of skin-to-skin, rate of completion of essential practices), practices to promote a positive care experience (explaining the procedure, taking the mother's permission, the proportion of time a pregnant woman was left alone during labour), and service efficiency (break's length and frequency). The two-meter air temperature data derived from the ECMWF Reanalysis data (ERA-5) were used for our exposure variable. We will estimate the effect of heat

using mixed-effect models, clustering sessions by midwives' IDs while accounting for workload, staffing levels, and complications.

Results

We collected data from 249 sessions in Zimbabwe and 241 sessions in SA. The median session length in the Zimbabwean hospital was 33.52 minutes [IQR 23.32-49.20] and 52.53 [IQR 31.54-95.22] in SA. Most sessions were observed in the morning shift (194 (80.50%) in SA; 128 (51.41%) in Zimbabwe), with no sessions observed at night in SA. Delivery complications were observed in approximately a quarter of the sessions in each country. The analysis is underway, and results will be presented at the conference.

Conclusion

This study represents a first-time example of using of the time-motion method to assess the impact of heat on HCW service delivery and quality of care during childbirth. The findings will guide adaptation interventions at the facility level and larger initiatives aimed at enhancing health system climate resilience in Zimbabwe, South Africa, and other regions.

abs-os661 Effect of Cost-Sharing On Buprenorphine Prescription Dispensing: Evidence From a Regression Discontinuity Analysis

PRESENTER: **Thuy Nguyen**

AUTHORS: Kao-Ping Chua, Amy Bohnert, Rena Conti, Ushapoorna Nuliyalu

Increasing access to buprenorphine could slow the U.S. opioid epidemic. Whether cost-sharing impedes buprenorphine dispensing is unclear, as prior studies on this topic have used cross-sectional designs.

We analyzed the 2021-2022 IQVIA Formulary Impact Analyzer, which reports pharmacy transactions for 63% of prescriptions from U.S. pharmacies. The database includes claims (transaction records) for prescriptions regardless of whether they are filled by patients. Analyses included claims for immediate-release buprenorphine among commercially insured and Medicare patients within 60 days of January 1, 2022. Using a regression discontinuity design, we estimated the effect of cost-sharing per 30-day supply on abandonment by comparing discontinuities in cost-sharing and abandonment on January 1, 2022, exploiting the fact that deductibles typically reset at the beginning of the year. We used nonparametric local polynomial estimations to evaluate abrupt changes in cost-sharing and abandonment on January 1, 2022.

Analyses included 674,249 and 362,748 claims among commercially insured and Medicare patients, respectively. On January 1, 2022, mean cost-sharing increased by $13.4 (95% CI: $12.2, $14.5) and $7.0 (95% CI: $6.0, $7.9), respectively, but abandonment did not change (commercial: -0.1 percentage points, 95% CI: -0.3, 0.1; Medicare: 0.2 percentage points, 95% CI: -0.02, 0.5). Estimates suggest a $10 increase in cost-sharing per 30-day supply of buprenorphine would be associated with no change in the probability of abandonment among commercially insured patients (-0.1 percentage points, 95% CI: -0.2, 0.1) and with a 0.3 (95% CI: 0.02, 0.6) percentage-point increase in the probability of abandonment among Medicare patients. To explore potential variation in the effect of cost-sharing on prescription abandonment, we repeated analyses among the following subgroups: (1) prescription claims for patients in demographic subgroups defined by sex, age group, and Census region of residence; (2) prescription claims for patients who did or did not have a dispensed prescription for buprenorphine in the 180 days prior to the claim date; and (3) prescription claims for each of the 5 types of buprenorphine products. Among claims for commercially insured and Medicare patients, the estimate for the two-stage least squares analysis was significant only for 1 and 3 subgroup analyses, respectively. Point estimates in the subgroup analyses were small, ranging from -1.3 percentage points to 0.6 percentage points.

The findings of this regression discontinuity analysis suggest that cost-sharing may not be an important factor in whether privately insured and Medicare patients decide to fill buprenorphine prescriptions. Thus, any efforts to decrease buprenorphine cost-sharing should be coupled with interventions that address other, more important barriers to buprenorphine use.

abs-os660 Racial and Ethnic Disparities in Substance Use Disorder Treatment and Harm Reduction Services: Findings From the VOICES Survey

PRESENTER: **Jason Brian Gibbons**

AUTHORS: Sachini Bandara, Benjamin Lê Cook, Brendan Saloner

Objective: Quantify racial and ethnic disparities in harm reduction and SUD treatment use among people who use drugs and compare estimates using a disparities measurement method aligned with the Institute of Medicine (IOM) definition of disparities against other regression approaches.

Study Setting & Design: 45-minute telephone survey of people who use drugs administered from January 2023-August 2024 across four US States (i.e., Milwaukee County, Wisconsin; Flint/Detroit, Michigan; statewide in New Jersey; and Bernalillo County, New Mexico). Service use disparities were estimated using propensity score models with rank-replace methods and compared against logistic regression models.

Data Sources & Analytic Sample: Survey response data from 1,651 respondents who identified as White non-Hispanic (N=572), Black non-Hispanic (N=479), Hispanic (N=453), or American Indian/Alaska Native (N=147) and had used drugs in the past 30 days. Exposures included respondent demographics, health status, social determinants of health, and race/ethnicity. Outcomes included use of any harm reduction services, fentanyl test strip use, naloxone possession, any substance use disorder (SUD) treatment use, and receipt of buprenorphine, methadone, or naloxone in the past 30-days.

Principal Findings: Compared to White non-Hispanic (NH) respondents, Black NH respondents were 15.5 to 19.8 percentage points less likely to use harm reduction services and 7.6 to 9.2 points less likely to use SUD treatment. They also had significantly lower naloxone possession rates (19.8 to 21.7 points) and fentanyl test strip use (12.4 to 13.7 points). Hispanic respondents were 5.6 to 5.0 points less likely to use fentanyl test strips and had a 12.4 to 11.7 point lower likelihood of any SUD treatment. Disparities were also found among American Indian/Alaska Native respondents, particularly in SUD treatment (8.5 to 10.0 points).

Conclusion: Racial and ethnic disparities in harm reduction and treatment necessitate policy reform. Social determinants adjustment should be performed carefully to prevent underestimating health inequities.

abs-os659 Sociodemographic Profile and Rehabilitation Experiences of Drug Treatment Patients in LMIC: Findings From Facility and Patient Surveys

PRESENTER: **Firman Witoelar**
AUTHORS: Lisa Cameron, Jenny Williams

To address the growing challenge of substance abuse, in 2015, the Indonesian government launched a large scale, publicly funded, drug rehabilitation program that provides treatment to dependent drug users. In 2019, the National Narcotics Agency (Badan Narkotika Nasional, BNN), the main provider of the rehabilitation programs, operated more than 50 inpatient and outpatient rehabilitation centres around the country.

The study leverages the administrative information from BNN's administrative system by combining it with (1) longitudinal survey data on individuals who have undergone drug treatment at BNN facilities, who were surveyed during and after their treatment, and (2) survey information from the outpatient and inpatient drug rehabilitation programs offered at each facility, to gain insights into the rehabilitation process and rehabilitation experiences of the patients in the program. To complement these surveys, we also conducted facility and patient surveys in 5 community-based rehabilitation centres which offer different treatment programs than BNN facilities.

While basic information about the patients' demographic profile, assessment of addiction severity, and patterns of drug use are available from BNN's administrative data base, no detailed information are available on the patients' experiences in the program.

In the facility survey, we visited 12 largest BNN facility to collect information on the characteristics of treatment provided at each facility, as well as the training and qualifications and other characteristics of staff providing treatment. In the patient survey, we randomly selected patients who were undergoing rehabilitation in the 12 facilities and interview them for the first time during the rehabilitation and again a few months after they completed the treatment. We use the survey to look at individuals' economic lives and contextual information before and after treatment, external supports received during the treatment, the nature of their entry into drug treatment, and what they think about their rehabilitation experience.

By combining the findings from the patient survey, which in terms of sociodemographic characteristics broadly representative of the patients listed in the BNN administrative data base, with the facility survey, we are able to account for differences in treatment regime across locations as well as within locations and across inpatient and outpatient care. In turn, this help increase our understanding of the aspects of treatment that are associated with better post-treatment outcomes and experiences.

abs-os292 Assessing Drivers of Health Care Spending Growth for 50 US States, 2010-2019

PRESENTER: **Joseph Dieleman**, University of Washington
AUTHORS: John W Scott, Sawyer Crosby, Maitreyi Sahu, Haley Kathryn Lescinsky, Meera Beauchamp, Max Weil, Drew DeJarnatt, Azalea Thomson, Kayla Taylor

Background: While US health care spending is more than any other country in per capita terms and is growing, there is substantial variation in spending and growth rates across the 50 US states. The state of Utah spends close to a third as much per person as the state of Alaska, while between 1991 and 2020 Florida had personal health spending increase by 336% and Vermont grew 548%. In this study we focus on this within-country, cross-state variation in health spending growth and assess drivers of different growth rates.

Methods: Data for four key drivers of spending per capita – (i) population age, (ii) disease prevalence, (iii) service utilization, and (iv) price and intensity of care – were extracted for t0 US states, 148 health conditions, 38 age-sex groups, four payers, and seven types of care for 2010-2019 from the University of Washington's Disease Expenditure Project. Service utilization was measured as service volume per prevalent case, while price and intensity was measured as spending per visit, admission, or prescription. We used demographic decomposition methods (ie Das Gupta decomposition) to estimate the contribution of each factor to per capita spending growth. We used linear regression to assess what policies and health system characteristics were associated with spending growth caused by increases in utilization and price and intensity.

Results: Our initial estimates show that across all types of care and all states, population aging and increases in price and intensity of care contributed to additional health care spending. When aggregating across all 148 health conditions, changes in disease prevalence had a marginal impact on spending growth as decreases in disease prevalence of key cardiovascular diseases overpowered the impact of increases in diseases prevalence for key diseases such as type 2 diabetes in most states. Increases in outpatient visits per prevalent case led to increases in health care spending on ambulatory care in most states. These increases in utilization, plus increases in price and intensity of ambulatory care led ambulatory care to contribute the most to increases in health spending in all states. Hospital inpatient admissions per prevalent case deceased in most states, as care was substituted away from inpatient care, but the increases in the price and intensity of hospital inpatient care more than made up for those declines in spending. Finally, Medicaid expansion was associated with more service utilization in ambulatory care, while hospital market and insurance market concentrations were associated with larger increases in price and intensity of care.

Conclusions: Across all 50 states, increases in price and intensity of care was the primary driver in increases of spending, across most types of care. For ambulatory care, service utilization also contributed to increases in spending rates. Key factors associated with increases in price and intensity of care were hospital market concentration, insurance market concentration, hospital bed density, and the supply of health services. Understanding the drivers of spending variation in the US can help policymakers reduce or at least maintain US health care spending in the future. **

abs-os213 Decomposing Health Expenditure Growth into Price and Volume across Countries

PRESENTER: **Luca Lorenzoni**
AUTHORS: Jon Cylus, Irene Papanicolas

Aims: To explore the approaches currently used to deflate health spending for international comparisons and examine the feasibility and implications of using alternative health price deflators which can be constructed from available international expenditure data.

Methods: We identified five countries that produce national price deflators specific to health care: Australia, Canada, France, the Netherlands, and the U.S., and obtained time series of health price indices from the respective national agencies in each of these countries for the years 2000-2020. Secondary data on health expenditure were extracted from international and national agencies spanning the years 2000-2020. International price indices specific for health were constructed using available international expenditure data and compared to existing health specific national and general international price indices.

Key Results: We find meaningful variation across countries in the rate at which health prices grow relative to general prices. The U.S. had the highest cumulative health price growth compared to general price growth over the years 2000-2020 at 14%, followed by Canada and the Netherlands. Unlike the other study countries, health prices in France grew consistently in line with general prices. Price growth for health care paid for by public funds and households grew at different rates across countries, where price growth was higher for public payers. U.S. households faced the greatest mean annual price growth. For all countries, the use of a general price index suggests greater volume growth, and a lower contribution of price growth, to overall health expenditures as compared to the health specific deflators. The results obtained using the health-specific consumption-based deflator are more closely in line with the results obtained using the national health-specific deflators, except in the case of France where the results were similar across all price indices.

Conclusions: The choice of price index has major implications for comparative analysis. Despite their widespread use internationally, general price indices likely underestimate the contribution of price growth to overall health expenditure growth. We find that in addition to its reputation for having high health price levels compared to other high-income countries, the U.S. also faces health price growth for goods and services paid for by government and households in excess of general price growth. Furthermore, U.S. households are exposed to greater health price growth than households in comparator countries.

Ind-2728 Healthcare Labor Trends and Health Care Spending Growth in OECD Countries

PRESENTER: **Melinda Buntin**
AUTHORS: Jonathan Staloff, Ms. Bianca Frogner

Background/Aims: A marked slowdown in the rate of growth of health care spending as a share of gross domestic product (GDP) has been observed in the US and in Organization for Economic Cooperation and Development (OECD) countries over the past 15-20 years except for a brief surge during the first peak of the pandemic. This slowdown has been noted across different demographic groups, payer types, and types of care. While other studies have focused on demand side factors contributing to health spending trends, this study investigates how supply factors relate to these trends. Specifically, we examine the extent to which growth in healthcare labor explains health spending growth slowdown across countries.

Methods: We used the 2023 OECD Health Statistics to extract total healthcare spending and total healthcare employment between 2000 and 2022 for the US, Australia, Canada, and the UK. We examined health spending trends as a share of GDP and per capita as well as total healthcare employment as a share of total employment and per capita. We compared regression models fitted separately on health spending and labor trends. We also examined correlations between health spending and labor trends. We examined trends including and excluding significant changes in health spending and labor in 2020 due to the pandemic.

Key Results: Preliminary findings show a high correlation (R2>90%) between health spending and healthcare employment across all countries except the UK where the correlation was 80.2%. Healthcare employment increased across all countries as a percent of total employment and per capita at the beginning and end of the study period were similar across countries. Healthcare employment ranged from about 10.0% to 10.5% of GDP (or 46 to 52 workers per 1,000 pop) in 2000 to 12.5% to 13.5% (or 61 to 64 workers per 1,000 pop) in 2022. Each country had a significant change in slope in the late 2000s. These trends were apparent when expressed both as a percent or as per capita. In general, we find that, putting aside the pandemic period, labor growth rate in the US, Australia, Canada and the UK were similar.

Conclusions/Implications: Healthcare labor growth is slowing across countries and healthcare spending across countries is strongly related to the growth of healthcare labor. Being a service industry heavily reliant on labor, healthcare competes with other industries for labor, particularly low wage workers, that may constrain growth in labor and hence healthcare spending. In the US, higher health spending compared to other countries does not appear to be driven by more labor but rather higher wages. Recognizing this constraint is important for policymakers as countries project the trajectory of healthcare spending in the future.

abs-os555 Career Duration in General Practice: Results From a Complete Nationwide Panel of General Practitioners in Norway (2002-2021)

PRESENTER: **Mr. Geir Godager**, Universitetet i Oslo
AUTHORS: Yvind Snilsberg, Johannes Bjørnstad Tyrihjell

Abstract **Background:** General practitioner (GP) resignations have been suspected to contribute to the capacity challenges that are facing Norway's GP scheme. Understanding trends in exit rates and identifying any systematic changes over time are critical for informing health policy and addressing capacity issues. **Aim:** This study aims to describe trends in age-specific exit rates for GPs and examine whether there are systematic changes in these rates over time. By analyzing a comprehensive nationwide panel spanning two decades, we seek to clarify whether the observed increase in GP exits reflects fundamental changes in GPs' exit behavior or simply demographic shifts. **Data and Methods:** This registry-based observational study covers all GPs practicing in Norway since the scheme's implementation in 2001, using data from the FLO register maintained by the Directorate of Health. The dataset includes quarterly observations from 2001 to 2023, encompassing 8,943 physicians with municipal contracts, of whom 4,238 ended their careers as GPs. Our data enable us to distinguish between exiting the profession from relocating the practice or taking temporary leave. To classify as an *exit*, a GP must discontinue all GP contracts and remain inactive for more than eight consecutive quarters. Overall and annual exit rates were calculated, stratified by GP age. To identify exit rates significantly differing from expected levels, Clopper-Pearson confidence intervals (CIs) were constructed, and Bonferroni correction was applied to account for multiple hypothesis testing. Survival curves were also used to visualize exit rates over time. **Key Results:** Our analysis revealed that exit rates decline as GPs approach 50 years of age and remain consistently low until around age 67, when they increase markedly as GPs near typical retirement age. This structure is reflected in annual exit rates, which have remained stable over time, contradicting claims of recent surges in GP exits. Only two cases of unexpected exit rates were found: for 41-year-olds in 2010 and for 67-year-olds in 2007. Overall, the number of observed GP exits closely aligns with expected counts based on historical data from 2002 to 2021. **Conclusions and Implications:** The findings suggest that age-specific exit rates have remained stable over the two-decade study period, implying that increases in exit rates are not a significant factor contributing to recent capacity challenges in Norway's GP scheme. Consequently, recruitment and retention strategies should focus on other aspects of the GP workforce dynamic. The study underscores the importance of using historical exit rates to make accurate predictions for future GP exits, thereby better informing policy and planning. Given the stability of exit rates,

policymakers can reliably use historical data to forecast future GP workforce needs and implement proactive measures to sustain healthcare capacity. Future research should explore physician exit propensity in other parts of the healthcare sector to validate the findings' generalizability.

abs-os576 Continuity and Switching in Primary Care

PRESENTER: **Mr. Tor Iversen**, Universitetet i Oslo
AUTHORS: Øyvind Snilsberg, Anne Karen Jenum, Yuting Zhang

This paper examines how continuity and discontinuity in patient-GP relationships relate to the provision of guideline-recommended healthcare services, focusing on patients with type 2 diabetes (T2D) in Norway. Using nationwide registry data from 2018 to 2023, we analyse how relationship duration and switching to a higher-performing GP are associated with the provision of recommended services. Consistent with previous research, we find that longer relationships with the same GP are associated with higher provision rates, with progressively stronger associations beyond 10 years. We also find that switching to a higher-performing GP is linked to an increased likelihood of receiving recommended care. By comparing estimates from the two analyses, we show that, in some cases, switching to a high-performing GP may be associated with greater improvements than extended continuity. These findings highlight the importance of both long-term GP-patient relationships and GP-level differences in the delivery of care. While policy efforts often emphasize continuity, our findings suggest that switching can also be beneficial when it involves a move to a higher-performing GP, indicating policies supporting informed switching as a way to improve care.

abs-os563 Hypothetical Bias in Patient-Regarding Preferences: Comparing Fully Incentivized and Conventional Stated Preference Experiments

PRESENTER: **Ms. Fan Yang**, Norwegian University of Science and Technology
AUTHORS: Arne Risa Hole, Ge Ge, Jian Wang, Mr. Geir Godager

Abstract:

Background: Preference elicitation studies applying stated preference data have faced criticism for the potential presence of hypothetical bias, a discrepancy between hypothetical valuations and actual, or “true” valuations. While various studies have sought to mitigate hypothetical bias, the origins and mechanisms remain poorly understood. This study examines hypothetical bias within the context of experiments used to elicit patient-regarding preferences.

Aim: The primary aim of this research is to test for the presence of hypothetical bias in patient-regarding preferences. Specifically, we investigate whether hypothetical bias exists in physicians' evaluations of the benefits of medical treatments for their patients and the consumption opportunities available to their patients.

Data and Methods: We conducted two different laboratory experiments to elicit medical students’ patient-regarding preferences both with- and without financial incentives. By replicating incentivized laboratory experiments in a non-incentivized setting, we isolated the impact of hypothetical bias. Data were collected from a sample of medical students, who participated in either fully incentivized economic experiment with real monetary incentives for each attribute, or a conventional Discrete Choice Experiment with hypothetical framing. We fitted scaled multinomial logit models to quantify the preference- and scale parameters in both the incentivized and hypothetical arms of the study.

Key Results: The results indicate that, as anticipated, the relative valuation of real money was higher than that of hypothetical money; participants consistently showed greater generosity in the hypothetical setting than in the incentivized choice experiment. However, we found that the relative valuation of patient benefit and patient consumption by medical students remained unaffected by whether data was collected in a purely hypothetical setting or a fully incentivized choice experiment. Surprisingly, there was no statistically significant difference in the scale parameter between the arms, meaning that the participants in in the two arms did not differ significantly in their *degree of randomness in behavior.* This finding suggests that participants in the hypothetically framed experiment conducted their tasks with as much careful diligence as those in the fully incentivized experiment.

Conclusions and Implications: The findings of this study have substantial implications for health economics research and health policy. The absence of hypothetical bias in the relative valuation of patient benefit and patient consumption introduces an interesting nuance to previous findings. Our results align with the hypothesis proposed by Johansson-Stenman et al that behaviors indicative of desirable personality traits, such as generosity and moral identity, become more pronounced in hypothetical scenarios where real financial costs are absent. Future research should extend these findings to other parts of the health care sector to validate the generalizability of these results. Preregistration of future experiments on hypothetical bias could enhance the scientific impact of these findings.

abs-os547 Impact of Remuneration Scheme on General Practitioners' Antibiotic Prescribing Practices for Respiratory Tract Infections

PRESENTER: **Ms. Yana Zykova**

** **Abstract:** While careful use of antibiotics is crucial to reduce growth in antibiotic resistance, there is widespread prescribing of antibiotics even when their effect is minimal or nonexistent. This is especially relevant for respiratory tract infections (RTIs) in primary care. Antibiotic prescriptions might be valued by patients and perceived as an indicator of quality. We hypothesize that, compared to a fixed salary, the GP remuneration scheme based on the number of provided services (fee-for-service (FFS)) and the number of registered patients (capitation (CAP)) may motivate GPs to prescribe antibiotics for RTIs more often because it allows keeping patients on the list, attracting new patients, and saving time by avoiding discussions and finding alternative solutions with the patient. To our knowledge, there is only one study about the effect of the GP remuneration scheme on antibiotic prescription behaviour. Hutchinson and Foley (1999) found that in 1996 in Newfoundland,

Canada, GPs paid by FFS, compared to their salaried counterparts, prescribed more antibiotics per unique patient receiving antibiotic treatment than their salaried colleagues. However, the study design could not account for the frequency of infections among patients and cases when a GP abstained from antibiotic treatment. In our paper, we study a link between the GP remuneration type and the likelihood of antibiotic prescription during patient contacts with RTI. We compare FFS and a mix of FFS and CAP with a fixed salary. We also study whether GPs choose broad- or narrow-spectrum antibiotics when providing antibiotic treatment. Broad-spectrum antibiotics increase the chance of treating an infection from the first attempt (which patients may consider a quality of care mark) but contribute much more to the development of antibiotic resistance since they kill a wider range of bacteria species. We use data on all antibiotic prescriptions in Norway made by GPs in the period 2015-2019 combined with data on patient contacts with the GPs for RTIs and other relevant information about patients and GPs from several nationwide registers. The analysis of regular GPs allows for comparing GPs paid by fixed salary and a mix of FFS and CAP, while the analysis of locum GPs allows for the study of the difference between fixed salary and FFS. We use a linear probability model and show that the results are robust using logit and probit models. We find that the probability of antibiotic prescription for RTI for GPs remunerated by FFS and CAP was, in relative terms, 13-15% higher than for salaried GPs. When antibiotics are prescribed, GPs paid by FFS and CAP had an 10-11% higher probability of prescribing a broader-spectrum antibiotic. The findings are consistent when analysing within-subject effects on the subset of GPs switching remuneration types. We did not find any significant difference between FFS and fixed salary. Our findings suggest that it is important to provide GPs with incentives to follow guidelines for antibiotic prescriptions, especially when the share of contracts based on CAP and FFS is high.

abs-os594 Expenditures Tracking for Sexual and Reproductive Health Care and Rights in the African Region: Insights from the System for Health Account 2011.

PRESENTER: **Sophie Faye**, Abt Associates
AUTHORS: Sabine Musange Furere, Hapsa Toure, Maria Aranguren, Ogochukwu Chukwujekwu, Ke Xu

Background: Sexual and Reproductive Health care and Rights (SRHR) is integral to realizing Universal Health Coverage (UHC) and is enshrined in the Sustainable Development Goals (SDGs).

Universal access to SRHR is particularly important in Africa where the population is dominated by the youth. Significant progress has been made in the continent towards the realization of SRHR. In the last 30 years voluntary use of modern methods of contraception has increased by nearly three times. Maternal mortality has declined by over 60% and a significantly higher number of young people are able to access age-appropriate comprehensive sexuality education. Despite progress, the promise of health for all remains to be fulfilled for millions in the region. One in five women's need for family planning remains unmet. Maternal mortality remains unacceptably high. Gender-based violence and the prevalence of other harmful practices is widespread. At the current pace of progress, SDG target 3.7 on ensuring universal access to SRHR will not be met by the region.

One of the major concerns to accelerating progress towards universal SRHR, is the lack of adequate and sustainable financing for health in general and SRHR in particular. The volume and flows of financial resources for health, including SRHR, in a country is assessed through Health Account (HA). This is mainly done using the System for Health account (SHA) 2011 framework which, can help capture expenditures related to the essential components of SRHR identified in the Guttmacher-Lancet Report's (GLR)1 .

Research Aim: This research uses the SHA framework to accurately measure how much currently goes into financing SRHR to be able to make the case for mobilizing more money, but also using the current funds more efficiently.

Methods: This research reviews the SHA 2011 classifications to identify where spending related to the nine essential components of SRHR identified in the GLR is captured, and highlights any missing elements. This will then guide the proposal of a *Measure of Current SRHR spending* using the existing SHA 2011 classification and suggest specific codes to more accurately classify SRHR expenditures.

Preliminary results: The results highlight the lack of disaggregation in the spending, especially for maternal conditions and the absence of information on counselling and education expenditures. The proposed measure of current spending on SRHR, aggregating different SHA 2011 codes identified as representing aspects of the nine interventions in the GLR, highlights important variations in the African region.

Conclusions and Implications: Estimates and findings from this study are relevant for policymakers, researchers, and organizations involved in advancing SRHR as they can be used for evidence-based advocacy and increased resource mobilization.

abs-os601 Health Accounts and National AIDS Spending Assessments: Optimizing Alignment and Divergence

PRESENTER: **Deepak Mattur**
AUTHORS: Hapsa Toure, Maria Aranguren, Ogochukwu Chukwujekwu, Ms. Teresa Guthrie, Sophie Faye, Ke Xu

Background: Over 60 countries have produced fully disease-disaggregated health spending data using the System of Health Accounts (SHA), and more than 70 have undertaken National AIDS Spending Assessments (NASA). While both frameworks contribute valuable data, they are often conducted independently, raising questions about potential opportunities for synergies and efficiencies. SHA provides a systemic perspective of health spending within the national economy, while NASA focuses on spending data specific to HIV, extending beyond the health sector. Both approaches share common principles, such as the financing triangle—consumption, financing, and provision—and the alignment of spending to calendar/fiscal years. However, NASA's detailed tracking of HIV spending offers granular insights that SHA's broader health spending categories are not equipped to capture.

Research Aim: This paper examines the convergence and divergence between SHA and NASA, exploring how their processes and outcomes can complement each other and serve broader health and HIV expenditure tracking purposes, ultimately strengthening financial information systems, accountability and optimal use of resources.

Methods: The study employs a comparative analysis of SHA and NASA frameworks, data sources, and analytic techniques. It reviews case studies to identify commonalities and divergences in their approaches and outcomes. A detailed “crosswalk” between SHA and NASA classifications is generated to help country teams navigate both frameworks and map their spending lines appropriately.

Key Results: NASA tracks both health and non-health HIV/AIDS spending, including activities in sectors such as education (e.g., school programs on stigma reduction), social protection (e.g., cash benefits for people living with HIV/AIDS), and social development (e.g., empowerment activities). NASA categorizes HIV/AIDS spending along six broad dimensions: financing sources, financing agents, providers, production factors, spending categories, and beneficiaries. All these dimensions align with SHA dimensions, but NASA classifications within some dimensions (e.g., AIDS spending categories—ASCs) can be more detailed than those typically used by HA teams. Harmonizing HA and NASA resource tracking efforts can minimize data collection costs, reduce the reporting burden on implementers of HIV/AIDS programs, and ensure compatibility of HIV/AIDS spending estimates from both exercises. To enhance the utility of both frameworks, data from NASA can be cross walked into SHA classifications, allowing for the inclusion of non-health categories within SHA’s broader health-related functions. This approach ensures cross compatibility of HIV/AIDS expenditure data while maintaining the distinct strengths and focus of both frameworks.

Conclusions and Implications: Integrating SHA and NASA exercises, especially at the data collection stage, can enhance the comprehensiveness and utility of health spending data, supporting better resource allocation and policy-making. Countries can benefit from synchronized data collection and analysis, reducing duplication of efforts and costs. This synergy can provide a more holistic view of health and HIV expenditures spanning multiple sectors, aiding in the achievement of global health targets, strengthened financial information systems and improving the sustainability of health systems.

abs-os588 Progress and Challenges in Institutionalizing Health Accounts in the African Region

PRESENTER: **Ogochukwu Chukwujekwu**
AUTHORS: Maria Aranguren, Ke Xu, Sophie Faye, Hapsa Toure

Background: The institutionalization of Health Accounts (HA) is vital for utilizing health expenditure data to improve health system governance and financing. HA offers detailed insights into health expenditures, which are crucial for policy-making, planning, and resource allocation. Despite its acknowledged importance, the degree of HA institutionalization varies widely across countries. Previous research has emphasized the advantages of institutionalized HA and provided a global perspective on its progress. However, it has yet to identify the factors that could enhance HA institutionalization in the African region, which has been particularly active in producing HA over the past two decades.

Research Aim: This study aims to evaluate the state of HA institutionalization in African countries, identify the influencing factors, and highlight the challenges and facilitators of the institutionalization process.

Methods: The research utilizes a survey-based approach in 32 African countries, applying the HA institutionalization maturity framework developed by WHO. Countries are classified into two groups: those where the government fully funds staff and those where staff are either partially or entirely funded by private or external sources. The research uses the WHO HA Institutionalization index and descriptive statistics to provide insights into the HA institutional characteristics of African countries across different domains (demand, governance and financing, technical capacity, dissemination, and use).

Key Results: The results highlight that in 22 out of 32 African countries, staff are fully funded by the government, while the rest rely on external aid. Even in countries where the government fully funds staff, external sources are critical in funding other activities in the HA production cycle (e.g., data collection and surveys, training, reports, and policy briefs). Countries where staff are fully funded by the government tend to have a formal mandate compared to those where staff are not fully funded. Still, both groups often need more authority and resources to implement these mandates. Additionally, countries with fully funded staff by the government have more HA organizational structures, coordination mechanisms, and routine access to information on various types of health expenditures. Despite having better technical capacity, countries with fully funded staff still need procedures and incentives to maintain institutional knowledge. Countries where government-funded staff perform slightly better in disseminating HA, producing HA reports and relevant policy briefs. In contrast, those with partially or externally funded staff focus mainly on HA reports. However, both groups need to improve the timeliness of HA data production, update their databases annually, and make data more publicly accessible to enhance data quality and promote data use.

Conclusions and Implications: The institutionalization of HA in the African region has yet to be fully country-led, with HA production still

heavily dependent on external partners. This reliance results in significant variations in demand, governance, technical capacity, and dissemination practices. Securing sustainable domestic funding and building local capacity is crucial to address these challenges. Prioritizing HA production in policy agendas, integrating HA into evidence-based policy-making, and enhancing technical capacity through improved staff retention and training are essential steps towards achieving a more self-sufficient and effective HA institutionalization process.

DISCUSSANT: **Zanfina Ademi**, Monash University

abs-os648 A Micro-Costing Analysis of Genomic Newborn Screening in England

PRESENTER: **Martin Vu**

AUTHORS: Melissa Hill, James Buchanan, Celine Lewis

Background

Routine genomic newborn screening (gNBS) could greatly enhance the detection of rare, treatable genetic disorders beyond what the current newborn screening (NBS) programme achieves. This provides opportunities for earlier intervention across many diseases to improve long-term outcomes. Over ten large-scale international prospective studies are currently generating evidence on the utility, feasibility and implementation of gNBS. One such study is the Generation Study, led by Genomics England, which aims to sequence the genomes of 100,000 newborns in England. Cost-effectiveness evidence will play an important role in decision-making regarding whether to roll out gNBS to the wider population, given that sequencing remains a relatively expensive technology compared to the biochemical and PCR-based genetic tests currently used in NBS programmes. It is therefore important to understand the resources and costs of delivering such a population-based screening programme. This study aims to estimate the costs associated with providing gNBS for infants as consented by their parents through the Generation Study compared with the current NBS programme.

Methods

We will present a time-driven activity-based micro-costing analysis of gNBS. The Generation Study protocol and consultations with key designers and implementers will be used to map out the processes, activities and resources consumed (e.g. labour, consumables and equipment) for the delivery of gNBS. Data collection will quantify staff involvement, time spent across different activities and resource usage, through clinical and laboratory staff interviews, trial and laboratory protocols and on-site hospital observations across six different sites across England. Hourly staff salaries will be derived from published salary scales (including those for the English National Health Service), and consumable costs will be determined based on purchasing orders and laboratory fees. Equipment cost calculations will factor in data on lifespan and sample throughput, with a 3.5% discount rate applied over this lifespan. The existing NBS programme costs will be estimated through healthcare professional interviews to assess consent and reporting times, and published literature to determine assay costs for the nine existing conditions screened in the UK. All costs will be expressed in 2024 GBP. Sensitivity analysis will be conducted to assess the impact of varying assumptions related to resource use, unit costs and sample throughput. Additional scenario analyses will consider the costs associated with modifying the current clinical service pathway to include gNBS.

Results

The gNBS workflow, from parent recruitment and consent through to sample collection, sequencing, genomic analysis, result return, and confirmatory testing for suspected infant conditions, has been charted onto a process map. Data collection to assess activity duration, quantities of consumables and equipment used is 60% complete at two sites. It will expand to four more sites in January 2025, with completion anticipated by March 2025.

Conclusions

The results of this micro-costing study will contribute to cost-effectiveness analyses of the use of gNBS in clinical practice in England. Evidence from these analyses will be used by key decision-makers (e.g. the UK National Screening Committee) to decide whether to expand the existing newborn screening programme to identify additional newborns with rare treatable genetic disorders.

abs-os644 Current Challenges and Potential Solutions When Evaluating the Cost-Effectiveness of Genomic Newborn Screening: A Long Road Ahead?

PRESENTER: **James Buchanan**

AUTHORS: Oliver Rivero-Arias, James B Chilcott, Hadley Stevens Smith

Background

Over the past five years there has been a growing interest in the use of genome sequencing to expand the scope of newborn screening programmes around the world. Several exploratory studies are currently exploring the risks and benefits of sequencing the whole genome of newborns at birth, including the Generation Study in England, the BabySeq Project in the USA, and BabyScreen+ in Australia. Many of these studies include a health economic evaluation. Evaluating the cost-effectiveness of genome sequencing in any context is challenging due to various well-documented methodological issues surrounding the measurement of costs and outcomes, uncertainty over the appropriate analytical approach, and weak data on the link between test effectiveness and patient outcomes. These challenges are exacerbated in a newborn context, in particular the measurement of health and non-health outcomes. The health technology assessment landscape for genomic newborn screening (gNBS) can also be complex.

This presentation will outline the challenges associated with evaluating the cost-effectiveness of gNBS. The approach to economic evaluation in the large gNBS studies underway around the world will be compared and contrasted, and potential solutions to some challenges will be proposed.

Methods

The challenges that health economists may face in this context were identified via discussions between the authors, informed by dialogue with screening experts and their experiences designing and evaluating existing newborn screening services. Challenges were grouped into categories that captured broad themes and steps when evaluating gNBS programmes. Information on analyses planned in current large gNBS studies was extracted from published sources.

Results

Six categories of challenges were identified. The first relates to cost-effectiveness modelling. Existing condition-by-condition modelling approaches may no longer be appropriate given that the number of screened disorders may increase from dozens to hundreds. Models also need to accommodate future expansions in gene lists, and uncertain data on gene penetrance and expressivity. A second category relates to evaluating outcomes. Few instruments exist to capture quality-of-life outcomes in newborns, and methods to combine benefits and harms for multiple stakeholders in one economic evaluation are still evolving. Further categories consider analytical scope (e.g. how to incorporate information on benefits across the life-course) and behavioural considerations (e.g. what factors impact on parental uptake). There are also issues surrounding the use of local versus global evidence, and the existence of multiple decision-makers within the same health technology assessment landscape. Key differences were identified across large gNBS studies – including different approaches to identifying a comparator population – that may lead countries and states to form different conclusions regarding the cost-effectiveness of gNBS. Potential solutions to the identified challenges include the development of new outcome instruments for this population, and global efforts to harmonise data collection to inform economic evaluations in this space.

Conclusions

Applying genome sequencing in the context of newborn screening could have a huge impact on health outcomes for newborns around the world. However, generating a robust economic evidence base to support implementation will not be straightforward – there is a long road ahead for health economists.

abs-os653 Discrete Choice Experiments to Inform the Evaluation and Implementation of Genomic Newborn Screening

PRESENTER: **Xiuqin Xiong**
AUTHORS: Riccarda Peters, Zornitza Stark, Ilias Goranitis

Background

Integrating genomic sequencing into newborn screening (NBS) programs provides an opportunity to significantly increase the early identification of rare genetic conditions. Various large-scale projects are underway to assess the feasibility of genomic NBS (gNBS), including BabyScreen+ in Australia. When considering introducing such a screening program at scale, it is crucial to consider societal values and beliefs. Using the example of gNBS, this presentation will focus on how discrete choice experiments (DCEs) can be used for the evaluation and translation of genomic technologies. The results of two discrete-choice experiment surveys will be discussed. The first DCE aimed to elicit the value of gNBS relative to standard NBS from members of the general public to inform an economic evaluation of BabyScreen+ (value DCE). The second DCE focused on preferences for the implementation of a gNBS program (implementation DCE).

Methods

Bayesian D-efficient designs were created. The value DCE employed an explicit partial profile design, whereas the implementation DCE utilised an implicit partial profile design. Data was collected from 1504 and 1005 members of the general public, respectively. The value DCE included six attributes, investigating preferences regarding conditions included in the screening program (severity, penetrance and treatment availability), performance of the screening program (diagnostic yield, accuracy), and cost of gNBS. The second DCE focused on eight attributes related to the implementation of gNBS, such as when and with whom gNBS should first be discussed and how results from gNBS should be returned. Survey data was analysed using a panel error component mixed logit model and a latent class model. Preference heterogeneity was explored using fractional logistic regression.

Results

Statistically significant preferences were identified across all attributes in the value DCE. Participants valued broad inclusion criteria for conditions included in gNBS, favouring screening programs that also provided information about conditions with mild severity, lower penetrance and conditions for which treatments may not be available yet. They further expressed preferences for higher diagnostic yield, accuracy, and lower costs. Preference heterogeneity was identified and associated with some sociodemographic characteristics. Willingness-to-pay estimates on the value of gNBS have been calculated and will be presented. For the implementation DCE participants valued who should provide information about gNBS, what support material should be available, who should return high-chance results and how high- and low-chance results should be returned.

Conclusions

DCEs offer valuable data sources for economic evaluation and decision-making. We demonstrate how DCEs can provide insights into the public's valuation of gNBS programs, including likely uptake and willingness-to-pay for such a service. The findings also highlight the importance of several aspects of service delivery that should be considered for the implementation of gNBS in Australia.

abs-os171 How Does the Hospital Market Respond to Universal Health Insurance?

PRESENTER: **Shin-Yi Chou**

AUTHORS: Hsien-Ming Lien, Chia-Lun Liu, Mary Deilye

Background The implementation of Taiwan’s National Health Insurance (NHI) in 1995 represented a major policy reform aimed at achieving equitable healthcare access and cost containment. While the positive effects of universal health coverage on patient outcomes are well-established, its implications for healthcare supply and market dynamics remain less understood. By altering the financial and regulatory landscape, the NHI reform likely disrupted the existing equilibrium in the hospital sector, prompting shifts in demand, pricing, and hospital operations. **Research Aim** This study investigates the impact of universal health insurance reform on healthcare supply, specifically examining how Taiwan’s NHI influenced the structure of the hospital sector. Additionally, it explores whether changes in market structure affected the quality of care, assessed through medical inputs and patient outcomes. **Methods** We utilize the 1990 census data to construct a measure of the NHI impact, alongside registry files from 1990-2001 and hospital utilization survey data to examine the NHI impact on the hospital market. To isolate the causal effects of these changes on hospital behavior and market structure, we adopt a treatment effect approach, comparing regions with higher pre-reform uninsured rates to those with lower rates. This strategy identifies the differential impacts of NHI-induced shifts in demand and pricing on hospital operations, while accounting for time-invariant regional characteristics and overarching national trends. Using 1990 census data, registry files from 1990-2001, and hospital utilization surveys, we construct a measure of the NHI’s impact on the hospital market. To identify causal effects, a treatment effect approach is employed, comparing regions with higher pre-reform uninsured rates to those with lower rates. This method captures the differential impacts of NHI-induced changes in demand and pricing on hospital behavior, while controlling for time-invariant regional characteristics and broader national trends. **Key results** We find the reform resulted in a significant decrease in the number of hospitals, and that most of those exiting were small hospitals that offered fewer services and employed fewer doctors. Examination of the input choices and utilization rates of individual hospitals shows that large hospitals increased staffing levels and other inputs, and experienced higher utilization rates, while small hospitals did not; instead, many became clinics. **Conclusion** The findings indicate that universal insurance facilitated the growth and expansion of large hospitals, while small hospitals either downsized or exited the market altogether. This highlights how universal health reforms can significantly reshape healthcare supply and market structure. Nonetheless, we do not find evidence showing that the market structure affects the quality of care, either medical input or patient’s outcome.

abs-os203 The Formulary Under the National Health Insurance in Taiwan in 30 Years: Price, Volume, Markup, and New Drugs Adoption

PRESENTER: **Meng-Chi Tang**

This paper uses the complete prescription records for one million Taiwanese patients from 1997 to 2011 and examines the slow drug adoption of newly introduced active ingredients. Our analysis reveals that, on average, these drugs require four to five years to reach substantial adoption across varied therapeutic classes. A mover-based instrumental variable approach exploits physician relocations to identify sizable peer effects: a one-percentage-point increase in peers' prescription rates raises a physician’s probability of prescribing by 0.4 percentage points in ordinary least squares and up to 0.8 with the instrument. We further show that adoption speed is shaped by local hospital settings, patient complexity, and demographic alignment among physicians. At the macro level, markets dominated by clinics exhibit slower diffusion, while academic institutions accelerate uptake. These findings underscore the crucial role of physician networks in accelerating new treatments, highlighting how targeted interventions could improve timely and equitable access to innovative therapies.

abs-os296 Beyond Coverage: Evidence, Equity, and the Need for Transparent Data on Out-of-Pocket Health Expenditures in Taiwan

PRESENTER: **Christy Pu**

Background: Out-of-pocket (OOP) health expenditures represent a critical factor in global health policy as they directly impact financial risk protection, health equity, and access to health-care services. Taiwan's National Health Insurance (NHI) system is internationally regarded for its extensive coverage, serving as a model for universal health care. However, OOP health expenses in Taiwan remain underanalyzed. With constrained reimbursements from NHI, hospitals increasingly rely on OOP payments, which now constitute approximately 25%-40% of their total revenue. A primary challenge within Taiwan is the lack of a standardized international framework, such as the System of Health Accounts (SHA), for systematically analyzing OOP expenditures. **Research Aim:** This presentation provides an overview of Taiwan's OOP expenditures, followed by an empirical analysis of the inequalities associated with these expenditures in the country. **Methods:** We utilized three data sources. First, we employed Taiwan's Household Income and Expenditure Survey to measure the prevalence of catastrophic health expenditures, the concentration index, and the Kakwani index over time. Although informative, this survey does not adjust for private health insurance reimbursements and is not based on the SHA standards. To address these limitations, we included another nationally representative survey, designed according to the SHA framework, to investigate equity issues related to OOP spending in Taiwan. Additionally, we focused on a disadvantaged subgroup—individuals with disabilities—to assess whether they bear a disproportionate financial burden from OOP expenses under NHI. **Key Results:** Our findings, based on the SHA definition, indicate that in 2021, OOP payments accounted for 29.6% of Taiwan's national health expenditure (NHE), with curative care (HC.1) comprising 50.1% of this total. Notably, around 39% of OOP spending is attributed to medical goods (HC.5), including items like wheelchairs, thermometers, and other medical supplies typically uncovered by NHI. This high expenditure on non-covered medical goods highlights a significant gap in NHI coverage that warrants policy consideration. Additionally, long-term care expenses, another contributor to OOP under the SHA framework, are often managed by departments outside of NHI administration. In 2022, Taiwan's Ministry of Health and Welfare reported that the private sector financed 56.7% of total long-term care costs, further demonstrating the extensive reach of OOP expenses beyond direct NHI coverage. Our analysis also indicates that there is a significant number of households facing catastrophic expenditure. Based on the SHA-based survey conducted in 2022, OOP payments are pro-rich but regressive. This means that, in absolute terms, the wealthy incur higher OOP payments. However, lower-income groups bear a disproportionately higher share of these costs relative to their income compared to higher-income groups. Notably, individuals with disabilities, as a disadvantaged group, incur high OOP costs. **Conclusion/policy implication:** Despite the NHI system, OOP healthcare expenditure in Taiwan remain significant. However, OOP expenses may not be directly related to essential curative care. in Taiwan, OOPs can be regressive from the perspective of both income and health status. Special policy consideration should be given to vulnerable populations, including individuals with disabilities. 1

abs-os298 Exploring a Public-Private Partnership Model to Enhance Financial Risk Protection

PRESENTER: **Jui-fen Rachel Lu**, Chang Gung University

Background A primary objective of the National Health Insurance (NHI) system is to provide financial risk protection to individuals seeking medical care. However, limited resources have led to unmet demands for innovative and life-saving treatment options. Since the NHI's establishment, many have opted to purchase supplementary or complementary private insurance to bolster their financial risk protection, driven by increasing real incomes. Unfortunately, existing private insurance policies often fall short in adequately covering the needs of critically ill patients. There are growing indications that out-of-pocket expenses for patients are steadily rising, and the unmet medical needs within the population pose a significant challenge that the NHI must confront effectively. **Research Aim** This study aims to develop a feasibility framework for a public-private partnership (PPP) between the NHI and private insurance to enhance financial risk protection through integrated supplementary private insurance coverage. **Methods** The research commenced with a comprehensive comparative analysis and a systematic literature review, supplemented by consultations with various international experts and scholars. This investigation focused on the role of private insurance in providing financial risk protection through supplementary coverage. Following this, a feasibility framework was developed through several rounds of stakeholder consensus meetings, incorporating insights from global best practices. **Key Results** The proposed feasibility framework builds upon the existing NHI, envisioned as a "second layer" of insurance policy. This structure stipulates that private market medical insurance must align with government policy objectives. In exchange, the government would offer administrative support—including premium collection and standardized claim filing systems—aimed at reducing the administrative burden on private insurers and making premiums more affordable for the general population. Under this PPP model, private insurance would operate as the insurer, following a financial principle of breaking even (no excessive profits). In the initial phase, the model would facilitate open enrollment, allowing all willing Taiwanese participants to join without excluding those with pre-existing conditions, with the government assuming financial risk for these individuals. While insured participants would bear the full cost of their premiums, government subsidies would be available for low-income individuals and other economically disadvantaged groups. Premium rates would adhere to community rating principles or simplified experience rating (adjusted solely by age) and would be reviewed periodically. **Conclusion and Policy Implications** The government must conduct thorough assessments to determine the costs associated with administrative support for insurance and financial responsibilities for enrollees with pre-existing conditions. Strengthening financial risk protection in healthcare will necessitate ongoing discussions focused on evaluating the government's financial commitments between "expanding the scale of the existing NHI" and an "enhanced medical protection policy insurance." Additionally, strategic incentives will be needed to encourage private insurance entities to engage in this public-private partnership model.

abs-os31 Excess Capacity and Low Value Care in a Mixed Public-Private Health System: The Case of Invasive Coronary Angiography

PRESENTER: **Mr. Jongsay Yong**, University of Melbourne
AUTHORS: Mr. Ou Yang, Vijaya Sundararajan

Objective: This paper investigates low value care in relation to the use of invasive coronary angiography (ICA) for stable ischaemic heart disease (sIHD). Unnecessary healthcare expenditure, overuse or low value care has been a policy concern in many countries. However, in practice it is difficult to detect due to unobserved patient factors that may necessitate more extensive care than indicated by guidelines. Guideline inconsistent care can be either appropriate or low value care. Methods: We propose a novel approach of using short-term capacity fluctuations to identify the presence of low value care in the use of ICA and investigate the difference between public and private hospitals in this practice. We make use of hospital administrative data from the state of Victoria, Australia. The data contain 59,192 episodes of ICA use for sIHD during a ten-year period, 2001/02--2010/11. We develop a proxy measure for short-term hospital capacity for ICA and allow for potential endogeneity of capacity using weekends as our instrument. we estimate linear and probit models as recursive bivariate models, with endogenous capacity interacting with other covariates in the model. Results: We find that guideline inconsistent use of ICA is about 30 percentage points more prevalent during periods of excess capacity, indicating the likely presence of low value care. We further find that private hospitals were more likely to engage in guideline inconsistent ICA use, and this tendency increases during periods of excess capacity. Conclusions: Using short-term capacity fluctuations to identify low value care, we find evidence of low value use of ICA and the incidence is greater in private than public hospitals. Further work is required to understand the interaction of consumer demand and provider characteristics in driving low value ICA use, so that appropriate policy response can be developed to reduce the incidence.

abs-os32 Impact of the GP-Specialist Referral Network on Referral Waiting Times and Out-of-Pocket Costs

PRESENTER: **Yuting Zhang**, The University of Melbourne
AUTHOR: Mr. Ou Yang

Objectives: Australia's universal healthcare system, Medicare, faces a significant challenge with rising waiting times to see medical specialists. Psychiatry has emerged as one of the most sought-after medical specialties outside of hospital settings, receiving substantial subsidies from Medicare. Nevertheless, there is a notable lack of evidence regarding waiting times for psychiatric specialist consultations for general outpatients in Australia. In a setting where fees are unregulated and patients receive a fixed subsidy from the government, as is the case in Australia, limited evidence exists on the major factors influencing psychiatric specialist pricing behaviour and their interactions with patients. Our study aims to bridge this gap in the literature by taking an innovative perspective and investigating how the General Practitioner (GP)-Specialist referral pattens affect specialist consultation waiting times and patients' out-of-pocket costs. Methods: We analyse all records of Medicare-rebated GP referrals to psychiatric specialist across Australia from Q1 2011 to Q3 2023 sourced from the Medicare Benefits Schedule (MBS) data collection within the Person Level Integrated Data Asset (PLIDA). We apply a fixed effects linear regression which respectively relates waiting times and patients' out-of-pocket costs for all non-hospital psychiatric services to GP-Specialist quarterly referral network concentration, controlling for specialist fixed effects. The quarterly GP-Specialist referral network concentration is measured by the well-known Herfindahl–Hirschman Index (HHI). As a robustness check, the regression is also run with a categorical variable, constructed based on the HHI, instead of the original continuous HHI, to capture the non-linear effects of the quarterly GP-specialist referral network concentration. Results: Our findings indicate that higher GP-Specialist referral network concentration leads to lower consultation waiting times; however, this comes at the cost of higher out-of-pocket expenses for patients. Both effects are statistically significant. Specifically, the average specialist consultation waiting time decreases by approximately 6 percent when comparing GPs with the highest referral network concentration to those with the lowest concentration. In contrast, patients' out-of-pocket costs are about 1 percent higher. Discussion: The research findings reveal a trade-off between lower waiting times and higher out-of-pocket costs for patients due to increased GP-Specialist referral network concentration. Policymakers should balance access and affordability, potentially through measures like monitoring specialist pricing, enhancing competition, implementing targeted subsidies, and incentivizing efficient referral practices. Continuous monitoring and a multi-faceted approach are crucial to address market power concerns and ensure an equitable healthcare system.

abs-os33 The Impact of Price Transparency on Patients Medical Costs for In-Hospital Services

PRESENTER: **Ms. Susan Méndez**, University of Melbourne
AUTHORS: Anthony Scott, Hana Sabanovic, Mr. Jongsay Yong, Camille La Brooy, Adam Elshaug, Khic-Houy Prang

A reason for market failure in healthcare is information asymmetry. Patients face considerable uncertainty about expected health and financial outcomes because they might be less likely to assess the complexity of their case or the type of services they require. In a setting where providers can freely set prices, patients face uncertainty in their expected fees and out-of-pocket costs. Price transparency is promoted as a key to empowering patients with information, and fostering more equitable healthcare decision-making processes. Objectives: We study the impact of two price transparency initiatives on medical costs for private in-hospital services in Australia. The first initiative is the Surgical Variance

Reports, published in 2016 by the Royal Australasian College of Surgeons to reduce variation in clinical outcomes. The reports also included information about surgeons out-of-pocket costs. They were targeted at surgeons but publicly available. The second initiative is the launch of a price comparison website in 2018 designed to help members of the insurance company find the location of specialists around their area and their expected cost when undergoing a procedure in a private hospital. Methods: We use administrative claims data from the largest private health insurance company in Australia. The data spans from 2014 to 2019 and it links records from over 1.6 million patients to the doctors who provided their care while undergoing treatment in a private hospital. The detailed information allows to risk-adjust for patient complexity. We compare the evolution of fees and out-of-pocket costs from targeted procedures exposed to price transparency to costs of procedures not exposed in the initiatives with a difference-in-difference approach. Results: We find a significant increase in fees for procedures that were included in the Surgical reports. We also show a decrease in fees after the introduction of the insurance company's webpage. Conclusions: While providing price information effectively promotes search and choice in other industries, it may be less effective in healthcare. Price transparency alone does not remove uncertainty in quality and doctors' perceived experience and skills can still drive price variation. In addition, the state of urgency and stress might hinder patients' ability and willingness to compare options before choosing their preferred provider.

abs-os30 Understanding Views on Value Based Mental Healthcare Payment Reform in a Complex Healthcare System. The Australian Experience

PRESENTER: **Henry Cutler**, Macquarie University
AUTHORS: Anam Bilgrami, Jonas Fooken, Frances Rapport, Alicia Norman, Mona Aghdaee

Objectives: Many developed countries have fragmented mental healthcare systems with costly care that is misaligned with patient preferences. To improve the integration of care, payers are exploring new payment methods that promote collaboration and care integration among multiple providers. Our study aimed to provide insights and recommendations for shifting mental health care payment models away from traditional fee-for-service toward innovative models that pay for outcomes. Methods: We gathered data by interviewing 21 executives from state and federal government departments, agencies, and mental health commissions in Australia. We also conducted three national online workshops with 70 non-government stakeholders, consumers, and public participants. Responses were transcribed and analysed to identify common themes using thematic and schema analysis methods. These themes were organized using the Consolidated Framework for Implementation Research (CFIR) to offer a concise overview of stakeholder perspectives. Results: Stakeholders generally agreed on the need for value-based payment models in mental healthcare, but there were differing opinions on how these new models should be governed in a federated system like Australia. Primary barriers to implementation included defining outcomes that matter to consumers, lack of evidence, workforce gaps, political complexities, procedural challenges, and costs. Contrasting perspectives between government and non-government stakeholders highlighted ideological differences that may need to be addressed before implementing payment reforms. Discussion: Reforming payment models in mental healthcare is complex and challenging, magnified by the often-large uncertainty in attributing outcomes to care. This paper offers potential recommendations for implementing outcomes-based payment reform at scale in mental healthcare, across areas such as governance and planning, evidence-based care promotion, and laying the groundwork for reform.

abs-os246 Comparing the Quality and Efficiency of Primary Care Providers in Soweto. A Standardised Patient Audit

PRESENTER: **Duane Blaauw**, University of the Witwatersrand
AUTHORS: Mylene Lagarde, Olukemi Babalola, Nicholas Stacey

ABSTRACT

|

Access to quality primary health care (PHC) is essential for addressing health inequalities in South Africa. However, effective strategic purchasing and regulation for PHC within a new National Health Insurance (NHI) system will require better information about the relative quality and costs of different providers.

The objective of the study was to compare the quality and efficiency of acute care provided by different PHC providers in Soweto. We used a standardised patient (SP) audit survey to evaluate the effort, quality and efficiency of PHC providers. SPs are fieldworkers trained to consistently portray a specific clinical case, attend health care providers as normal patients, and then accurately record details of the consultation. SPs presented five different clinical cases: angina, tuberculosis (TB), asthma, migraine and post-partum depression (PPD). They were sent to 33 public clinics, 75 private general practitioners (GPs) and 19 private mid-level worker (MLW) clinics in Soweto. Consultation

details were recorded immediately after each visit on a tablet-based questionnaire. We compared indicators of provider effort, technical quality, patient-centredness and efficiency.

A total of 793 consultations were completed: 328 in public clinics, 374 with private GPs and 91 at private MLW clinics. We found low technical quality of care across all three groups, with only 40% of cases managed according to evidence-based guidelines. Private GPs performed slightly better than other providers managing 45.2% of the SPs correctly, compared to 38.1% in public clinics and 37.4% by private MLW clinics. Low sputum testing of the TB case was a concern though management of the PPD case was better than expected. We also found significant wastage with over-prescribing of unnecessary and harmful medicines especially in the private sector. Problems with patient-centred care were mostly reported from public clinics.

The technical quality of care, patient-centredness and wastefulness of PHC providers requires improvement in order to provide more cost-effective care. Private providers may provide slightly better quality care but are also less efficient. Strengthening the quality and efficiency of PHC across both the public and private sectors is imperative if NHI is to be successful in promoting equitable health outcomes.

abs-os255 Examining Patient Choice and the Role of Quality Information in Healthcare Markets in South Africa

PRESENTER: **Nicholas Stacey**
AUTHORS: Olukemi Babalola, Mylene Lagarde, Duane Blaauw

ABSTRACT

|

Reforms that rely on private providers to deliver care, such as those envisaged in South Africa, are premised on the notion that the effect of market competition will increase efficiency, quality and sensitivity to consumers. However, insights from economic theory suggest a more nuanced picture, and in particular highlight the important consideration of whether the demand side is indeed responsive to quality. In settings where consumers are not able to judge the quality of services, such as healthcare markets, it is widely held that giving information about provider quality would improve the responsiveness of demand, and therefore the allocative efficiency of the market. Yet there is hardly any evidence of responsiveness of demand to information and quality in healthcare markets in low- and middle-income settings.

The project aims to inform the policy debates in South Africa around the introduction of a national health insurance (NHI) scheme by answering two questions:

1. To what extent do patients choose healthcare providers based on quality versus other attributes (proximity, type of providers, reputation, etc)?

2. Does information about provider quality influence patients' choice of providers?

To answer the first question, we use detailed healthcare utilisation data collected from approximately 850 households in Soweto during a three-month period where they had free access to a small network of public and private providers. We fit a choice model that analyses provider choice as a function of provider characteristics: distance to household, perceived quality and attitude (both elicited at baseline), type of provider (private or public), and expected provider category (nurse or doctor).

To answer the second question, we extended the free access to providers by an extra two months and randomly allocated half of the household clusters to receive information about the best two providers in the network. We monitor household choice of providers over the period and collect information about provider preferences and information spillover at endline.

Results show that proximity and ease of access, more than quality, is the key factor that determines choice of providers. Even equipped with information about quality of providers, most individuals continue to choose the closest providers, rather than the better ones. Findings illustrate the inelasticity of the demand with respect to quality compared to barriers such as distance. Those results also cast doubts on the notion that healthcare markets can operate efficiently.

abs-os252 Free Access, Indirect Barriers and Healthcare Efficiency: Experimental Evidence from Soweto

PRESENTER: **Mylene Lagarde**, London School of Hygiene & Tropical Medicine (LSHTM)
AUTHORS: Nicholas Stacey, Olukemi Babalola, Duane Blaauw

ABSTRACT

|

Despite free access to public health care in South Africa, barriers such as long waiting times and perceptions about poor quality may inhibit optimal healthcare utilisation. Plans to expand private sector access through National Health Insurance (NHI) could modify these patterns, but the likely impacts on utilisation remain uncertain and may depend on the location of contracted providers.

The objective of this study was to assess the impact of providing access to private PHC providers in Soweto on healthcare utilisation,

appropriate health-seeking and healthcare spending, and to investigate if distance influences these effects. A randomised controlled trial was conducted with 1400 households without private health insurance and children under six. Households were randomly assigned to three groups: a control group with standard public healthcare access, a group with access to a network of nearby private providers, and a group with access to more distant private providers. The health card intervention granted free private PHC access for one child for three months. Caregivers used a pictorial diary to capture daily symptoms and health care visits. Fieldworkers completed surveys at baseline and endline, and also visited households weekly to collect the diary information. We applied the WHO community IMCI guidelines to the diary data to determine whether health provider visits during illness episodes were appropriate or unnecessary. We also identified episodes with under-use where care was not sought although the guidelines recommended it.

Free access to private providers increased healthcare usage, with the highest care-seeking in the nearby provider group. Although free private care doubled appropriate care-seeking, it also led to a significant rise in unnecessary visits. Importantly, the rate of underuse remained unchanged. Pharmacy spending decreased but transport costs increased, particularly for the far-network group. Distance did influence utilisation, with further travel reducing both appropriate and unnecessary visits.

Expanded access to private PHC providers increased beneficial healthcare utilisation but also increased low-value visits. Unfortunately, it did not improve the problem of under-use. The implementation of NHI needs to consider and plan for the likely effects on household healthcare utilisation patterns.

Measuring and Valuing Health-Related Quality of Life in Infants, Toddlers, and Young Children

MODERATOR: **Lisa Gold**, Deakin University

CONVENER: **Christine Mpundu-Kaambwa**, University of Melbourne

abs-os618 Challenges in Evaluating Health-Related Quality of Life (HRQoL) in Children: Selecting the Value-set for the EQ-5D-Y-3L

PRESENTER: **Diana Khanna**
AUTHORS: Christine Mpundu-Kaambwa, Jyoti Khadka, Rachel Milte, Julie Ratcliffe

Objective: There is limited guidance on whether to apply a child-specific value set from another country or use a country-specific adult EQ-5D-3L value set when the former is unavailable. This study aims to examine how the choice of value set, i.e., child- versus adult-specific, influences the inter-rater gap between child self-reported and proxy-reported health-related quality of life (HRQoL).

Methods: An online sample of 845 dyads (children aged 6-10 years and their parents) completed the self and proxy versions of the EQ-5D-Y-3L independently. HRQoL values were derived using the 'Y' and the adult-specific value sets for five countries: Germany, Hungary, Japan, Netherlands and Spain. Analyses were stratified by age (6-7 versus 8-10-year-olds), gender, and health condition. Group differences were identified using paired t-tests with a Bonferroni corrected significance level (α=0.0014). The percentage of directional consistency in child-proxy discrepancies across value sets was also examined as a secondary analysis.

Results: Proxies significantly overestimated HRQoL values across most 'Y' value sets (Hungary, Japan, Spain); marginal significance was observed for Germany and the Netherlands. Similar pattern using the corresponding 'adult' value sets was observed only for Germany. Significant inter-rater differences were observed for children without health conditions across all value sets. Proportional agreement in direction was marginally higher when using 'Y' value sets, except for Germany.

Conclusion: The choice of value set influences child-proxy HRQoL assessments. In the absence of a country-specific 'Y' value set, using an alternative child-specific value set is preferable to relying solely on a country-specific 'adult' value set.

abs-os687 Exploring Valuation of the Adapted EQ-5D-Y-3L for 2-4 Year Olds: A Qualitative Think-Aloud Study

PRESENTER: **Alexander van Heusden**
AUTHORS: Kim Dalziel, Renee Jones, Brendan Mulhern, Alice Yu, Nancy Devlin

Objective

This study aims to qualitatively explore the views of the general public regarding valuation of HRQoL in young children, 2-4 year olds, including 1) whose preferences should be sought 2) which perspective should be used 3) what age framing to use, 4) whether and how participants consider spillover effects, and 5) the feasibility of completing a discrete choice experiment (DCE) task for the adapted EQ-5D-Y-3L for 2-4 year olds.

Methods

Individual online semi-structured think-aloud interviews were conducted with Australian adults, including both parents/caregivers and non-parents. The interview consisted of six think-aloud DCE tasks (imagining a hypothetical 3-year-old) using health states derived from the adapted EQ-5D-Y-3L for 2-4 year olds, followed by a range of open-ended questions to explore the key aims. Interview transcripts were double coded using an inductive and deductive approach and analysed using framework analysis.

Results

Interviews were conducted with 17 adult participants, including parents/caregivers (n=9) and non-parents (n=8). Almost all participants found the DCE task easy to understand and reported high confidence completing the task. Participants' emphasised the inclusion of preferences from parents/caregivers or professionals who interact with children. Despite asking participants to consider a hypothetical child, participants tended to instinctively think of themselves as a child, their own child, or a child they know. All participants stated that they would respond differently if asked to consider an older child (e.g. a 10 year old). Caregiver spillover effects were observed in valuation task considerations made by many parents/caregivers (e.g. how the child's health state impacts the parent's life), whereas future spillover effects (e.g. impacts on children's future health and non-health prospects) were considered by many of the total sample. Almost all participants used information beyond the description of the task when making decisions, such as imagining if health states were treatable.

Conclusions

DCEs tasks appear to be feasible for obtaining stated preferences of dimension importance for the adapted EQ-5D-Y-3L for 2-4 year olds. There was strong preference for inclusion of those with experience of young children for valuation. It is important for those conducting or using results from valuation studies to understand the types of considerations being made and the extent to which spillovers are being incorporated in participant's valuations of health states for young children.

abs-os611 Methodological Study to Develop a Short Form of PedsQL Infant Scale to Measure Preference-Weighted HRQoL for Children Under 2 years

PRESENTER: **Xinyang Hua**, University of Melbourne
AUTHORS: Valerie Sung, Kim Dalziel

Background

Limited instruments are available to measure health-related quality-of-life (HRQoL) for children under age two. The PedsQL Infant Scale (36 and 45 item) was designed as a generic HRQoL instrument for infants aged 1-24 months. However, it is not a preference-weighted measure and thus cannot be directly used in economic evaluation.

Aim

To develop a short form of the PedsQL Infant Scale to measure preference-weighted HRQoL for children under two years of age, enabling its application in economic evaluation.

Methods

Data from the BabyBiotics study was used in this analysis. BabyBiotics is a randomised controlled trial to determine whether the probiotic Lactobacillus reuteri reduces crying or fussing in a broad community-based sample in Melbourne, Australia. Infants with colic aged less than 3 months were included in the trial, with the PedsQL Infant Scale collected 6 months after the intervention. Confirmatory factor analysis was conducted to identify the core dimension structure of the new health state classification system based on the PedsQL Infant Scale. Three competing conceptual models were tested: (a) the original 5-dimension structure of the PedsQL Infant, (b) a modified version with the lowest loading factors omitted, (c) a modified version with 2 single-item dimensions (Play, Hurt) isolated consistent with other available HRQoL instruments for children under two. Model fit was evaluated by examining standardised factor loadings and various fit indices. Rasch analysis and psychometric analysis will be used to select the best item for each dimension in the next step of analysis.

Results

132 infants with the PedsQL Infant data available at a median age of 8.5 months were included in this study. The original structure of the PedsQL Infant Scale had acceptable fit indicators (Tucker-Lewis Index (TLI)=0.969, Root Mean Square Error of Approximation (RMSEA)=0.051), with relatively low loading for item 6 (Being constipated, loading=0.312) and item 8 (Having diarrhoea, loading=0.399) in the Physical Symptoms dimension. Taking out these items or isolating play and hurt as single-item dimensions results in a similar model fit to the base model (TLI =0.968-0.971, RMSEA=0.53-0.55).

Conclusion

The original 5-dimension structure of the PedsQL Infant Scale exhibited adequate model fit in this Australian community-based sample of children under 12 months. Further quantitative exploration and engagement with experts will be made to determine the best model structure, and to select a single best item for each dimension. This study will provide a short form of the PedsQL Infant Scale that is amenable to preference elicitation methods and to calculate utilities for children under two years.

abs-os646 Psychometric Properties of the EQ-5D-Y-3L Self-Complete Version for Bangladesh: Testing Feasibility, Reliability and Validity

PRESENTER: **Marufa Sultana**, Deakin University
AUTHORS: Shakhawat H Rana, Md Badruddin Saify, Mimmi Åström, Rumana Huque, Shumia Islam, Ms. Lisa Gold

Background

Assessing Health-Related Quality of Life (HRQoL) in children is crucial for healthcare decision-making. The EQ-5D-Y-3L is a simple tool consisting of five dimensions (mobility, looking after myself, doing usual activities, having pain or discomfort, feeling worried, sad or unhappy) with three response levels (no problem, some problems, a lot of problems) and a visual analogue scale (VAS) to assess the current health status of children aged 8–18 years. This study, for the first time, piloted the self-complete Bangla version of EQ-5D-Y-3L among school children in Bangladesh to assess the feasibility, reliability, and validity of the tool, as well as exploring differences in HRQoL between age groups, sex, and geographical locations.

Methods

Children and adolescents attending primary or secondary level public schools were recruited from two districts in Bangladesh (one urban, one rural). Children aged 8–18 years completed the Bangla versions of the EQ-5D-Y-3L and KIDSCREEN-27 questionnaires, along with a few acceptability-related qualitative questions, at baseline, and a sub-sample repeatedly answered the EQ-5D-Y-3L one week later. The psychometric performance of the EQ-5D-Y-3L was assessed in terms of: (a) feasibility (missing values, completion time, acceptability); (b) test-retest reliability, using expected agreement and Prevalence-Adjusted and Bias-Adjusted Kappa (PABAK), with recommended values for reliability being a Kappa of ≥0.70 for strong agreement; and (c) convergent validity, by Spearman's correlation coefficients between the EQ-5D-Y-3L dimensions and KIDSCREEN-27 scales, with a value for strong correlation as ≥0.50. Variations in proportion of reported problems were assessed based on age, sex, and geographical location.

Results

A total of 120 children/adolescents participated, with a mean age of 13.1 years (SD ± 2.8); 37% were aged 8–11 years, and 52% were from urban areas. The mean completion time of EQ-5D-Y-3L with VAS was 5.2 minutes (SD ± 2.0), with no missing responses. Overall, 48% of participants reported no problems across all five dimensions (profile 11111), followed by 16% reporting 11121. 'Some/a lot of problems' were most reported in the having pain or discomfort dimension (36%) and the feeling worried, sad or unhappy dimension (30%). Test-retest reliability indicated strong agreement for the mobility, looking after myself, and doing usual activities dimensions (PABAK ≥ 0.70), but poor agreement for the having pain or discomfort dimension (PABAK = 0.06). Overall, convergent validity between the EQ-5D-Y-3L and KIDSCREEN-27 indicated weak correlation ($r \leq 0.30$). Reports of any problems in the feeling worried, sad or unhappy dimension were significantly higher among 15–18 year-olds (56%) compared to other age groups ($\chi^2 = 11.3$, $p < 0.01$) and higher among urban respondents (39%) compared to rural ($\chi^2 = 8.6$, $p < 0.01$). Any problems in the having pain or discomfort dimension were reported more frequently by female participants (43%) compared to males (28%).

Conclusions

The Bangla version of the EQ-5D-Y-3L demonstrated feasibility and reliability for measuring HRQoL among children in Bangladesh, although convergent validity showed a weak correlation between the EQ-5D-Y-3L and KIDSCREEN-27 dimensions scores and needs to be further explored.

Health Financing Equity and Universal Health Coverage

MODERATOR: **Ching-Ching Claire Lin**,

Ind-1473 Social and Developmental Impact Bonds in Achieving Universal Health Coverage in Low-and-Middle Income Countries

PRESENTER: **Natasha Ogeto**

Background: Sustainable Development Goal (SDG) 3.8 is dedicated to achieving Universal Health Coverage (UHC). The coverage of essential health services and financial protection from catastrophic health spending are both indicators of progress towards the SDG. Out-of-pocket

expenses account for 40% of health expenditures in Low-and-Middle Income Countries (LMICs), making achieving UHC a priority as they limit access to essential health services. Social and Developmental Impact Bonds tailored for health interventions, also known as Health Impact Bonds, have emerged as innovative financing mechanisms to address these challenges. This scoping review aims to explore the implementation of Health Impact Bonds for financing UHC in LMICs and assess their alignment with key financial coverage objectives Methods: This scoping review followed Arksey and O'Malley's framework and complied with PRISMA-ScR guidelines. A systematic search was conducted in EconLit, PubMed, Scopus, Web of Science, and Ovid Embase for articles published between January 2010 and August 2024. Grey literature was also included and critically appraised by AACODS. The key components of the World Health Organization Health Financing Framework, which includes financial protection, equity and quality of care, were used to evaluate the Health Impact Bonds. Data extraction focused on target populations, interventions, evaluation methods and outcomes. Results: This scoping review identified 14 Health Impact Bonds implemented across various health sectors in LMICs, including maternal and child health, infectious diseases and water, sanitation and hygiene. The findings showed that Health Impact Bonds contribute to achieving the financial coverage goals outlined in the World Health Organization Health Financing Framework. These are reducing out-of-pocket expenses, improving healthcare utilisation relative to need and enhancing service quality. However, their overall effectiveness was limited by inadequate data infrastructure, institutional barriers and a priority on immediate results. Conclusion: By addressing gaps in healthcare access and financial protection, Health Impact Bonds show potential as innovative financing tools for achieving UHC in LMICs. However, long-term impact is dependent on improving data systems, encouraging stakeholder engagement and expanding their scope to address chronic health issues. These adaptations ensure Health Impact Bonds promote sustainable health system improvements and equity in LMICs.

Ind-426 Comparison of Pregnancy-related Out-of-pocket Expenditure in Bangladesh and Pakistan

PRESENTER: **Farjana Misu**
AUTHORS: Taslima Rahman, Dominic Gasbarro, Khurshid Alam

Abstract

Background

The burden of out-of-pocket (OOP) healthcare expenses for pregnancy-related conditions is a significant concern in resource-prone countries. Bangladesh and Pakistan, two historically connected countries with similar socioeconomic standings, rank among the highest globally in OOP share in total health expenditures. Excessive OOP costs pose financial barriers to maternal healthcare utilisation, leading to catastrophic health expenditures (CHE) and deepening poverty. Our study aims to compare pregnancy-related OOP expenditures between Bangladesh and Pakistan, examining key disparities in spending patterns and financial burden.

Methods

This study utilises data from the Bangladesh Household Income and Expenditure Survey (HIES) 2022 and published secondary evidence for Pakistan in the absence of primary data. For Bangladesh, we included all women of reproductive age who reported pregnancy-related health issues in the past 30 days or were hospitalised in the last 12 months. We estimated the share of OOP in total household expenditure on pregnancy-related healthcare, assessed CHE using budget share, actual, and normative food expenditure methods, and evaluated impoverishment effects. Descriptive and equity-based analyses were conducted to examine expenditure variations across socioeconomic groups.

Results

In Bangladesh, pregnancy-related OOP expenditures (USD 434.4) accounted for 50% of total household healthcare spending (USD 892.6). The share of OOP in total household expenditure was significantly higher for private healthcare facilities (USD 417.1) and among rural women (USD 384.8). Low-income households spent a greater proportion (two-thirds) of their total expenditure on pregnancy-related care. The CHE incidence was around 94.6%-80.9% among the lowest quintile households and 26.8%-66.5% among rural households under normative capacity-to-pay (CTP) method. Impoverishment rates were highest, with 31.7% low-income and 3.9% rural households falling into poverty due to OOP expenses. In Pakistan, OOP costs for pregnancy care were significantly higher in private facilities (USD 209.88-255.49) than in public facilities (USD 23.30-63.87).

Conclusion

Pregnancy-related OOP healthcare costs constitute a significant financial burden in Bangladesh and Pakistan, with higher expenses in private facilities. Low-income and rural families in Bangladesh face the greatest hardship, often leading to financial catastrophe and poverty. Strengthening public healthcare funding, expanding maternal health insurance, and regulating private sector pricing could reduce OOP costs and improve maternal healthcare equity.

Ind-1027 Financing Community Governance for Primary Care Facilities in Khyber Pakhtunkhwa, Pakistan: A Critical Analysis

PRESENTER: **Dr Shabana Haider**
AUTHORS: Mir Sana Ullah Khan, Nida Hameed, Mr. Sven Engels

Background: Direct facility financing (DFF) is increasingly recognized as critical for improving primary healthcare service delivery in resource-constrained settings. However, implementing DFF in contexts with limited institutional capacity presents significant challenges. In 2020, Pakistan’s Khyber Pakhtunkhwa (KP) province introduced Primary Care Management Committees (PCMCs), which combine elements of DFF with community governance. PCMCs, comprising facility staff and community representatives, were established across primary care facilities to manage supplementary funds alongside traditional district-managed budgets. This reform aimed to enhance facility responsiveness

to local needs by empowering communities to collaborate with facility managers in utilizing resources and improving infrastructure, supplies, and staffing, marking a significant shift from the province's historical reliance on centralized, input-based budgeting. **Research Question:** How do PCMCs receive, prioritize and utilize their resources, and what factors impact their ability to utilize these funds efficiently and effectively? **Approach:** The study employed a mixed-methods approach examining PCMC implementation from 2020-2023. We analyzed financial data of PCMCs at 439 facilities (out of 1,076) where complete and verifiable data was available across fiscal years 2021-22 and 2022-23. This was complemented by stakeholder interviews to understand fund flows, allocation patterns, and institutional arrangements. **Results:** We identified that PCMCs receive grants from the recurrent budget, development grants (through time-bound projects), and revenue from nominal service fee. While PCMCs showed promise in addressing immediate facility needs through infrastructure improvements (91% of expenditure), spending on service delivery inputs remained limited - equipment (3%), medicines (1%), and operational costs (5%). The analysis identified three key implementation challenges: fragmented oversight, weak data management systems, and heavy reliance on development rather than recurrent budgets, which may affect long-term sustainability. PCMCs expenditure analysis demonstrates how quickly infrastructure improvements can be made using PCMCs rather than traditional province wide infrastructure improvement projects which can be spread over several years. It also highlights the preference of using development funds instead of recurrent funds, identifying the need to ease access to recurrent funds, a longer term sustainable source. In addition, the lack of oversight and ownership of PCMCs by the Department of Health (DoH) has led to limited visibility of expenditure. **Conclusion**: PCMCs represent one of Pakistan's first systematic attempts to combine direct facility financing with community governance at the primary care level. The analysis shows that PCMCs are operational and capable of managing public funds to address local facility needs, though initial spending has primarily focused on infrastructure. To leverage PCMCs' full potential for improving service delivery, we recommend the KP Health Department establishes dedicated oversight mechanisms, improves data systems, and ensures sustainable funding through recurrent budgets. As the model matures, PCMCs can expand beyond infrastructure to address broader aspects of service delivery and quality improvement. The experience of PCMCs in Pakistan offers valuable insights for other low- and middle-income countries implementing DFF reforms in resource-constrained settings. **Key Words:** Direct Facility Financing, Community-based Health Governance, Pakistan, Primary Care Management Committees (PCMCs), Decentralized Financial Management, Community Involvement, Sustainability

Ind-797 Equity in Health Financing Towards Universal Health Coverage in China

PRESENTER: **Tiange Chen**

AUTHOR: Hongqiao Fu

Background: Equity in health financing is essential for achieving universal health coverage (UHC), particularly in low- and middle-income countries (LMICs). This study aims to examine the equity in both burdens and benefits of China's health financing system.

Methods: We used data from the Chinese Household Income Project (2007, 2013 and 2018), a nationally representative household survey. The progressivity of various financing sources and the overall financing system were measured using the Kakwani index (KI), and the distribution of benefits from social health insurance (SHI) was evaluated using the concentration index. We further conducted counterfactual policy scenario analyses to explore the impact of potential solutions to mitigate inequalities

Results: The overall health financing system remained mildly regressive, with KIs of -0.032 (95% CI: -0.044, -0.020) in 2007, -0.038 (95% CI: -0.053, -0.022) in 2013, and -0.036 (95% CI: -0.046, -0.025) in 2018. Among the financing sources, direct tax payments, SHI contributions by employees, and private health insurance premiums remained progressive, while indirect tax payments, SHI contributions by non-employed residents, and out-of-pocket payments were regressive. In addition, the distribution of benefits from SHI did not align with healthcare needs. The wealthiest 20% of households bore only 11.8% of the health burden but received 52.9% of the benefits in 2007 and this inequity in SHI benefit distribution persisted in 2018.

Conclusion: Lower-income households bore disproportionately greater health financing burdens relative to ability to pay, and received fewer SHI benefits relative to health needs. To address these inequities, China should reform the flat-rate contribution mechanism, set out-of-pocket payment caps for households, and reduce disparities in benefit packages across different SHI schemes.

Ind-1344 Strategic Purchasing for Quality Improvement: Evaluating Quality of Care and Client Satisfaction in Myanmar's Sun Private Clinics

PRESENTER: **Han Win Htat**

Background: Myanmar faces significant healthcare challenges, with many individuals accessing services through the private sector and paying out-of-pocket, leading to financial burdens and underutilization of essential health services. To support Myanmar's universal health coverage goals, Sun Community Health (SCH) contracted with 10 Sun General Practitioners (GP) clinics for one-year period in 2023 to provide a comprehensive package of primary care services. To enhance service delivery and ensure high-quality care, SCH conducted quarterly assessments and an end-of-project evaluation focusing on client satisfaction, quality of care, and implementation challenges. **Aim:** This study aimed to evaluate the quality of care and client satisfaction at SCH-contracted clinics, identify challenges and opportunities in implementing strategic purchasing for healthcare services, and inform future initiatives to improve service delivery and achieve universal health coverage in Myanmar. **Methods:** A mixed-methods approach was employed, combining quantitative assessments and qualitative interviews. Quarterly client satisfaction surveys were conducted using the Lot Quality Assurance Sampling (LQAS) method. In each of the 10 clinics, 19 clients were randomly selected per round (except one clinic in Q2 with 17 clients due to security challenges), totaling 568 client surveys across Q2, Q3, and Q4 of 2023. Concurrently, quarterly quality assurance assessments to all 10 clinics were conducted, aligned with the Royal Australian College of General Practitioners (RACGP) Standards (5th edition). Qualitative interviews were conducted at the end of the project with 10 medical doctors, 10 clinic assistants, and 30 clients to gather insights on recruitment, service coverage, financial systems, and client satisfaction. Data were analyzed to identify strengths, gaps, and actionable recommendations. **Results:** Quantitative assessments revealed consistently high client satisfaction across Q2, Q3, and Q4 of 2023, with clinics achieving 100% satisfaction increasing from three in Q2 to five in both Q3 and Q4. Areas needing improvement included communication about drug side effects and information on free or out-of-pocket services. Quality

assurance assessments showed all clinics meeting the 90% compliance threshold by Q4, with strengths in clinical management and adherence to guidelines. Gaps persisted in patient education and emergency preparedness. Qualitative interviews revealed challenges such as brief recruitment periods hindering full integration, gaps in the benefit package (e.g., exclusion of skin infection treatments), and delays in payment systems, especially for maternal health investigations. Clients reported improved financial access and positive maternal health outcomes, emphasizing strong provider-client relationships and the need for clear communication about available services and potential costs. **Conclusions:** The findings indicate high levels of client satisfaction and quality care across SCH clinics, with significant improvements over time. Challenges remain in enhancing patient education, emergency preparedness, and financial systems. Strategic purchasing has transformative potential for addressing healthcare challenges in Myanmar. Future programs should consider extended recruitment periods, regular benefit package reviews, streamlined financial processes, and enhanced client engagement to sustain impact and adapt to evolving health needs. Ongoing assessments and targeted interventions are crucial for maintaining and improving service quality on Myanmar's path toward universal health coverage.

Ind-79 Financing Landscape for Key Populations HIV/AIDS in Uganda: March 2022

PRESENTER: **Arnold Taremwa**
AUTHORS: FELIX RUTARO, CHARLOTTE MUHEKI

Background: Key Populations (KPs) such as sex workers and people who inject drugs face heightened vulnerability to HIV/AIDS due to social, legal, and structural barriers. Despite their elevated risk, HIV funding in Uganda for KPs remains disproportionately low, representing less than 1% of total HIV prevention funds in recent years. This funding gap jeopardizes Uganda's progress in controlling HIV/AIDS, particularly among marginalized groups. This research examines the funding landscape for KPs in Uganda and identifies strategic priorities to enhance HIV prevention, care, and treatment services. **Aim:** To assess the current HIV/AIDS funding allocations for KPs in Uganda and propose recommendations to address funding gaps and improve service delivery for these vulnerable groups. **Methods:** This research employs a mixed-methods approach. Quantitative data from Uganda's National AIDS Spending Assessment (NASA) was analysed to understand trends in resource allocation between 2016-2019. Qualitative data was gathered from policy documents, interviews with stakeholders in the health sector, and reports from donor agencies. The analysis focuses on the distribution of funding between government, donor agencies, and private contributions, highlighting disparities in resource allocation to KPs. **Results:** Between 2016 and 2019, Uganda's HIV response was primarily funded by international donors, contributing over 80% of resources. However, only a marginal portion of these resources were allocated to KPs. In 2018/19, KPs received just 0.3% of total HIV prevention funding, with most of it directed toward sex workers (95% of KP-specific funds). Other KPs, including people who inject drugs and transgender individuals, shared the remaining 5%. The analysis revealed a significant funding gap in addressing the specific needs of these groups, despite them being disproportionately affected by the HIV epidemic. For instance, the HIV prevalence among sex workers was estimated at 31.3%, far exceeding the national average of 6.2%. Similarly, people who inject drugs and other KPs faced higher risks of infection but remained largely underserved. Moreover, the report found that donor contributions, while substantial, are declining, with a predicted drop in future allocations due to shifting global priorities. The government's domestic contribution to KP-focused HIV programs remained below 1%, further exacerbating the resource gap. This inadequate funding allocation raises serious sustainability concerns, as over-reliance on donor funding leaves the HIV response for KPs vulnerable to fluctuations in international aid. **Conclusions and Policy Implications:** Sustainable HIV/AIDS control in Uganda requires re-prioritization of KP funding in national HIV responses. The study advocates for increased domestic funding, strategic donor engagement, and the development of KP-led health initiatives. Without addressing these funding disparities, Uganda risks stagnating in its fight against HIV, particularly among high-risk populations. The findings support calls for policy changes aimed at equitable resource distribution and the removal of legal barriers that hinder access to care for KPs.

Ind-2806 Assessing the Effectiveness of Social Health Insurance in Reducing out-of-Pocket Health Expenditure in Mixed Health Systems: The Philippine Case

PRESENTER: **Shem Pava**, De La Salle University - Carlos L. Tiu School of Economics
AUTHORS: Bernardo II Cielo, Alellie Sobrevinas, Arlene Inocencio, Emi Obina, Dariafel Faith Mararac, Nathaniel Bangalan

The Universal Health Care (UHC) Act of 2019 positioned the National Health Insurance Program (NHIP) as a central mechanism for achieving UHC in the Philippines, transitioning membership from contribution-based eligibility to citizenship. Despite this shift, some Filipinos remain unregistered, in part, due to distrust in the NHIP's ability to reduce out-of-pocket (OOP) health expenditures relative to the premiums and tax subsidies it collects. This distrust has been fueled by public controversies, including ineffective price negotiations under prospective payment mechanisms, pandemic-era administrative relief through advanced payments, and recent challenges in maintaining actuarial fairness. Additionally, the diminishing share of NHIP's social health insurance (SHI) payments in national health expenditures and inadequate coverage for catastrophic cases have intensified calls to reassess the program's value. This study evaluates the effectiveness of the NHIP in reducing OOP health expenditures for hospital admissions, focusing on inpatient care, given its limited coverage for outpatient services. Using data from the 2022 National Demographic and Health Survey, a Tobit regression model was employed to assess the impact of SHI payments on OOP spending, controlling for cost drivers and alternative payment sources, including private insurance, government subsidies, and inter-familial transfers, among others. Furthermore, the study analyzed OOP reductions across wealth quintiles to determine the NHIP's capacity for cross-subsidization and equitable cost coverage. Findings indicate that NHIP participation significantly reduces OOP expenditures for inpatient care, with insured individuals paying an average of Php 14,110.95 (USD 253.20) less for premium-based members and Php 15,286.33 (USD 274.29) less for state-subsidized members compared to the uninsured. However, coverage remains insufficient in offsetting OOP relative to other payers, with inpatient cost drivers linked to length of hospital stay and private hospital utilization. Across wealth quintiles, the lowest-income NHIP contributors exhibit higher OOP spending than their uninsured counterparts, suggesting potential gaps in complementary financing and confirming the assumed effect of insurance-induced demand. The results underscore NHIP's positive, though limited, role in reducing OOP expenditures for hospitalizations. Strengthening the program is imperative to improve efficiency in payment mechanisms. Key recommendations include addressing the widening public-private provider gap, as private hospitalizations are a major cost driver. Cost containment strategies, such as expanding public sector investments to enhance competition and leveraging NHIP's market power to negotiate

prices, are essential. Additionally, increasing NHIP population coverage and expanding the proportion of care costs covered by SHI can enhance the program's ability to provide financial risk protection towards achieving UHC.

abs-os167 Indonesia's National Health Insurance and Maternal Health Outcomes

PRESENTER: **Ms. Dina Anjayani**
AUTHORS: Mr. Praptadi Agung Sadyoga, Mr. Antokalina Sari Verdiana, Ms. Esterlita Putri Pamungkasari

Background: Sustainable Development Goal (SDG) 3.8 aims to ensure universal access to quality healthcare. Indonesia introduced the National Health Insurance (JKN) in 2014 to support this goal. By 2024, JKN covered 98% of Indonesia's population, including East Nusa Tenggara (NTT) Province, where the poverty rate is 19.48%. JKN is expected to improve healthcare utilization, particularly for maternity care. This study examines the impact of JKN on maternity care utilization in NTT Province before and after its implementation.

Methodology: This study analyzed data from the 2013 and 2023 National Socioeconomic Surveys (Susenas) focused on mothers who gave birth in healthcare facilities. A total of 3,936 women were surveyed in 2013 and 1,725 in 2023. The Andersen Behavioral Model was used to explore factors influencing JKN enrollment, considering predisposing (age, education, marital status, employment), enabling (wealth index, residence, internet access), and need (health service access) factors. Logistic regression identified variables related to health insurance ownership for each year. The sample was divided into JKN holders (treatment) and non-holders (control). Propensity Score Matching (PSM) and Difference-in-Differences (DID) were applied to measure JKN's effect on maternity care utilization across the two years. Concentration Index (CI) using Lorenz curves assessed disparities in healthcare access and facility-based childbirth in 2013 and 2023.

Results: In 2013, key determinants of JKN ownership were healthcare access and wealth index (Q4 and Q5), while in 2023, education (basic and secondary) and healthcare access were the main factors. PSM for 2013 showed an Average Treatment Effect on the Treated (ATT) of 0.0207, while for 2023, it was 0.0683. Post-matching, variables were balanced, reducing potential bias. DID analysis indicated a 4.76% treatment effect for JKN holders, suggesting a stronger impact of JKN on facility-based childbirth. CI for healthcare access among JKN holders was 0.074 in 2013, dropping to 0.057 in 2023. For facility-based childbirth, CI decreased from 0.163 in 2013 to 0.043 in 2023. These findings show that JKN has helped reduce inequalities in healthcare access and facility-based childbirth in NTT Province.

Conclusion: JKN has positively influenced maternity care utilization in healthcare facilities, particularly in NTT. Policy recommendations include increased governmental involvement and public education to encourage facility-based childbirth, maximizing JKN's benefits for maternal health. Additional policy measures are needed to address out-of-pocket costs and unmet needs for facility-based childbirth services, especially in NTT's remote areas.

Ind-2188 Canada's Old Age Security Program: A Path to Alleviating Food Insecurity Among Seniors

PRESENTER: **Mohammad Hajizadeh**
AUTHORS: Catherine L. Mah, Mevlude Akbulut?Yuksel, Thiago Ferro

The Old Age Security (OAS) program, comprising the universal OAS pension and the Guaranteed Income Supplement (GIS) for low-income seniors, serves as the foundational pillar of Canada's retirement income system, effectively providing a guaranteed annual income for the senior population. We investigate the impact of OAS income on food insecurity, a critical issue with significant implications for physical and mental health, among primary beneficiaries of the program, low-income seniors. Using a sharp regression discontinuity design (RDD), we analyze pooled data from the 2015–2019 Canadian Community Health Survey (CCHS), focusing on seniors with annual incomes below $26,000 who become eligible for GIS and OAS benefits at age 65, resulting in a significant increase in their income. To assess the causal impact of program participation, we measure the likelihood of food insecurity using the Adult Scale from the Household Food Security Survey Module (HFSSM), a validated tool that identifies food insecurity through questions on running out of food, skipping meals, and experiencing hunger due to financial constraints. We find that receiving OAS at age 65 reduces food insecurity in Canada by 7-8%, with the impact varying by sex and province of residence. Significant reductions in food insecurity were observed among both sexes in Ontario, and females in Nova Scotia and Quebec, while other provinces showed minimal or no improvement. Our study suggests that OAS financial support is an effective policy tool against food insecurity among low-income seniors, potentially explaining why food insecurity is lower in this group compared to the general population. The observed heterogeneity in the estimated effects of the program across Canadian province indicates that provincial factors also contribute to food insecurity levels. **Keywords:** Old Age Security program, Seniors, Regression discontinuity design, Food insecurity, Canada

Ind-1304 Nutrition-Sensitive Cash Transfers and Lean Season Food Insecurity

PRESENTER: **Dan Maggio**
AUTHORS: Aulo Gelli, Anissa Collishaw

Significance/Background Across sub-Saharan Africa, poor rural households experience intra-annual cycles of hunger. During these "lean

seasons" – the period between planting and harvest when crops are in the field but not ready for consumption – households deplete their grain stores, food prices rise, and income-generating opportunities decline, leading to widespread food insecurity. These spells of severe food insecurity not only harm households' ability to pull themselves out of poverty but may also co-occur with periods of crucial importance to children's growth, causing stunting and poor cognitive development. **Research Question** We study the degree to which social protection programs can protect against these lean season shocks. Specifically, we ask if unconditional cash transfers combine with complementary nutrition behavior change programming can protect household food security during the lean season. **Methods** We study a cluster randomized controlled trial designed to evaluate the effectiveness of augmenting the Government of Malawi's (GOM) early childhood nutrition and development approach with more intensive social behavior change communication and unconditional cash transfers. Our trial randomly assigns communities to one of four trial arms: 1. Control – The GOM's Standard of Care (SOC) 1. Social behavior change (SBC) – A bundle of SBC interventions to augment the SOC. 1. SBC + Low Cash – The SBC intervention + an MWK 17,204 monthly cash transfer 1. SBC + High Cash – The SBC intervention + an MWK 43,516 monthly cash transfer We study the effectiveness of this package at maintaining food security during Malawi's severe 2022-2023 lean season. **Key Findings** We find that the SBC + High Cash Arm was particularly effective. Among households who received this package, we observe 16 percent higher food consumption and 14 percent lower food insecurity. In contrast with control households, who experiences sharp deterioration of dietary quality during the lean season and consumed 385 fewer calories per person per day relative to our baseline survey, these households consumed 226 more calories. They also had fewer micronutrient inadequacies and consumed 31 percent more thiamin, 11 percent more niacin and 15 percent more. These findings can be largely explained by greater agricultural yields and food storage that insulated these households against the sharp price spikes of staple grains in the lean season. In our other treatment arms, we see improvements in dietary diversity but observe no evidence of a protective effect regarding dietary quantity. **Knowledge Contribution** Our results present a clear tradeoff between scale and treatment intensity when looking to reduce seasonal food insecurity. We show that this is likely because the income elasticity of demand for food is quite low, while several of the substitution elasticities are much higher; meaning that households may prioritize diverse diets over adequate diets, even in the context of a large economy-wide negative shock. These findings also the highlight the importance of transfer timing, as the "high cash" households did not improve their food consumption through purchases, but rather by using the cash to purchase agricultural inputs and sure-up their food stocks for the lean season.

Ind-1807 Impatience and Present Bias do not Predict Weight Loss in Obesity: Evidence from Lab-in-Field and Nationally Representative Data

PRESENTER: **STEFANIE SCHURER**
AUTHORS: Ian Caterson, Nicholas Fuller, Xueting Wang, Agnieszka Tymula

This paper demonstrates that impatience and present bias, the key building blocks of behavioral economics models of choice, do not predict success in attempts at reducing body fat and BMI for people with obesity. Behavioral economic theory attributes the inability to lose weight to impatience and present bias, assuming they lead to excessive food consumption and inadequate exercise. We use data from a large-scale lab-in-field study that tracks 293 participants with obesity who attempted to improve their health as part of a 12-month randomized controlled trial conducted in a clinical setting. We find no statistically and economically significant relationship between impatience or present bias and body fat/BMI loss within a 6 and 12 months window. We rule out that our results are driven by measurement issues or internal validity concerns. First, we replicate our key finding in nationally representative survey data of 6,118 adults with obesity, regardless of their weight loss intentions. Second, we find that impatience significantly predicts the risk of drop-out from the trial before completion in an economically meaningful way. Increasing participants' impatience by 1 standard deviation above the mean implies that an extra 1 in 12 participants would fail to complete the trial ($p<0.05$). Our results suggest that inability to complete medically advised treatments is a behavioral condition, but obesity itself is not. Treatments that focus on correcting impatience or self-control alone may not be the right approach for weight loss in clinically relevant populations.

Ind-2215 The Impact of Volume Based Promotion Removal on the Sales of Soft Drinks and Confectionery Products

PRESENTER: **Viktorija Kesaite**
AUTHORS: Thijs van Rens, Jean Adams, Martin White, Oliver Mytton

Background: Studies have shown that in-store price promotions disproportionately target the sale of less healthy foods. Removing such promotions may reduce these purchases. In this study, we evaluated the impact of removing multi-buy promotions on the purchases of soft drinks and confectionery products at one major UK supermarket in April 2016, relative to other major UK supermarkets which hadn't implemented this intervention. We had three main objectives: i) to assess whether removing multi-buy promotions led to a shift toward other types of price promotions among households in the intervention group compared to those shopping at other UK supermarkets; ii) to examine whether the intervention affected the expenditure and quantity of soft drinks and confectionery products purchased; and iii) to explore whether the effects varied by educational level and household size.

Data: We used household purchase data on soft drinks and confectionery products from Kantar Worldpanel's UK consumer panel, which includes approximately 30,000 households. Our dependent variables were log transformed purchases, analysed separately for expenditure and quantity, and the main variable of interest was the interaction variable between a post-treatment dummy for April 2016 and the proportion of spending in the intervention group. For the purposes of this analyses we used data for the years 2014 -2018.

Methods: To evaluate the effect of removing multi-buy promotions in the intervention group on household supermarket purchases, relative to purchases for households who shop at other major UK supermarkets, we used a difference-in-difference methodology, which we estimated using two-way fixed-effects. Our empirical strategy exploits the exogenous variation across supermarkets on the impact of multi-buy promotion removal on sales outcomes in the intervention group.

Results: We found a statistically significant decrease in both expenditure and unit sales of soft drinks and confectionery products following the removal of multi-buy promotions. Soft drink expenditure decreased by 0.4725 (95% CI: -0.5319 to -0.4131) and unit sales by 0.2509 (95% CI:

-0.3097 to -0.1921). For confectionery products, expenditure fell by 0.2108 (95% CI: -0.2829 to -0.1387) and unit sales by 0.1803 (95% CI: -0.2427 to -0.1178). While purchases on other price promotions increased, total promotional purchases of these products decreased overall. Sub-group analyses indicate that this effect was more pronounced among households with children and those where the highest education level was a degree or higher.

Conclusions: Our analysis showed that removing multi-buy promotions led to a statistically significant shift toward other price promotions. However, this substitution did not fully offset the impact of the intervention, resulting in an overall decline in promotional sales of soft drinks and confectionery products. This suggests that removing multi-buy promotions on unhealthy products in-store might help to reduce the demand for these products.

Economic Evaluation of Non-communicable Disease Interventions

MODERATOR: **Fernando Postali**,

Ind-207 Optimising Radiotherapy Access: A Cost-Effectiveness Analysis of Hypofractionated vs. Conventional Radiotherapy for Breast and Prostate Cancers

PRESENTER: **Nayyereh Ayati**
AUTHORS: Jing Jing Li, Andrew Scott, May Abdel-Wahab

Introduction:

Global access to radiotherapy remains critically limited, particularly in low- and middle- income countries, where patients often face limited or delayed treatment due to resource constraints. Hypofractionated radiotherapy (HRT), which delivers shorter treatment courses with comparable efficacy compared to conventional radiotherapy (CRT) presents a promising option for optimising resource use. However, its potential to improve accessibility is yet to be fully explored. This study addresses this knowledge gap by estimating the global demand for radiotherapy for two high burden cancers -breast and prostate -and assessing the potential cost savings and resource efficiencies achievable with HRT over a one-year period from the perspective of national healthcare systems.

Method:

We conducted a comprehensive review of the comparative efficacy and safety of HRT versus CRT to guide our economic evaluation. Using the unique Global Cancer Observatory (GLOBOCAN) 2022 database, we estimated the global incidence of breast and prostate cancers in 2024, providing a robust foundation for estimating global radiotherapy demand, adjusted for country-specific population growth. Optimal radiotherapy rates and fraction requirements for CRT and HRT were determined based on practice guidelines and validated with real-world data from 207 radiotherapy centres across 55 countries across all income levels. Costs—including equipment, staffing, and infrastructure—were estimated using income-specific data from the International Atomic Energy Agency (IAEA) activity-based costing model. Cost savings were estimated by comparing the reduced number of fraction requirements in HRT to those of CRT, with freed-up capacity assumed to allow treatment of additional patients, thereby expanding global access to radiotherapy.

Results:

This analysis included 174 countries classified as 15% low-income, 27% lower-middle-income, 26% upper-middle-income, and 32% high-income split. In 2024, the estimated radiotherapy demand encompassed 895,249 prostate cancer and 2,101,986 breast cancer patients. CRT would require 33.1 million fractions for prostate and 52.5 million for breast cancer, while HRT would reduce these needs to 17.9 million and 31.1 million fractions, respectively. These 36.2 million reductions in fractions could free capacity to treat an additional 2.2 million patients. Cost-savings from substituting HRT over CRT were estimated at $5.5 billion, with savings divided between prostate ($2.6 billion) and breast cancer ($2.9 billion). High-income countries achieved the largest savings in absolute terms especially in labour costs, but low-income countries showed substantial relative gains when adjusted for GDP per capita and population size, especially in equipment and infrastructure costs. Sensitivity analysis confirmed a linear relationship between cost-savings and the rate of HRT substitution, with even partial adoption yielding significant financial benefits.

Conclusion:

This study demonstrated significant cost-savings with HRT over CRT, particularly for prostate and breast cancers given their high global incidence. Leveraging global cancer data through GLOBOCAN allowed for precise, region-specific estimates of radiotherapy demand, underscoring its utility in health resource allocation worldwide. The findings support HRT as a cost-effective strategy to expand radiotherapy access, address resource limitations, and improve patient care, especially in low- and middle-income countries. These results suggest potential policy shifts, such as reimbursement models that encourage HRT use, to drive sustainable and efficient radiotherapy expansion globally.

Ind-289 Cost-Effectiveness of IoT-Based Management of Home NPPV in COPD Patients With Hypercapnic Chronic Respiratory Failure: Trial Based Economic Evaluation

PRESENTER: **Ruihua Feng**
AUTHORS: Hui Liu, Jiu Cheng, Yuanlin Song, Yueying Cui, Xi Wang, Yinghao Lv

Background The management of chronic obstructive pulmonary disease (COPD) presents a significant burden to healthcare systems across the world. For COPD patients with hypercapnic chronic respiratory failure, home noninvasive positive pressure ventilation (NPPV) is an established treatment option associated with significant benefits, but challenges still remain in ensuring treatment effectiveness. This study aimed to assess the cost-effectiveness of Internet of Things (IoT)-based management versus standard management of home NPPV in COPD patients with hypercapnic chronic respiratory failure. **Methods** A Markov decision analytic model was developed to simulate real-world COPD progression and predict health outcomes and costs associated with IoT-based and standard management of home NPPV. Efficacy and cost inputs were primarily sourced from a published multicenter, prospective, randomized controlled trial and supplemented by official Chinese databases where necessary. The discounted lifetime cost per quality-adjusted life-year (QALY) gained was calculated from Chinese healthcare payer perspective and sensitivity analyses were conducted to test the robustness of model results across different assumptions. **Results** Compared to standard NPPV, IoT-based NPPV increased costs by ¥3,607.26 and improved QALYs by 0.24 per person across the lifetime horizon, resulting in an incremental cost-effectiveness ratio of ¥15,030.25 per QALY with a 93.6% probability of being cost-effective at the given willingness-to-pay threshold. Base case results were also robust to multiple one-way sensitivity analyses, with the main drivers being hospitalization costs of standard and IoT-based NPPV groups during the period of serious exacerbation. **Conclusions** IoT-based NPPV was cost-effective compared to standard NPPV for COPD patients with hypercapnic chronic respiratory failure. **Keywords:** Chronic obstructive pulmonary disease; Noninvasive positive pressure ventilation; Hypercapnia respiratory failure; Internet of things; Telemedicine; Cost-effectiveness analysis; Economic evaluation.

Ind-562 Estimating the Healthcare Costs of *In Situ* and Thin Invasive Melanoma Overdiagnosis in Australia

PRESENTER: **Daniel Lindsay**
AUTHORS: Thanya Pathirana, Louisa Collins, Catherine Olsen, Katy Bell, David Whiteman

Background: International research suggests that a high proportion of melanoma *in situ* may be overdiagnosed, potentially contributing to overtreatment, patient harm and inflated costs for individuals and healthcare systems. However, Australia-wide estimates of the magnitude of melanoma overdiagnosis are potentially outdated and there has been no estimation of the cost to the healthcare system. We aimed to estimate the magnitude and subsequent cost to the Australian healthcare system of overdiagnosed *in situ* and thin invasive melanomas in Australia.

Methods: Using the competing mortality and adjusted for multiple primary methods to calculate lifetime melanoma risk, we used routinely collected national-level data to estimate overdiagnosed melanoma *in situ* and thin invasive melanomas (stage IA) in Australia in 2017 and 2021, separately for men and women. We multiplied the number of overdiagnosed melanomas by the estimated annual cost of a melanoma *in situ* or thin invasive melanoma, to quantify the financial burden of melanoma overdiagnosis to the Australian healthcare system in the year following diagnosis.

Results: We estimated that 67–70% of melanoma *in situ* were overdiagnosed in 2017, rising to 71–76% in 2021, contributing to between 19 829 (95%CI: 19 553 – 20 105) and 20 811 (95%CI: 20 528 – 21 094) cases of overdiagnosed melanoma *in situ*. In 2021, the estimated costs in Australia for melanoma overdiagnosis ranged between $17.7 million Australian dollars (AUD; 95%CI: AUD$17.4 – AUD$17.9 million) and AUD$18.6 million (95%CI AUD$18.3 – AUD$18.8 million). We estimated that 22–29% of thin invasive melanomas were overdiagnosed in 2017, rising to 28–34% in 2021, contributing to between 2831 (95%CI: 2726 – 2935) and 3168 (95%CI: 3058–3279) overdiagnosed thin invasive melanomas in Australia. In 2021, the estimated costs from thin invasive melanoma overdiagnoses ranged between AUD$2.5 million (95%CI: AUD$2.4 – AUD$2.6 million) and AUD$2.8 million (95%CI AUD$2.7 – AUD$2.9 million). The total cost of overdiagnosed melanomas to the Australian healthcare system was approximately AUD$21.6 million in 2021.

Conclusions: Melanoma overdiagnosis is a growing clinical and public health problem in Australia, producing significant economic costs in the year following overdiagnosis. Limiting melanoma overdiagnosis may prevent unnecessary healthcare resource use and improve financial sustainability within the Australian healthcare system. Redirecting costs incurred for overdiagnosis to fund skin cancer prevention programmes aimed at reducing incidence might be a more cost-effective use of government resources.

Ind-621 Healthcare Resource Utilisation and Cost of Coronary Heart Disease Care Pathway Across the Continuum in Australia Using Linked Administrative Data

PRESENTER: **Sangita Shakya**
AUTHORS: Richard Varhol, James Boyd, Crystal Lee, Bernard Asiamah-Asare, Kevin Chai, Lan Gao, Suzanne Robinson, Sean Randall

Background:

Coronary heart disease (CHD) is the leading cause of morbidity and mortality, imposing a substantial burden on healthcare systems. The coexistence of type 2 diabetes mellitus (T2DM) further amplifies this burden. As the socio-economic impact of CHD continues to rise, a clearer understanding of care pathways and their associations with health outcomes and costs is critical for informed healthcare planning and policy.

Objective:

To examine integrated care pathways for individuals with CHD and T2DM, identify healthcare interactions associated with rehospitalisation and mortality, and estimate incremental healthcare cost for CHD patients with and without T2DM.

Methods:

We used linked administrative datasets for CHD patients (ICD10-AM code block I20-I25) from MedicineInsight general practices (GP) and secondary care data (emergency, hospital, and mortality) in Western Australia (n=694,004) recorded between 2010-2023. First, CHD cases presented at emergency departments (ED; index event) were matched with hospital and GP records. Among CHD patients with T2DM (n=2,085), we analysed pre-and post-CHD care pathways and their associations with rehospitalisation and mortality using descriptive statistics, Cox regression and discrete-time generalised linear model (GLM) with $\log_2$-transformed GP visits counts in StataSE 18. Second, we conducted an incremental cost analysis over a 3-year post CHD period comparing CHD patients with T2DM (n=1,006) to propensity score matched CHD-only controls (n=1006), drawn from a larger population (n=3,240). Direct healthcare costs (GP visits, ED presentations, hospital admissions, prescribed medications, and pathology tests) were estimated for 2024 from a government perspective. All models were adjusted for age group, sex, remoteness, and socio-economic status (comorbidities included only in pathway analysis).

Results:

Each doubling of post-CHD GP visits was associated with reduced odds of recurrent rehospitalisation (OR=0.94; 95% Confidence Interval (CI) 0.92-0.97; p<0.001) and lowered mortality risk (HR=0.87, 95% CI: 0.84-0.90; p<0.0001). Conversely, a doubling of pre-CHD GP visit was associated with increased odds of recurrent rehospitalisation (OR=1.04, 95% CI: 1.01-1.06; p=0.005) and mortality (HR= 1.09, 95% CI: 1.05-1.11; p<0.0001). Older age (≥ 60 years), remote residence, comorbid heart failure or chronic kidney disease were significantly associated with elevated mortality. Overall, 73.7% (95% CI: 71.8-75.6%) of patients received at least one of the guideline-recommended medication, 34% (95% CI; 31.9%, 36.4%) were prescribed metformin, often alongside Insulin, or DPP4 inhibitors. Patients with CHD and T2DM incurred an additional AUD 10,213 than patients only having CHD in 3-year post CHD follow-up largely due to hospitalisation. Cost peaked in the first year post-CHD in both groups of patients.

Conclusion:

Post-CHD GP engagement was linked to improved survival and reduced risk of rehospitalisation, suggesting its potential value in improving outcomes and containing long-term costs. In contrast, frequent GP visits before the index event may reflect underlying health complexity and elevated risk. The higher cost burden in CHD with T2DM patients, largely driven by hospitalisations, underscores the need for integrated, cost-effective care models and improved uptake of guideline recommended therapies. Targeted interventions for older adults, remote population, and those with multimorbidity may help reduce avoidable system burden and improve health equity.

Ind-1143 Cost-Utility Analysis of Radiofrequency Ablation (RFA) Among Facet Joint Chronic low Back Pain Patients in Thailand

PRESENTER: **Manit Sittimart**

Background: Chronic low back pain (CLBP) is among the top ten leading worldwide causes of years lost to disability. Radiofrequency ablation (RFA) is widely recommended as a secondary treatment for facet joint-related chronic low back pain (CLBP). However, evidence on its cost-effectiveness in Thailand remains insufficient to inform reimbursement decisions. **Aim:** This study aimed to evaluate the cost-effectiveness of conventional RFA compared to conservative treatment for facet joint originated CLBP patients over 16-month and 28-month time horizons in Thailand. **Method:** A cost-utility analysis was performed using a Markov model and guided by the Thai health technology assessment (HTA) guidelines. The model used a monthly cycle length and adopted a societal perspective. RFA, including a diagnostic medial branch block (MBB), was compared to conservative treatment (medications, physical therapies, and integrative treatments). Data were collected from both primary and secondary sources. Clinical data were obtained from multiple randomised controlled trials, while medical cost data—including doctor fees—were extracted from claim databases of three university hospitals in Bangkok. Direct non-medical costs were based on patient interviews (n=64; RFA group: 31, conservative group: 33). Utility values were derived using the EQ-5D-5L (Thai version) questionnaire, with health states classified by a numeric rating scale (NRS ≥4 for pain state). THB values were converted to international dollars (Intl $) using a 2022 purchasing power parity rate (THB 11.7236 = 1 Intl $). The results were shown as incremental cost-effectiveness ratios (ICER) in Intl $ per quality-adjusted life year (QALY), with a willingness-to-pay (WTP) threshold of approximately I$13,652 per QALY gained. Sensitivity analyses, including one-way and probabilistic analyses, were conducted to explore influential parameters and uncertainty. A threshold analysis was performed to identify the RFA pricing at which it could become cost-effective. **Results:** The probabilistic ICER for RFA was estimated at I$99,267/QALY for the 16-month horizon and I$52,380/QALY for the 28-month horizon, both exceeding the WTP threshold. One-way sensitivity analysis showed that the ICER was most affected by variations in utility parameters, RFA pricing, opportunity costs, and the direct medical costs associated with CLBP. At the current WTP threshold, RFA pricing would need to decrease fourfold—from I$4,897 to I$1,158 for the 16-month horizon and to I$1,779 for the 28-month horizon—for RFA to have a 50% chance of being cost-effective. **Conclusion:** This study is the first economic evaluation of RFA for CLBP in Asia. At its current price, RFA is not considered cost-effective in Thailand. However, it may offer potential benefits, including reduced need for unnecessary lumbar spine surgeries. Price negotiation is recommended to make the intervention more cost-effective before it is included in Thailand's benefit package.

Ind-1384 Lifetime Direct Costs of Managing Cervical Cancer in South Africa: Medical Schemes Perspective

PRESENTER: **Evelyn Thsehla**

Background

South Africa bears 2.3% of the global burden of cervical cancer incidences and 1.8% of the estimated global death. Cervical cancer is a leading cause of cancer mortality in South African women. Approximately 5 870 women died of cervical cancer in 2018. The lifetime cost of managing cervical cancer in medical schemes is unknown. This study estimates the lifetime direct medical costs of managing cervical cancer using the

prescribed minimum benefits (PMB) funding guidelines in medical schemes in South Africa.

Methods

A Markov model was used to estimate the long-term costs of managing cervical cancer as a PMB in medical schemes. Based on the number of girls below the age of 9 in medical schemes, a hypothetical cohort of 150 000 girls was followed over a 55 –year time horizon. The PMB funding guidelines were used to identify services for managing cervical cancer. Unit costs were sourced from medical schemes and the Council for Medical Schemes. Epidemiological data and transition probabilities were sourced from literature. Total costs were estimated over the follow up period from the medical schemes perspective and expressed in South African rands.

Results

A total of R5.3 billion (no discount) was estimated for managing cervical cancer cases after following the cohort for 55 years. This amount translates to R899 million when a discount rate of 5% is used. When analysed by different groups, R187 million (discount) was estimated for managing cervical cancer in the age group 25 to 34 as compared to R537 million (discount) in the age group between 35 and 55. Approximately R233 billion, R170 million, R117 million and R378 million was estimated for managing the cohort in stage I, stage II, stage III and stage IV, respectively.

Conclusion

The lifetime costs of cervical in medical schemes are substantial. Effective interventions such as screening and vaccination should be encouraged to reduce new infections and lifetime costs in the covered population.

Ind-1478 Direct Medical Costs of Nasopharyngeal Carcinoma in Indonesia: A Healthcare Payer Perspective

PRESENTER: **Royasia Viki Ramadani**
AUTHORS: Cosphiadi Irawan, Erna Kristin, Susanna Hilda Hutajulu, Yussy Afriani Dewi, Gregorius Ben Prajogi, Lucia Rizka Andalucia, Donni Hendrawan, Sudi Indrajaya, See-Hwee Yeo, Shikha Dhawan, Junice Ng

Background: Nasopharyngeal carcinoma (NPC) is a common and deadly cancer in Indonesia. The objective of this study is to estimate the direct medical hospital costs of NPC using the national health insurance (*Jaminan Kesehatan Nasional* [JKN]) database in Indonesia. **Methods:** The annual costs were estimated using a nationally representative sample of 1% of the JKN population, comprising 2.1 (2019) to 2.4 million (2022) JKN members, from 2019 to 2022. Patients newly diagnosed with NPC, who had at least two NPC-related visits and no prior cancer diagnosis in the year before, were included. Annual costs were calculated over one year (365 days) from the first visit associated with NPC. Costs captured under Case-Base Groups (CBGs) comprised hospitalization and specialist outpatient visits. Non-CBGs costs included radiotherapy, diagnostic procedures, and other costs such as prostheses. Chemotherapy costs were not available for analysis. Costs in Indonesian Rupiah (IDR) were inflated using the Consumer Price Index in 2022 and converted to United States dollars (USD) (1 USD = IDR 15,731). **Results:** Of the 590 NPC patients with records in JKN, 262 patients met the inclusion criteria. Around 29% of these patients did not receive any NPC-related treatment one year after diagnosis. The annual mean cost was USD 4644 per patient. CBGs accounted for 92% of the total mean cost, with inpatient and outpatient CBGs costing USD 2014 and USD 2278 per patient, respectively. Non-CBGs cost per patient was USD 353. The total direct medical hospital cost for all NPC patients in the JKN population was extrapolated to be USD 40.5 million per year. This comprised 14% of the JKN cancer expenditure. **Conclusions:** NPC imposes a significant economic burden on Indonesia's health system. To contain health expenditures, specific policies are needed to improve cancer prevention and early diagnosis, as well as to efficiently allocate healthcare resources. **Editorial acknowledgement:** This study was sponsored by BeOne Medicines, Ltd. Editorial support, under the direction of the authors, was provided by Envision Pharma Inc., and was funded by BeOne Medicines.

Ind-1510 Budget Impact Analysis of Biosimilar Denosumab Versus Xgeva for the Prevention of Skeletal Related Events in Cancer Patients with Bone Metastases

PRESENTER: **Arun Jones**
AUTHORS: Linda Siachalinga, Hansoo Kiim, Joshua Byrnes, Kyoo Kim

Background

In advanced solid cancers, metastases to the bone are a common marker of disease progression with poor prognosis. Once cancer metastasizes to the bone, the patient becomes at high risk of Skeletal-Related Events (SREs) such as bone fracture or spinal cord compression. SREs are expensive to treat and result in massive quality-of-life reductions, they therefore represent a large clinical and financial burden to society. Denosumab is a monoclonal antibody effective in delaying the occurrence of SREs in patients with advanced solid cancers. For this indication, denosumab’s patent is soon expiring. Non-inferior biosimilars are primed to enter the market thereafter, as such we aim to estimate the budget impact of switching to a biosimilar in Thailand.

Methods

A budget impact model was created in Microsoft Excel which estimates the number of patients to be treated with denosumab in the next five years. We then calculated the difference in costs between a scenario where all patients over the next five years were treated with the originator brand at list price and one where they are treated with a discounted biosimilar. An alternate scenario was analyzed which aimed to emulate market conditions affecting total budget impact, such as market share split and originator brand price drop. Input parameters were varied by +-20% to quantify the impact of parameter uncertainty on model results.

Results

Over the next five years, we project a total accumulated saving over five years equal to 6.5bn THB in the base case when the biosimilar is sold at a 25% discount to the originator. In the scenario analysis, total accumulated savings were estimated at 2.2bn THB. Results were robust to one-way sensitivity analysis, with the switch being cost saving in all cases. The lower bound of total cost-savings found through sensitivity analysis was 5.2nn THB in the base case and 1.8bn THB in the scenario analysis. The upper bounds were 7.8bn THB in the base case and 2.6bn in the scenario analysis. All inputs are found to be unitarily elastic to the total cost saving.

Conclusions

Switching from originator to biosimilar denosumab for the prevention of SREs in patients with advanced cancers will result in significant savings for payers in Thailand.

Ind-1519 Using Modeling Tool to Estimate Country-Specific Costs for Policy-and Decision-Making in Cervical Cancer Secondary Prevention in Burkina Faso

PRESENTER: **Fadima Inna Kamina YAYA BOCOUM**, Institut de Recherches en Sciences de la Santé
AUTHORS: Winthrop Morgan, Nayi ZONGO, Jacques Fabrice Ella, Linda TRAORE, Cindy L. Gauvreau, Ann Levin, Lisa HUANG

Background Cervical cancer is the second most common cancer among women in Burkina Faso. In 2018 the World Health Organization (WHO) launched the Global Initiative for the elimination of cervical cancer with the goal of 70% of women screened with a high-performance test by the age of 35 and again by the age of 45. To meet this target, national cancer control programs need to plan and develop a budget forcast. Cost estimates of cervical cancer secondary prevention are important for well-informed strategic policy- and decision-making. To support planning efforts, we used a costing tool that 1) estimated cost of scaling up cervical cancer interventions in Burkina Faso for two scenarios and 2) provides five-year scale-up scenarios to support implementation. Method Within the SUCCESS project, the Burkina Faso costing team conducted a micro-costing of scaling-up screening and precancer treatment over five years. Data for target populations by HIV status, facility availability and capacity, healthcare personnel utilization and wages, and supplies and equipment costs were collected and verified with the Ministry of Health. These data were applied to the updated WHO Cervical Cancer Prevention and Control Costing (C4P) Tool . Key stakeholders consisting of policymakers, clinicians and public health advocates were convened for consensus-based model validation and development of country-relevant scenarios. We conducted two scenario analyses to address alternative screening and precancer treatment strategies – 1) continuation of current efforts using visual inspection with acetic acid (VIA); and 2) using a higher-performing test, HPV DNA for 30% of its target population. In both scenarios, the screening coverage is assumed to increase from 10% in 2025 to 70% in 2029. Results Over 5 years, the total cost for scenario 1 is estimated to be $15,285,342 and for scenario 2 $26,035,865. In scenario 1, the largest share of total costs is for program support activities for both financial and economic costs, 53% and 49%, respectively. In scenario 2, the costliest category is cervical cancer service delivery for both financial and economic costs, 55% and 60%, respectively. The financial and economic cost drivers in scenario 2 are HPV DNA testing and laboratory processing (42% and 44%) and training activities (23% and 21%), respectively. With 100% VIA, scaling-up is projected to provide approximately 2 million screenings and 84 000 precancer treatments. In scenario 2 with 30% HPV DNA and 70% VIA, scaling-up is projected to provide approximately 2 million screenings as well; but provide 35% more precancer treatments. Conclusion As Burkina Faso progresses towards universal health coverage, new strategic approaches to prevent cervical cancer are required. Implementing the more ambitious scenario will take the country closer to reaching WHO cervical cancer elimination goals. However, additional funding will be required to reach this scenario, The costs from this study can help inform policymakers to develop effective strategies for implementation in Burkina Faso and act as an effective tool in advocating for budgetary allocations.

Ind-1654 The Health and Economic Benefits of Improving Prehospital Identification of Stroke in Australian Women: a Modelling Study

PRESENTER: **Laura Downey**
AUTHORS: Lei Si, Emily Atkins, Tom Gadsden, Stephen Jan

Objective: In the prehospital setting, emergency medical services are more likely to accurately identify stroke in young men than women. We aimed to estimate the long-term cost savings and gain in quality-adjusted life years (QALYs) that could be achieved if ischaemic stroke was identified in women with the same level of accuracy received by men, versus the status quo. **Design:** Decision tree and** Markov model decision analysis. **Settings, participants:** Two arms including 5,513 women aged under 70 years: (1) a 'hypothetical' scenario, whereby women receive the same level of accurate stroke identification as men (yet experienced symptoms relevant to women); and (2) the status quo. Transitions between post-stroke health states, recurrent stroke and death were made in one-year cycles over 50 years from a societal perspective. **Main outcome measures:** Years of life lived,** costs and QALYs in the hypothetical scenario relative to the status quo. Results were extrapolated to the national level based on the annual number of ischaemic stroke hospitalisations among women across Australia in 2020-21. **Results:** Compared to the status quo, the hypothetical arm gained 0.14 years of life, 0.08 QALYs and cost savings of $2,984 per patient. At the national level for 2020-21, this equates to 252 life years,144 QALYs gained, and cost savings of $5.4 million. Outcomes were most sensitive to the probability of an accurate assessment of stroke, short-term treatment costs, patient age and transition probabilities to 90-day post stroke health states. **Conclusions:** Enhancing the timely and accurate identification of ischaemic stroke among Australian women in the prehospital setting would yield significant health benefits and cost savingsto Australian society as a whole.

Ind-1926 Health State Utility Values in Oesophageal Cancer: a Systematic Review and Meta-analysis.

PRESENTER: **Josipa Petric**
AUTHORS: Victoria Kollias, Norma Bulamu, Maziar Navidi, Muktar Ahmed, Tim Bright, Jonathan Karnon, Sonia Hines, David Watson

Background: Patients receiving treatment for esophageal cancer often experience an array of symptoms affecting their health status, along with physical, psychological and social functioning, which affect their quality of life. Significant limitations exist in the low quality of studies in previous systematic reviews and no application of a MAUI, meaning that QALY inputs for cost utility analysis are scarce. The aim of this systematic review was to critically appraise the literature and summarize utility values for the different health states associated with esophageal cancer care and treatment to inform inputs for cost utility analysis.**Methods:** The following databases were searched: MEDLINE (Ovid), Embase (OVID), Scopus, Web of Science Core Collections, Cochrane Register of Controlled Trials, CINAHL (EBSCOhost) and ProQuest, for articles with data in English from database inception until September 2023. Empirical studies reporting utility values elicited directly or indirectly were included. The quality of the article was assessed using a combination of tools and mean utility values for studies applying the same utility elicitation methods and heath state (disease stage, treatment or treatment timepoint) were pooled using random-effects models.**Results:** A total of 5,929 records were identified and 13 studies were included. Most studies were conducted in China (n=3), the UK (n=2), the Netherlands (n=2) and Australia (n=2). There was a clear description of HRQoL generation with direct evidence collection in each study, and each study was of adequate quality. Utilities were mostly elicited using EQ-5D-3L (53.8%) and EQ-5D-5L (23.1%). Six studies applying EQ-5D-3L were included in the meta-analysis. The pooled utility estimate for EQ-5D-3L at baseline was 0.66 (95% CI 0.56–0.75, I2=83%) for stage I, 0.84 (95% CI 0.81–0.87, I2=48%) for stages II/III and 0.67 (95% CI 0.57–0.78, I2=85%) for stage IV esophageal cancer.**Conclusion and implications for policy:**The EQ-5D is the most prevalent utility-based patient-reported outcome measure applied in esophageal cancer. This review provides utility estimates using EQ-5D-3L at diagnosis for the different stages of esophageal cancer. However, due to heterogeneity in heath states and studies, obtaining robust utility estimates for cost-utility analyses remains a challenge. Larger studies are needed to generate sufficiently accurate estimates.

Ind-2103 Distributional Cost Effectiveness Analysis of Colorectal Cancer Screening Program in Beijing Based on Markov Model

PRESENTER: **Haoran Zhan**
AUTHORS: Shangyao Li, Yitong Lu, Tingting Xu, Yu Su, Yu Tian, Yuxin Sun

OBJECTIVE: This study aims to investigate the impact of a colorectal cancer(CRC) screening program on population health and equity among urban and rural residents in Beijing, as well as what screening strategies are economically feasible to maximize improvements in population health and equity.

METHODS: A Markov model was used to simulate the screening intervention process in Beijing, and a distributional cost-effectiveness analysis was conducted for 37 strategies based on three different screening techniques at different intervals and with different age ranges. We obtained 16 groups of district-specific CRC incidence rates as the anchor target, and constructed district-specific colorectal cancer screening models by adjusting and calibrating the initial state distributions and the all-cause mortality rate. The 1x per capita GDP of Beijing (132,600 yuan) in 2017 was utilized as the willingness-to-pay level. Net monetary benefit (NMB) was calculated for optimal strategy identification. The Atkinson index was used to calculate the health equity level Aε of the health outcomes produced by each strategy. The social welfare function based on Atkinson's index was also used to calculate the Equally distributed equivalent(EDE)-NMB value of each strategy for the trade-off between equity and cost-effectiveness. Parametric and probabilistic sensitivity analysis were used to verify the robustness of the results. Scenario analyses were also used to explore the cost-effectiveness and equity implications of each strategy in suburban populations under scenarios of relatively higher or lower adherence or compliance.**

RESULTS: When the NMB were considered, an annual FIT screening among people aged 40-79 years(FIT (1Y, 40-74 years)) was the optimal strategy among all districts, with a weighted average incremental value of ¥85,809.04 relative to no screening. When the equity impacts were considered, all 37 strategies increased regional health inequality(Aε value for no screening: 0.0002128), and the Aε of each strategy was significantly inversely related to the NMB, with a correlation coefficient of 0.837 ($p<0.001$). When the equity and cost-effectiveness were considered together, FIT (1Y, 40-79 years) was still the optimal screening strategy, with an EDE-INMB of ¥85,764.33 relative to no screening. Probabilistic and parametric sensitivity analyses at a WTP level of 1x GDP per capita demonstrated the robustness of the results. While the sensitivity of FIT screening for nonprogressive adenomas at a WTP level of 3x GDP per capita may be the only parameter influencing the conclusions. Scenario analyses shaowed that the cost-effectiveness and equity of each strategy improved as compliance increased among suburban residents.

CONCLUSION: All strategies were cost-effective for all districts in Beijing, while keeping the unequal impact of health benefits low. FIT (1Y, 40-74 years) was the optimal strategy for all districts in Beijing, in terms of maximizing equity and cost-effectiveness combined. Interventions to improve compliance and adherence for suburban populations can increase the value of the screening program in terms of both equity and health improvement efficiency, Efficiency in health improvement may be a key driver of social value. Care needs to be taken for the sensitivity of the FIT used for non-advanced adenomas.

Addressing Health Financing Gaps for Mental Health and Other NCDs

MODERATOR: **Hongqiao Fu**,

Ind-377 How Mental Health Shapes Healthcare Costs: Evidence From Australian Longitudinal Survey

PRESENTER: **Mr. Md Ehsanul Haque Tamal, MS, MEcon**
AUTHORS: Kamrul Hassan, Khurshid Alam, Dominic Gasbarro

Background: Mental health conditions pose a significant burden on human civilisation. These conditions not only affect emotional and psychological well-being but also have severe implications for economic outcomes. While research has highlighted association between mental health and healthcare utilisation, the long-term impact of mental health on health expenditure, particularly considering the role of education, remains underexplored.

Objective: We aim to address this gap by examining longitudinal relationship between mental health and health expenditure. We investigated how mental health influences out-of-pocket (OOP) healthcare costs, including expenses for health professionals and medications in a well-functioning health system with universal health coverage like Australia. Additionally, we explored whether education could mitigate the negative impact of poor mental health on healthcare spending by employing theoretical framework of Grossman model.

Methods: Using 22 waves of the Household, Income and Labour Dynamics in Australia (HILDA) survey (2001-2022), we applied fixed-effects regression models to analyse association between mental health and detailed health expenditure components. We controlled for socioeconomic factors and examined the role of education as an effect modifier. To quantify mental health status, we used Mental Health Inventory-5 (MHI-5) metric, which ranges 0-100, implying 100 as good mental health and 0 as severe mental health condition.

Results: Our findings reveal a strong negative association between good mental health and higher OOP healthcare expenditure. A one-unit decrease in MHI-5 score (indicating mental health degradation) is associated with a 0.25% increase in OOP spending (β=-0.0025, $p<0.05$), along with a 0.23% increase (β=-0.00232, $p<0.01$) in health professional fees and a 0.23% increase (β=-0.00231, $p<0.01$) in medication costs. The increase in OOP spending was also associated with long-term illness by 4.8% and regular annual increments by 1.6%.

We further examined relationship between education and health expenditure as postulated in the Grossman model and the efficient producer hypothesis. Our analysis indicates that OOP health expenditure rises with the increase in individual education levels. Individuals with a postgraduate degree spend 16-21% more on health professional fees and 9-18% more in overall OOP expenditures, compared to those with secondary or lower education levels, suggesting that postgraduates are efficient producers of health. Similarly, graduate diploma holders spend 4-12% more, and bachelor's degree holders spend 1-6% more than those who completed high school or below, which supports the Grossman theory.

However, this relationship is nuanced for individuals with poor mental health. Those with graduate diplomas (10% less) or bachelor's degrees (3% less) with poor mental health tend to spend less on healthcare compared to high school graduates. This suggests that mental health issues may diminish the benefits of higher education in terms of efficient health production.

Conclusion: Our study highlights substantial economic burden of mental illness in Australia. While higher education can improve health outcomes for many, it may not fully mitigate the negative impact of poor mental health on OOP healthcare costs. Policy interventions prioritising mental health support and access to affordable healthcare could help alleviate this burden and enhance overall well-being. 2

Ind-2745 Healthcare Use and Costs in Traditional Medicare Versus Medicare Advantage among Older Adults With and Without Dementia: 2011-2020

PRESENTER: **Elham Mahmoudi**

Research Objective. Dementia is a rapidly growing public health concern and an escalating economic burden. In 2024, the direct healthcare cost of dementia in the U.S. is expected to be $360 billion ($1 trillion by 2050).** Improving healthcare efficiency for these high-need, high-cost people is an economic imperative. We examined healthcare use and costs in traditional Medicare (TM) and Medicare Advantage (MA) among White, Black, and Hispanic Medicare beneficiaries (65+) with and without dementia. MA plans are private insurers paid by Medicare on a prospective capitated model, incentivized to provide more efficient healthcare. We hypothesized total and out-of-pocket healthcare costs and Black-White and Hispanic-White variations in these outcomes are lower in MA vs. TM.

Study Design. In a cross-sectional case-control study, we pooled 2011-2020 Medical Expenditure Panel Survey data (nationally representative). We used multivariable generalized linear models to examine total and specific healthcare use/costs (hospitalization, emergency, outpatient, office, home health, and prescription refills). We used gamma and negative binomial distributions for healthcare use and cost, respectively. Two-part regression models were applied, and all models were adjusted for age, gender, race/ethnicity, chronic conditions, family income as a share of the federal poverty level, Medicaid, education, comorbid conditions, perceived physical and mental health, and survey year. Cost measures were inflated to 2020 value. Furthermore, we used the Average Treatment Effect (ATE) to examine the effect of MA on healthcare use and cost. We applied Inverse Propensity Weighting (IPW) to address a potential selection bias into MA.

Populations Studied: Community-dwelling older adults (65+) with and without dementia diagnosis who enrolled in TM or MA. [N=41,546

(MA=17,974; with-dementia=814); TM=23,572; with-dementia=982)].

Principal Findings: Adjusted predicted total healthcare costs among non-dementia beneficiaries were higher in TM vs. MA by $1,444 (no significant difference between TM and MA among dementia patients). There was no difference in out-of-pocket costs between TM and MA. Similarly, while the probability of hospitalization [by 1.1 percentage point (PP)] and cost of hospitalization (by $2,111) was higher among non-dementia beneficiaries in TM vs. MA, there were no differences between TM and MA among dementia patients. White patients with dementia, compared with their Black and Hispanic counterparts, had the highest total (by $5,106 and $2,519, respectively) and out-of-pocket costs (by $1,435 and $1,558, respectively). Hispanic patients with dementia had the lowest likelihood of any hospitalization and emergency visits compared with White (by 8.7 and 13.4 pp, respectively) and Black patients (by 7.6 and 10.33 pp, respectively). White patients with dementia had the highest number of use and costs associated with office visits and prescription refills compared with their Black (by 6.4 visits and $1,874; by 10.5 refills and $1,420, respectively) and Hispanic counterparts (by 2.3 visits and $1,023; by 11.9 refills and $1,414, respectively).

Conclusions: Racial/ethnic variations in healthcare use and costs exist in Medicare. Healthcare costs and racial/ethnic variations among non-dementia patients were lower in MA vs. TM. However, we did not find any evidence of lower costs or lower racial/ethnic variation in healthcare use/costs among beneficiaries with dementia in MA vs. TM.

Ind-1504 Classification of Psychosocial Interventions for Severe Mental Illness: Evaluating the Applicability of WHO's ICHI for Resource Allocation

PRESENTER: **Kuo-yi Jade Chang**
AUTHORS: Richard Madden, Jennifer Smith-Merry, Ivy Yen, Firew Bobo, Nicola Fortune, Luis Salvador-Carulla

Background: Severe mental illnesses affect approximately 4% of the global population. Restoring functioning often requires diverse psychosocial interventions, such as illness management, case coordination, supported employment, family psychoeducation, and housing assistance. However, the lack of standardised terminology for these interventions leads to inconsistent descriptions, inaccurate data collection and inefficient reimbursement processes. As a results, many interventions are not adequately captured or recorded in broader health and social care systems, further undermining resource allocation decisions and evidence-based service planning. **Aims:** This study evaluated the applicability of WHO's International Classification of Health Interventions (ICHI) for classifying psychosocial interventions, its capacity to clearly describe key components, and its potential for integration into routine data collection and billing systems. **Methods:** Three coders independently assigned ICHI codes to psychosocial interventions described in 460 studies identified through a scoping review using a five-stage iterative process. Coding involved ICHI's three axes - Target (entity on which the Action is carried out), Action (deed done by an actor to the Target), and Means (processes and methods by which the Action is carried out) - and extension codes for recipient types, session quantifiers, and factors such as tele-practice and assistive technology use.** A consensus meeting with coders and an experienced ICHI developer was held at each stage to reflect on coding process, refine strategies, and improve consistency. Inter-coder reliability was assessed using Jaccard Similarity Coefficient. Coding patterns - one-to-one (one intervention, one code), one-to-many (one intervention, multiple codes), and many-to-one (multiple interventions, one code) - were documented. **Results:** The ICHI's three-axis structure and alignment with the ICF framework effectively categorise a wide range of interventions, accounting for the interplay between health conditions, functionality, and environment. It supports linking interventions to functionality-focused outcome measures (e.g., engaging in remunerative employment), potentially aiding outcome-based funding decisions. The Action axis captures dynamic processes central to psychosocial interventions, for example, "navigating", "planning" and "collaborating" in case management. Inter-coder reliability for coding the initial 100 interventions yielded a mean Jaccard similarity coefficient of 0.34 (fair agreement) for Target coding, and ranged from 0.54 (moderate) to 0.80 (strong) for Action coding. This variability was attributed to initial unfamiliarity with the ICHI framework, the complexity of the interventions, and vague descriptions of the interventions. All interventions received at least one stem code. One-to-many matches (n = 58) reflected the multifaceted nature of the interventions, requiring multiple codes, while many-to-one matches (n = 14) highlighted gaps in ICHI's specificity, often due to limited codes under the Means axis, which primarily focuses on medical and surgical methods. ICHI's precision and applicability could be enhanced by adding a purpose-designed extension code. The ICHI framework is not designed for fee-for-service reimbursement as it lacks categories for intervention intensity, frequency, duration, service providers and facilities/settings. However, it may hold potential for use in capitation or other remuneration models. **Conclusions:** Integrating ICHI can ensure consistent documentation, enable like-for-like comparisons, support outcome-based resource allocation, and improve client-focused service planning.** Future research should collaborate with practitioners to evaluate ICHI's feasibility and scalability for routine data collection.

Ind-704 Towards Sustainable Mental Health Financing in Ghana: An Analysis of Budget Trends, Challenges and Opportunities

PRESENTER: **Lucy Owusu**, Kumasi Centre for Collaborative Research, Kumasi
AUTHORS: Tessa Roberts, Barbara Barrett

INTRODUCTION

About 13% of Ghanaians are estimated to suffer from a mental disorder yet more than 90% do not receive appropriate treatment. With a psychiatrist to population ratio of 0.13 per 100,000 population, the treatment gap is substantial and attributed mainly to gross underfunding. Addressing this treatment gap and working towards achieving the sustainable development goal to promote mental health(MH) requires sustained financing to build infrastructure and human resource across the country. Unfortunately, very little evidence exists on understanding current patterns in mental health financing including challenges and opportunities to guide policy action. This study reviews mental health budget allocation and explores barriers to mental health financing, highlighting its implications for mental health care and existing opportunities.

METHODS

We used a qualitative situational analysis design using a documentary analysis and in-depth interviews. A total of 10 stakeholders were carefully selected to reflect mental health financing at national and sub-national levels. The documentary analysis involved extracting trends of government budgets allocated to mental health, analysis of reports on mental health expenditure and flow of allocated funds to mental health departments and units at the regions and districts where services are delivered. The interviews focused on understanding barriers to mental health financing, their implications, and the existing opportunities for improving MH financing. A thematic analysis was conducted to synthesise the findings from the data sources.

FINDINGS

Ghana is making progress in recent years to prioritize mental health in the health budget to support mental health services, though the results show evidence of inconsistent budget allocation to mental health. Between 2020 and 2023, budget allocation to mental health declined by 90%. Approximately 98% of the MH budget allocated over these years were spent on the three main psychiatric facilities without evidence of fund transfers to subnational mental health units and facilities. External assistance from donors and development partners, reported to be unreliable and restricted to selected regions, remained the main source of support to sub-national units. The main barriers to inadequate mental health financing in Ghana were highlighted by stakeholders to include increase national debt payment affecting overall health budget and the lack of contextual MH data to inform prioritization and financial investment. Stakeholder interviews also indicated that beyond inadequate health care access, poor MH financing also led to staff attrition, increased out-of-pocket payments for healthcare which causes delays to treatment seeking and consequently worsening patient wellbeing. There is currently plan to include three mental health conditions in the health insurance service package which will be a significant financing breakthrough that can reduce patients' out-of-pocket payments for treatment.

CONCLUSION

While some effort is being made to have a dedicated mental health allocation in the health budget in Ghana, this should be complemented with innovative financing strategies to expand government commitment to the mental health budget. Additionally, research regarding best approaches to address data gap is needed to generate nationally representative mental health data to estimate the true burden that can inform prioritisation and investment.

Ind-2058 Mobile-Money Self-Financing to Improve Hypertension Medication Supply: Evidence From Rural Uganda

PRESENTER: **Caterina Favaretti**, Technical University of Munich

AUTHORS: Vasanthi Subramonia Pillai, Mr. Nikkil Sudharsanan

Background: Health systems in low-resource contexts often struggle to consistently deliver essential services and treatments. In rural Uganda, patients with hypertension (HTN) frequently face medication stockouts at government health facilities that lead to treatment discontinuation or high out-of-pocket costs from private pharmacies. In response to this gap in access, community members in our study setting have developed informal resource-pooling systems to collectively purchase medications in bulk. While these initiatives are crucial, they face challenges such as minimum funding thresholds and logistical delays, which can hinder access to essential medications and adversely affect health outcomes. This study aimed to formalize these informal community-based purchasing systems, by implementing a mobile-money-based self-financing program to improve access to anti-hypertensive medications at a public non-communicable disease (NCD) clinic in Nakaseke, Uganda. The primary objective of our study was to evaluate the program's effectiveness in ensuring consistent medication supply and receipt of medication. We also examined factors related to the scheme's uptake, including any adverse selection effects, and investigated whether participation influenced patients' blood pressure levels. **Methods:** Between August 2023 and February 2024, we recruited 183 participants with HTN from a public NCD clinic in Nakaseke, Uganda. All participants were invited to contribute 5000 Ugandan Shillings monthly via a mobile money account to the health facility to ensure the availability of their anti-hypertensive medications during their next visit. Contributors received medications from a study supply if government stocks were unavailable, while non-contributors relied solely on government stocks. Our primary outcomes included contribution rates and improvements in the overall supply of medications. **Results:** Participants contributed in 47% of eligible months on average. Contribution rates showed no significant differences across education levels or medication need, suggesting minimal equity concerns or adverse selection. Government pharmacies fulfilled only 9% of total prescriptions; however, for contributors, MoPuleesa closed 84% of the remaining gap. Due at least in part to implementation challenges, some non-contributors also received medications, with pooled funds covering 53% of their shortfall. **Discussion and Conclusions:** Our findings demonstrate the feasibility and effectiveness of mobile money pooling in addressing chronic medication shortages. MoPuleesa achieved broad participation and equitable outcomes in a resource-constrained setting, significantly improving medication availability. While not a substitute for systemic reform, such community-driven financing models can serve as effective interim solutions in under-resourced health systems. Future research should explore scalability, sustainability, and integration with the national supply chain and financing mechanisms.

Equitable and Sustainable Workforce Policies

MODERATOR: **Chris Schiling**,

Ind-1631 Promoting Equity in Health Care: Evidence on The Rural and Remote Allied Health Workforce and Determinants of Retention and Turnover

PRESENTER: **Jenny Cleland**
AUTHORS: Diana Khanna, Rachel Milte, Ali Dymmott

Background

Rural and remote communities are negatively affected by complex challenges in recruitment, retention and turnover of the allied health workforce which result in reduced access, despite a growing demand. Adding to the inequity, those in rural and remote populations are more likely to experience higher rates of chronic disease, increased hospitalisations, and lower SES status. High costs relating to lost time, recruitment, relocation and training are experienced by employers who have a high turnover of staff. There is a need for a detailed examination of quantitative evidence to aid policy makers develop interventions to increase the rural and remote allied health workforce. The aim of this review was to determine the extent of available evidence from studies with a quantitative component to examine the length of stay and costs associated with the recruitment, retention and turnover of rural and remote Allied Health Professionals (AHP), and any potentially non-modifiable or modifiable factors which have been shown to impact length of stay or turnover.

Methods

Six databases were systematically searched to identify studies that included a quantitative approach. Included studies had to report on either recruitment, retention, turnover, length of stay or associated costs of AHPs in rural or remote settings. Data was extracted using a specifically adapted proforma, analysed, and further examined to synthesise factors- 'personal' and 'organisational'- reporting significant associations. The review was conducted using the PRISMA extension for scoping reviews.

Results

Twenty-four studies were included from Australia, Canada, USA, South Africa and Europe. Only two studies reported costs associated with turnover and recruitment, both from Australia. The studies reported median direct costs ranging from AUD $18000 to $22000, with indirect costs further incurred. Findings indicated length of stay was short in comparison to urban AHPs, with the median duration ranging from 1-3.2 years, and a survival probability of 0.54 at two years which bears significant cost implications for employers. Consistent evidence for statistically significant associations was found between a variety of personal and organisational factors (such as rural education, and rural work placements) and recruitment, retention and turnover. Being integrated into the community, opportunities for career development, good working conditions and financial incentives were also found to be significantly associated.

Conclusion

There remains a significant challenge in maintaining an adequate rural and remote allied health workforce across Australia, but also in several other countries. Despite this, there has been limited evaluation of the direct or indirect cost implications for the public or private healthcare sector. On a more positive note, the findings of this review indicate that there is much evidence for policy makers to design programs to improve workforce access in rural and remote areas, including through supported university places for rural students, targeted educational programs and career and financial incentives. However, while supports such as educational programs supporting recruitment and retention of workers have been shown to be effective, without detailed evidence of the costs and benefits of such programs sustainable funding is likely to remain elusive.

Ind-2302 The Effect of Informal Caregiving on Presenteeism and Absenteeism: Evidence From the United Kingdom

PRESENTER: **Mr. Charles Smith, BSc**
AUTHORS: Sean Urwin, Matt Sutton

Background

Informal (unpaid) caregiving is widespread and has substantial consequences for carer's health, wellbeing and on labour market outcomes. Previous research on the labour supply impacts of caregiving have mainly focused on participation, hours and earnings. There is less research on those who combine informal care and work, including: (i) presenteeism – the reduced productivity whilst working and (ii) absenteeism – the number of days with missed work. These are important to consider given that one in seven UK workers are informal carers.

Aim

To quantify the impact of caregiving on work-related productivity loss focusing on presenteeism and absenteeism.

Data

We use the UK Household Longitudinal Study, a large and nationally representative survey which tracks respondents since 2009 over 13 survey waves. Presenteeism is measured using responses to three questions from the Short Form-12 questionnaire. Absenteeism measured by missing any days of work in the last week due to either personal/family reasons or being sick/injured. We categorise carers as high intensity (at least 20 hours per week) or low intensity (1-19 hours of care per week).

We include a rich set of covariates that account for individual demographics as well as job and health-specific characteristics.

Methods

To quantify presenteeism and absenteeism impacts we apply random and fixed effects regression techniques. Comparisons between the two methods allow us to explore to what degree unobservable and time-invariant individual factors explain any differences between carers and non-carers.

We also test whether informal carers are more likely to leave the labour market than non-carers in our sample.

Results

Our final sample consists of 208,163 individual-wave observations (15.4% are unpaid carers) from 44,266 employed individuals. We identify 12.2% of the sample as experiencing presenteeism, and 1.29% experienced absenteeism in the previous week. We find that high and low intensity carers are 3.27 [95% CI: 2.12, 4.42] and 0.62 [95% CI: 0.15, 1.10] percentage points more likely to report presenteeism than non-carers, respectively, using a random effects specification. Accounting for individual fixed effects we find high and low intensity carers are 1.34 [95% CI: 0.004, 2.78] and 0.22 [95% CI: -0.34, 0.78] percentage points more likely than non-carers to report presenteeism.

High intensity carers are also 1.08 percentage points [95% CI: 0.55, 1.61] more likely to have missed work in the last week due to illness or family reasons than non-carers. This is consistent whether random or fixed effects models are used.

We find that carers are less likely than non-carers to be employed in the subsequent survey wave.

Conclusion

Our study finds that informal carers in employment are more likely to experience presenteeism and absenteeism than non-carers in employment, an effect that is larger for more intensive carers. This suggests that more support is required for informal carers to continue working. Estimates of the productivity losses due to informal caregiving are underestimated if they only consider reductions in labour force participation and do not account for presenteeism and absenteeism.

Ind-2535 The Impact of Motherhood on Female Medical Doctors' Earnings

PRESENTER: **Jia Song**
AUTHORS: Mr. Terence Cheng, Julie Ratcliffe

Background Gender equity in education and labour markets has enabled more women to enter high-prestige professions such as medicine, yet persistent inequalities remain. Despite achieving parity in education and training, female doctors continue to face significant challenges in their professional trajectories, particularly after becoming mothers. Existing literature demonstrates that the arrival of children creates a marked divergence in the labour market outcomes of men and women, with women often bearing the brunt of household and caregiving responsibilities. This effect is especially pronounced in demanding, high-skilled professions like medicine, where long hours and inflexible schedules compound the difficulties of balancing work and family roles. While extensive research has documented the motherhood penalty across general populations, there is limited evidence regarding its impact on elite professions, particularly in the context of Australia. Understanding how childbirth affects earnings trajectories in this group is critical to inform policies that address gender disparities in professional advancement and labour market outcomes.

Aim

This study examines the causal effect of childbirth on the earnings trajectories of Australian female doctors. It investigates the magnitude and duration of earnings changes, explores differences by specialty and family size, and evaluates the role of childcare accessibility in shaping employment outcomes. Providing new insights into the intersection of parenthood and professional career progression.

Methodology Using longitudinal data from the "Medicine in Australia: Balancing Employment and Life" (MABEL) survey (2008–2018), this study employs an event-study approach to track changes in annual gross earnings around the birth of a first child. The sample includes 7,191 doctor-year observations of female doctors, covering a period from four years before to eight years after childbirth. By controlling for individual fixed effects and time-varying factors, the analysis provides robust causal estimates of the earnings impact of motherhood.

Results The findings highlighted a sharp and immediate decline in earnings for female doctors, averaging 42.2% in the year of childbirth. While earnings gradually recover, they remain 35% below pre-birth levels three years after childbirth and only return to baseline eight years later. The impact varies significantly by specialty and family size: general practitioners experience more prolonged earnings penalties compared to specialists, and mothers of three or more children face the greatest long-term reductions. Accessibility to childcare near the workplace emerges as a significant factor, with limited availability delaying mothers' return to full-time employment and earnings recovery.

Conclusion Motherhood imposes substantial short- and medium-term earnings penalties on female doctors in Australia, highlighting the enduring challenges of balancing professional and family responsibilities. These findings underscore the importance of targeted interventions, including improved workplace childcare access and flexible working arrangements, to mitigate the effects of parenthood on career progression. By addressing these barriers, healthcare organizations can promote gender equity and better support female doctors, ultimately contributing to a more sustainable and efficient healthcare workforce.

Ind-2158 Fishing in the Same Pool? The Impacts of Hospital Hiring on Long-Term Care Employment and Quality Outcomes

PRESENTER: **George Stoye**, Institute for Fiscal Studies
AUTHORS: Max Warner, Carol Propper, Ben Zaranko

Objectives: Global demand for both hospital and long-term care (LTC) is rising, and both sectors increasingly struggle to recruit and retain adequate numbers of staff. However, recruitment efforts are rarely coordinated across sectors, with the LTC and the wider healthcare system managed separately in most countries. For example, in England, many care workers leave the LTC sector to join the public healthcare provider – the National Health Service (NHS) – which typically offers higher pay, more job stability and greater opportunities for career progression. This may in turn have negative impacts on the LTC sector, which are so far poorly understood. We aim to fill this evidence gap by examining the consequences of hospital hiring decisions for the labour supply of care workers in residential care homes in England, and the potential health impacts on care users.

Methods: Using monthly NHS hospital payroll data and six-monthly data on staff employed by care homes in England, we first use geographic and time variation in the availability of NHS jobs to study how social care worker numbers change in relation to hospital employment. Specifically, we compare changes in care home staff employed by providers across Travel-to-Work-Areas (TTWAs) with differential changes in the number of relevant NHS staff employed in the same year. We carry out this analysis separately for care workers and registered nurses, using different groups of NHS workers to measure the relevant amount of NHS employment in each case. One key challenge is that local NHS and care home staffing levels may be driven by common factors (e.g. an ageing population demanding both health and LTC services). To address this, we employ a shift-share instrumental variables approach, instrumenting changes in NHS staffing levels with predicted changes based on historical employment patterns and national trends in each staffing group. This relies on the identifying assumption that changes in care home staffing are otherwise unrelated to the share of each NHS staff group employed before our analysis begins. We repeat this with care user health outcomes as the outcome variable to study how changes in staffing impact care quality in residential care homes.

Results: We show hospital hiring decisions have large impacts on employment in care homes. The estimates indicate that if the NHS hires an additional healthcare or nursing assistant, a local care home loses 0.35 care workers, while an additional nurse hired in the NHS reduces registered local care home employment by 0.06 nurses. Preliminary results indicate no impact on emergency admissions from care homes due to these staffing changes. Further work will examine other measures of care home performance and patient outcomes.

Discussion: The results show hospital hiring decisions have significant impacts on employment in the LTC sector in England. This indicates that both hospital and care homes are competing for the same set of workers, and a lack of coordination could undermine policy efforts to improve service outcomes.

Ind-1827 A Health Workforce Planning Model for Palliative Care: Development and Applications

PRESENTER: **Chris Schilling**

Abstract

Introduction

With growing demand for palliative care and an ageing workforce, there is a critical need to develop planning tools that can identify potential shortfalls in the palliative care workforce before they occur. This presentation introduces a new palliative care service planning (PCSP) model for Australia, designed to support strategic planning and workforce development. We discuss the development and validation of the model and use it to project the baseline palliative care workforce over the next 20 years. We then compare policy response scenarios based on the 'Wellbeing in the palliative care workforces' survey.

Methodology

A bespoke systems dynamics PCSP model was developed to capture inflows (new graduates, re-entering the workforce) and outflows (retirements/exiting labour force, death) of the palliative care workforce. The PCSP model projects the counts, full-time equivalents (FTEs) and clinical FTEs of the palliative care workforce by profession (palliative medicine physicians and palliative care nurses), age group, sex, and region (State, rurality). Key data were sourced from the Health Workforce Data (HWD) tool and the 'Wellbeing in palliative care workforces' survey with 1,400 responses. Model validation compared model results with observed results for 2014-2023.

Results

Under the business-as-usual approach, the rate of palliative care physicians is expected to increase to 1.5 FTE per 100,000 population by 2035, and to 1.6 FTE per 100,000 population by 2045, still well short of the service delivery target of 2.0 FTEs. Scenario analysis highlights that a 60 per cent increase in the number of annual graduates would be required to reach the target coverage by 2035. Policy responses to improve the wellbeing of the palliative care workforce has a moderate impact on long-term supply.

Discussion

The results from the PCSP model are sobering. Baseline projections suggest there is little chance that the palliative care workforce will be able to meet current let alone future levels of demand without substantial increases in the number of new graduates.

Within Trial Economic Evaluations

MODERATOR: **Carl Asche**, Guidelines and Economists Network International (GENI)

Ind-597 Is Prehospital Video Triage for Suspected Stroke Cost-Effective? A Stepped-Wedge Analysis Using Real World Data

PRESENTER: **Jing Yi Jessica Weng**
AUTHORS: PHOTONIC Study Team, Ms. Rachael Hunter

BACKGROUND

Prehospital video triage (PVT) for suspected stroke patients was implemented in four areas of the English National Health Service (NHS) during COVID-19. It enables hospital-based stroke specialists to communicate remotely with ambulance clinicians at the scene of emergency ambulance calls of suspected stroke patients via telephone or videoconferencing; potentially improving the responsiveness of the receiving stroke unit.

RESEARCH QUESTIONS

As part of a mixed-methods study, we aimed to address the following research questions:

\1) Does PVT impact on care delivery and patient outcomes across the prehospital and acute stroke pathways?

\2) Is PVT for stroke cost-effective?

METHODS

To study acute stroke care delivery and stroke patient functional independence, we analysed data from Stroke Sentinel National Audit Programme (SSNAP). To account for sites implementing PVT at different timepoints, we used a stepped-wedge design fitting a mixed effects logistic regression model with age, sex, ethnicity, rurality, stroke type, out-of-hours arrival and stroke severity as covariates, with hospital site as a random effect. Comparator patients were areas of England where PVT was not implemented and pre-implementation timepoints. A second model fitted an interaction with COVID-19. Outcomes included stroke unit as the first ward of admission and functional independence at discharge.

Logistic regression and general linear models employing the same stepped-wedge design will be used to evaluate the effect of PVT on 30-day mortality and length of hospital stay, respectively, using data from Hospital Episode Statistics.

We will conduct an economic evaluation comparing PVT to no triage using a 10-year decision analytic model. The decision model will draw on the same data sources as mentioned above, along with national reference costs and Trust estimates of the cost of PVT. We will report the incremental cost per quality-adjusted life-year gained of PVT compared to no PVT over a 10-year time horizon from a health and social services perspective. The probability that PVT is cost-effective for a range of decision thresholds will be calculated using probabilistic sensitivity analysis.

RESULTS

206,144 patients who had a new hospital admission for stroke in England between April 2019 and August 2022 were included in the SSNAP analysis. There was a significant increase in the likelihood that the 8,434 patients treated in areas with PVT were admitted to a stroke unit as their first ward (Odds ratio (OR): 1.04, 95% confidence interval (CI) 1.03, 1.05) and had improved functional independence (OR:1.005, 95% CI 1.001, 1.010). This effect was stronger during COVID-19 (stroke unit as first ward OR: 2.15, 95% CI 1.89, 2.46; functional independence OR: 1.13, 95% CI 1.02, 1.25). Analysis of care delivery, patient outcomes and cost-effectiveness is ongoing.

CONCLUSIONS

Our preliminary SSNAP analysis found that services using PVT for suspected stroke saw improvement in stroke ward admission and functional independence at discharge, particularly during COVID-19. Our evaluation of the clinical and cost-effectiveness of PVT will contribute to the national priority of rapid deployment and scale-up of digital technologies.

Ind-981 Uncovering the Cost-effectiveness of Theory-based Implementation Approaches: a Health Economic Analysis of the Hide and Seek Project (HaSP) Trial

PRESENTER: **Bonny Parkinson**, Macquarie University

Background: Evidence that a healthcare intervention is clinically and cost-effective, and subsequently funded, does not guarantee adoption into

routine clinical practice. Implementation science can help ensure benefits are realised by improving adoption, although it also involves valuable resources, such as staff time. This study aimed to assess the cost-effectiveness of a theory-based compared to an intuition-based implementation approach to improve referral rates for genetic testing for Lynch syndrome (LS) – a common cause of colorectal cancer (CRC) and a range of other cancers – from the Australian health system perspective. **Methods:** A pragmatic two-arm cluster randomised controlled trial (the Hide and Seek Project, HaSP) compared the approaches across seven large hospitals (N=3,321 patients). Costs associated with the implementation approaches and the strategies were collected during the trial, including staff time, consumables, and once-off and ongoing costs of the strategies. Results were incorporated into Policy1-Lynch, a microsimulation model of testing, surveillance, prophylaxis and treatment of LS probands and at-risk relatives. Costs were reported in 2021 Australian Dollars (AUD). **Results:** Compared with the intuition-based approach, the theory-based approach was previously shown to significantly improve genetics services referral in high LS risk patients ($p<0.0001$); and there was a nominally significant improvement in risk-appropriate tumour testing (P=0.0306). The within-trial analysis found that a theory-based approach reduced once-off and ongoing implementation costs by AUD$2.47 and AUD$0.75 per patient, respectively, versus an intuition-based approach over five years. The modelled analysis estimated that a theory-based implementation approach increased health system costs by AUD$103.74 per CRC patient, but resulted in fewer CRC deaths and more life years gained (LYG), and thus cost AUD$37,679 more per LYG than an intuition-based approach. **Conclusions:** The once-off costs with the theory-based implementation approach were marginally more than with the intuition-based approach, but resulted in more effective strategies that were less costly on an ongoing basis based on the within-trial analysis. Overall, the theory-based implementation approach was cost-effective compared to an intuition-based approach based on the modelled analysis and a threshold of AUD$50,000/LYG. Further research is needed to confirm these results in larger trials, other settings and conditions.

Ind-1168 Cost-Effectiveness of Home-Based COVID-19 Treatments: Findings From the PRINCIPLE Trial

PRESENTER: **May Ee Png**, University of Oxford
AUTHORS: Victoria Harris, Ly-Mee Yu, Christopher Butler, F.D. Richard Hobbs, Paul Little, Mr. Stavros Petrou

Background: SARS-CoV-2, the virus causing COVID-19, infected over 676 million people and caused 14.9 million deaths globally between 2020 and 2021. In the UK, an estimated 1.5 million individuals have experienced lasting symptoms beyond four weeks post-infection, with 20% reporting significant activity limitations. The PRINCIPLE (Platform Randomised trIal of treatmeNts in the Community for epidemic and Pandemic iLlnEsses) trial is a community-based clinical trial designed to identify effective treatments for managing acute COVID-19 symptoms in higher-risk populations (e.g., individuals aged 18+ with comorbidities or aged 65+ without comorbidities). The population was largely unvaccinated when the trial began with azithromycin and remained so until favipiravir and ivermectin were introduced. While the trial evaluated the clinical effectiveness of six treatments, their cost-effectiveness remains unexplored.

Aim: To assess the cost-effectiveness of six COVID-19 treatments (azithromycin, doxycycline, inhaled budesonide, colchicine, favipiravir, and ivermectin) compared to usual care for home-based recovery.

Methods: Within-trial cost-effectiveness analyses were conducted among participants testing positive for SARS-CoV-2 in the PRINCIPLE trial's primary analysis population. Incremental cost-effectiveness ratios (ICERs) were calculated for mean costs versus two co-primary outcomes: hospitalisation/death avoided and day saved until recovery. The base case analysis, from an NHS and personal social services perspective, evaluated costs and effects over 28 days post-randomisation, using multiple imputation for missing data. Sensitivity analyses included adopting a societal perspective, conducting a complete case analysis, extending outcomes to 12 months, and examining pre-specified subgroups. Results were presented as cost-effectiveness acceptability curves across willingness-to-pay thresholds. All costs were reported in 2022/23£, with no discounting for the one-year trial follow-up period.

Results: Base case findings indicated that inhaled budesonide was consistently cost-effective, with an ICER of £6,386 per hospitalisation/death avoided and -£821 per day saved until recovery (south-east quadrant). Colchicine showed the most favourable ICER for hospitalisation/death avoided at £2,858, but its ICER for day saved until recovery was £283, suggesting limited cost-effectiveness in accelerating recovery. Azithromycin and doxycycline were cost-saving in terms of day saved until recovery but had high ICERs for hospitalisation/death avoided (£27,490 and £21,278, respectively), indicating limited cost-effectiveness for preventing severe outcomes. Favipiravir, although having an ICER of £136 per day saved until recovery, showed a dominated ICER for hospitalisation/death avoided. Ivermectin exhibited the least favourable ICERs for both outcomes, making it unlikely to be cost-effective relative to usual care. Sensitivity and subgroup analyses largely supported these findings.

Conclusions: Inhaled budesonide is a cost-effective option for home-based management of acute COVID-19 symptoms, reducing hospitalisations and accelerating recovery compared to usual care. This finding aligns with clinical insights suggesting inhaled budesonide may provide benefits in managing COVID-19 in the community setting.

Implications for policy and practice: This study provides essential insights for policymakers regarding resource allocation in community-based COVID-19 management. Establishing willingness-to-pay thresholds for COVID-19-related clinical outcomes can guide funding decisions, particularly for outpatient management strategies that reduce hospitalisations and support faster recovery. Future work should explore strategies for implementing the most cost-effective treatments, supporting sustained at-home care, and addressing long-term impacts on post-acute COVID-19 symptom management.

Ind-1222 Effect and Economic Evaluation of Pharmacist- led Multi-agent Collaboration Medication Reconciliation:A Randomized Controlled Trial in Hubei Province

PRESENTER: **Zhe Jin**, Huazhong University of Science and Technology
AUTHORS: Da Feng, Xiao Li, Yangfan Sun, Jiaxin Lv, Zhanchun Feng

Background: Polypharmacy among chronic disease patients is a significant global challenge, particularly in China, where the prevalence of

chronic diseases continues to rise. The 2018 National Health Service Survey reported that 34.3% of individuals aged 15 and above in China have chronic conditions, with 23.8% of those over 60 having two or more chronic diseases. Polypharmacy increases the risks of adverse drug interactions, side effects, and poor medication adherence, leading to higher hospitalization and readmission rates, influencing the healthcare costs and patient safety. Although medication reconciliation is recognized as an effective intervention, systematic studies evaluating its effectiveness and economic impact in China remain limited. This study aimed to assess the impact of a pharmacist-led multi-agent medication reconciliation model on the medication safety and cost-effectiveness for chronic disease inpatients. Through a randomized controlled trial, this research addressed an evidence gap by validating the intervention's effectiveness and economic benefits, providing empirical support for its application in chronic disease management.

Methods: This multi-center randomized controlled trial was conducted across 10 tertiary hospitals in Hubei Province,China, from July 2023 to the present,enrolling 1,250 chronic disease inpatients, with 625 patients in the intervention group receiving pharmacist-led medication reconciliation and 625 in the control group receiving standard care. The intervention involved pharmacists' comprehensive medication history collection, discrepancy identification, resolution of medication-related issues, and discharge counseling, while the control group received usual care. Key outcome measures included 30-day all-cause readmission rates, unplanned readmissions, medication discrepancies, and adverse events. Data analysis was conducted by generalized linear mixed models and difference-in-differences methods to assess the intervention's effects and conduct a cost-effectiveness analysis.

Results: Medication reconciliation significantly reduced the incidence of medication discrepancies (44.80% vs. 48.32%, OR=0.840, 95% CI: 0.712-0.993, p=0.041) and adverse events during hospitalization (5.60% vs. 6.72%, OR=0.826, p=0.202). The intervention group showed a significant decrease in 30-day unplanned readmission rates (9.80% vs. 13.26%, OR=0.638, p=0.019), though no significant difference was observed in 30-day all-cause and drug-related readmission rates (p>0.05). The economic evaluation showed an incremental cost-effectiveness ratio (ICER) of ￥5,331.37, indicating that for each readmission prevented, the healthcare system incurs an additional cost of ￥5,331.37, suggesting favorable cost-effectiveness.

Conclusion: The pharmacist-led medication reconciliation model significantly enhanced medication safety for chronic disease patients, demonstrating strong cost-effectiveness. By reducing medication discrepancies, adverse events, and unplanned readmissions, this model shows potential for improving medication adherence and optimizing healthcare resources. Expanding this model across healthcare settings, especially in primary care, could help manage polypharmacy and reduce complications and hospitalizations from inappropriate medication use. To support broad adoption, enhancing the clinical pharmacist workforce and implementing systematic training are essential, as is reinforcing policies that support quality assessment and collaboration within care teams.

Ind-1594 Economic Evaluation of Point-of-Care Testing and Treatment of Sexually Transmitted Infections during Pregnancy in Papua New Guinea (WANTAIM trial)

PRESENTER: **Qinglu Cheng**
AUTHORS: Virginia Wiseman, William Pomat, Lisa Vallely, Handan Wand, Andrew Vallely, Neha Batura, Michaela Riddell

Objectives

Left untreated, sexually transmitted infections (STIs) in pregnancy can lead to serious adverse outcomes for mother and child. Papua New Guinea (PNG) has among the highest prevalence of curable STIs including chlamydia trachomatis (CT), Neisseria gonorrhoea (NG), trichomoniasis vaginosis (TV) and bacterial vaginosis (BV), and high neonatal mortality rates. Advances in STI diagnostics through point-of-care (PoC) testing hold promise for resource-constrained countries such as PNG. This study aimed to conduct an economic evaluation of a cluster-randomized cross-over trial comparing antenatal PoC testing and immediate treatment of curable STIs with standard antenatal care in two provinces in PNG.

Methods

This economic evaluation was conducted prospectively over the trial period (2017–2021) from a societal perspective, including both provider costs and participant costs. Provider costs were incurred by the institutions implementing the PoC tests for CT, NG, and BV, and providing antenatal care. Participant (treatment) costs were the direct and indirect costs of healthcare seeking incurred by women and their families such as medical costs, transport costs and the opportunity costs in terms of lost productivity due to care-seeking visits. Costs were adjusted for inflation using the Consumer Price Index for PNG and converted to 2022 international dollars (INT$) using the Purchasing Power Parity. Incremental cost-effectiveness ratio was calculated and expressed as the additional costs per reduction in the proportion of either preterm birth and/or low birth weight.

Results

Preliminary results showed that over the trial period, the total costs were INT $2,107,101 in the intervention group and INT $1,795,911 in the control group. The proportion of preterm birth, low birthweight, or both among women with gonorrhoea at enrolment (secondary outcome of WANTAIM trial) was 16.2% in the intervention group and 34.2% in the control group (p=0.024). Therefore, the WANTAIM trial costed an additional INT$311,190 to achieve a reduction of 53% in the proportion of preterm or low weight birth among women with gonorrhoea at enrolment.

Conclusions

Further sensitivity analysis will be conducted to account for uncertainty in key model inputs. Scenario analyses will be conducted to identify scale-up options, and budget impact analysis will be undertaken to understand short-term financial impacts of intervention adoption on the national budget. The findings of this study will have the potential to provide decision-makers in PNG and similar settings evidence on the

relative value for money of this intervention and the likely level of investment required for implementation at scale.

Growing up Is Hard to Do: Causes and Consequences of Child and Adolescent Health

MODERATOR: **Devaki Nambiar**, The George Institute for Global Health- India

Ind-381 Parental Absence, Bullying Victimization, and Associated Child Health-Related Outcomes in Rural China

PRESENTER: **Yangling Ren**, Southwestern University of Finance and Economics
AUTHORS: Peirong Yang, Gang Chen, Yixiao Liu

Abstracts

Background and Objective: Parental absence is a potential contributor to bullying victimization and its subsequent negative effects on children's health and well-being, especially in rural China. However, the associations, mechanisms and heterogeneous linking parental absence, bullying victimization, and health outcomes remain inadequately understood. This study aims to explore the relationships between parental absence and child health outcomes, including physical health (doctor visits), health-related quality of life (measured by the Child Health Utility 9D [CHU9D] and Pediatric Quality of Life Inventory™ 4.0 [PedsQL]), and subjective well-being (WHO-5), with a focus on the mediating role of bullying victimization.

Methods: Self-reported data from 1912 school-aged children and adolescents in western China were analyzed. Logistic and linear regression models were used to examine the associations between parental absence, bullying victimization, and health outcomes. An instrumental variable approach was employed to assess the robustness of the results. Additionally, subgroup regressions and the Chow test were used to evaluate differences between children with and without siblings for each health outcome.

Results: Parental absence was associated with increased odds of children experiencing both higher probabilities (OR ranging from 1.286 to 1.353) and frequencies (OR ranging from 1.193 to 1.263) of bullying victimization. It also significantly correlated with higher odds of medical visits (coefficient = 0.311, $p < 0.01$), as well as lower CHU9D (coefficient = -0.014, $p < 0.05$), PedsQL (coefficient = -1.631, $p < 0.05$), and WHO-5 (coefficient = -0.256, $p < 0.05$) scores. Bullying victimization partially mediated the effects of parental absence on these outcomes, with frequency of victimization further amplifying the negative effects on physical health, especially regarding medical visits. Cumulative exposure to both parental absence and bullying resulted in increasingly severe health consequences. Children with siblings experienced more pronounced negative effects on health-related outcomes.

Conclusion: This study highlights the complex interactions between parental absence, bullying victimization, and health outcomes among adolescents in rural China. While both parental absence and bullying negatively affect mental health, their cumulative impact on physical health is particularly severe. Furthermore, the presence of siblings, typically viewed as a protective factor, may exacerbate the adverse effects of these challenges. These findings underscore the need for interventions that strengthen family support and provide resources for at-risk children to mitigate these vulnerabilities. Targeted programs focusing on improving family function and addressing bullying are crucial for safeguarding the health and well-being of vulnerable youth.

Key words: parental absence left-behind child, bullying victimization, physical health

, health-related quality of life, child wellbeing, rural China

Ind-2349 The Persistent Effects of Early-Life Stunting on Adolescents: Causal Evidence from the Philippines

PRESENTER: **Eeshani Kandpal**, The World Bank
AUTHORS: Jed Friedman, Deon Filmer

This study estimates rigorously identified, causal medium-run effects of malnourishment in the first 1000 days of life across a range of developmental and human capital measures thirteen years later when the affected individuals are between 14 and 18 years of age. The consensus in the literature is that stunting has negative associations with cognitive achievement (Sanchez, 2017; Hoddinott et al., 2011; Maluccio et al., 2009; Walker et al., 2005), educational attainment (Hoddinott et al., 2011; Martorell et al., 2009), long-term economic outcomes (Grantham-McGregor et al., 2007; Thomas and Strauss, 1997; Galasso and Wagstaff, 2017), and even adult physical health (Alderman, 2011). However, virtually all this evidence has been generated from observational studies with the possibility that these estimates are upward biased (in absolute value) due to the influence of unobserved confounders such as parental choices of child investment, home environment, and even unobserved aspects of income and wealth. Another common approach to the identification of long-run stunting impacts leverages child- or household-level shocks, however these estimates also run the risk of confounding by other child development inputs also affected by the shock.

In contrast, we leverage our previous research in which we identified large, exogenously induced increases in stunting among children from

vulnerable households in remote parts of the Philippines (Filmer et al., 2023). This earlier research showed that the Philippine cash transfer, *Pantawid*, raised the prices of perishable, protein-rich foods in remote areas and therefore *increased* stunting rates among children not born into the program. This original study was a cluster randomized controlled trial in 130 villages across 8 municipalities in 4 provinces of the Philippines. In the current study, we return to these 130 treated and control communities that constituted the experimental sample of *Pantawid* and resurvey 650 children who were 6–59-month-old children in 2011 (Chaudhury, Friedman, and Onishi, 2013). To understand the persistence of stunting impacts, we compare non-beneficiary cohorts in treated communities to the same cohort in similarly poor households in communities that were randomized out of the program. The identifying assumption is that stunting occurs in the first 1000 days of life and is largely irreversible after that (Georgiadis and Penny, 2017). We assess impacts on child anthropometry, cognition, socio-emotional skills, education and health, as well as biological impacts through fecal, buccal, and blood samples. We also account for differences in caregiving, household conditions, and COVID-19 impacts.

Early results show evidence of broad-based catch up on anthropometric and cognitive outcomes, but persistent detriments to measure of noncognitive wellbeing, including executive function. Perhaps most striking, we find that girls who were stunted in early life experience an earlier onset of menarche. Epigenetically, this is likely due to the young infant or in-utero fetus learning that it was in a resource scarce environment and therefore would have fewer years to reproduce, which in turn hastens the onset of menarche. Consistent with there not being a "menopause" for men, there are no impacts on the onset of puberty for boys.

Ind-228 The Role of Dental Health in Human Capital Formation During Adolescence

PRESENTER: **Shuhei Kaneko**
AUTHOR: Cheolmin Kang

Background

Although water fluoridation is widely recognized as an effective public health intervention, the appropriate dosage of fluoride remains a subject of ongoing debate. While numerous studies have demonstrated that fluoridation policies significantly reduce the prevalence of dental cavities, some recent research—including a well-executed causal analysis by Roberts (2024)—has raised concerns about potential adverse effects on cognitive function from childhood exposure to fluoride at levels commonly used in artificial fluoridation programs.

Objective

This study estimates the causal effects of childhood fluoride exposure at levels lower than those typically used in artificial fluoridation programs, leveraging quasi-exogenous variation in naturally occurring fluoride concentrations driven by regional geology in Japan. By combining this variation with unique longitudinal data tracking individuals from birth, nationally representative medical claims and patient survey data, we examine impacts on dental health and human capital development.

Main Results

We find that even low concentrations of fluoride significantly improve multiple dental health outcomes, despite the widespread availability of preventive measures such as fluoride toothpaste. Children in higher-fluoride areas are less likely to visit medical institutions for dental cavities and incur lower monthly dental expenditures.

Contrary to concerns raised by prior studies examining higher-dose exposure, we find no evidence of adverse effects on cognitive outcomes. Specifically, fluoride exposure has no detectable impact on educational attainment, including high school quality or college enrollment.

Importantly, we find that low-level fluoride exposure in early childhood leads to meaningful improvements in non-cognitive skills—particularly among females. A 0.1 mg/L increase in fluoride concentration during childhood (ages 2–12) increases Rosenberg self-esteem by about 4% of a standard deviation. It also enhances the "openness to experience" and "conscientiousness" dimensions of the Big Five personality traits, again only among females. These findings suggest notable gender heterogeneity in fluoride's developmental effects. As a potential mechanism, the results support that improved appearance-related confidence driven by better dental health is a key mechanism.

Validity of Identification Strategy

To support the validity of our identification strategy, we conduct a series of placebo tests. First, we show that fluoride concentrations are not significantly correlated with birth outcomes such as birthweight or gestational age, suggesting no association with underlying health endowments. Second, we find no systematic relationship between fluoride exposure and parental characteristics—including education, age, and parenting quality—reducing concerns about endogenous residential sorting. Third, we show that fluoride levels are not associated with healthcare utilization for non-dental conditions such as asthma, allergies, or influenza, indicating that fluoride is unlikely to affect unobserved health conditions other than dental health.

Policy Implication

Amid recent policy developments—such as U.S. Health Secretary Robert F. Kennedy Jr.'s announcement to end CDC support for community water fluoridation—our findings offer timely empirical insight. Taken together with recent studies, our results suggest that the fluoridation debate should shift from a binary choice of whether to fluoridate toward identifying optimal fluoride dosage. Such discussions must weigh not only the potential cognitive risks of higher exposure but also non-cognitive benefits linked to better dental health.

Ind-966 The Association of Maternal and Child Quality of Life: Australian Cohort Experiencing Psychosocial and Socioeconomic Adversity

PRESENTER: **Shalika Bohingamu Mudiyanselage**
AUTHORS: Anna Price, Jennifer Watts, Eric HY Lau, Julie Abimanyi-Ochom, Ms. Lisa Gold

Background and Objectives Evidence of the relationship between mothers and their children's quality of life (QoL) during early childhood is limited. Our previous systematic review highlighted a particular research gap in mothers' and young children's QoL in disadvantaged communities, especially within well-developed healthcare systems. Therefore, this study aims to explore the associations between maternal and child QoL from children aged three to five years in a cohort experiencing psychosocial and socioeconomic adversity in Australia. **Methods** This study used secondary data from the right@home randomised controlled trial (RCT) of sustained nurse home visiting. The right@home RCT recruited pregnant women experiencing psychosocial and socioeconomic adversity across two Australian states between 2013-2014, and 722 mother and child pairs were followed up from pregnancy to children's fifth birthdays (2013-2021). Mothers' QoL (exposure) was measured at multiple time points using the self-reported Assessment of Quality of Life Eight Dimensions (AQoL-8D) instrument. Children's QoL (outcome) was measured using the parent (proxy)-reported Pediatric Quality of Life Inventory (PedsQL) 4.0 when children were aged three, four, and five. A mixed-effects linear regression model was used to examine the association between maternal QoL and child QoL over the three-time points, adjusting for individual, psychosocial and socioeconomic factors. Missing data was handled using multiple imputations. **Results** Data from 491 (68%) mothers and child pairs and 1,473 observations over 3 years were included. The mean age of mothers at childbirth was 27.6 (SD 6.2), ranging from 14-49 years. 80% of mothers lived in poor neighborhoods, 33% smoked, and 33% had no income during pregnancy. At the age of 3 years, the mean QoL score of children was 87.35 (SD 10.50), and mothers' mean AQoL utility was 0.70 (SD 0.19). The child's QoL was positively associated with the mother's QoL (Adjusted Coefficient (ACE) 13.45, 95% CI: 8.51; 18.37, P < 0.001) and the child's health (ACE 5.34, 95% CI: 4.33; 7.35, P < 0.001). Children's QoL was negatively associated with child age (year 3=ACE -2.64, 95% CI: -3.83; -1.45, P < 0.001) and year 4=ACE -2.93, 95% CI: -4.17; -1.70, P < 0.001), residence in a disadvantaged area (ACE -4.07, 95% CI: -7.06;-1.08, P= 0.008), child body mass index (ACE -1.22, 95% CI: -1.90; -0.54, P < 0.001), premature birth (ACE -4.03, 95% CI: -7.26; -0.88, P = 0.012), formal childcare use (ACE -1.85, 95% CI: -3.15; -0.54, P = 0.006), mother's education (ACE -2.92, 95% CI: -5.37; -0.46, P = 0.020). **Conclusion** Mothers' quality of life is an important predictor of children's quality of life during the first five years. Quality of life in early childhood is associated with maternal, child, and neighborhood determinants of psychosocial and socioeconomic adversity. Government policies across health and welfare need to address the poor maternal and child quality of life in communities facing adversity.

Ind-2232 Childcare Quality and Maternal Mental Health

PRESENTER: **Miryana Dayanti**
AUTHORS: Eric Ochieng, Anne Fitzpatrick, Emily Beam, Maira Reimao

Introduction: Maternal mental health is important, as mothers often shoulder significant childcare burdens, with poor-quality or unreliable arrangements contributing to stress. Prolonged stress negatively affects mental health, impacting both mothers and their children. While much research focuses on childcare availability, perceived quality and satisfaction remain understudied despite their potential role in maternal mental health. Maternal depression, which harms child outcomes, may be influenced by how mothers evaluate childcare. Evidence is mixed. Some studies link high-quality care to reduced depressive symptoms, particularly when care meets expectations, while others find inconsistent effects. Perceptions of limited care availability are more reliably associated with depressive symptoms. Previous studies often assess childcare quality using structured observations and professional ratings, which can be challenging in unregulated settings. Our study evaluates quality across multiple dimensions—caregiver training, practices, nutrition, and infrastructure—while incorporating mothers' perceptions to provide a nuanced understanding of how childcare impacts maternal mental health.

Objective: We examine the relationship between childcare and maternal depressive symptoms, considering type of care, satisfaction, and quality. Using a rich dataset capturing supply (providers) and demand (mothers), we explore how actual and perceived childcare quality and maternal satisfaction relate to maternal mental health. This research adds evidence from a developing country context, where childcare markets are largely informal and unregulated, emphasizing the importance of not just availability but also quality that provides peace of mind.

Methods: We canvassed 51 communities in urban informal settlements across 11 counties in Kenya, mapped boundaries, and surveyed 978 daycare providers and 2,820 caregivers (daycare and non-daycare users). Our analysis focuses on 1,714 biological mothers who completed all mental health questions. Maternal depression was assessed using the 10-item Center for Epidemiological Studies Depression Scale (CESD-10), with 40% scoring 10 out of 30 or higher, indicating depression. Perceived childcare quality was measured as above or below average, and satisfaction with care arrangement was categorized as satisfied, neutral, or dissatisfied. We performed descriptive analysis using OLS with enumerator and strata fixed effects, controlling for household demographics, education, marital status, time use, labor force participation, and socioeconomic characteristics.

Results: We find evidence that perceived below average childcare quality is associated with higher maternal depression scores ($\beta = 2.391$, p-value < 0.01) and clinical depression diagnoses ($\beta = 0.188$, p-value < 0.01) . Similarly, lower satisfaction with childcare arrangements correlates with higher depression scores (βVery Unsatisfied = 2.265, p-value < 0.01), controlling for household demographics, socio-economic status, number of care arrangements, and interviewer and strata fixed effects. Consistent with prior studies, the results underscore maternal perceptions of childcare quality as crucial determinants of maternal well-being.

Conclusions: High-quality childcare supports child development and alleviates maternal stress. Limited access to reliable childcare exacerbates depressive symptoms, increasing burdens on mothers. This study provides suggestive evidence linking childcare quality and satisfaction to maternal mental health and lays the groundwork for future research to explore causal pathways. It underscores the need to consider maternal preferences when designing sustainable childcare solutions, particularly in informal markets with high demand and inconsistent quality.

Innovations in the Payment and Delivery of Primary Care

MODERATOR: **Laurence Baker**,

Ind-2221 Effects of Integrating Primary Care and Specialist Physician Practices

PRESENTER: **Laurence Baker**
AUTHORS: Gabriel Sekeres, Kate Bundorf, Anne Royalty

Background: The organization of physician practices may affect the cost and quality of care delivered. In the U.S., primary care physicians (PCPs) may work in practices that also include specialists ("multi-specialty'), or in practices with only primary care physicians. There have been significant shifts toward PCPs working in multi-specialty practices. Economic theory suggest that reduced frictions and improved information flow between primary and specialty care from having PCPs in multi-specialty practices could reduce costs and improve quality. On the other hand, theory also suggests the potential for delivering primary care in multi-specialty practices to increase incentives for inefficient specialist referrals. Understanding whether and how this dimension of practice organization affects care delivery is increasingly important, but relatively little literature examines this question. We investigate effects of having PCPs in multi-specialty practices on the cost and quality of care.

Data: We focus on the U.S. Medicare program, the government-operated health insurance program primarily for the elderly. Following methods developed by Finkelstein, Gentzkow, and Williams, we identify 181,075 individuals age 65-99 in "traditional" Medicare who move from one Hospital Referral Region (HRR) to another between 2007 and 2019, tracking each for up to 13 years before and after the move (1.9m person-years). When individuals move, they must change PCPs. We identify each mover's source of primary care in the pre- and post-move periods and identify those who switch between primary-care-only and multi-specialty groups and those who do not. We measure each mover's total annual spending (including physician, inpatient and outpatient facility, prescription drug, skilled nursing, home health, hospice, and equipment spending), spending and utilization by categories, and ambulatory care sensitive admissions as a quality measure.

Methods: We estimate stacked event study models to determine the impact of practice type on a range of outcome variables, identifying effects from those who switch relative to those who stay in the same type of practice, including individual and calendar time fixed effects and controlling for characteristics of the origin and destination HRRs. The stacked event study models account for heterogeneous treatment timing and allow investigation of possibly heterogenous treatment effects. We emphasize results from models that separately examine those who begin in primary-care only practices, some of whom switch to multi-specialty, and those who begin in multi-specialty practices, some of whom switch to primary-care only.

Results: Switchers and non-switchers have similar demographic characteristics. Event study models find no evidence of pre-trends. Receiving primary care in a multi-specialty practice is associated with a decrease of $300-$400 per year in total spending, about 4% ($p<.01$). Multi-specialty patients have 0.41 fewer primary care visits per person per year, 0.06 more specialist visits, and 0.01 fewer hospitalizations (all $p<.01$). Quality of care measures are not changed. A broad range of specification tests yields generally stable results. Changes in health status do not appear to differentially lead movers to switch to or from multi-specialty practices.

Conclusions: Primary care delivered in multi-specialty practices leads to increased efficiency. Policies that would affect the further development of multi-specialty practices should account for this.

Ind-2418 Private Equity Investments in Primary Care and Changes to Medicare Spending and Utilization

PRESENTER: **Yashaswini Singh**
AUTHORS: Christopher Whaley, Meehir Dixit

Research Objective: Private equity (PE) firms have increasingly acquired physician practices in the United States. This trend is of particular importance within primary care, given provider shortages and declining independent practices. On the one hand, PE's emphasis on short-term profitability may increase overuse of health care services to increase health care spending without commensurate patient benefit. On the other hand, PE investments may facilitate improved coordination of care through technological investments. Despite its significance, no prior research has examined the effects of PE acquisitions in primary care. The objective of this study is to examine changes in Medicare spending, patient out-of-pocket spending, and utilization of primary care services following PE acquisitions in primary care from 2016-2022.

Study Design: We identified 177 PE acquisitions in primary care between 2016 to 2022 using data from Pitchbook and the Medicare Data on Provider Practice and Specialty. We linked acquisition data to outcomes constructed using a 20% sample of Medicare fee-for-service data from 2016-2022.

We examined the effects of PE acquisitions relative to matched controls using a difference-in-differences design. Each PE-acquired practice was matched to up to 3 control practices. We used data from 6 quarters prior to acquisition through 6 quarters after, with the quarter of acquisition as the reference period. The unit of analysis was the physician-quarter. All regressions included physician and time fixed effects to account for time-invariant practice-specific attributes and secular trends. Standard errors were clustered at the level of the matched group (PE-acquired practice and its set of matched controls).

Primary outcomes include measures of spending and utilization, including Medicare spending, number of services billed, and number of unique

patients per physician. In secondary analysis, we examined patient-level measures of care coordination, including out-of-pocket spending on primary care vs specialty care and the number of physicians seen for primary vs specialty care.

Principal Findings: Relative to matched controls, physicians in PE-acquired primary care practices exhibited an average increase in Medicare spending of $1894 per physician-quarter or a 29.8% increase from baseline ($p<0.01$). This increase was driven by increases in the number of services billed per physician by 61 claims or 33.2% ($p < 0.01$) and increases in the number of patients by 26 patients or 26.2% ($p < 0.01$). Following acquisition, patients in PE-acquired primary practices had visits with a greater number of physicians for primary and specialty care and higher out-of-pocket spending on specialty care by $36 per patient-quarter or 14.3% ($p < 0.01$).

Conclusion: PE acquisitions in primary care increased Medicare spending by 30%, driven by increases to both the number of billed services and patients seen. Patients in PE-acquired practices had visits with a greater number of physicians, resulting in increased out-of-pocket spending on specialty care. Take together, our results suggest that PE acquisitions increase health care spending and utilization of primary care services with no evidence of improved care coordination. Policymakers must monitor the growth of PE investments in primary care to mitigate the undesirable effects on the cost and quality of care.

Ind-2284 Integrating Virtual Primary Care: Evidence and Learnings from Lower-Middle Income Countries

PRESENTER: **Divya Srivastava**, London School of Economics & Political Science
AUTHOR: Anooj Pattnaik

Background Digital health communication technology in primary care (also termed virtual primary care, VPC)) allows patients to interact with health practitioners remotely through email, text, online chat, video or phone. Use of VPC grew exponentially in lower-and-middle-income countries (LMICs) during Covid-19. However, they grew within health systems that were not set up for this type of service delivery, from the regulatory and financing side to the underlying infrastructure and information systems. A question also remains on whether the growth of VPC contributes to persisting digital exclusion for underserved populations. This paper reviews the evidence and challenges LMICs faced when trying to set up these virtual primary care systems in the face of increasing demand but intransigent legacy health systems. **Methods** We apply an adapted novel framework, built on the World Health Organization building blocks for health systems functions. First, we conduct a targeted literature review that includes PubMed, CINAHL, EBSCO, Web of Science, Scopus, Cochrane Review, Google Scholar, between 2013 and 2023. We then map LMIC findings from three illustrative countries which have had significant activity in virtual primary care in recent years: Indonesia, Kenya,Thailand against the adapted WHO's framework. The targeted review is complemented with a three-round Delphi consensus building exercise which is currently underway. The Delphi exercise involves an international group of experts focussed along seven themes to examine virtual primary care systems: (1) stated policy objectives, (2) regulation and governance, (3) financing and reimbursement, (4) delivery and integration, (5) workforce training and support, (6) IT systems and data sharing, and (7) patient involvement. **Results** Preliminary results, indicate that the deployment of VPC in LMICs was largely in the private sector with little regulation or policy guidance. Common challenges include lack of basic infrastructure (especially in rural areas), non-existent governance, legal, and regulatory systems for digital health, fragmented and often paper-based information systems, and nascent or limited national health insurance schemes for providers to contract with and be incentivized by. This is in the face of growing public demand for virtual primary care systems coupled with real equity and access barriers around infrastructure and costs associated with private provision. **Conclusions** LMIC experiences highlight how the intense need for digital alternatives during the pandemic led to the rapid and innovative growth of VPC primarily in the private sector. We found that LMIC governments struggled to keep up with this rapid deployment, with little effective regulation or policy change to integrate this private VPC into the health system, protect the privacy and data of citizens, or ensure access to those in most need. The standardized framework itself proved valuable in allowing a comparative approach to facilitate the assessment of VPC in LMICs. 2

Ind-2670 Unlocking Fiscal Autonomy: The Economic Impact of the BLUD Model on Strengthening Primary Health Care in Decentralized Indonesia

PRESENTER: **Rooswanti Soeharno**
AUTHORS: Hadrian Marta, Mrunal Shetye

Background. Decentralized governance in health systems is a strategy for improving equity and efficiency by empowering local authorities. In Indonesia, the BLUD (Regional Public Service Agency) model grants financial and operational autonomy to Puskesmas (community health centers), enabling them to address local health needs effectively. However, evidence on the economic impacts of fiscal autonomy in low- and middle-income countries is limited. This study evaluates the BLUD model's economic implications in West Nusa Tenggara (NTB), focusing on its potential to transform primary health care (PHC) delivery within decentralized systems. **Research Aim.** The study investigates how the BLUD model impacts revenue generation, resource allocation, and health outcomes in decentralized health systems and assesses its scalability and sustainability. **Methods.** A mixed-methods approach was employed, combining quantitative analysis of financial and health performance data (2021–2023) from BLUD-enabled Puskesmas in West and East Lombok with qualitative insights from stakeholder interviews. Financial metrics included revenue growth, expenditure patterns, and service utilization rates. Strategic flexibility was used as the theoretical framework to explore its role in enhancing innovation and organizational performance. **Results.** The BLUD model significantly improved fiscal performance and operational efficiency. In West Lombok, BLUD-enabled Puskesmas achieved a 20% revenue increase over two years, reinvesting funds into infrastructure, workforce expansion, and innovative health initiatives such as TB detection and vision screening programs. East Lombok demonstrated similar gains despite geographic and resource challenges. Qualitative findings highlighted the model's ability to foster innovation and responsiveness while emphasizing disparities in governance, technical expertise, and resource allocation. Strategic flexibility emerged as a critical enabler, with innovation partially mediating the relationship between financial autonomy and organizational performance. **Conclusions.** The BLUD model offers a scalable framework for strengthening fiscal autonomy and operational efficiency in decentralized PHC systems. By fostering local innovations and targeted investments, it enhances service quality and responsiveness. However, successful nationwide implementation requires capacity-building, equitable resource allocation, and robust monitoring systems. **Policy and Practice Implications.** The BLUD model's success hinges on key strategies: building local capacity through

financial management and governance training, addressing fiscal and technical disparities across districts, and promoting strategic flexibility to enhance innovation and performance. Standardized monitoring frameworks are crucial for ensuring accountability and transparency. Globally, the BLUD model offers actionable insights for low- and middle-income countries, providing a replicable framework to strengthen decentralized health systems and advance Universal Health Coverage through equitable and sustainable primary health care delivery.

abs-os139 Accounting for Morbidity in Capitation Payments: A Person-Based Model for Primary Medical Care in England

PRESENTER: **Ms. Laura Anselmi**, The University of Manchester
AUTHORS: Shaolin Wang, Evangelos Kontopantelis, Michael Anderson, Matt Sutton, Yiu-Shing Lau

Background: Accurate needs-based capitation is key to effective and equitable primary care funding. Most existing capitation formulae use only basic demographic and area characteristics. Payment to general practices in England are informed by capitation weights based on a formula developed and are now outdated and unlikely to reflect the additional needs of general practices serving more deprived populations. We developed needs-based capitation weights for England using alternative sets of morbidity indicators recorded in primary and secondary care.

Methods: We used nationally representative data on 12,667,755 million patients registered with 1,397 general practices in England on 1 April 2018 from the Clinical Practice Research Datalink (CPRD) linked with secondary care records from the Hospital Episode Statistics (HES). We used linear regression to estimate the association between cost-weighted We used linear regression to estimate the effects of age and gender, ethnicity, area-level deprivation, new registration and morbidity on cost-weighted consultations with primary care staff. We measured morbidity using three sets of indicators recorded in primary or secondary care, covering 20 to 209 conditions. We computed relative expected workload by applying the regression coefficients to person level data in CPRD and to available national data on registered populations for all 6,892 practices in England.

Results: Workload was on average £110 per patient per year, varying between £7 and £882 for patients with at least one appointment and between £47 and £179 across practices.** Workload increased with age and with deprivation, but these gradients halved when morbidity was included. When primary and secondary diagnoses were included, the range of average relative workload per patient widened from 0.84-1.14 to 0.73-1.20 between practices at the 5th and 95th percentiles, and from 0.96-1.03 to 0.94-1.06 between the least and most deprived deciles. Alternative sets of diagnoses produced similar patterns.

Conclusion: The inclusion of morbidity represents needs more accurately and re-directs resources toward practices in more deprived areas. Strengthening of routine diagnostic recording and data linkage is recommended to support the practical use of more refined, complete and comprehensive morbidity indicators. Further analysis and discussion on implementation aspects will be presented.

Ind-2403 Financial Burden of Non- Medical Expenditure Due to Long Travel Distance in Cancer Patients Treated As Tertiary Cancer Center

PRESENTER: **Mohit Pandey**
AUTHORS: T R Dilip, Manish Bhandare, Shailesh Shrikhande

Abstract

Background & Aim:

Cancer care offered in India and large part of the world is heterogenous with few regions having dedicated high volume centres with established referral patterns. Due to scarcity of the specialized units treating cancer, patients often have to travel for long distances for medical care. Our study examines the impact of additional financial burden (non-medical expenses) on cancer patient's families due to long distance travelled while seeking treatment for gastric and pancreatic cancer.

Methods:

The data (n=244) was collected as part of a prospective, non-interventional cohort study conducted at Tata Memorial Hospital (TMH), Mumbai, India; from March to December 2023. Consecutive patients with gastric and pancreatic cancers registered under GI A division of the GI & HPB surgery unit were included. The medical and non-medical expenditures were collected for each visit along with other cancer specific and treatment details.

Results:

The mean distance travelled by patients was 1,475 km. 63.1% of patients travelled greater than 1,500 km. The mean Non-Medical Health

Expenditure (NMHE) for patients traveling more than 1,500 km was ₹107,040 ($1278), nearly two times higher than the expenditure for patients traveling less than 500 km, ₹49,112 ($587). A total of 42.9% of NMHE was spent on travel, 33.3% on accommodation, and 17.2% on food. The logistic regression results depict that patients traveling >500km are three times more likely to experience Catastrophic NMHE (CNMHE) compared to <500km.NMHE . The distress financing due to cancer treatment was 39.3%. Distress financing was higher with CNMHE at 25% (52.8%) compared to CNMHE at 10% (45.8%), and was two times higher in patients travelling >500 km compared to <500 km

Conclusions:

A structured decentralization of cancer care is the need of the hour to negate the additional financial burden and CNMHE experienced by the cancer patients and their families. If adequate infrastructure is provided at the non-urban areas, well trained oncologists can be deployed in hospitals closer to patients homes to treat cancers at earlier stage.

Ind-434 Restricting Mothers' International Migration and Child Health

PRESENTER: **Takuya Hasebe**, Sophia University
AUTHORS: Bilesha Weeraratne, Yuma Noritomo

Abstract

International migration provides significant economic opportunities and a vital source of income through remittances in developing countries. However, it can negatively impact children left behind by separating them from their parents, especially their mothers. Although the effects of maternal migration on children are important for policy and scholarly interest, they remain relatively understudied. Leveraging a 2013 policy change in Sri Lanka—a country with a long history of female international migration—we examine how restricting mothers of young children from migrating for employment impacts children's health outcomes. This policy, aimed at protecting children under five, provides a unique natural experiment for our study. We specifically focus on child health outcomes, which are likely influenced by the increased maternal presence and caregiving at home.

To identify the impacts, we employ a difference-in-differences (DID) approach, using nationally representative, repeated cross-sectional data from the Household Income and Expenditure Survey. Our DID approach leverages temporal variations before and after the policy change, along with cross-sectional differences between households with the youngest child under 5 (treated group) and those with the youngest child over 5 (control group).

We find that the policy exposure leads to a significant decrease in impatient care for illness and injury, indicating improvements in child health. Specifically, the policy reduces inpatient care for illness by 0.8 percentage points and for injury 0.3 percentage points. Our analysis suggests that this improvement is likely driven by the increased presence of mothers at home induced by the policy change. As intended, the policy discourages mothers from migrating abroad and encourages them to stay home, decreasing the likelihood of any household member migrating abroad by 1.7 percentage points and increasing the likelihood of maternal presence at home by 1.2 percentage points. Maternal presence may improve child health through more investment in child health capital by preventing serious injuries through supervision.

One concern is the income effect—restricting international migration may limit economic opportunities to earn and send remittances from abroad, which could negatively affect child health. Even though the policy reduces international remittances significantly, this is offset by an equivalent increase in domestic remittances, resulting in no significant change in total household incomes. We also observe greater labor supply from male household members, suggesting that households respond to potential income reductions by adjusting intra-household labor supply.

The results highlight the trade-offs between the economic opportunities provided by international migration and the benefits of maternal presence for child health. As intended, increased maternal presence appears to enhance childcare at home. However, this effect may be facilitated by intra-household labor adjustments, as the availability of local labor opportunities, particularly domestic migration for men, helps to offset the economic impact of reduced international remittances. The policy implication is that ensuring sufficient domestic labor opportunities is essential for compensating households for the loss of international remittances.

Ind-445 Charitable Giving for Health: Who Benefits From Aotearoa New Zealand's Givealittle Crowdfunding Platform?

PRESENTER: **Paula Lorgelly**, University of Auckland
AUTHORS: Daniel Exeter, Richard Edlin, Nick Young

Background: Crowdfunding for health has become an increasingly popular way to finance healthcare expenses. Crowdfunding is a means to address gaps in health coverage and limitations in social welfare systems. There are numerous crowdfunding web-based platforms globally, where patients, caregivers or friends request donations to support and fund a range of unmet needs: from experimental therapies abroad to lost income and wages due to incapacity. Previous research has considered the risks and benefits of crowdfunding medical expenses, including that it may exacerbate inequities. Much of the literature focuses on cross-sectional analysis. Exploiting new methods of collating publicly available data and text mining, this paper seeks to understand crowdfunding of health in a country with universal health coverage but a system with growing inequities over time.

Aim: We sort to understand the level of unmet health need in Aotearoa New Zealand by exploring the nature of health-related charity request over time, and additionally investigating the determinants of success with respect to charitable donations received.

Methods: Web scraping was used to collect data from health-related crowdfunding campaigns from *Givealittle*, Aotearoa New Zealand's most

prominent crowdfunding platform. We undertook a process of data mining on both open and closed campaigns, extending back to April 2016. Natural language processing (NLP) and large language models (LLM) extracted information from the narrative/pitch/description of the campaigns to understand the nature of illness or condition, the age of the individual, the reason for the request and the location. Numerical information on the goal, amount raised, number of donors and days active were also downloaded. We employed dimensionality reduction techniques for data visualisation of topics and traditional statistical analyses to understand the predictors of success.

Results: We collected data on 10,418 crowdfunding campaigns focusing on health. The number of campaigns has increased steadily over time from 1,225 in 2017 to 1,338 in 2023, with an expected reduction in 2020 & 2021 due to Aotearoa's pandemic response. A large number of campaigns were requesting funds for cancer care; at any one month during the period there were on average 38 requests for donations for cancer. Causes mentioning coronavirus increased in prominence in 2020 and 2021 but have since diminished. On average campaigns are open for 4.7 months, raise NZD7,950 from 81 donors. Health-related campaigns achieve on average 65% of the targeted funding goal. Data visualisation and regression analysis to understand relationships and determinants of success is ongoing.

Conclusions: We explore the unmet health need in Aotearoa New Zealand using machine learning techniques to exploit publicly available data on charitable requests. Not only does it offer insights with respect to what needs are unmet and which campaigns are most successful, it also offers at example of the application of machine learning techniques to health economic issues.

Ind-1 What is Patient-Preferred Tuberculosis Care? A Discrete Choice Experiment Among Patients with Tuberculosis in Nepal

PRESENTER: **Tara Prasad Aryal**
AUTHORS: Jeevan Thapa, Vijay G.C., Kedar Baral

Background

Directly Observed Therapy (DOT) is a well-established treatment approach for tuberculosis (TB). However, the health outcomes of people with TB continue to be less than optimal, and there is often lack of emphasis on prioritizing patient-centered care. Gaining insight into patients' preferences regarding TB management is crucial for developing a more patient-focused care model. There is a dearth of research that considers patients' preferences in TB management in Nepal, and this study aims to address this research gap by evaluating patients' preferences for improving TB care in Nepal.

Methods

We conducted a discrete choice experiment to elicit patients' preferences for TB care. Drawing upon the findings from the review of literature, in-depth interviews with patients, and consultations with experts, we identified six TB care attributes (five attributes with two levels and one with three levels): type of patient card; gender of the healthcare provider; psychosocial support; waiting time; type of TB care provider; and transportation incentive. A total of 24 choices were generated using a fractional factorial design in R and then organized into four blocks, each containing six unlabelled choice sets. Participants were randomly assigned a block number through a lottery and were instructed to select their most preferred option between two hypothetical TB care models.

Data were collected between December 2022 and February 2023, from 138 participants (age ≥ 18 years) receiving treatment for drug-susceptible pulmonary TB. Participants were proportionally recruited from the top 20 government DOTs centers selected based on annual TB case notification in Chitwan district. We employed a conditional logit model to determine the patient preferences for different attributes of TB care and estimated the relative importance of each attribute using the range method.

Results

The final analysis included 133 participants (96% response rate). Overall, participants had significant positive preferences for three attributes: patient card with instructions (Relative importance (RI): 38.4%, $p<0.001$); provision of psychosocial support (RI: 30.7%, $p<0.001$); and a patient waiting time of less than 30 minutes (RI: 15.6%, $p=0.002$), for improving TB care. Sub-group analyses showed that illiterate participants, compared to literate, preferred to have a patient card with instructions ($p=0.01$) and provision of psychosocial support ($p=0.03$).

Conclusion

The DOT approach to TB treatment and control should consider patients' preferences to improve the TB care provision in Nepal. Including patients' preferences in TB care help improve the effectiveness of the DOTs programme and can also be used to evaluate the cost-effectiveness of patient-centred TB care. This will have policy and healthcare resource usage implications for low-resource settings like Nepal.

Ind-45 Examining NHIF Members' Preferences and Trade-Offs for the Attributes of Contracted Outpatient Facilities in Kenya: A Discrete Choice Experiment

PRESENTER: **Jacob Kazungu**
AUTHORS: Edwine Barasa, Matthew Quaife, Justice Nonvignon

Background Patient choice of health facilities is increasingly gaining recognition for potentially enhancing the attainment of health system goals globally. In Kenya, National Health Insurance Fund (NHIF) members are required to choose an NHIF-contracted outpatient facility before accessing care. Understanding their preferences could support resource allocation decisions, enhance the provision of patient-centered care, and deepen NHIF's purchasing decisions. **Methods** We employed a discrete choice experiment to examine NHIF members' preferences for attributes of NHIF-contracted outpatient facilities in Kenya. We developed a d-efficient experimental design with six attributes, namely availability of drugs, distance from household to facility, waiting time at the facility until consultation, cleanliness of the facility, attitude of health worker, and cadre of health workers seen during consultation. Data were then collected from 402 NHIF members in six out of 47 counties. Choice data were analysed using panel mixed multinomial logit and latent class models. **Results** NHIF members preferred NHIF-contracted outpatient facilities that always had drugs [β=1.572], were closer to their households [β=-0.082], had shorter waiting times [β=-0.195], had respectful staff [β=1.249] and had either clinical officers [β=0.478] or medical doctors [β=1.525] for consultation. NHIF members indicated a willingness to accept travel 17.8km if drugs were always available, 17.7km to see a medical doctor for consultation, and 14.6km to see respectful health workers. Furthermore, NHIF members indicated a willingness to wait at a facility for 8.9 hours to ensure the availability of drugs, 8.8 hours to see a doctor for consultation, and 7.2 hours to see respectful health workers. **Conclusion** Understanding NHIF member preferences and trade-offs can inform resource allocation at counties, service provision across providers, and purchasing decisions of purchasers such as the recently formed social health insurance authority in Kenya as a move towards UHC.

Ind-226 Developing a Personalised Decision Aid Incorporating a Discrete Choice Experiment: A Case Study in Ulcerative Colitis

PRESENTER: **Tara Wickramasekera**

Background: Choosing the best treatment option is difficult for patients with ulcerative colitis given the range of medical and surgical options, with different side-effects and effectiveness. A well-established literature shows that decision aids used in parallel with clinical advice, can have a positive effect on reducing decisional conflict and enhancing informed decision making. While there are some decision aids for ulcerative colitis, they mainly contain static information and do not adapt to the dynamic nature of individual patient needs and preferences. The proposed study aims to fill a knowledge gap by developing an innovative decision tool that can tailor the choice of treatment to fit patients' preferences using the discrete choice experiment (DCE) method. **Aim:** To develop a personalised decision tool to promote informed decision making for patients who are considering medical or surgical treatments for ulcerative colitis. **Methods:** A DCE survey was developed containing competing treatment profiles, described using all important aspects of the treatment (effectiveness/side-effects/family planning). Patients (n=300) with ulcerative colitis were asked to consider the benefits and disadvantages of each treatment profile and select the treatment that they would choose. The DCE data was analysed using mixed logit and latent class models. The model results were integrated to an online platform using a Shiny app. **Results:** R Shiny was successfully used to enable the real-time personalisation of DCE results. The developed decision aid contains two aspects of personalisation. First, attribute importance scores showed the treatment characteristics that mattered most to patients based on their DCE choices. Second, a "best-match" treatment that aligned with their preferences were provided from uptake rate calculations. User testing of the developed decision aid is ongoing. However, initial feedback from patients has been positive. **Conclusions:** A key challenge in developing personalised decision aids is providing real-time, tailored recommendations based on individual preferences. This study demonstrates the feasibility of integrating DCE methods into personalised decision aids for ulcerative colitis. By tailoring treatment recommendations to individual patient preferences, this tool has the potential to empower patients, reduce decisional conflict, and enhance shared decision-making between patients and healthcare providers.

Ind-575 Preferences of Men Who Have Sex with Men Towards the Distribution of HIV Self-Test Kits Through Social Networks in Australia

PRESENTER: **Jason J. Ong**, Monash University
AUTHORS: Ying Zhang, Eric PF Chow, Tiffany Phillips, Christopher K. Fairley

Background: Since the World Health Organization (WHO) endorsed HIV self-testing (HIVST) in 2016, its implementation has been scaled up worldwide to complement existing HIV testing strategies. Among the HIVST distribution models, distribution of HIVST kits through social-networks has emerged as a promising strategy to enhance testing accessibility and acceptability and to increase linkage to care following self-testing. This approach leverages existing personal, social, or community connections to disseminate information, resources, or interventions. Using a discrete choice experiment (DCE), we aimed to identify the factors that influenced gay and bisexual men who have sex with men (gbMSM)'s preferences regarding the distribution of HIV self-test kits through social networks and examine their relative importance. Understanding these preferences can inform targeted interventions to increase HIV testing rates among this key population.

Methods: An online DCE survey was conducted among gbMSM in Australia between December 2023 and May 2024. Participants were recruited through both social media and posters in clinics and community organisations. Each participant was presented with a series of seven choice sets related to distributing HIVST kits, each containing two hypothetical scenarios described by attributes such as cost, location, training, support system, and self-reporting of HIVST results. Mixed logit models with interactions (country of birth, first language) and latent class analysis were used to explore heterogeneity in preferences.

Results: There were 251 participants, including 140 (56%) overseas-born gbMSM, with a mean age of 36.5 (SD= 11.9). Participants who did not speak English as their first language (29/251, 12%) showed a lower preference for paid HIVST kits ($30 or $60 out-of-pocket cost for three

HIVST kits) and were less likely to favour online video chats with sexual health professionals as pre-test support for their sexual partners or social contacts. Overseas-born participants also preferred not to attend 30-minute or one-hour training sessions on distributing HIVST kits to social contacts. Participants in Class 1 (61.7%) were willing to pay up to AUD 30 for a set of three HIVST kits, whereas those in Class 2 (38.3%) exhibited strong resistance to paying for the kits and showed a lack of interest in self-reporting their test results via phone calls.

Interpretation: Our findings highlight the importance of subsidising HIVST kits and developing alternative support systems for overseas-born gbMSM who do not speak English as their first language. Moreover, the limited preference for pre-test support through online video chats and resistance to lengthy training sessions among these subgroups emphasises the need for culturally sensitive, time-efficient, and accessible support mechanisms. Aligning interventions with these identified preferences—such as offering affordable kits and simplifying support options—can improve HIV testing accessibility, reduce disparities, and promote equitable HIV prevention outcomes across diverse gbMSM communities.

Ind-1219 Preferences of Infertile Women for In Vitro Fertilization Treatment in China: A Discrete Choice Experiment

PRESENTER: **Shunping Li**

Objective: Vitro fertilization (IVF) is the primary treatment for infertility, offering a viable pathway to natural conception and full-term pregnancies. However, financial costs, side effects, and treatment inconveniences often result in many women discontinuing IVF prematurely or opting not to pursue it. Addressing these issues could significantly improve patient adherence to treatment protocols and, consequently, enhance the likelihood of successful pregnancies and overall fertility rates. This study aimed to investigate the preferences of Chinese infertile women when selecting in IVF plans. **Methods:** A discrete choice experiment (DCE) was conducted with five key attributes: number of visits per cycle (3 levels), side effects (3 levels), treatment costs per cycle (3 levels), information disclosure about IVF (3 levels), and pregnancy rate per cycle (4 levels). To identify relevant attributes and levels, we adopted a comprehensive approach involving literature review, in-depth interviews (25 patients and clinicians), and expert consultations (5 methodological and medical specialists). D-efficient design was implemented and each task presented two options with an opt-out choice. Twelve choice tasks were generated and divided into two blocks, randomly assigned to respondents. Attribute order within each task was randomized to minimize sequencing effects. Additionally, a “quality control” task was included. The survey was conducted across five hospitals in five provinces of China. Six hundred and fifty participants completed the questionnaire through face-to-face, computer-assisted interviews. Preference weights were estimated using the mixed logit model (MLM). Willingness to pay and relative importance of the attributes were derived from MLM estimates. Additional scenario and heterogeneity analyses were performed. **Results:** A total of 591 participants were included in the final analysis. The mean age was 34.2 years. Over 60% of participants were planning to have their first child, and nearly 75% had undergone IVF-ET treatment. All five attributes were found to be statistically significant. Pregnancy rate per cycle, side effects, and treatment costs per cycle were identified as the top three factors influencing participants’ preferences for IVF. Specifically, an increase in the pregnancy rate from 15% to 60% per cycle corresponded to a 3.63 increase in marginal utility. Participants showed a willingness to pay additional fees to improve non-cost attributes; for example, enhancing the pregnancy rate from 15% to 60% per cycle was associated with a willingness to pay CNY 56,100 (over USD 7,700). Interaction terms involving education level, annual family income, and attribute levels were statistically significant, indicating that these factors contribute to preference heterogeneity. **Conclusion:** The success rate of pregnancy is the foremost factor influencing treatment decisions, with concerns about side effects and treatment costs following closely. Although factors such as the level of information disclosure and the frequency of clinic visits have a lesser impact, they still affect patient decision-making regarding IVF. Additionally, our analysis reveals variability in preferences among different patient subgroups, indicating the need for further research to explore these differences in greater depth.

Ind-1832 Dynamic Preferences for HIV Prevention Among Women and Girls at High-Risk in Nairobi and Kampala: A Longitudinal Discrete Choice Experiment

PRESENTER: **Pitchaya Peach Indravudh**

AUTHORS: Mr. Kenneth Roger Katumba, Laura Lulani, Joelle Mak, Melissa Neuman, Yunia Mayanja, Omu Anzala, Yvonne Machira, Mitzy Gafos, Gabriela Gomez

Background

Effective HIV prevention requires strategies that adapt to the evolving needs and preferences of women and girls at high-risk in endemic settings. Multipurpose prevention technologies (MPTs) combining HIV prevention with other sexual and reproductive health benefits are under development, yet evidence is needed on how user preferences for these products and other prevention services might change over time. This study evaluated dynamic preferences for HIV prevention services including MPTs and assessed the before-and-after impact of product exposure on preferences.

Methods

We conducted a longitudinal discrete choice experiment within a cohort of women and girls at high-risk. Eligibility criteria included HIV-negative adolescent girls and young women (AGYW) in Nairobi and women engaged in sex work (WESW) in Kampala. Cohort participants received integrated services for HIV prevention, including oral pre-exposure prophylaxis (PrEP), and family planning. The DCEs, which were administered at baseline and six months post-enrolment, included 10 choice scenarios with six attributes and three alternatives, including to opt-out. Data analysis used mixed logit models stratified by subgroup and time period.

Results

Baseline and endline DCEs were administered to 233 participants. At baseline, AGYW reported the strongest preferences for post-visit follow-

up from peers and delivery of services through standard health clinics. Demand was also demonstrated for subdermal implants, service provision through pharmacies, trained health care providers, and post-visit follow-up from local community members. AGYW showed disutility for oral pills, combined protection against HIV and unintended pregnancies, service providers who were peers, service delivery through community-based clinics, and follow-up from health care providers. At endline, preferences remained largely consistent, with some observed shifts in the magnitude of preferences. AGYW expressed a measurable preference for service providers from their local community, which they were indifferent to at baseline.

For WESW, preferences at baseline included oral pills, injectables, and combined protection against HIV, sexually transmitted infections, and unintended pregnancies. Dislike was stated for vaginal and transdermal routes of administration, protection against HIV only, and service fees. Strong utility for injectables and disutility for vaginal and transdermal administration and service fees remained at endline. Shifts in the magnitude of preferences were observed for the type of service provider, with participants demonstrating an increased preference for no provider (e.g., dispensary) and a decreased preference for provision from local community members, which they had been indifferent to at baseline.

Conclusion

This DCE provides insights into dynamic preferences to guide delivery of HIV prevention with sexual and reproductive health services as well as development of future MPTs. Our findings revealed that preferences remained largely consistent following exposure to oral PrEP and short and long-acting contraceptive options. While the direction of utility was unlikely to change over a six-month period, some shifts in magnitude were observed. These findings highlight the need for HIV prevention services to consider and remain responsive to stability and variability in user preferences to maximise uptake and effectiveness.

Ind-2015 Preferences for Fertility Support Policies Among Married Women in China: A Discrete Choice Experiment

PRESENTER: **Ms. Yeqing Zhang, PhD Candidate**
AUTHORS: Jue Liu, Ana Correa Ossa, Jie Deng, Wenxin Yan, Stuart Gietel-Basten, Lu Gram

Background

China's fertility rate has been in continuous decline since 2013, despite policy shifts such as the relaxation of the one-child policy in 2015 and the introduction of a three-child policy in 2021. Financial burdens, inadequate childcare support, and career disruptions have been identified as major barriers to women's fertility intention in China. Although the government is considering more comprehensive fertility support policies, little evidence exists on how Chinese women might respond to such policies. We used a discrete choice experiment (DCE) to elicit married Chinese women's preferences for different fertility policy initiatives, with the aim of understanding the potential effectiveness of future fertility policies in the Chinese context.

Methodology

We conducted a single-profile DCE on a randomly selected sample of 1,005 married women aged 27–49 from 31 provinces in China having exactly one child. Participants were randomly assigned to one of three survey blocks, each containing 12 hypothetical policy scenarios. In each scenario, respondents answered on a 6-point scale, ranging from "no intention of having a second child" to "really want a second child." Scenarios varied across five policy attributes: maternity leave, paternity leave, childcare support, monetary incentives, and career progression. The experiment was fielded in the summer of 2024, via Wenjuanxing, an online survey platform.

A mixed ordinal logistic regression model was employed to estimate preference weights for policy attributes and calculate marginal effects of policy change on fertility intentions. Willingness to Pay (WTP) for non-monetary policies was calculated using a bootstrapped method. Additionally, a partial proportional odds model examined how policy preferences differed across intention levels.

Results

All policy attributes are significantly associated with intention to have a second child ($p<0.001$), with career progression having the largest effect, followed by paid maternity and paternity leave, childcare support, and monetary incentives. Compared to a two-year delay on promotions, leaving promotion prospects intact was associated with 5.0 percentage point increase (95% CI 4.4 to 5.6) in intention to have a second child. Extending paternity leave from 0 to 20 days had a greater effect (2.6 pp, 95% CI 2.3 to 3.0) than extending maternity leave from 96 to 156 days (1.8 pp, 95% CI 1.5 to 2.1).

WTP aligned with preference weights, with the implicit WTP for career progression without penalties being 743 RMB per month (95% CI: [673, 814]) over three years, amounting to 26,763 RMB in total. For childcare support, WTP was 229 RMB per month for part-time access and 444 RMB for full-time access, both significantly below market rates.

Heterogeneity analysis showed robustness and suggested women with higher baseline fertility intentions were more responsive to policy changes.

Conclusion

The results highlight the critical role of career protection in fertility decisions. Providing free childcare support was less cost-effective in promoting fertility intentions. Policies promoting gender equity, such as paternity leave, were highly valued. However, overall marginal effects remained modest, suggesting only small shifts are possible under existing policy proposals.

Ind-2407 Donor Preferences for Aid Allocation to Indonesia: a Discrete Choice Experiment

PRESENTER: **Duncan Mortimer**, Monash University
AUTHORS: Jack Hennessy, Rohan Sweeney, Maame Woode

Frequent humanitarian disasters, economic shocks, and a rapidly changing climate suggest that the world's most vulnerable populations will remain reliant on international support for the foreseeable future. The most visible mechanism of providing international support for vulnerable populations is through distribution of development aid, which topped an all-time high of USD 225 billion in 2023. Official development assistance, or aid delivered by governments using funds sourced from taxpayers, is the largest contributor to global international development aid.

In pursuit of the public interest, democratically governed societies might reasonably seek to distribute aid according to population preferences. Previous research suggests that modifiable aspects of aid programs *are* important to members of the general population in donor-countries. Findings from this previous research suggest *inter alia* that distribution based on recipient need may be preferred over distribution in line with cost-effectiveness and that aid should be delivered as in-kind contributions rather than cash. Unfortunately, it remains unclear whether findings from these studies apply to all donor-countries and to all donor-recipient pairs. None of the existing studies describe preferences for allocation of Australia's international development aid.

Using Indonesia as the recipient country setting, we conducted a discrete choice experiment amongst 1,523 Australians aged 18+ to describe preferences for ten characteristics of Australia's health aid program. Contrary to previous studies, we found the effectiveness of aid was the most important characteristic, ahead of the cost of the aid program, the age of the target population, and the size of recipient burden. Respondents preferred highly effective aid targeting younger populations in areas where the burden of disease was high. Recipient government type (*i.e.* highly functioning public service), control of aid (*i.e.* how much influence donors have on projects), target health issue, and the sex of the target population were also significant predictors of preference, but to a lesser extent. Latent class analysis revealed that younger, lower-income individuals were more concerned with recipient characteristics (*e.g.* age, sex) than were older, higher-income individuals who were more concerned with the cost of aid programs.

Our research is the first to quantitatively estimate the Australian public's preferences for aid allocation through a discrete choice experiment and is an essential first step in developing an aid policy that aligns with citizen's views. Our findings appear at odds with Australia's current aid policy, which has moved away from comprehensive, objective measures of aid effectiveness in Government-funded development programs to a policy that prioritises recipient need and broader geopolitical concerns.

Furthermore, while the international aid landscape is dominated by calls for 'locally-led development' and 'decolonisation of aid', our results suggest that Australian donors prefer aid distributed with less recipient control – including aid delivered in pursuit of *donor* (rather than *recipient*) aims and implementation, and aid delivered as technical advice and services rather than delivered as cash.

These findings can be used by governments and international development organisations to better understand how citizen preferences align (or otherwise) with current development priorities, which in turn can be leveraged to underpin support for this much-needed resource.

Ind-2823 Preference Heterogeneity of Online Takeaway Users: A Discrete Choice Experiment

PRESENTER: **Dr. Yuan Yuan Wang, PhD**

Abstract

Background: Consumers are increasingly using online-to-offline (O2O) takeaway apps rather than phone calls to order food from local restaurants. Taste is a significant determinant of food choices. Extensive research has been conducted into taste in the context of restaurants. However, the heterogeneity of online takeaway food preferences is currently unknown, as is whether these preferences are healthy.

Aim: The objective of this study is to address the heterogeneity of taste of O2O takeaway by utilizing a discrete choice experiment (DCE).

Method: A final list of attributes and their levels for the DCE was generated using a detailed iterative process. This included a literature review, six focus group with those O2O takeaway users. From this process a list of attributes was obtained. Following a three pilot studies, the final list of attributes was selected (meal types, price, online reviews and delivery time). We used D-efficient design to construct an experimental design for the survey. The survey consisted 24 choice cards with three alternatives and one non-option. To evaluate the heterogeneity of taste for O2O takeaways, a latent class model (LCM) is employed. China is the biggest O2O takeaway market in the world. Thus, the model was applied using data from a DCE with a representative sample of 484 individuals aged between 18 and 40, drawn from ten cities in China. All best-sell 48 meals were collected from China O2O takeaway apps.

Results: Our model identified three classes of online takeaway users, with an 'Affluent' class (57.82%), a 'Taste-driven' class (26.9%), and a 'Money saver' Class (15.2%). The 'Affluent' class is comprised of affluent individuals who frequently consume takeaway food. These individuals tend to order heavy and very heavy meals and pay attention to diet control. The 'Taste-driven' class is characterized by a preference for taste, with takeaway orders occurring three or more times a week. This group also exhibits a preference for heavy or very heavy meals and a tendency to consume meals with a higher salt content compared with affluent class. Compared with other two classes, the 'Money saver' class is characterized by lower incomes, a lower frequency of takeaway consumption, less attention paid to dietary control, and a greater propensity to order high-calorie dishes. The study identified a group of takeaway users who are motivated by financial considerations. It is noteworthy that the study revealed that O2O takeaway users do not always make optimal decisions regarding their daily takeaway food. Individuals who regularly order takeaways and primarily consume very heavy and heavy meals are at an elevated risk of obesity. Furthermore, they tend to select less healthy options, including takeaways with high fat, high carbohydrate, and high salt content.

Conclusions and Implications: These findings indicate that policymakers may consider the utilization of nudging intervention tools with the objective of encouraging consumers to make healthier O2O takeaway food choices. Policies targeting unhealthy foods could prove beneficial for 84.72% members of the 'affluent' and 'taste-driven' social classes by providing nutritional information on online takeaway menus, thus reducing excess energy intake.

Ind-1329 Understanding Public Preferences and Willingness to Pay for Seasonal Influenza Vaccines in India: Insights from a Discrete Choice Experiment

PRESENTER: **Jeffrey Pradeep Raj**
AUTHOR: Yashika Nandkumar Zagade

Introduction: Seasonal influenza poses a significant global health threat, with 3–5 million severe cases and 290,000–650,000 deaths annually. Vulnerable groups in low- and middle-income countries (LMICs), such as pregnant women, infants, and those with chronic conditions, face higher risks due to limited healthcare access. Africa and Southeast Asia account for 51% of global influenza deaths, with rates 1.4 times higher than in high-income countries. Vaccination, while not foolproof, effectively reduces severity, complications, and mortality. Yet, coverage remains under 1% in Africa and Asia. Hence, identifying vaccine attributes valued by the public is key to boosting uptake. A discrete choice experiment (DCE) is a useful way to understand what influences people's choices—in this case, for an influenza vaccine. It breaks preferences into key features, like safety, effectiveness, and cost, with each feature having different levels, such as effectiveness at 40%, 60%, or 80%. By examining how people prioritize these factors, a DCE reveals their preferences and decision-making patterns. *Methods*: A statewide digital survey was conducted in Maharashtra, India from January to May 2023, targeting adults over 18 years who had lived in the country for at least six months. The DCE presented participants with seven pairs of hypothetical influenza vaccines, including a "trap question" where one option was clearly superior. Respondents failing the trap question were excluded. Each vaccine was described using key features—effectiveness, side effects, route of administration, duration of protection, and cost—with varying levels for each attribute across the pairs. *Results*: A total of 2146 respondents consented, of which 146 were screen failed, 148 failed the trap question and 1852 responses were finally analysed. The most important attributes were effectiveness followed by side effect profile. The respondents were willing to spend approximately INR2607 (31·03USD), and INR3538 (42.12USD) per dose to take vaccines that offer 60% and 80% effectiveness, respectively (relative to 40% protection). With regards to side effects, they were willing to pay an additional money of INR 1422 (16.93USD) and INR 1506 (17.93USD) on vaccines with either no side effects or minimal local effects, respectively (relative to a vaccine that causes systemic side effects). Vaccine hesitancy (to at least 3/6 vaccine pairs) was seen in 9.01% *Conclusions:* This study highlights effectiveness and side effect profile as key attributes influencing vaccine preferences in India. Respondents demonstrated a willingness to pay higher for vaccines with greater effectiveness and fewer side effects. Despite these preferences, vaccine hesitancy persists in a small segment despite an ongoing influenza epidemic in India. These findings can guide strategies to improve influenza vaccine uptake.

Social Gradients and Social Security - Impacts Beyond the Healthcare System

MODERATOR: **Marshall Makate**,

Ind-919 Social Determinants of Health and Diabetes Self-Care Management in South Africa.

PRESENTER: **Assegid Hellebo**
AUTHORS: Sue Cleary, Andre Pascal Kengne, Amarech Obse, Olufunke Alaba, Bronwyn Myers, Naomi Levitt

Background Diabetes affects around 4.2 million South Africans aged 20-79, leading to complications, premature morbidity, and strain on healthcare systems. Effective self-care management is key to preventing these adverse effects and reducing negative economic impact. However, Social Determinants of Health (SDoH), including socioeconomic and environmental factors, often hinder adequate self-care and adherence to treatment. This study explored the relationship between SDoH and diabetes self-care management, using the Healthy People 2020 (HP2020) framework to examine how these social factors influence adherence to self-care practices among individuals with diabetes in South Africa. **Method** This cross-sectional study utilized baseline data from Project Mind, collected in 2017. Self-care management was coded on a scale from '0' (never) to '7' (daily adherence). For analysis, the scale was dichotomized into two categories: low self-care (scores 0–5) and high self-care (scores 6–7). Additionally, adherence to daily self-care activities was categorized into three levels: no adherence, partial adherence (inconsistent or partial adherence), and full adherence (consistent adherence to all self-care activities). The study analysed the associations between socio-demographic factors (such as age, gender, education), economic conditions, lifestyle factors (including obesity and food insecurity), and access to healthcare services with self-care practices among individuals with diabetes. **Results** The analytical sample (n=539) was predominantly female (76%), with a mean age of 54 years. Participants were mostly urban residents (60%), unemployed (70%), and had attained secondary education (11.3%). Age (AOR=1.02, CI=[0.99, 1.05]) and secondary education (AOR=1.13, CI=[1.02, 2.03]) were positively associated with higher levels of self-care. In contrast, urban residency (AOR=0.50, CI=[0.29, 0.88]) and obesity (AOR=0.43, CI=[0.19, 1.00]) were linked to lower self-care adherence. Though not statistically significant, food insecurity (showing a decreasing association), being a woman, and having a stable home were found to influence self-care practices. Longer travel distances to healthcare services were positively associated with poor adherence, and urban residency was negatively associated with full adherence compared to partial adherence. **Conclusions:** The study highlights the significant role of SDoH in shaping diabetes self-care management in South Africa. The findings underscore the need for more holistic, tailored interventions that address the socio-demographic, economic, and environmental factors affecting self-care practices aimed to improve diabetes management and health outcomes. Future research should explore these determinants in

greater depth and develop integrated strategies to enhance self-care and overall health outcomes for people with diabetes in South Africa. **Keywords:** Social Determinants of Health, Diabetes, Self-care Management, Adherence, South Africa, Healthy People 2020, Socioeconomic Factors, SDOH, Health Inequities 1

Ind-1099 The Impact of Social Determinants on Anxiety Levels Among the Elderly During the Pandemic

PRESENTER: **Ziyan Zhang**
AUTHORS: Wenbin Liu, Qiwen Deng

Background The COVID-19 pandemic poses significant threats to health and life, leading to economic instability and increased living stress, which triggers widespread emotional and psychological challenges. Existing studies have shown that anxiety levels in the elderly are influenced by multiple factors, including social isolation, chronic disease burden, economic pressures, and lifestyle changes. Gender and educational attainment are widely recognized as critical social determinants of mental health. Elderly people with chronic diseases face heightened health risks, resulting in anxiety levels significantly higher than other age groups. However, most studies focus on the acute phase of the pandemic, and there is a lack of systematic exploration into the long-term impact on elderly anxiety, research on social support and policy interventions exists, empirical studies on designing more targeted mental health interventions remain scarce. **Methods** This study is based on the Social Determinants of Health (SDOH) theory. In this study, we uses data from the 2020 China Health and Retirement Longitudinal Study(CHARLS).with a final sample of 7139 respondents after cleaning. Structural equation modelling (SEM) approaches were employed to analyze the relationship between social determinants and anxiety levels among the elderly, focusing on several variables such as gender, educational attainment, and disease prevention awareness. Descriptive statistics and multiple linear regression analyses were conducted using Stata to summarized the characteristics of the sample and examine the correlation between factors. **Results** The results show that gender is a significant factor influencing anxiety levels (path coefficient = -0.2341, $p < 0.001$), with women exhibiting significantly higher anxiety levels than men. Additionally, there is a significant negative correlation between educational attainment and the level of anxiety(path coefficient = -0.0538, $p = 0.005$), indicating that higher levels of education are associated with lower levels of anxiety. Additionally, the impact of disease prevention awareness on anxiety is relatively weak but still positive (path coefficient = 0.0378, $p < 0.05$). Individuals with greater disease prevention awareness exhibited higher anxiety levels, this may be due to the diverse and complex information received during the pandemic, excessive exposure to negative information may heighten awareness but also exacerbate anxiety. The regression results indicate that higher disease prevention awareness and lower education levels significantly increase anxiety, while gender differences also play a crucial role. **Conclusion** Using pandemic-related data, this study reveals the social determinants of elderly anxiety levels and their complex mechanisms during public health emergencies. It highlights the significant effects of gender differences, and educational attainment on anxiety, while systematically exploring the key factors affecting the mental health of the elderly in the later stages of the pandemic. The findings address gaps in the existing literature regarding the long-term impacts and interaction mechanisms of these variables. They provide empirical support for developing more targeted mental health interventions for the elderly, offer new perspectives on building social support networks and improving health equity, and serve as a robust foundation for formulating public health policies. **Keywords** Social Determinants Anxiety Levels Elderly

Ind-1210 Quantifying the Social Capital Burden due to Cardiovascular Disease: Implications for Outcome Measurement

PRESENTER: **Anthony Niu**
AUTHORS: Dieu Nguyen, Peter Lee, Lan Gao

Objectives

This study examines the associations between **cardiovascular diseases (CVD)** and self-reported **social capital** among older individuals (aged 50 and above) in Australia. Leveraging the longitudinal richness of a nationally representative survey dataset, this study aims to make three novel contributions to the health economics literature. First, the study investigates potential **CVD gradients** in social capital by categorising individuals into three groups: those without CVD, those with CVD but no medication, and those with CVD regularly taking prescription medication. Second, it compares the impacts of three specific types of CVD - **heart disease (HD)**, **high blood pressure (HBP) and hypertension**, and **other circulatory conditions (OCC)** (e.g., stroke or hardening of the arteries. Third, it distinguishes between two dimensions of social capital: **cognitive social capital**, reflecting emotional aspects like social support and loneliness (e.g., “I often feel very lonely”), and **structural social capital**, reflecting participation in social networks and civil communities (e.g., “I make time to keep in touch with friends”).

Methods

This study utilises data from four waves of the **Household, Income and Labour Dynamics in Australia (HILDA)** survey - 2009, 2013, 2017, and 2021 - providing a total of **26,364 individual-year observations** from **10,205 unique respondents**. Both measures of social capital - cognitive and structural - were constructed using responses to a series of questions from the HILDA Self-Completed Questionnaires (SCQs). **Factor analysis** techniques were applied to derive two index outcomes for each measure: social support and loneliness for cognitive capital, and civil participation and social engagement for structural capital. These indexes were standardised with a mean of 0 and a standard deviation (SD) of 1 to enable consistent comparisons. To account for potential biases arising from unobserved individual-specific characteristics (e.g., childhood experiences), the analysis employs two econometric methods. First, a **Correlated Random-Effects (CRE)** Model (Mundlak approach) was used to control for within- and between-individual variations while preserving time-invariant covariates. Second, a **Dynamic Model** with a lagged dependent variable (t-1) was employed to capture temporal effects and the persistence of social capital outcomes over time.

Results

The CRE results show that individuals with CVD requiring prescription medications report significantly worse social capital outcomes. They experience a 0.174 SD (P < .001) higher loneliness index, and a 0.064 and 0.073 SD lower civil participation and social engagement, respectively, compared to those without CVD. Among CVD types, OCC (e.g., stroke) have the largest impacts, increasing loneliness by 0.225 SD and decreasing social engagement by 0.210 SD. Female respondents with HD and medication dependence report the highest loneliness levels (0.300 SD higher, P < .001), while no significant differences are observed by age, immigration status or geographic location.

Conclusions

This research addresses critical gaps in understanding the broader social and economic burden of chronic diseases in Australia, offering insights into how CVD shapes both individual well-being and societal connectedness. This will stimulate discussion around the outcome measure selection in CVD population. A quality-of-life instrument that lacks the dimension of social capital may lead to sub-optimal measurement of the benefit.

Ind-1576 Wealth Gradients in Mortality and Morbidity: Heterogeneity in Ecuador during COVID-19 and Beyond

PRESENTER: **Omar Galarraga**, Brown University

Background: Wealth gradients for mortality have been described in high income countries since the 19th century. Documented gradients by cause of death are less common in low- and middle-income countries, particularly during and after COVID-19.

Research Questions: Are there mortality wealth gradients in Ecuador? If so, are there differential patterns by cause of death? Are there gradients for morbidity? If so, do social health insurance and pension fund availability reduce disparities? Are there differences by race/ethnicity self-identification?

Methods: Data come from the complete 2022 Census for Ecuador with N=16,938,986 individual observations. All-cause mortality is the dependent variable as well as mortality by three large groups of causes: (i) Violent deaths (accidental, suicide, assassinations); (ii) COVID-19; (iii) other causes (other diseases, natural causes). Reported permanent functional disability is the secondary dependent variable; measured as a composite index from Likert-scale responses to permanent difficulty with activities of daily living (walking, bathing, etc.), as well as difficulty with hearing, vision, speech and/or concentration. The main independent variable is rank of households as measured by their relative position by a wealth index constructed with principal components analysis of 28 variables (including house ownership, house construction materials, persons per room, ownership of various assets). Concentration curves and concentration indices are used to characterize relative inequality; specifically, the Erreygers standardized index is used for mortality.

Results: There were 237,382 households reporting at least one death during the prior three years (starting on January 1, 2020). This implies that 4.57% of the total 5,193,548 households reported at least one death. Of all deaths, 9.3% are violent, 18.8% are due to COVID-19, and 71.9% are due to other causes. A total of 6.7% of individuals report permanent functional disability. There was no negative gradient for overall deaths, nor for COVID-related deaths, nor differences by self-identified Indigenous status. However, violent deaths exhibited a strong and significant negative gradient; the Erreygers index was -0.0664 [SE: .001, p-value=0.000], and yet contrasting differences by social health insurance status was not significant [p-value: 0.11]. Permanent functional disability was also concentrated among the least wealthy; the concentration index was -0.022 [SE:.00006, p-value: 0.000] and presence of social health insurance / social security at the household level reduced disparities in functional disability [from -0.022 to -0.018, p-value=0.000].

Conclusions and implications for policy: This presentation documents negative gradients in violent deaths and permanent functional disability in Ecuador. The current social health insurance and pension fund system does not seem to help to reduce the disparities in deaths related to accidents, murder, and suicides; however, it seems to reduce disparities for functional disability. The lack of observed gradients in COVID-19 deaths, particularly among Indigenous people, may be because of poor access to testing and diagnosis prior to death. The public system (of social health insurance and pension fund) may need to be reformed to better address emergency care as well as mental health so that it becomes more progressive and provide better protection against violent-deaths mortality, particularly for the lower economic echelons.

Ind-992 Potentially Modifiable Lifestyle Factors and Cognitive Impairment Risk Among Older Adults with Hypertension: A Community-Based Study

PRESENTER: **Mingze Ma**
AUTHOR: Jian Wu

Background The epidemiology of cognitive impairment has paid little attention to the older adults with hypertension in rural and urban China, and the association of comprehensive lifestyle factors with cognitive impairment has rarely been investigated. **Objectives** To investigate the prevalence of cognitive impairment and its association with potentially modifiable lifestyle factors among older adults with hypertension in rural and urban communities in China, aiming to identify high-risk individuals and promote targeted health strategies for maintaining cognitive health. **Methods** A cross-sectional study involving 18,963 hypertensive individuals aged 65 years and older from 15 communities (2 urban and 13 rural) in Jia County, Henan Province, China, was conducted from July to August 2023 via a cluster sampling method. Cognitive impairment was assessed via the Mini-Mental State Examination (MMSE), with thresholds on the basis of education level. Logistic regression models were used to assess the associations of sociodemographic information, eight lifestyle factors, and clinical physiological and biochemical indicators with cognitive impairment. **Results** Cognitive impairment was prevalent in 33.6% of the older adults with hypertension, with a higher prevalence in females (35.4%) compared to males (31.1%), and showed an age-dependent increase. The adjusted odds ratio of cognitive impairment was 0.76 (95% confidence interval(CI), 0.60-0.95) for alcohol consumption, 0.62(95%CI 0.56-0.68) for adequate physical activity, 0.85 (95%CI 0.78-0.92) for a healthy diet, 0.85(95%CI 0.78-0.93) for 7-8 hours of sleep, 1.38 (95%CI 1.22-1.55) for depression, 1.36 (95%CI 1.20-1.54) for anxiety, and 0.63(95%CI 0.58-0.69) for high social participation. Higher composite healthy lifestyle scores were associated with

a significantly lower risk of cognitive impairment(p<0.001). Compared to participants with the lowest scores, those with the highest scores for a healthy lifestyle had their risk of cognitive impairment reduced to 0.30 (95%CI 0.25-0.38). **Conclusions** Our research revealed that the prevalence of cognitive impairment was high and increased with age among the older adults with hypertension in rural and urban China, regardless of sex differences. Potentially modifiable healthy lifestyle factors (e.g., alcohol consumption, adequate physical activity, healthy diet, sufficient sleep, good mental health (absence of depression or anxiety), and high social participation) were all negatively associated with cognitive impairment. Increases in healthy lifestyle scores were strongly correlated with a reduced risk of cognitive impairment. These findings support promoting healthy lifestyles to maintain cognitive health later in life. This composite healthy lifestyle score can help identify high-risk individuals with cognitive impairment, leading to more targeted health promotion strategies. This will improve the overall cognitive health and quality of life of older adults with hypertension and provide significant long-term public health benefits to the community. **Keywords** Ageing; Hypertension; Community; Cognitive function; Lifestyle factor; Healthy lifestyle score.

Ind-1061 Does Work from Home Contribute to Increased BMI and Obesity?

PRESENTER: **Anastasia Semykina**
AUTHOR: Brenda Gannon

As a by-product of COVID-19 pandemic, the world had discovered work from home (WFH) as a viable and acceptable strategy to engage in the workforce. Even after the pandemic was officially over, all restrictions were lifted, and COVID-related health concerns substantially diminished, WFH persisted beyond pre-pandemic levels, and hybrid work became a more widely accepted and popular option. Recent studies find that WFH has no detrimental impact on productivity and improves the worker job and life satisfaction, suggesting that WFH may be a win-win for both employers and employees. However, some researchers voiced concerns about possible adverse mental health consequences of social isolation when staying at home. A few studies also considered changes in individual body weight during the pandemic, but the impact of WFH on body weight outside of the pandemic period has not been explored. The freed-up time from a decreased commute opens a possibility of devoting more attention to health, increasing the frequency of exercise and cooking meals at home. On the other hand, the sedentary nature of most jobs done from home may result in less physical activity and unhealthy lifestyle choices. The present paper studies the effects of WFH arrangements on health by considering the person's body mass index (BMI) and obesity before and after the COVID-19 pandemic.

We explore the relationship between WFH and workers' body weight using panel data from the Household, Income and Labour Dynamics in Australia Survey, years 2006-2019, 2022-2023 – a nationally representative dataset. Estimation is performed using a two-way fixed effects linear model, which accounts for unobserved individual characteristics, such as genetics, chronic health conditions, and family background. The analysis is performed separately for men and women and for pre- and post-COVID periods.

We find that prior to COVID, the intermediate WFH intensity (50 to 70% hours worked at home) among women is associated with about 0.4 higher BMI and 10 percentage points higher probability of obesity as compared to women with zero WFH. The effects are stronger for women in office jobs. During the post-pandemic period, the likelihood of obesity is approximately 6 percentage points higher for women with high WFH arrangements (70% or more hours worked at home). There are no systematic effects for men.

To explore the potential mechanisms, we study the link between WFH and physical activity, time use and diet using the two-way fixed-effects analysis. Our results indicate that women with intermediate WFH tended to have less healthy diets and spent less time on physically active home tasks during the pre-COVID period. On the other hand, women with high WFH were less physically active than women with intermediate WFH after the pandemic. Furthermore, the share of WFH workers in office jobs has increased after the pandemic.

These findings suggest that staying physically active while working at home can help to avoid the unhealthy weight gain. Hence, informational interventions highlighting the importance of exercise and healthy foods might be warranted.

Ind-1412 Impact Of Conditional Cash Transfers On Adolescent Pregnancy: Evidence From Colombia

PRESENTER: **Ana Correa Ossa**
AUTHORS: Lara Gosce, Neha Batura, Jolene Skordis

Background and research aim Latin America and the Caribbean have the second-highest adolescent pregnancy rates globally (Aguía-Rojas et al., 2020). Colombia ranks among the highest in the region, with nearly one in five adolescent girls having been pregnant, rising to one in three among the poorest and in areas with large Afro-descendant, indigenous, or displaced populations. (Daniels, 2015; Gimenez et al., 2015). Conditional cash transfers (CCTs), such as Colombia's *Familias en Acción*, provide a monetary stipend conditional on school attendance, potentially reducing adolescent pregnancy by improving economic and educational opportunities (Ribas et al., 2021). Evidence on their effectiveness remains limited, particularly for younger adolescents and across rural/urban settings (Ribas et al., 2021). This research aims to evaluate the impact of *Familias en Acción* on adolescent pregnancy in Colombia, disaggregating results by age group and rural/urban setting. **Methods** We used *Familias en Acción* beneficiary data and Colombian census data to create a treatment variable, representing beneficiary density, continuous from 0 to 1, for three adolescent girl groups (ages 10-14, 15-19, and 10-19). Adolescent pregnancy rates, disaggregated by age, were sourced from the Colombian Ministry of Health. Covariates included municipality-level data on rural/urban category, annual income per capita, and adolescent girls' population size for each age group. The panel dataset covered 1,101 municipalities from 2008 to 2017 (10,913 observations). A two-way fixed effects model with lags of up to 4 years was used, following a recent study exploring the impact of Mexico's PROGRESA on adolescent pregnancy rates (Parker et al., 2023). Results were estimated separately by age group and rural/urban category. **Results**Full sample results show sustained and significant reduction in adolescent pregnancy for all age groups, up to 4 years after beneficiary increase. There is an increasing trend as time from treatment increases. The largest effects were seen for girls aged 10-14 (3 years post beneficiary increase), who had almost a five-fold reduction of the national mean rate for this age group. There was significant heterogeneity of results depending on rural/urban location, with most reductions seen in urban and peri-urban settings. **Discussion** These impacts may stem from the CCT increasing school enrolment (Attanasio et al., 2006, 2010), reducing economic vulnerability (Tovar et al., 2017), and increasing health knowledge (Llano et al., 2014) among beneficiaries; all of which can contribute to reduced adolescent pregnancy rates. Findings align with prior literature showing stronger programme impacts in urban and peri-urban areas

(Cortes et al., 2016; Attanasio et al., 2021). The significant reductions among girls aged 10–14 are particularly noteworthy, as this group faces greater risks of mortality, morbidity, and disrupted education. The mostly null results in rural areas show that the CCT impact may be diminished due to limited access to relevant sexual health services. Further research could focus on identifying the mechanism of action, helping develop effective integrated strategies to address adolescent pregnancy.

Ind-1498 Maternal and Child Health Impacts of Integrated Social Safety Nets: Cash Transfers, Information Meetings, and Home Visits

PRESENTER: **Damien de Walque**, The World Bank
AUTHORS: Harounan Kazianga, Richard Akresh, Abigail Stocker

For over 25 years, governments in developing countries have used cash transfers delivered to poor households to help children reach their full potential in terms of health, education and psychosocial development. More recently, integrated programs combining either information or home visits have been adopted and added to cash transfers to help households overcome barriers to improving maternal and child health and child development.

Working with the Burkina Faso government, we conduct a cluster-randomized experiment in 225 rural villages to assess the impact on maternal and child health of an integrated social safety net over the child's life cycle. Villages were randomized to a control group or one of the 3 following treatments: 1) cash transfers; 2) cash transfers plus government-run information meetings focused on children's health and psychosocial development; or 3) cash transfers, information, and home visits reinforcing the information meetings.

Fifteen months after the treatment ended, results indicate that households receiving the combined full intervention have lower fertility, increased age at each pregnancy, increased use of medical care at birth, prenatal care visits, bed nets usage and handwashing as well as improved child anthropometrics. The home visit component is critical for improving early childhood development indicators. Cash transfers alone, with or without village-level information meetings do not impact these outcomes.

This study makes three main policy relevant contributions. First, this is the first study to compare in the same setting, interventions that provide only cash, cash plus information, or cash plus information plus home visits. Existing evidence shows that each component (cash, information, and home visits) could lead to improved maternal and child health, but it is not clear where the behavioral constraints lie and whether removing all these barriers leads to larger impacts. Given that many governments in developing countries are considering adopting home visits as part of their social safety nets, it is also important to understand why home visits work and whether they are necessary or if simply providing cash or knowledge is sufficient.

Second, due to insecurity in parts of Burkina Faso, the endline survey was delayed by approximately 15 months after the treatment intervention ended. Therefore, all our program impacts should be interpreted as the medium-term effects once the program ended. There are a limited number of evaluations that can look at impacts beyond the program ending and given that the previously discussed literature found maternal and child health impacts disappeared or faded out, it is therefore promising that we still are able to observe positive impacts of the full treatment intervention 15 months after the program ended.

Third, while it was not the intention of the Burkina Faso government to be evaluating this social safety net in an environment with insecurity and conflict, those factors did present themselves and allow us to contribute to a very limited literature looking at the role of social safety nets in conflict settings. Our setting also allows us to examine whether the interventions, or specific components, had different effects on more vulnerable households.

Ind-2209 Do Social Protection Programmes Mitigate Health Shock Vulnerability to Poverty in Sub-Saharan Africa?: Empirical Lessons from Nigeria

PRESENTER: **Adelakun Odunyemi**
AUTHORS: Khurshid Alam, Hamid Sohrabi

Background: Health shocks are increasingly driving vulnerability to poverty in Sub-Saharan Africa (SSA). However, studies on the mitigating impacts of social protection mechanisms on induced vulnerability to poverty are sparse and inconclusive. Apart from very few studies on health insurance, the few studies on health-related vulnerability to poverty in SSA rarely assessed the role of social protection mechanisms.

Therefore, this study assessed the impact of health shocks on vulnerability to poverty in a nuanced manner, the mitigating role of social protection programmes and their rural-urban disparities in Nigeria as a microsome of reality in SSA. Moreover, the study provides valuable insights into geographical inequality in the dynamics of health shocks and social protection mechanisms, which is crucial for informing policy interventions to reduce rural-urban inequalities.

Methods: We used large and most recent nationally representative Nigeria Living Standards Survey data, Chaudhuri's vulnerability as expected poverty (VEP) and three-stage Feasible Generalized Least Squares proposed by Amemiya (1977) to estimate vulnerability to poverty. We classified households into poverty dynamic categories, using their current poverty status and risk of (future) vulnerability to poverty: persistent poverty (current poverty and poverty vulnerability), transient poverty (current poverty but no poverty vulnerability), potential poverty (no current poverty but poverty vulnerability), and poverty escapes (no current poverty and no poverty vulnerability). We employed multinomial probit regression to analyse the impact of health shock and social protection programmes on these dynamics. This classification offers a nuanced understanding of the heterogeneous and dynamic nature of poverty beyond the simple vulnerability commonly found in the literature.

Results: Our findings reveal that 32% of households were vulnerable to poverty, with 23.3% experiencing persistent poverty and 16.8% facing

potential poverty. Death/disability of income-earning household members, non-communicable diseases and malaria substantially increased vulnerability to poverty (more than 20% likelihood), mainly persistent and potential poverty. Rural households were more vulnerable than their urban counterparts across all poverty categories.

Social protection mechanisms showed mixed effects. While safety net coverage was associated with increased poverty, enrolment into the National Health Insurance Scheme and receipt of remittances significantly reduced (> 80%) the likelihood of potential and persistent poverty. However, coverage of these programmes remains low, particularly in rural areas.

Conclusion: These findings underscore the need for policies targeting health shocks and improved and adequate social protection programmes to reduce poverty from health shocks in SSA, especially in rural areas. This study provides compelling evidence that the implementation of social safety net programmes in SSA requires review to position them effectively to combat poverty.

Cost of Healthcare Seeking and Service Delivery

MODERATOR: **Mardiati Nadjib**, InaHTAC

Ind-387 Examining Disparities in Maternal Health Care Costs Among Scheduled Tribes in Odisha and Jharkhand States in India

PRESENTER: **Rekha S**

Background: Illness often plunges households into poverty due to substantial out-of-pocket expenses (OOPE) and indirect costs like loss of income or employment. Evidence from the existing literature indicates that catastrophic health spending is incurred for general health care and maternal health services. The findings from studies specify that women belonging to particular social groups, rural households, who are less educated and poor, incur delivery costs which are catastrophic, and these further push them into poverty

Methodology: The analysis uses data from the National Family Health Survey (NFHS) rounds 4 (2015-16) and 5 (2019-21). A multivariable linear regression identifies the effects of selected socio-economic variables on OOPE in both public and private healthcare facilities. The Concentration Index (CI) and curves are used to measure inequality in OOPE within ST groups. To analyse the nature of OOPE, we use the Kakwani Index (KI) is employed.

Results: The multilinear regression analysis reveals a positive correlation between wealth and OOPE in India, suggesting higher OOPE with increasing wealth. In Odisha, the CI values for OOPE in public health facilities are positive in both NFHS-4 and NFHS-5, indicating that a larger share of OOPE is incurred by women from wealthier quintiles. However, there is a marginal reduction of 0.21 percentage points (p.p.) in CI values from NFHS-4 to NFHS-5. In contrast, for private healthcare facilities, the CI was negative in NFHS-4, signifying that poorer women bore a greater OOPE burden. By NFHS-5, the CI turned positive, indicating a shift in the OOPE burden toward wealthier individuals, with an increase of 0.9 p.p. In Jharkhand, the CI values for OOPE in both public and private health facilities are positive across both rounds of the NFHS. In public facilities, the CI increased by 0.3 p.p. from NFHS-4 to NFHS-5, showing a greater concentration of OOPE among wealthier quintiles over time. For private facilities, there was a slight decrease of 0.1 p.p. in CI values between the two rounds, indicating a small redistribution of OOPE burden among wealth quintiles.

In Odisha, the KI for OOPE in public health facilities in NFHS-4 (2015-16) was positive (0.12), indicating progressivity, but in NFHS-5 (2019-21), it became negative (-0.056), indicating regressivity. In private facilities, the KI was consistently negative (-0.97 in NFHS-4 and -0.06 in NFHS-5), highlighting a regressive burden, with poorer individuals bearing a larger income proportion in OOPE. In Jharkhand, the KI for public health facility costs was positive in both surveys (0.18 and 0.58), showing progressivity, while private facility costs consistently showed regressivity (KI of -0.12 in NFHS-4 and -0.10 in NFHS-5).

Conclusion and Discussion: The findings of the study indicate that ST women with lower incomes face a disproportionately high OOPE burden compared to wealthier groups, specifically with respect to private-sector delivery care costs, showing strong regressivity. To mitigate this financial strain, we recommend targeted financial assistance programs, improved monitoring, and strengthened public healthcare infrastructure in ST regions. These measures would promote equitable maternal healthcare access and reduce the economic burden on ST women.

Ind-1003 The Long-term Health System Costs of Adverse Perinatal Outcomes in Northern Territory, Australia: A Two-Decade population-based study

PRESENTER: **Tsegaye Haile**

AUTHORS: Richard Norman, Gizachew A. Tessema, Gavin Pereira

Background: The economic burden of adverse perinatal outcomes—including preterm birth, small-for-gestational age (SGA), low birthweight (LBW), and mortality (including stillbirth)—on individuals, families, societies, and health systems remains a prevailing issue in Northern Australia. The burden spans from healthcare costs to family psychological challenges, extends into adulthood and may result in significant economic losses later in life. Despite its importance, this issue has received limited attention. Therefore, we examined the incidence,

hospitalisations, and emergency department (ED) presentations associated with these outcomes, analysing the related healthcare costs up to age five from a health system perspective. **Methods:** We used a retrospective cohort study of births from July 1, 2000, to December 31, 2020, linked to hospitalisation, ED presentation, and cost-weight data. The healthcare cost measurement was conducted from a health system perspective, encompassing both direct medical and non-medical costs. Cost trends were examined by year from 2000 to 2020 and across the childhood period from birth to age five years. All costs were standardised to Australian dollars (A$, as of June 2024). To identify the drivers of cost, we used a Generalized Additive Model (GAM) with a gamma distribution and log link function. Model fitness and comparisons were assessed using the Akaike Information Criterion (AIC) and Restricted Maximum Likelihood (REML). Thin plate and cubic spline terms were employed to capture the smooth, non-linear relationships between cost and covariates. **Results**: We found 87.5 preterm births/1,000 live births, 123.9 SGA/1,000 live births, 77.9 LBW/1,000 live births and 6.5 stillbirth/1,000 total births. The hospitalisation and ED presentation rates among preterm children were 2.4 and 4.9 per child year. The mean cost of hospitalisation and ED presentation was A$10,435 (A$10,086) and A$816(A$305) per preterm child, respectively, in the first five years of life. We also found that mean hospitalisation cost of A$7,294(A$5,765) and A$774(A$297) cost of ED presentation per a child with SGA, in the first five years. We observed higher costs of hospitalisations and ED presentations in later cohorts, while individual costs decreased as the child aged. Child-related clinical characteristics and length of hospital stay were the main drivers of combined costs. **Conclusions**: The substantial financial burden of adverse perinatal outcomes impose on the healthcare system is largely driven by extended hospital stays at birth and at subsequent admissions. Vulnerable populations, particularly children from indigenous parents and those in remote areas have significantly higher healthcare costs relative to the average. These findings underscore the need for further research to quantify the disparity and identify the underlying contributors, enabling more targeted interventions to reduce the dual health and economic impacts driven by these vulnerable populations.

Ind-1279 Estimating the Financial Burden of Cancer in Nepal: A Cross-sectional Study of Patient Costs

PRESENTER: **Pratik Khanal**
AUTHORS: Krishna Kumar Aryal, Kjell Arne Johansson, Biraj Karmacharya, Shiva Raj Adhikari, Achyut Raj Pandey, Ravi Mishra

Background Estimating financial burden on patients with cancer is crucial for the evaluation of national cancer programs and policies. However, there is a dearth of comprehensive research on the costs associated with cancer care in low-resource settings. Additionally, the financial protection provided by existing social health protection schemes remains largely unexplored. This gap in evidence may hinder policy makers from designing effective financial protection mechanisms and prioritizing cancer interventions within national health benefit packages. **Aim** This study aims to estimate the financial burden of cancer in Nepal from the patient's perspective. We estimated the annual cost of cancer care and catastrophic health expenditure (CHE) among patients seeking cancer treatment . **Methods** This cross-sectional study was conducted in two tertiary public cancer hospitals of Nepal. Face-to-face interviews were conducted with 353 patients undergoing treatment for five cancers. To estimate the annual cost of cancer, we calculated and summed up annual direct medical, direct non-medical and indirect costs. The incidence of CHE was measured as the proportion of households whose out-of-pocket payments for cancer treatment exceeds 10 and 25 percent thresholds of annual household expenditure. A generalized linear model was used to identify the predictors of annual cost, while a multivariable logistic regression model was used to assess the determinants of CHE. **Results** Overall, 58.6% of the patients were members of at least one social health protection scheme and 81.6% had utilized treatment subsidies for cancer (a separate subsidy for chronic diseases). The annual average cost of cancer care was estimated at 3687 United States Dollar (USD). Direct medical costs constituted the largest proportion of the total cost (53.8 %), while indirect costs and direct non-medical costs accounted for 30.5% and 15.7% of the total cost, respectively. Factors significantly associated with higher annual cancer costs included longer duration of treatment, combined treatment modalities, admission to inpatient care, and prior visits to the private health facilities. At the 10% threshold, the overall incidence of CHE was 96.9%, with 98.6% in the poorest and 91.5% in the richest quintile experiencing CHE. Similarly, at the 25% threshold, 83.9% of the patients experienced CHE with 98.6% in the lowest quintile, and 59.2% in the highest wealth quintiles affected. Factors significantly associated with higher odds of CHE included treatment duration of 6-12 months (compared to less than 6 months), admission to inpatient care, and those in the lower wealth quintiles. **Conclusion** This study highlights a substantial financial burden of cancer care in Nepal and identifies the drivers of annual cost and CHE. The annual cost of cancer care was nearly three times the Nepal's GDP per capita. Almost all the patients experienced CHE at the 10% threshold while significant differences in CHE were observed across wealth quintiles at the 25% threshold. These findings warrant the urgent need for strengthening social health protection schemes and prioritizing cancer interventions within the country's health benefit packages.

Ind-2168 The Economic Burden of Tobacco-related Diseases in the Philippines

PRESENTER: **Julienne Lechuga**
AUTHORS: Mr. Patrick James Encarnacion, Miharu Kimwell, Dante Salvador Jr., Joseph Oraño, Denese De Guzman

Background: Despite declining tobacco use prevalence in the Philippines following the implementation of the Sin Tax Law, the economic impact of tobacco-related diseases (TRDs) remains substantial. This study aimed to estimate the economic burden of TRDs and evaluate the potential impact of policy interventions on health outcomes and associated costs in the Philippine setting. Methods: We employed a prevalence-based, population-attributable fraction (PAF) approach to estimate direct and indirect costs of 37 TRDs (27 causally-linked and 10 associated diseases) from a societal perspective across a lifetime horizon. The list of the TRDs were aligned in consensus with the Department of Health. Data sources included the 2015 Philippine Global Adult Tobacco Survey, 2019 Global Burden of Disease Study, Philippine Health Insurance Corporation claims, and published literature. We calculated direct medical costs (inpatient and outpatient care), direct non-medical costs (transportation and meals), indirect morbidity costs (productivity losses), and indirect mortality costs (years of life lost) in 2021 Philippine pesos. Results: We identified 3.90 million tobacco-attributable disease cases and 1.95 million years of life lost, with around 60% attributed to ischemic heart disease, tuberculosis, and COPD. Direct medical costs contributed the largest at PHP 247 billion (67.5%), with higher costs in females (PHP 136.58 billion) than males (PHP 110.41 billion). Conversely, indirect costs were higher in males (morbidity: PHP 17.58 billion; mortality: PHP 51.05 billion) compared to that of females (morbidity: PHP13.13 billion; mortality: PHP22.05 billion). The top economic burden contributors were ischemic heart disease (PHP 65.55 billion), peripheral artery disease (PHP 58.17 billion), and COPD (PHP 56.19 billion), with notable gender variations in disease rankings. The 2012 Sin Tax Law implementation was associated with a 14.49% decrease in TRD prevalence in males and 42% in females, potentially saving PHP 149 billion in healthcare costs. Limitations: The analysis faced

constraints regarding data availability and the generalizability of relative risk values. Model assumptions about patient outcomes may underestimate the true economic burden of TRDs. Conclusion: This analysis demonstrated the substantial economic impact of TRDs in the Philippines, highlighting the need for strengthened tobacco control policies and sustained Sin Tax Law implementation. Our findings suggest that additional price increases could further reduce disease burden and generate significant healthcare cost savings. The results support continued investment in tobacco control measures while emphasizing the importance of robust health information systems for monitoring policy impacts.

Ind-999 High-Cost Users under Universal Health Coverage in Thailand

PRESENTER: **Picharee Karunayawong**
AUTHORS: Thanayut Saeraneesopon, Piyada Gaewkhiew, Ms. Wanrudee Isaranuwatchai

Background: The High-Cost Users (HCUs) phenomenon in healthcare systems exists when a small proportion of patients account for a large share of healthcare expenditure. By understanding this phenomenon, tailored interventions can be designed to ensure patients receive the necessary care while reducing the burden on health systems, particularly during resource-scarce periods such as the COVID-19 pandemic. To the best of our knowledge, this is the first study that able to combine and analyze individual healthcare expenditure data across Thailand's three major public health insurance schemes. **Objectives:** This study aimed to: (1) Determine whether the HCUs phenomenon existed in Thailand across different public health insurance schemes by analyzing inpatient health expenditure patterns from 2016 to 2023; (2) Identify the characteristics of HCUs; (3) Examine the top five primary diagnoses among HCUs; and (4) Explore potential predictors associated with becoming an HCU*.* **Methods:** Secondary data analysis was conducted using Inpatient Department (IPD) e-Claim data from the National Health Security Office for the Universal Coverage Scheme (UCS), which provides healthcare to approximately 80% of the Thai population. Data from the Central Office for Healthcare Information was used for the Social Security Scheme (SSS) and the Civil Service Medical Benefits Scheme (CSMBS), which collectively serve the remaining 20% of the population. Descriptive analysis was employed to calculate health expenditures over time and examine population characteristics. Multinomial logistic regression was used to identify potential predictors of HCUs. **Results:** The findings of the earlier phase of studies confirm that under the UCS, HCUs (i.e., the top 5% of the population) utilized approximately 40% of the annual healthcare expenditure. This trend persisted even during the pandemic year of 2020, affirming the existence of the HCUs phenomenon in Thailand. The characteristics of HCU patients remained relatively the same from 2016 to 2021, in terms of proportion of male to female patients (~55% and ~45%, respectively), age across 5 years (55 to 57 years old, min-max: 0-118), average length of stay per visit (~7 days, min-max: 0-5151), average number of admissions per patient per year (~3 visits), and the average healthcare cost per patient per year (≥THB 100,000). In addition, the top 5 primary diagnoses for HCUs did not change over time. For SSS and CSMBS, we also expected the existence of HCUs phenomenon but to a lesser degree due to differences in payment mechanisms population coverage, and budget allocation across the three schemes. **Conclusion:** High-Cost Users phenomenon existed in Thailand, even during the COVID-19 pandemic time where healthcare resources were carefully utilized. By understanding trends in healthcare utilization and expenditure, along with the predictors of HCUs, policies can be developed to optimize resource allocation, ensure care for those in need, and sustain Thailand's Universal Health Coverage system. **Keywords:** High-Cost Users, Health Expenditure*,* Universal Health Coverage, Big Data*,* Thailand

Access to Care and Patient Preferences

MODERATOR: **Santosh Gautam**,

Ind-1701 Trade-off Between Travel Distance and Quality of Care: A Discrete Choice Experiment

PRESENTER: **Moo Hyuk Lee**
AUTHORS: Soela Kim, Young Kyung Do, Un-na Kim

Background:

Patients' hospital choice often involves a trade-off between quality of care and distance to hospitals. This is especially prominent in South Korea, where patients with severe diseases such as cancer *outmigrate* to the capital city Seoul – that is, they bypass regional hospitals and travel to Seoul in the hopes of receiving better treatment. South Korea provides an ideal context for exploring such trade-offs due to its extensive transportation network and relatively small nation size, allowing patients in provincial areas to easily travel to Seoul. Previous studies examining hospital choice behaviors worldwide have quantified the relative importance of distance and quality through healthcare utilization data. However, quantitative insights into their trade-offs based on general population's stated preferences remain underexplored, particularly regarding their inter-regional bypassing behavior. This study aims to fill this gap by providing a quantitative analysis for understanding how distance and quality show trade-off in hospital choice, using a discrete choice experiment on a general population.

Methods:

A discrete choice experiment was conducted with a nationwide sample of 1,679 respondents (excluding Seoul residents), stratified by age, gender, region, and income. Five key attributes influencing hospital choice and their levels were identified based on focused group discussions: physician competence (middle, high, very high), facilities/equipment (middle, good), hospital reputation (middle, high), recommendation from friends or families (no, yes), and one-way travel distance (1, 2, 3, 4, or 5 hours). Respondents were presented with a hypothetical scenario in which they were diagnosed with severe diseases such as cancer, and were asked to choose between two hospitals with varying attribute levels.

Coefficients were estimated using a conditional logit model, and willingness-to-accept (WTA) values were calculated to quantify trade-offs between distance and other attributes. Subgroup analysis was also conducted, based on whether the respondent had intention to outmigrate.

Results:

Increasing physician competence from middle to very high would allow respondents to accept 5.50 additional hours of travel. Improvement of facilities/equipment from middle to good would allow respondents to accept 1.54 additional hours, and the presence of recommendation from friends of families would allow them to accept 0.77 additional hours. Subgroup analysis revealed that respondents willing to outmigrate in case of cancer diagnosis were willing to accept greater travel time increases for increased physician competence (WTA = 6.46 hours) and increased facilities/equipment (WTA = 1.79 hours), while they would require shorter distances when recommendations were present (WTA = 0.66 hours).

Discussion:

The results show that respondents were willing to travel further for hospitals with higher physician competence or better facilities. This highlights the importance of both perceived (physician competence) and objective (facilities/equipment) quality. The exceptionally high WTA values for physician competence suggests that perceived quality plays a crucial role in hospital choice. In addition, higher WTA values for quality factors among respondents willing to outmigrate supports that outmigration is strongly driven by quality gradients between Seoul and non-Seoul regions. Policy efforts to mitigate the severe concentration of patients into Seoul should prioritize enhancing quality factors in non-Seoul regions to shift the perceptions of the population.

Ind-1541 A New Tool for Patient Experience and Preferences in Urgent Care: Psychometric Validation and Discrete Choice Experiment Study

PRESENTER: **Jyoti Khadka**, Flinders University
AUTHOR: Julie Ratcliffe

Background Older people (age ≥65 years) are significant users of emergency department (ED) services. In 2023-23, more than one quarter of all ED presentations were by older people and over half of those presenting at the ED were subsequently admitted to hospital. To reduce pressure to ED and hospitals, the Australian government introduced Medicare-funded Urgent Care Clinics in June 2023, aiming to reduce the number of older people presenting to ED with urgent but non-emergency healthcare needs. However, the patient experience and preferences of older people in the new urgent care settings remain underexplored, limiting the ability of health systems to improve services that align with their care needs. Globally, patient experience is increasingly recognised as a critical indicator of healthcare quality, yet instruments specifically tailored to urgent and emergency care for quality assessment and economic evaluation are scarce.

Research questions/aims

This study addresses two key gaps: (1) developing and validating a new instrument, the Urgent and Emergency Care Patient Experience Measure (UEC-PEM), a brief patient-reported experience measure developed for urgent care for quality assessment and economic evaluation, and (2) exploring older people' preferences for urgent care service attributes used in the UCE-PEM using a discrete choice experiment (DCE).

Methods Two complementary studies were undertaken. In the first, the UEC-PEE, a 5-item patient experience measure developed through expert and patient consultation. The UCE-PEM was completed by 205 older people (mean age 75±6.0 years, 59% females) who had received urgent or emergency care within the past year. Psychometric evaluation included Rasch analysis and assessment of construct validity using spearman's correlations with validated tools (Quality of Life-Aged Care Consumers, QOL-ACC; EQ-5D-5L; and Urgent Care System Questionnaire, UCSQ). In the second study, a DCE with 995 older people (mean age 76±6.0 years, 49% females)) identified preferences for urgent care service attributes. The DEC responses were analysed using conditional and mixed logit regressions.

Results The UEC-PEM demonstrated strong psychometric performance, with all items fitting Rasch model expectations (Infit/Outfit 0.83–1.29). It showed moderate correlations with UCSQ domains (rho=0.40–0.68, $p<0.001$), but weaker correlations with QOL-ACC (rho=0.28, $p<0.001$) and EQ-5D-5L (rho=0.15, $p=0.03$), supporting construct validity. Respondents indicated strong preferences for an urgent care service with reduced waiting times (within 2 hours of making the triple zero call), medical professionals with specialist training in the care of older people, holistic support and regular communication updates, physical environment to support older people and a comprehensive discharge summary and follow up with all of these attribute levels being highly statistically significant ($p<0.001$) in influencing preferences for the total sample and by sub groups reflecting key socio-demographic characteristics and emergency care experience.

Conclusions The UEC-PEM is a valid and reliable tool for assessing patient experience in urgent and emergency care settings. Our DEC findings highlight the importance of tailoring urgent care services to the needs of older adults, particularly by prioritizing shorter waiting times. specialised staff training and holistic supports, providing actionable insights for clinicians and policymakers aiming to improve urgent and emergency care experience for older adults.

Ind-1555 You Can Either Get or Miss the Service That Brought You : Understanding Patient Journeys in Accessing Hypertension Care in Rural Coastal Kenya

PRESENTER: **Robinson Oyando**
AUTHORS: Pablo Perel, Benjamin Tsofa, Brahima Diallo, Anthony Etyang, Syreen Hassan, Edwine Barasa, Ellen Nolte, Nancy Kagwanja

Background: The increasing burden of non-communicable diseases (NCDs) poses challenges to health systems globally, including in Kenya. Research on health system capacity for the management of NCDs has focused on system 'hardware' (e.g., availability of equipment) while less is known about health system 'software' (e.g., relationships). Yet, 'software' elements are key for the organization and delivery of person-

centred health services. This study applied a complexity lens to assess the subnational health system's capacity to deliver primary care services for hypertension in rural Kenya. **Methods:** We collected qualitative data at five health facilities (dispensaries (n=2), health centres (n=2) and a county hospital (n=1)) in two sub-counties in Kilifi County where the prevalence of hypertension is high (26%) and blood pressure control is poor (3%). We conducted in-depth interviews with front-line health workers (FLHWs), facility managers, sub-county and county health officials, Ministry of Health officials and NCD stakeholders (n=37). We transcribed the interviews verbatim and managed data using QSR NVivo 12. We applied a thematic approach to data analysis. We utilized organizational capacity theory as our analytical framework. **Results:** We use organizational capacity dimensions to present findings. **Health system hardware capacity**: there were gaps in financing, number and skill mix of FLHWs, infrastructure and commodities, which undermined comprehensiveness of care. Access was supported through decentralizing hypertension care to lower-level facilities, but cost barriers reduced access. **Health system tangible software capacity:** organizational arrangements such as FLHWs responsible for hypertension clinics and dedicated hypertension clinic days were present, though others such as availability of treatment guidelines and FLHW training were absent. Bureaucratic approval processes hindered FLHWs ideas of implementing support for patients who had difficulties adhering to medication regimen. Coordination and continuity of care were affected by poor referral systems and lack of mechanisms for patient follow-up. **Health system intangible software capacity:** participants reported that power resided with political leaders and controllers of finance who influenced the resourcing and consequently the management of hypertension. As a result, facility managers felt unable to address the resource gaps that would have improved service delivery. **Conclusion:** Health system software such as organizational norms is core to shaping health system capacity for primary care management of hypertension. There is a need to systematically invest in capacity to enable access to care and person-centred health systems. Enhancing referral systems through strengthening community linkages and establishing mechanisms to channel ideas for improving patient management are examples of urgent interventions.

Ind-2325 Effect of Antenatal Care on Birth Outcomes in the Gambia: A Propensity Score Matching Analysis

PRESENTER: **Santosh Kumar**, Notre Dame University
AUTHORS: Elizabeth Wood, Alasana Suso

Background The prevalence of low birth weight (LBW) is disproportionately high in developing countries, particularly in African countries. LBW infants have a greater risk of mortality and suffer from physical and cognitive impairment. Adequate antenatal care (ANC) can improve birth outcomes and mitigate the risk of LBW; however, there is limited evidence on the effectiveness of ANC on birth outcomes in resource-poor settings. The objective of this study was to estimate the causal association between ANC and birth outcomes in the Gambia. **Methods** The 2019-20 Gambian Demographic and Health Survey (GHDS) was used for the analysis. The GHDS collected birth weight information for 8,362 children born in the five years preceding the survey. After excluding observations with missing birth weight information, the final analytical sample included 4,443 children. A multivariate regression model and propensity score matching method were used to assess the associations between ANC and birth outcomes. The regression models were adjusted for sex and birth order of the child, maternal age and education, wealth quintiles, marital status, rural area, number of children under five years of age, and region fixed effects. **Results** Multivariate regression analysis revealed that one additional ANC visit increased birthweight by 22 grams and the probability of LBW by 1.2 percentage points. Mothers who had four or more ANC visits (ANC 4+) had a 3.9 percentage point lower likelihood of giving birth to LBW infants than mothers with fewer than four ANC visits. The matching analysis revealed that the average treatment effect of ANC 4+ was a 71-gram increase in birth weight and a 4.7 percentage point reduction in LBW. **Conclusions** Having more ANC visits is associated with improved birth outcomes in Gambia after controlling for the socioeconomic status of the households. Thus, it is important to design health policies that can ensure that women have adequate ANC visits during pregnancy to reduce the disproportionate burden of LBW in countries with limited resources. 1

Ind-1794 The Smart one Asks When They Don't Know: Exploring the Barriers & Facilitators to Attending Cancer Testing for Patients With Anxiety and/or Depression

PRESENTER: **Anne Spencer**, University of Exeter
AUTHORS: Sarah Price, Elizabeth Shephard, Laura Gill

Background

Previous research has found that anxiety and/or depression is associated with a higher 30-day mortality after cancer diagnosis and lower odds of diagnosis via an urgent referral route. Anxiety and/or depression may present barriers to attending cancer testing appointments, leading to poorer outcomes.

Aim

Complex health interventions require an understanding of user preferences to maximize uptake and effectiveness. This qualitative study explores the attitudes and priorities that people with anxiety or depression consider when deciding to attend urgent referrals for cancer tests. The

qualitative results capture the determinants of behaviour to support intervention design and prepares the way for a future discrete choice experiment (DCE) to quantify the strength of user preferences and uptake of new interventions.

Methods

People (n=24) with anxiety and/or depression were recruited from five rural, urban or coastal general practices in the Southwest Clinical Research Network in the UK. Semi-structured interviews used hypothetical scenarios to explore decision-making around appointment attendance. Interviews were transcribed and coded deductively and inductively in NVivo drawing on the 14 domains of the Theoretical Domains Framework (TDF) capturing determinants of behaviour to support intervention design. Results were synthesised narratively.

Results

Six important TDF domains emerged as barriers or facilitators to appointment attendance, acting within a meta-theme of how an individual's experiences and situation influence their decision-making. Personal *Identity* could reinforce decisions to attend appointment or be a barrier. *Knowledge* (of cancer itself, of cancer testing or the logistics of attending) could reassure or exacerbate anxiety about attendance. *Social influences*, particularly support while waiting for the appointment, were important to people. Some stated they would need someone to support them through the process, whereas others felt they would be better on their own. *Beliefs about consequences and current emotions* were linked with fatalistic tendencies and increased chances of non-attendance*.* Additionally, the *Environmental context* highlighted barriers such as taking time off work, getting to the appointment (including parking) and the waiting room environment. How the referral was communicated was important (*Resources*), including the mode (letter or phone call) and the amount of detail provided.

Inductive themes of *Avoidance* arose, along with *continuity of care* and *Responsibilitisation* (namely, shifting responsibility from healthcare to the individual with many saying they would have good intentions to attend).

Implications for practice/policy

Anxiety and/or depression influence decision-making around urgent referral attendance in variable and nuanced ways. Barriers and facilitators to attendance ranged from lack of social support to attend the appointment, emotions and avoidance, as well as previous experiences of hospital appointments or cancer referrals. The study lays the groundwork for informing a future DCE to develop interventions that could help to facilitate the uptake of referrals, including adjusting the wording of the initial referral letter through to offering support to attend the referral.

Ind-1491 Hybrid Choice Models: The State of the Practice and Applications in Health

PRESENTER: **Eline M. van den Broek-Altenburg**, University of Vermont
AUTHOR: John Rose

Discrete Choice Models (DCMs) have over the past few decades, become the dominant modelling approach for understanding preferences and behavior within different healthcare settings. The estimation of DCMs requires that the analyst specifies unique utility functions for each of the alternatives faced by various decision makers operating within the market being modelled. The most common utility specifications employed within the health economics arena depict the relationship between utility and a set of observable variables, typically consisting of attributes that describe the alternatives being modelled, characteristics of the decision makers making the observed decisions, or some combination of both. Noting over four decades ago that modelling rational utility-maximizing behavior need not be limited to the inclusion of directly observable variables as is commonly the case, McFadden (1986) developed the theoretical framework for what has become known as the hybrid choice model (HCM) specifically to allow for the inclusion of other plausible aspects of decision making that may help explain observed choice behavior, such as attitudes and perceptions.

The HCM is not yet been widely adopted in health preferences which is striking since attitudes and perceptions are considered plausible aspects of decision making in health that may help explain observed choice behavior. This may be since HCM are not very well understood. In this paper, we therefore set out to describe what the HCM is, what it is not, and the state of practice related to estimation of the model. The paper describes alternative specifications of the HCM and their different interpretations, as well as describing the limitations of the model itself. In doing so, the paper also seeks to delineate between attitudes and perceptions and how both can be measured using stated preferences data for individual diagnostic testing.

We use data from a discrete choice experiment identifying barriers to COVID-19 testing with the goal to develop optimal strategies to increase testing in future pandemics or public health crises. A particular challenge during the Covid-19 pandemic was to provide testing and treatment for already disadvantaged and vulnerable populations. It is unclear that if potential barriers to testing were due to systemic challenges or whether there were underlying individuals motivations for not getting tested. In the DCE, we collected demographic data, data on housing and employment, vaccination acceptance, testing attitudes, risk taking behaviors using the GRiPS score, conspirational thinking and anti-expert sentiment, trust in public health authorities, political preference and religion.

The preliminary results of the HCM suggest that important social, behavioral and even policy factors affect choice for testing. Contrary to our hypotheses, rurality did not significantly impact preferences for testing, but attitudes towards government and other beliefs did. Health care interventions intended to reduce rural health disparities that do not reflect the underlying values of individuals in those subpopulations are unlikely to be successful. This paper outlines the importance of the use of HCM in health economics to include individuals' attitudes, beliefs and perceptions in the analysis of preference heterogeneity.

Ind-637 Patient Preferences for Second-Line Anti-hyperglycaemic Medication in China: A Multi-center Best-Worst Scaling Case 2 study

PRESENTER: **Dai Lian**
AUTHORS: Jing Liu, Yan Wei, Yi Yang, Yanfeng Ren, Shiyi Bao, Liu Liu, Shimeng Liu, Yingyao Chen

Background: China faces the world's largest diabetes burden, with a 12.4% prevalence. A wide range of second-line therapies is available for patients with type 2 diabetes mellitus (T2DM), each with distinct characteristics. Although current guidelines advocate for a patient-centered approach in selecting second-line treatments, Best Worst Scaling profile case (BWS-2) evidence on patient preferences for these therapies in the Chinese population remains limited.

Method: A seven-attribute instrument was designed through literature review, expert input, and a pilot BWS object-case study, captured benefit-risk and cost dimensions. We applied an orthogonal main-effects design to generate choice sets. The survey was conducted through in-person interviews at healthcare institutions in three Chinese regions (eastern, central, and western), each with one selected provincial capital and one non-provincial city. Data were analyzed using counting approach, conditional and mixed logit regression. Preference heterogeneity was explored with latent class analysis (LCA).

Results: Among 1,517 respondents analyzed, most attribute coefficients were statistically significant in mixlogit analysis, with patients showed the highest preference for reduction in HbA1c, cardiovascular protection, and free out-of-pocket costs compared to the reference levels. Weight change and mode of administration exerted modest influence. LCA identified the following six unobserved subgroups: Cardiovascular Benefit-Focused, Injection-Averse, Adverse Drug Reaction-Insensitive, Glycemic Control-Driven, Extreme Cost-sensitive Preference, Neutral Attitude.

Conclusions: Chinese T2DM patients prioritize efficacy and costs attributes; however, LCA revealed significant heterogeneity. Understanding these preference variations supports personalized second-line treatment decisions to enhance patient adherence and satisfaction.

Ind-1285 Willingness to Accept Trade-offs in a Pandemic in Developing Countries: How Past Pandemic Experiences Shape Preferences For Future Pandemics.

PRESENTER: **Vinh Anh Huynh**
AUTHORS: Eric Finkelstein, Semra Ozdemir

Introduction

Past pandemics, including COVID-19, have forced governments and the general public to make difficult trade-offs between health and economic activities. Social and economic restrictions helped mitigate health risks but caused significant increase in mental health risk and income loss. Current literature studying the health and wealth trade-off in pandemic contexts have focused mostly on lifting of restrictions or vaccination strategies and few are set in low- and middle-income countries (LMICs) which have greater resource constraints, different societal values and priorities. This study aims to quantify the public's willingness to accept (WTA) trade-offs between pandemic-related societal health outcomes, personal health risks, and household income losses that may result from a future pandemic, focusing on Indonesia and Vietnam, two LMICs with vastly different COVID-19 responses and outcomes. We hypothesized that there is significant heterogeneity in WTA trade-offs across individuals and that individuals' COVID-19 traumas, such as suffering financial hardship, or having friends or family members died, influence their WTA trade-offs.

Methods:

We fielded a discrete choice experiment asking respondents to choose between hypothetical future pandemic scenarios, described in terms of societal number of deaths, suffering long-term complications, developing anxiety/depression, mirroring personal risks of those outcomes and lastly household income (HHI) loss. Latent-class analyses (LCA) with a non-attendance class were used to estimate relative preferences and attribute importance. Multinomial logit regressions were used to assess associations between COVID-19 experiences and class membership.

Results:

A total of 534 Vietnamese and 526 Indonesians were recruited from online panels and were broadly similar to their respective general population in terms of sociodemographics. LCA revealed a non-attendance class (20%) and 2 distinct preference patterns among the Vietnamese sample. The largest class (Class 1, 42%) represented societal death minimizers, who were willing to accept up to 7.9% (95% confidence interval (CI): -5.0% to 20.8%) reduction in HHI to avoid 10,000 societal deaths. Class 2 (38%), however, represents income protectionists who were only willing to accept 0.6% (0.2% to 1.0%) reduction in HHI for the same reduction in societal deaths. While Indonesians also had a non-attendance class (32%) and 2 similar classes as Vietnam, there was a small third class (14%) with more balanced preferences. Societal death minimizers (Class 1) remained the largest (31%) and were willing to accept up to 2.1% (1.2% to 3.0%) reduction in HHI to avoid 10,000 societal deaths as compared to 0.1% (0.0% to 0.2%) among income protectionists (Class 2, 23%). As hypothesized, those with friends or family members died because of COVID-19 were more likely to be societal death minimisers, although this was only observed among Vietnamese but not Indonesians. Contrary to hypothesis, those who experienced financial hardship because of COVID-19 were not more likely to be income loss minimizers.

Conclusion:

While Indonesians and Vietnamese had diverse WTA trade-offs, there were similar preferences patterns across both countries. Governments should consider less restrictive or tailored policies to different groups with varying risk tolerance and past experiences, such as in areas where there were high COVID-19 mortalities, to ensure policies are social welfare maximising.

Ind-2075 Stated Preferences and Numerical Ability: Implications for Public Policy Analysis

PRESENTER: **Michael Eber**

Research Question:

Stated preference surveys are an important way to assess the economic value people place on health improvements. These surveys ask respondents how much they would be willing to pay for hypothetical outcomes that often cannot be fully valued in economic markets. Surveys frequently ask respondents to value complicated numerical quantities such as small health risk reductions, which may be difficult for them to process. The objective of this study was to assess whether people's responses to these surveys are influenced by their ability to work with numerical information. Understanding whether numerical ability leads to bias in value estimates informs the use of these estimates in cost-benefit analysis and other policy analyses.

Methods:

In a preregistered survey experiment with 1,200 participants, we asked respondents to report their willingness to pay (WTP) for a hypothetical food safety program that reduced their risk of mortality by a randomized amount. WTP was measured using a single binary choice question, as well as a multiple price list. To assess numerical ability, we measured participants' objective numeracy using the validated Weller et al. (2013) abbreviated numeracy scale.

In a first analysis, we tested the hypothesis that high numerate respondents would provide valuations more sensitive than low numerate respondents to the magnitude of the randomized health risks provided. We categorized respondents with a numeracy test score of greater than four out of eight as high numerate and categorized other respondents as low numerate. In a second analysis designed to examine the causal relationship between numerical ability and sensitivity, we conducted a randomized intervention that presented some participants with compound risks instead of simple risks.

Results:

A total of 1,195 respondents correctly answered three comprehension questions and an attention check question, and these participants were included in the study. Among survey respondents randomized to receive simple risks (N=898), average willingness to pay increased significantly and nearly linearly with the risk reduction for respondents who had high levels of objective numeracy, while for those respondents with lower levels of objective numeracy, average valuations did not consistently increase with the risk reduction. Using a continuous measure of numeracy in regression analysis, higher numeracy was associated with increased sensitivity ($p<0.05$) and lower valuations ($p<0.01$).

The high numerate who received compound risks had lower sensitivity to risk reduction magnitudes compared with the high numerate randomized to receive simple risks ($p<0.05$). For the low numerate population, who did not show significant sensitivity to simple risk reduction magnitudes, there was no significant effect of the provision of compound risks.

Conclusion:

The current study provides evidence that stated preference surveys may misrepresent the preferences of people with low numerical ability. Survey designers and policymakers should interpret valuations that are insensitive to benefit magnitudes with caution and potentially as indicative of survey takers being unable to process the information provided. The current study also suggests a way that future research can test whether informational interventions like decision aids can eliminate disparities in comprehension according to respondents' numerical ability.

abs-os575 Empowering LMIC Researchers: NIHR's Approach to Decolonising Funding and Collaboration

PRESENTER: **Kara Hanson**, London School of Hygiene & Tropical Medicine (LSHTM)

Equitable research partnerships and capacity strengthening are vital for decolonising global health research. This presentation delves into the strategic approaches undertaken by the National Institute for Health Research (NIHR) United Kingdom, to address historical inequities in research collaborations with low- and middle-income countries (LMICs). The NIHR is actively restructuring its funding mechanisms to empower LMIC researchers, removing the previous requirement for UK-based co-leads and prioritising research driven by local contexts and needs. By enabling LMIC institutions to lead projects, these changes foster sustainable, context-specific research that directly benefits local populations. A notable initiative in this effort is the introduction of the Global Research Advanced Fellowship, designed to nurture leadership and research management skills among LMIC researchers. By investing in capacity strengthening, NIHR aims to shift traditional power dynamics, ensuring that LMIC researchers play a central role in setting research agendas. Additionally, NIHR emphasizes collaborative frameworks that incorporate mutual learning, respect for local expertise, and equitable authorship practices, thereby challenging entrenched

colonial models of research partnership. This presentation will highlight practical examples of how these strategies are being implemented, showcasing NIHR's commitment to fostering more inclusive and sustainable research ecosystems. By prioritising locally-led projects and equitable collaboration models, NIHR seeks to advance a more decolonised and inclusive approach to health economics research, ultimately contributing to global health equity.

abs-os569 Power Dynamics in Health Economics Research & Impact of Colonial Legacies

PRESENTER: **Shankar Prinja**

This presentation will critically examine the enduring influence of these colonial structures on health economics research in low- and middle-income countries (LMICs) to highlight challenges in terms of dictating research priorities, funding decisions, methodologies, and dissemination strategies. These power imbalances often relegate LMIC researchers to a subordinate role and restricting their participation in intellectual leadership. For instance, exclusion from lead authorship, despite making substantial contributions to data collection and contextual analysis. Such practices perpetuate systemic inequities in the production and ownership of knowledge.

Continued dependency on external funding is a key challenge, which drives research priorities based on funder's decisions and not to generate datasets and solutions which are more relevant to local problems in research and evidence-based policy making. To counter this, there is a pressing need to harness to strengthen research capacity and foster self-determined agendas. Innovative approaches, such as mobilizing long term national funding sources can be a way forward. Establishment of Health technology Assessment Board in India (HTAIn) and Regional Resource Centres in an excellent example of capacity development which supported budding health economists and led to multiple international research collaborations. Such policy decisions not only empower local researchers but also enhance the applicability of research outcomes to inform national policy.

The presentation will also address the barriers which researchers face for publication of their work. Not just the publication charges but also varied research interests and inability to contextualize local needs (editor/reviewer and researcher) can hinder the timely publication of results in international peer reviewed journals. Ultimately, this presentation will argue for decolonising health economics research by undertaking a fundamental restructuring of how partnerships are formed, funded, and operationalized, to ensure that LMIC researchers can meaningfully contribute to and lead the health economics research.

abs-os571 Rebalancing Power: Using the Equipar Tool to Build Equitable Partnerships in Health Economics Research

PRESENTER: **Catherine Goodman**, London School of Hygiene & Tropical Medicine (LSHTM)

Addressing power imbalances in research partnerships is critical to decolonising health economics research. The EquiPar Tool, developed to support equitable collaborations, offers a structured approach to fostering fairness and mutual benefit in research projects, especially between high income and low- and middle-income country (LMIC) institutions. EquiPar is a flexible, question-driven tool designed to prompt research teams to critically reflect on key aspects of their collaborations across three domains: people management, research activities, and contracting and resource management. It guides users through assessing topics such as their governance structures, communication strategies, shared responsibilities, and the equitable distribution of resources, considering equity both between research organisations and within the professional heirarchy. By incorporating principles such as mutual capacity strengthening, transparency, and co-creation, EquiPar ensures that partnerships are built on trust and shared decision-making. This presentation will provide practical examples of how EquiPar has been applied within research partnerships, reporting on results from a recent pilot evaluation. Ultimately, this presentation will reflect on how EquiPar and other similar tools can be used as a catalyst for more equitable, context-sensitive, and impactful research partnerships, driving the decolonisation of health economics research.

Unpacking the Effects of Floods and Heatwaves on Maternal Health Care Coverage and Vulnerability Drivers.

MODERATOR: **Josephine Borghi**, IIASA

DISCUSSANT: **Manuela De Allegri**, University of Heidelberg

abs-os196 Assessing the Impacts and Mechanisms of Heat Waves and Floods on Maternal Healthcare Utilisation: A Realist-Informed Systematic Review.

PRESENTER: **Ivan Augusto Cecilio e Silva**

AUTHORS: Everton Nunes da Silva, Dell Saulnier, Huiqi Chen, Giacomo Balbinotto, Cherie Part, Nikita Strelkovskii, Chitalu Chama Chiliba, Ms. Josephine Borghi, Sari Kovats

Background: The increasing frequency and intensity of heatwaves and floods worldwide pose significant challenges to healthcare systems, with potential to affect service coverage, especially among vulnerable groups like pregnant and postpartum women. Developing strategies for health sector adaptation to reduce climate risks requires an understanding of whether and how extreme weather events affect the utilisation of maternal healthcare (MH). We undertook a realist-informed systematic review to examine in which geographic, socioeconomic and health

system contexts MH utilization is affected and the underlying mechanisms driving these impacts.

Methods: A comprehensive literature search across multiple databases (Medline, Embase, EconLit, Global Health, Web of Science, CINAHL, Global Index Medicus) identified 5280 studies which were dual screened against set inclusion/exclusion criteria, resolving discrepancies by consensus. For inclusion, studies considered heatwave and/or flood impacts on service utilization by pregnant, postpartum women (up to 6 weeks post-delivery) and women of reproductive age (for family planning), without restrictions on study design, period, setting, or language. Based on the evidence gathered, an initial theoretical framework was developed and refined through the creation of a Causal Loop Diagram (CLD), to map out the causal mechanisms underpinning flood and heatwave effects on MH utilisation.

Results: Thirty-six papers, 23 on floods, 12 on heatwaves and one on both, were included.** Preliminary findings suggest floods can reduce utilization of antenatal, delivery and postnatal care. Although evidence on heatwaves is more limited, studies suggest that high temperatures can discourage individuals from seeking necessary care, particularly antenatal visits, where travel involves long or exposed routes. Utilisation impacts were also due to disruptions to healthcare supply: damage to infrastructure and shortages of supplies and personnel. Additionally, the economic strain from floods can deplete family resources, making healthcare less affordable for affected communities, reducing service use. Heatwaves exacerbate existing health conditions, leading to a surge in demand for emergency healthcare services, as individuals experience acute health risks that require immediate attention. This increased demand can indirectly impact the utilization of MH services by diverting resources and limiting access to routine care. Heatwaves also raise operational costs for health facilities, such as those associated with air conditioning. Floods often lead to displacement which can worsen health outcomes by reducing income, land ownership, food security, and access to clean water and sanitation, increasing healthcare demand while also limiting service affordability due to socioeconomic challenges and weakened social networks. To summarize, we found evidence of five mechanisms through which heatwaves and floods impact MH utilisation: (1) travel restrictions, (2) displacement and migration, (3) income loss affecting affordability, (4) health risks, and (5) disruptions in healthcare supply. These mechanisms interact with each other and can have differential effects according to context.

Conclusion: This review finds evidence of some common and some hazard specific demand and supply side effects of floods and heatwaves on MH utilization, together with contextual factors driving vulnerability. The results can inform policymakers, healthcare providers, and researchers, guiding the development of targeted strategies to safeguard MH against climate change.

abs-os199 The Effect of Extreme Heat on Place and Type of Delivery in Brazil.

PRESENTER: **Everton Nunes da Silva**, University of Brasilia
AUTHORS: Letícia Xander, Deivson Costa, Ivan Augusto Cecilio e Silva, Huiqi Chen, Andre Marques dos Santos, Cherie Part, Walter Ramalho

Background: Climate change results in increasing temperatures and extreme heat events with implications for population health and well-being. Heat extremes pose a particular risk to pregnant women, increasing the chance of preterm birth, stillbirth, gestational hypertension and diabetes. These consequences may in turn affect where women deliver and the need for c-section. Equally, heat impacts on health worker productivity and facility patient load may affect caesarean section (c-section) rates. However, there is limited evidence of the impact of heat on maternal health care-seeking behaviour and on health service provision. We investigate the effect of extreme heat on place and type of delivery in Brazil. The study also explored whether individual and local area factors moderated this relationship.

Methods: We obtained data on more than 25 million singleton births, in 5,570 municipalities between 2010 and 2019, from Brazil's Live Birth Information System (SINASC/DATASUS). Our primary outcomes were type of delivery (c-section or not) and place of delivery (hospital or not). Daily maximum air temperature was calculated from ERA5 reanalysis data (obtained from Copernicus Climate Data Store) and aggregated to municipality-level. We also assessed the impact of heatwaves to capture the cumulative effect of heat exposure over a sequence of unusually hot days. Heatwaves were defined as five or more consecutive days above the location-specific 95th, 97th, and 99th percentiles of daily maximum temperature during the last 30 years. Exposure data were linked to individual-level birth data by date of delivery and municipality of mother's residence. The analytical approach involved a logistic regression including cohort and municipality fixed effects to account for unobserved heterogeneity. All models adjusted for maternal characteristics (age, education, marital status, and ethnicity), birth outcomes (length of gestation and birth weight), and number of antenatal care visits during pregnancy. We also considered whether hospital ownership (public versus private); municipality location (urban versus rural); climate zone (cooler versus hotter) and health system characteristics (ratio of family health teams and hospitals to population) moderated the relationship. In addition, we considered potential delayed effects of heat, 1-6 days before the outcome, following a distributed lag nonlinear framework.

Results: Preliminary results indicate that higher temperatures increase the rate of delivery by c-section. Effects are larger in public hospitals, where the rate of c-section is typically lower. Temperature lags are robustly associated with type of delivery, with a slightly greater effect of high temperature 5 and 6 days before delivery compared with exposure 0-4 days before delivery. Deliveries by c-section also increase during heatwaves. We find no association between maximum temperature and place of delivery. Hospital delivery increases only during the 95th percentile heatwave. Local factors, such as hospital distance and rural location, moderate the relationship between place of delivery and heat.

Conclusion: Our study highlights the geographical distribution of heatwaves across Brazil, and assesses the impact of heatwaves on place and type of delivery. By examining how context moderates this relationship, our study also sheds light on the role of geography, health and other social systems in enhancing or reducing vulnerability to heat.

abs-os197 The Effect of Floods and Heat Extremes on Coverage of Routine Maternal Health Services in Zambia.

PRESENTER: **Chitalu Chama Chiliba**
AUTHORS: Dell Saulnier, Ms. Josephine Borghi, Cherie Part, Moses Chisola

Background: The global climate is changing rapidly, with rising temperatures, erratic rainfall, and an increasing frequency of extreme weather

events such as floods and heatwaves. These climatic shifts pose significant risks to maternal health, particularly in resource-limited settings striving to achieve universal health coverage. Extreme weather events disrupt livelihoods, reduce access to affordable care, and displace populations to areas with limited health services. Damage to transport networks and medical supply chains further increase costs and limit the availability of care. Public health facility operations may also suffer, pushing patients towards costlier alternatives. Despite these challenges, the effects of extreme weather on the use of maternal health services remains underexplored, particularly in low-income countries.

Aim: The study estimates the causal effect of flooding and heatwaves on the utilization of maternal health services, including institutional deliveries, caesarean births, antenatal care, and postnatal care.

Methods: We use data from two nationally representative Demographic and Health Surveys conducted in Zambia, linked with high-resolution climate data, to implement a difference-in-difference analysis exploiting the geographic and temporal variation in exposure to extreme weather events, whilst controlling for household and area level characteristics. Household data are linked to climate exposure based on survey cluster geo-coordinates. Flood exposure is determined using NASA's MODIS Global Flood Product and the Global Surface Water database. A household is classified as flood-exposed if water is detected within a 2km² radius of the household, or within a 2km (urban) or 5km (rural) catchment area of its nearest health facility. Flood intensity is measured by the extent of water coverage. Heatwave exposure is identified using ERA5-Land re-analysis data and is defined as three or more consecutive days above the 90th, 95th, and 99th percentiles of daily maximum temperatures during the three hottest months (reference period 1990-2019). Annual heatwave frequency is also recorded. We also explore heterogeneous effects, by socio-economic status and distance to facility, of the exposure to flooding and heatwaves.

Key Results: We present the effects of flooding and heatwave exposure on maternal health service use in Zambia by service type. We also show differential effects across subgroups, identifying those most at risk, and explore mediators of effect.

Conclusions: The study provides evidence of how climate change, through more frequent weather events, affects maternal service utilisation, and drivers of vulnerability. The findings highlight the need for adaptive health system strategies to mitigate the impacts of extreme weather events. Interventions that promote health equity and system resilience, are essential to ensuring that maternal health services remain accessible and affordable to all despite escalating climate risks.

abs-os557 Exploring the Links Between Sexual Risk Behaviour and Cognitive Biases Among Female Sex Workers in Kampala and Nairobi

PRESENTER: **Kenneth Roger KATUMBA**

AUTHORS: Yunia Mayanja, Ms. Giulia Greco, PhD, Edel Koki, Yvonne Machira, Gabriela Gomez, Janet Seeley, Matthew Quaife, Gloria Omosa, Mitzy Gafos

Background: There is need for cognitive biases, which are mental shortcuts that simplify information processing and decision-making, to be considered more in interventions targeting structural and individual drivers of HIV transmission. We investigated links between cognitive biases and SRB among women engaged in sex work. **Methods:** We used respondent-driven sampling from September to December 2022 to identify HIV-negative women engaged in sex work, aged 18-44 years in Kampala and Nairobi. Trained enumerators collected survey data using a mobile data collection platform. We examined relationships between cognitive biases including locus of control and risk aversion, individual factors (including age, education, having children, depending on sex work as the only income source) interpersonal factors (including arrest in the last 3 months, level of violence experienced, and the influence of peers), and structural factors (including providing services outdoors, and the level of stigma experienced) and SRB variables (including the number of clients and condom use at last sexual act, PrEP use, pricing, and the price premium for condomless sex). We used logistic and ordinary least squares regression models for binary and continuous outcomes respectively. **Results:** We included 330 women with a mean age of 30.2 years (SD=6.75). A significant positive association was found between locus of control and the price premium for unprotected sex (β =12.6, $p<0.01$), but no association with other SRB variables. Risk aversion was not associated with SRB. The price premium was also associated with level of education (β=4, $p<0.05$), and negatively associated with the level of violence experienced (β= - 2.4, $p<0.05$). The number of clients women provided services to on their last day of work was negatively associated with women's level of education (β= -0.35, $p<0.01$), and positively associated with earning solely from sex work (β=0.2, $p<0.05$), and having experienced a moderate level of violence (β=0.3, $p<0.01$). Provision of condomless sex at the last act was positively associated with the level of education (OR=5.5, $p<0.01$) and providing services outdoors (OR=3.3, $p<0.05$). Women not always using condoms was positively associated with age (OR=0.3, $p<0.01$) and level of education (OR=3.4, $p<0.05$). PrEP use over the preceding 12 months was negatively associated with women's level of education (OR=0.3, $p<0.05$). Pricing was negatively associated with women's age (β= -0.7, $p<0.05$) and having been arrested for sex work (β= -0.3, $p<0.01$) and positively associated with the level of education (β =2, $p<0.01$). **Conclusion:** Besides individual, interpersonal and structural factors, SRB is associated with cognitive biases. Complex interventions aimed at interpersonal and structural levels but also increasing women's locus of control are necessary to reduce new acquisitions.

abs-os596 Individual Preferences, Sexual Risk Behaviors and Demand for Preventive Care Services Among Sex Workers

PRESENTER: **Paul Dourgnon**, IRDES
AUTHORS: Antoine Marsaudon, Florence Jusot, Jerome wittwer

This study examines how risk aversion and time preferences may shape both sexual risk behaviors and the demand for preventive care, among sex workers, from an online survey representative of sex workers working from escort websites in France. While the literature has explored how individual preferences influence the demand for preventive care, we lack evidence on the interaction between risk-taking and the demand for preventive care. The study also sheds light on how these interactions may be influenced by the socioeconomic status (income, education, household structure) and migration background (country of origin, legal status, length of stay in the host country), gender, and sexual orientation of the respondents. Most sex workers in France are immigrants, among which a majority are undocumented, leading to potential fragility toward clients' requests, and more exposure to risks, whether deportation or violence. Besides some of the respondents may have suffered from violence in their country of origin due to their sexual orientation. Our study is based on an online representative survey of sex workers working in France from escort websites. The sampling base is generated from the scrapping of the main escort websites operating in France. The questionnaire includes health status, living conditions, immigration history, working conditions and description, sexual risk behaviors, illegal drug consumption, experiences of violence, and healthcare services use and insurance. Questionnaires are collected in 6 languages. Our study intends not only to better understand the interactions of risk-taking and demand for care but also to shed light on an utterly fragile yet barely known population. No consensus exists in France on the number of sex workers, their actual needs, and access to healthcare services.

abs-os578 The Role of Health Expenses on Condomless Sex Among Female Sex Workers in Urban Senegal

PRESENTER: **Henry Cust**
AUTHORS: Timothy Powell-Jackson, Aurelia Lepine

Out-of-pocket payments for healthcare present significant economic challenges for many households in low- and middle-income countries. In Senegal and Cameroon, a limited number of individuals have access to health insurance, leaving most to face high out-of-pocket costs for medical care. New evidence suggests economic shocks are driving risky behaviours in female sex workers, a high-risk HIV group, because of risk premiums associated with condomless sex. This relationship plays a crucial role in the ongoing HIV crisis and gender disparity in new infections in sub-Saharan Africa. Whilst the risk premium and behavioural impact of health expense shocks in female sex workers are well established, there exists only limited and mixed evidence that it exists amongst women in transactional sex. In this study, we are the first to examine the range of economic shocks suffered by women in commercial and transactional sex and examine the behavioural response to health shocks. We find that our sample frequently experiences economic shocks, with health shocks being the most common and impactful. To cope, many increase their involvement in sex work, and some engage in riskier sexual behaviours. We also find there is between a 62% and 72% drop in condom use at the last sex act if someone else in the household is sick at the same time for female sex workers. We highlight the implications for HIV transmission in stigmatized contexts and offer methods for protecting against economic shocks as an HIV prevention method, primarily by drawing attention to the often-overlooked population of women engaged in transactional sex.

abs-os586 Time Preference and Risky Sexual Behaviour Among Women Engaging in Commercial or Transactional Sex in Cameroon

PRESENTER: **Aurelia Lepine**, University College London
AUTHORS: Henry Cust, Tamoufe Ubald, Serge Billong, Emilemichel Nitcheu, Julienne Noo, Lauren Dechaumont, Iliassou Mfochive-njindam, Eric Defo Tamgno, Sandie Szawlowski

Background:
Despite overall progress in reducing HIV prevalence in Cameroon, women engaging in sex work and transactional sex remain disproportionately affected. These groups experience significantly higher HIV incidence, yet the behavioral mechanisms driving their sexual risk-taking are not well understood. This study explores the role of time preferences—specifically impatience (discount factor, δ) and present bias (β)—in shaping risky sexual behaviors among this high-risk population.

Methods and Data:
We analyze data from a randomized controlled trial conducted in Yaoundé, Cameroon, involving 1,146 women: 578 sex workers and 568 women in transactional sexual relationships. Time preferences were elicited through two hypothetical Money Earlier or Later experiments at midline and endline, allowing estimation of both δ (discount factor) and $\beta<1$ (present bias) and assessment of their temporal stability. Risky sexual behavior was measured using both self-reported STI symptoms and biomarker-confirmed STI and HIV outcomes.

Findings:
Participants displayed low discount factors, suggesting impatience and potential self-selection into risky sex. Most exhibited time-consistent preferences, though around 24% (δ) and 41% (present bias) showed no variation over time, indicating moderate instability. Associations between time preferences and STI/HIV outcomes were directionally consistent with theory and statistically significant for some STI proxies—particularly abdominal pain and genital ulcers—but overall results were mixed. Time preferences were influenced by socioeconomic factors, risk preferences, and education level.

Discussion:
While the study offers some support for the predictive role of time preferences in risky sexual behavior, several limitations—such as hypothetical task design, comprehension challenges, and limitations of STI diagnostic tools—temper the conclusions. Nonetheless, these findings underscore the relevance of behavioral traits in understanding sexual health risks and suggest that targeted interventions may benefit

from incorporating time preference profiles into risk stratification and program design.

Balancing Sustainability, Access, and Affordability for Pharmaceutical Innovation: Results from the HI-PRIX project

MODERATOR: **Oriana Ciani**, SDA Bocconi

abs-os268 Does HTA Undermine the Goals of EMA Authorization Pathways? Time-to-Access of Drugs Licensed Under Conditional vs. Standard Marketing Authorization

PRESENTER: **Vittoria Ardito**
AUTHORS: Ms. Oriana Ciani, James Robinson, Caridad Pontes, Jonas Schreyögg, Lasse Falk

Background: The European Medicines Agency (EMA) uses expedited programs, like the Conditional Marketing Authorization (CMA), to facilitate early access to drugs addressing significant unmet medical needs, based on initial, incomplete evidence that requires further validation. However, while EMA's focus remains on evaluating the risk-benefit profile, national Health Technology Assessment (HTA) bodies in Europe prioritize long-term benefits, cost-effectiveness, and budget impact. This misalignment in incentives and missions raises concerns about whether accelerated EMA pathways translate into quicker patient access at the national level, particularly in systems with extensive HTA and reimbursement procedures.

Objectives: This study investigates whether CMA drugs experience shorter time-to-access, defined as the number of days from EMA approval to national reimbursement decision, compared to drugs with Standard Marketing Authorization (SMA) in three European countries: Italy, Germany, and Spain. The study examines if the intended speed of access facilitated by CMA aligns with national payer timelines.

Methods: We analyzed a sample of drugs approved via the EMA's CMA pathway from 2006 to 2022, matched with a comparable group of SMA drugs based on therapeutic area and centralized approval timing. Data collection included EMA authorization details, drug characteristics, pivotal trial data, and national reimbursement dates from relevant databases in Italy, Germany, and Spain (Farmadati®, Lauer-Taxe® and BIFIMED, respectively). Statistical methods included descriptive analyses, Kaplan-Meier survival curves, and Cox regression models to explore the relationship between authorization type and time-to-reimbursement across countries. The models controlled for factors like drug characteristics (e.g., orphan status, cancer indication) and trial design (e.g., controls, blinding, primary endpoint) to account for factor-specific variations in access.

Results: The study sample included 127 CMA-SMA matched drugs. Results indicate substantial delays in Italy and Spain for CMA drugs compared to SMA drugs, with median time-to-access of 523 days (CMA) versus 455 days (SMA) in Italy, and 682 days (CMA) versus 541 days (SMA) in Spain. By contrast, Germany's reimbursement system allowed for rapid access for both CMA and SMA drugs, with median timelines of 43 days (CMA) and 39 days (SMA). Kaplan-Meier analysis demonstrated country-specific disparities in access timelines, while sequential Cox regression models isolated specific factors that contribute to accelerate or slow reimbursement approvals. Trial characteristics like surrogate endpoints and orphan designation were associated with prolonged access timelines, especially in Italy and Spain where HTA assessments are rigorous.

Conclusions: Despite EMA's accelerated pathways, CMA drugs often experience significant delays in national reimbursement decisions, particularly in countries with stringent HTA requirements. The findings suggest that while regulatory bodies prioritize expedited access, national payer systems may conduct longer assessments due to enhanced clinical and economic uncertainties of CMA drugs. This divergence risks undermining the benefits of CMA pathways. Policy reforms, such as the upcoming Joint Clinical Assessment (JCA) as part of the HTA Regulation in the European Union, aim to harmonize HTA processes across countries, potentially improving access speed. However, without alignment between regulatory and payer perspectives on evidentiary requirements, CMA drugs may continue to face access challenges, limiting their impact on addressing unmet medical needs in a timely manner.

abs-os273 Implementation Costs and Benefits of Innovative Payment Models: An Assessment of Four Case Studies in Europe

PRESENTER: **Matthias Hofer**
AUTHORS: Mikel Berdud, Mireia Jofre-Bonet, Amanda Cole, Sian Hodgson

Background: Member States in the EU are struggling to balance sustainability of health innovation with sustainability of health care systems. Central to this challenge is the role of pricing and payment models for pharmaceutical innovation, as they influence affordability, affect access to products, and provide incentives for directing efforts towards areas of the highest societal value. Therefore, it is important that policymakers have a thorough understanding of Innovative Pricing and Payment Model (IPM) implementation experiences aimed at providing market access solutions to breakthrough pharmaceutical innovation. A key feature of IPM to understand for policy makers is their cost and benefit of implementation. **Objectives:** We aimed to evidence costs and benefits of IPMs along all phases of implementation for key stakeholders (e.g. payers/HTAs, innovators, providers, patients). **Methods:** We developed an IPM cost-benefit evaluation framework adapting implementation assessment models from implementation science literature. The framework breaks down the implementation stages into design,

implementation, maintenance, closing. We selected four case studies, which covered four distinct families of IPM: instalments, revenue guarantees, outcomes-based agreements, and portfolio agreements. We conducted semi-structured interviews with relevant stakeholders involved in the implementation of IPMs. Based on interviews, we collected additional data to quantify, estimate and document IPM implementation costs and benefits. **Results:** In all case studies, IPMs were considered as solutions to specific issues that otherwise cannot be addressed with simple discounts in 'a conventional' contract. These issues included the long-term uncertainty on the product effectiveness, the uncertainty on the use and expected return, or the lack of an existing sufficient market. In some cases (e.g., outcomes-based agreements) the IPM solved the issue and were considered temporary approaches, while in others (e.g., revenue guarantees) the IPM seemed to have a more permanent role in providing access to innovation. All implemented IPM involved increased complexity and a proportional increase in the cost of their implementation for all stakeholders, though to different degrees. We documented significant costs, which are spread over all phases of implementation and included human resources costs, opportunity costs, and transaction costs. We also documented benefits for all stakeholders, which were mainly associated with access and early access to pharmaceutical innovation including health related benefits, anticipated revenue, cost savings and certainty on expected returns. Overall, such benefits are primarily realised during implementation and maintenance phases. **Conclusion:** IPMs help mitigating issues related with access or early access to pharmaceutical innovation in "conventional" agreements, and offer benefits for payers (cost savings and risk-sharing), patients (health-related benefits) and pharmaceutical industry (revenue and risk-sharing). Despite these benefits, IPMs were deemed more complex and more costly than "conventional" agreements and not all stakeholders experience costs and benefits in the same degree, leading to potential implementation conflicts and incentive incompatibilities. The best strategy when implementing an IPM is to make IPMs a win-win for all stakeholders by reducing the burden of IPM implementation and limiting their duration until the issue that motivates its implementation is addressed and benefits have been realised.

abs-os271 Modelled Impact of Risk-Sharing Agreements on Costs for Haemophilia B Gene Therapy in Germany

PRESENTER: **Lasse Falk**
AUTHOR: Jonas Schreyögg

Background: Gene therapies promise new treatment options for rare and often incurable diseases like Haemophilia B. While often among the most expensive drugs in the world, conclusive evidence on (long-term) effectiveness is limited. Accordingly, concerns about the financial sustainability of paying for such treatments are growing. Risk-sharing agreements aim to reduce financial and outcome uncertainties for payers by sharing such risks with the manufacturers. Although such agreements have been in use for a while, details on their implementation and actual impact is scarce due to confidentiality of agreements.

Objectives: We aim to simulate how risk-sharing agreements, specifically the choice of agreement type, influence costs for payers in Germany using the example of a Haemophilia B gene therapy.

Methods: We developed a microsimulation state-transition model to simulate the long-term effectiveness of the gene therapy Hemgenix for men with moderately severe to severe Haemophilia B from age 18 until their death. The disease progression was modelled around haemophilic arthropathy with transition probabilities based on bleeding rates. Costs were calculated on an individual level from the perspective of German payers using publicly available literature and cost data like DRG catalogues, tariff agreements and the Lauer-Taxe. We simulated refund and multi-annual instalment agreements varying payment mechanisms, agreement duration, and treatment failure conditions.

Results: For agreements with a duration of up to 5 years, we find that multi-annual instalment agreements provide larger cost savings potential for payers than refund agreements when treating patients with Hemgenix. For durations of longer than 5 years, refund agreements are the better choice. Over time the cost savings potential of instalment agreements decreases while it increases for refund agreements. The long-term effectiveness of the treatment affects the feasibility of multi-annual instalments. If the treatment effect lasts longer, instalment agreements are also viable for longer agreement durations. Lastly, when considering the risk pool of the German health care system, we find that multi-annual instalments do not provide any savings potential. Employing multi-annual instalments increases costs for payers compared to both refund agreements and standard of care.

Conclusion: Risk-sharing agreements can reduce the costs of gene therapies for payers depending on the treatment durability and the agreement type. The optimal choice of the specific agreement type should be guided by aspects of affordability and risk preference. Additionally, stakeholders need to consider that while many forms of risk-sharing agreements may provide savings, not all of them are able to cover the costs from negotiating agreements and monitoring outcomes. Finally, current regulatory frameworks in Germany limit the choice to refund agreements and may even hinder the adoption of new therapies if the choice is only between standard of care and multi-annual instalments.

abs-os265 What Works for Pharmaceutical Innovation: Key Policy Feature Drivers Behind Global R&D Activities from 42 Countries, 2000-2022

PRESENTER: **Chuanzi Yue**
AUTHORS: Hilde Stevens, Shiri Mermelstein, Mujaheed Shaikh, Xixian Niu, Mathias Dewatripont, Marisa Miraldo

This study explores how various policy incentives drive pharmaceutical innovation, with a novel focus on the mechanisms and interactions of policy features rather than individual policies. Recognising that policy impact can vary due to diverse structural elements, we assess the relationship between these key features and pharmaceutical R&D outcomes across 42 countries from 2000 to 2022. We identify seven core features within six types of pull-and-push policies and evaluate their specific impacts on pharmaceutical R&D activities at the disease-year level, utilising detailed data from the proprietary Cortellis database. Our analysis examines both the extensive margin (number of firms investing in a specific disease area) and the intensive margin (average number of drugs invested in by each firm within a disease area). To mitigate the potential endogeneity of policies implementation in response to R&D activities, we control for disease prevalence, employ fixed effects for disease and year, and instrument our features with disease-specific "sudden shocks," defined by sharp increases in the policy

features' annual changes within six-year intervals. Results indicate that financial benefits, particularly monetary incentives to offset innovation costs or enhance revenue, are consistently associated with increased R&D activity. However, time benefits—policies that expedite regulatory approval—appear to decrease R&D activities at the intensive margin when controlled for conditionality, potentially signalling that time benefits increase R&D primarily through attracting firms with higher R&D productivity. Knowledge-based incentives, such as regulatory or collaborative support, are associated with significant R&D growth, with each 10% increase in knowledge support driving a 10% rise in R&D activities across both margins. Conversely, increases in intellectual property (IP) sharing (requirements to share IP with other innovators or the public) and supply constraints (restrictions on price or distribution) correlate with declines in R&D activity by 49% and 4.6%, respectively, at the intensive margin. Early-stage intervention (policies targeting research rather than regulatory or post-market stages) generally mitigates negative impacts on R&D compared to their late-stage counterparts, underscoring the revenue-driven nature of pharmaceutical innovation. Our findings emphasise the pivotal role of financial and revenue incentives in fostering pharmaceutical innovation. While IP sharing and supply conditions may reduce immediate R&D investment, they hold potential long-term benefits for innovation sustainability and healthcare accessibility. However, these positive impacts in the long run are contingent upon sufficient financial incentives to offset the initial negative effects on R&D activity, underscoring the need for a balanced policy approach that supports both short-term innovation investment and enduring healthcare advancements.

The Cost of Reaching Zero-Dose Children in High-Priority Areas: Real-World Evidence from Key Immunization Strategies in Pakistan, Ethiopia and Nigeria

MODERATOR: **Laura Boonstoppel**, ThinkWell

DISCUSSANT: **Tewodaj Mengistu**, Gavi, the Vaccine Alliance

abs-os519 Cost to Reach Zero-Dose Children Through Novel Interventions in Kano, Nigeria

PRESENTER: **Salisu Sulaiman**
AUTHOR: Sorbari Igbiri

Vaccines are a powerful tool for saving lives, improving lifelong health, and promoting gender- and wealth-related equity. However, too many children—particularly those in hard-to-reach and conflict-affected settings still miss out on life-saving vaccines. Nigeria has more zero-dose children than any other country in the world, which was further exacerbated by the COVID-19 pandemic. While reaching the global goal of reducing zero-dose children by 50% will require additional investment, there is limited information on the costs of reaching zero-dose children and the potential budget implications. This study was designed to fill that gap in information for Kano State in Nigeria.

This study presents the methods and results on the costs of reaching zero-dose children (those without any vaccinations) in Kano, Nigeria through two new interventions: a new approach to identifying zero-dose children, and training of health care workers to improve vaccination of zero-dose children.

Costs were evaluated through two perspectives: 1) provider costs in a sample of primary healthcare facilities; and 2) household costs. A novel costing methodology that focused on measuring incremental inputs was employed, and surveys were designed to be conducted at baseline, midline and endline to create a panel data set of primary healthcare facilities. Analysis was conducted in both Excel and STATA15.

There was significant variation in the incremental cost per additional zero-dose child across the primary healthcare facilities. Facility costs were compared with current government spending to understand the affordability of different strategies. 70% of households paid for transportation to the facility, spending roughly 500 Naira ($0.30), compared to the average daily income of $1 per day in rural Nigeria. Long waiting and travel times contributed to indirect household costs of reaching facility services. Reducing zero-dose prevalence will require additional investments to reduce household costs and improve access.

Once the study's results are final, we will assess the policy implications for Nigeria on the affordability and feasibility of scaling up these novel zero-dose interventions.

abs-os500 Estimating The Cost of Identifying and Vaccinating Zero-Dose Children in Urban and Rural Geographies in Pakistan

PRESENTER: **Rachel Archer**, ThinkWell
AUTHORS: Zille Huma, Tahmeena Hassan, Ali Turab, Ms. Laura Boonstoppel

While Pakistan has made great strides in improving routine immunization coverage in recent years, almost 400,000 zero-dose children failed to receive a single dose of Penta1 in 2023. Despite Pakistan being one of only two countries where polio is still endemic, many children do not receive their first birth dose of oral polio vaccine (OPV) on time. The Expanded Program on Immunization (EPI) and the Polio Eradication Initiative (PEI) are implementing numerous initiatives to reduce zero-dose prevalence, varying in scale, resource intensity, and whether they are vertical or integrated. However, how these compare in terms of cost and output (zero-dose children reached) is unknown. To fill this evidence gap, we evaluate the cost and output of three key interventions targeting zero-dose children in urban and rural areas in Punjab and Sindh: 1. The cost of integrated outreach activities (IOA), which are intensified outreach activities taking place 3-4 time per year, and compare this to the cost of regular routine outreach and facility-based delivery 1. The cost of OPV house-to-house campaigns (a long-standing component of Pakistan's

PEI, a fully vertical and well-resourced program), and the savings from these being leveraged to identify and track children that have missed out on other injectable vaccines. 1. The cost of reaching zero-dose children using Clinics on Wheels (CoW) in Punjab, which are mobile clinics that deliver integrated primary health care services in urban slums. These are high-cost interventions, though due to their integrated nature, result in large efficiencies on a per person reached basis. We retrospectively estimate the incremental and full financial and economic cost of the selected zero-dose interventions, using an ingredients-based costing approach from a payer perspective. Costs and contextual information are being collected from clinic, facility, district, and province levels. The sample includes 42 facilities, two mobile clinics, seven district EPI offices, and four provincial offices (the EPI and PEI in both Sindh and Punjab). We also assess the financial and programmatic enablers and challenges of each intervention. The output of the interventions will be recorded in terms of zero-dose children identified and vaccinated, the overall number of doses delivered and children vaccinated, and the number of other interventions delivered and persons reached. Our preliminary findings show that two key barriers inhibit facilities' ability to prevent zero-dose prevalence consistently: a shortage of lady health workers, and inadequate transport provision. The additional interventions come with significant additional resources which fill gaps in key activities such as social mobilization. Integrated outreach and CoW reach a higher number of zero-dose children compared with fixed-site delivery, but they are also high-cost interventions. CoW is largely financed by the Government of Punjab, while IOA is heavily reliant on donor funding, which raises important questions around its long-term sustainability. We find that cost savings are incurred by integrating the identification of zero-dose children into OPV campaigns, though once these end, EPI will have to take over these activities. Our findings can guide the PEI and EPI in strategic planning, budgeting, and optimization of these initiatives.

abs-os507 The Cost of Periodic Intensification of Routine Immunization and Mobile Health and Nutrition Teams in the Afar and Somali regions in Ethiopia

PRESENTER: **Firew Bobo**
AUTHORS: Abdi Gari, Mirkuzie Woldie, Ms. Flavia Moi, Girmaye Deye, Ms. Laura Boonstoppel

Ethiopia is home to over 1.1 million zero-dose children, ranking fourth globally in terms of children who have never received a dose of the DTP vaccine. The Ministry of Health has developed a plan to reduce the prevalence of zero-dose children, which covers a variety of strategies. Periodic intensification of routine immunization (PIRI) and mobile health and nutrition teams (MHNTs) are two major strategies being implemented in remote areas where the routine vaccination program lacks the capacity to reach all children. PIRI are intensified outreach activities conducted a few times per year in low-coverage areas to catch up communities missed by regular routine services. MHNTs are active in nomadic areas to deliver a package of maternal and child health services to communities that are far away from health facilities. Communities are visited frequently for a given period of time, and when selected health indicators have adequately improved, they move on to a next underserved community. Both have been implemented in Ethiopia for several years, but the cost of implementing them is not known.

To fill this evidence gap and support Ethiopia's strategy to reach zero-dose children, this study evaluates the cost and implementation of PIRI and MHNTs. Using standardized bottom-up costing methods, we estimate the cost of both strategies as well as regular routine delivery in two regions: Afar in the north, and the Somali region in the east, both predominantly rural regions with pastoralist populations. We collect data from a provider perspective from 6 woredas, including health centers and health posts within these respective woredas. Through key informant interviews at all levels of the health system, we identify programmatic and financial bottlenecks to implementing the two strategies, and document providers' lessons and recommendations. The analysis will result in recommendations for Ethiopia's Ministry of Health and partners.

Our preliminary findings show that on a per dose delivered, and per child reached, both interventions are more costly compared with routine immunization. We find that MHNT results in cost efficiencies due to the integrated nature of the delivery strategy, compared with PIRI where only occasionally limited child health interventions are co-delivered. Key informants at all levels express financial barriers as the key constraint to being able to deliver routine immunization services as per the protocol, primarily manifested in a lack of transport and fuel. Both MHNT and PIRI are perceived as a suitable response to addressing specific health needs of pastoral communities that cannot be reached through regular facility- or outreach-based delivery, though some operational improvements were suggested. However, neither is perceived as having a long-lasting effect to prevent zero-dose prevalence or dropouts in the future.

This study provides valuable cost and programmatic evidence of interventions targeting zero-dose children, which can be compared with other supply and demand-side interventions in Ethiopia as well as similar hard-to-reach areas in other countries. Both interventions are successful at reaching zero-dose children in their specific settings. However, predictable and continuous financing is critical to strengthen the routine immunization program, and prevent zero-dose prevalence increases going forward.

abs-os516 What Are The Costs of Immunizing Zero-Dose Children in Nigeria Through Outreach?

PRESENTER: **Florence Tochukwu Sibeudu**, Nnamdi Azikiwe University
AUTHORS: Ogochukwu Treasure Obionwu, Ms. Christina Banks, Ms. Laura Boonstoppel

Nigeria has the highest number of children who have never received a vaccine dose, termed zero-dose children, in the world, estimated at 2.1 million in 2023. To address this, Nigeria has developed the Zero-Dose Immunization Recovery Plan 2023-2028, and the country has kicked off its Zero-Dose Reduction Plan (Z-DROP) in high-priority areas. Delivering vaccine through outreach is a key strategy of this plan, though the cost of conducting different types of outreach activities, and the requirements to implement outreach effectively are uncertain. This study supports Nigeria's aim to effectively reduce zero-dose prevalence by estimating the cost of conducting outreach activities in high-priority areas in Nigeria.

This retrospective, bottom-up costing study estimates the cost of reaching zero-dose through various outreach strategies from the provider perspective in three high zero-dose prevalence states: Jigawa, Kaduna and Lagos. Jigawa and Kaduna state represent primarily rural remote areas, while in Lagos, outreach activities target urban slums. This study estimates the financial and economic costs of outreach delivery targeting zero-dose children. We estimate the cost per dose delivered, and per zero-dose child reached, and compare the cost and output of the various outreach and facility-based delivery strategies. We collect quantitative cost data from a sample of 50-65 health facilities, as well as the

local government areas in which they are based. We also interview health workers on how outreach is planned, conducted, and funded, any operational and financial barriers that prevent outreach from being implemented as planned, and their insights on what is needed to optimize future outreach efforts aimed at reducing zero-dose prevalence. Outputs are presented as volume-weighted average unit costs.

We find that although outreach protocols are similar across the states, actual implementation practices vary, and Z-DROP is not fully implemented as planned. Outreach are organized from all levels (facilities, wards, local government areas), and take different forms (static and mobile teams). Only mobile delivery organized at local government area level also delivers other primary healthcare services, all others only deliver immunization services. The cost of delivering vaccines through outreach differs considerably across geographic locations, depending on existing health system resources available, and the availability of financing resources. The cost findings will help the government of Nigeria and its partners to tailor planning and budgeting subnationally to reach zero-dose children with interventions that are adapted to their respective contexts.

abs-os546 Interprofessional Team-based Primary Care and Production of Physician Services: Evidence From a Blended Capitation Model

PRESENTER: **Sisira Sarma**, Western University

Background and Aims: An interprofessional team-based primary care approach can improve access to and the efficiency of the primary care system. In Ontario's Family Health Team (FHT), introduced in 2006, physicians are remunerated based on blended capitation, while allied health professionals are salaried. The main mechanism by which FHTs can improve access and efficiency is through task shifting; limited empirical evidence exists on this mechanism. By utilizing longitudinal health administrative data on physicians and their patients, we investigate the impact of FHTs on the quantity and corresponding dollar values of capitated in-basket and out-basket services produced by FHT physicians. We investigate the extent to which in-basket services are provided by own physicians, group/team physicians and outside physicians.

Methods: Physicians practicing in Ontario's blended capitation model (with and without FHTs) between April 2007 and March 2023 and their patients were included in the analyses. Using health administrative data, we constructed several outcomes at the physician level: in-basket services provided to enrolled patients by (i) own physicians, (ii) team/group physicians, (iii) outside physicians; out-basket services provided to both enrolled and non-enrolled patients; in-basket services provided to non-enrolled patients; and in-basket services provided to enrolled patients during regular- and after-hours. We also constructed the corresponding dollar values of these services at fee-for-service rates. We used two-way fixed effects and high-dimensional fixed effects Poisson regressions to analyze the impact of FHTs on the production of physician services.

Results: We used 53,952 physician-year observations (24,984 FHT physicians and 28,968 non-FHT physicians) of 6,386 physicians with a minimum of two years of follow-up for each physician. Our preliminary results show that, compared with non-FHT physicians, FHT physicians provide approximately 100 fewer in-basket services ($2,000–$2,900 at fee-for-service rate) per physician (1000 patient-year) per annum, whereas outside physicians provide approximately 28–62 fewer in-basket services ($2,100–$2,800 at fee-for-service rate). We did not find any difference in out-basket services or in-basket services provided to non-enrolled patients between FHTs and non-FHTs. Analyses by regular and after-hours revealed that FHT physicians provide fewer services during both regular- and after-hours than non-FHT physicians.

Conclusions: Our results reflect task substitutions in Ontario's interprofessional team-based care, leading to fewer services produced by physicians and their patients receiving fewer services from outside physicians. Our findings highlight no incentive effects for providing more out-basket or in-basket services to non-enrolled patients in FHTs. Overall, patients' access to primary care is not hampered by team-based primary care. Whether the substitution effect of the team-based care approach leads to efficiency gains remains to be studied. Since both FHT and non-FHT physicians are compensated with the same capitation and incentives/bonuses, our results indicate that physicians in team-based practices are likely to be better off financially than non-team capitated physicians. However, an interprofessional team-based primary care approach may be desirable from the perspective of physicians, as funding for allied health professionals and administrative staff enables physicians to maintain a better balance between work and leisure activities.

abs-os531 Patient Outcome Differences in the Presence of Nurse Practitioners: A Patient-Shift-Level Analysis in the ICU Setting

PRESENTER: **Kathryn Lee**

AUTHORS: Lara Khadr, Monica O'Reilly-Jacob, Deanna Marriott, Thuy Nguyen, Deena Costa, Marianne Weiss, Olga Yakusheva

Background and Aims: In light of the growing integration of advanced practice providers (APPs; i.e., physician assistants and nurse practitioners) into intensive care unit (ICU) provider teams, concerns have been raised about the quality of APP care. Individual patients' ICU provider teams–the prescribing providers (i.e., physicians, APPs) who participate in each patient's care during every shift–may differ, both across patients during a shift, and for the same patient shift to shift. Yet, our current knowledge of the impact of APPs in the ICU on quality of care and patient outcomes is methodologically limited by unit-level or encounter-level analyses. An individual patient-shift-level analysis is needed to improve causal evidence. We examine whether presence of APPs in a patient's ICU provider team on a shift impacts opioid prescribing and mortality in the ICU. Methods: The study is a patient-shift-level secondary analysis of interprofessional ICU teams in 5 adult ICUs in an academic medical center in the United States. We linked patients to providers within the Electronic Health Records (EHR) data for 22,944 patient admissions from 2018 to 2023. Primary exposure was the presence of one or more APPs on a patient's shift-level ICU provider team, versus physicians only at three separate COVID-19 Pandemic time points: pre-pandemic, phase 1, and phase 2. The outcomes were prescribing of opioids and whether at the next shift (to preserve temporal sequencing) the patient died in the ICU, was discharged from the ICU, or remained in the ICU (base category). Analyses were performed at the patient-shift-level using patient fixed effect regression adjusting for time-variant factors (total number of providers, patient acuity score, and day versus night). Key Results: There was no significant association between patient-shift provider teams that included APPs and the probability of death in the ICU across all time points. However, patients had a 2.5% higher probability of being discharged from the ICU during shifts when APPs were present in the patient-shift provider teams during phase 2 ($p<0.05$). Patients had a higher probability of being prescribed an opioid when APPs were present ($p<0.01$ for all 3 time points). Conclusions and Implications for Policy and Practice: Our findings suggest mixed evidence on whether or not inclusion of APPs in ICU provider teams impacts patient outcomes. Greater use of APPs in critical care teams may be warranted under circumstances that leverage their potential in improving both patient outcomes and the overall functioning of ICU teams.

abs-os524 Physician-Practice Growth After the Interstate Medical Licensure Compact in the United States

PRESENTER: **Ms. Alicia Plemmons**

US physicians' licenses do not transfer between states, which limits their labor mobility compared with other professions. The Interstate Medical Licensure Compact (IMLC) reduces this barrier in participating states. We estimate whether the IMLC expanded physician labor mobility by measuring the number of physician-practice locations and the number of states in which physicians practice using a staggered difference-in-differences model and data from the Centers for Medicare and Medicaid Services. We find a 3% increase in out-of-state practice locations for physicians whose state of primary licensure participates in the IMLC. Further, the IMLC increased the number of states in which physicians practiced, with growth concentrated in participating states, even after accounting for other policy reforms.

abs-os540 Team Incentives and Primary Health Care Team Performance in India

PRESENTER: **Krishna D. Rao**
AUTHORS: Akriti Mehta, Harsha Joshi

Background: High-performing primary health care (PHC) is widely recognized as the foundation for achieving universal health coverage. Team based approaches to delivering primary care services is widely acknowledged as important for comprehensive and coordinated services. To address concerns about PHC team productivity, many low and middle-income countries like India have provide performance incentives to public sector PHC teams. In India, PHC teams - comprised of Community Health Officers, auxiliary nurses, and community health workers - receive team-based financial incentives for achieving benchmarks on a set of fifteen process and service coverage indicators sourced from routine information systems like outpatient visits, pregnancies and births registered, screening and treatment for hypertension and diabetes.

Objective: This study aims to understand if team-based financial incentives are associated with improved facility service readiness and service delivery outcomes of vaccination coverage and hypertension screening. These outcomes require coordinated action among members of the PHC teams. A second aim, is to understand if there are unintended consequences of team incentives – principally, if non-incentivized services

Methods: This study is located in the district of Bhavnagar in the state of Gujarat in India, where a sample of 40 primary health care facilities were surveyed in 2024 to evaluate facility readiness to provide a range of health services. The service readiness measures are based on WHO's Service Availability and Readiness Assessment tool. Catchment population information on service coverage and immunization was sourced from routine data systems. Service readiness and coverage indicators that are incentivized and non-incentivized are compared using regression analysis to understand their relative performance. Bivariate and multivariate analysis is used to understand the association between team incentives and facility service readiness.

Findings: Our preliminary results suggest that there is a weak association between receipt of team incentives and the outcomes of facility service readiness. Further, no significant association was found between services that required coordinated action by PHC teams (i.e. hypertension screening coverage and immunization) and receipt of team incentives. Further, we find that teams underperformed on un-incentivized indicators. Both design and implementation issues are responsible for why team incentives may not have their invented effects. For example, while health workers receive incentives based on a common set of indicators, they are individually paid through different budget lines at differential times, which does not provide a collective sense of accomplishment.

Conclusions: Team performance incentives are an important policy tool to improve team performance. However, in scaled programs team incentives need to be carefully designed and calibrated to avoid attenuation of their effects on team performance, as well as, unintended consequences by depressing performance on non-incentivized activities.

Designing Health Benefits Packages for UHC: Complete Overhaul Vs. Incremental Adjustments. Different Approaches, Processes and Mechanisms

MODERATOR: **Wanrudee Isaranuwatchai**, HITAP

CONVENER: **Gavin Surgey**, Radboudumc

abs-os602 Designing Universal Health Coverage Benefits Packages in Thailand: A Continuous Balance of Comprehensive Overhauls and Incremental Adjustments

PRESENTER: **Pritaporn Kingkaew**, Health Intervention and Technology Assessment Program (HITAP), Ministry of Public Health, Nonthaburi, Thailand

Designing health benefits packages (HBPs) for Universal Health Coverage (UHC) requires a delicate balance between addressing the comprehensive health needs of populations and managing limited resources, particularly in low- and middle-income countries (LMICs). Over the past two decades, Health Technology Assessment (HTA) has been instrumental in shaping HBPs, offering a robust, evidence-informed approach to decision-making. An annual process for Topic Identification, Selection, and Prioritization (TISP) ensures that HBPs address the most pressing population health needs identified by diverse stakeholders. Appraisals of individual health technologies follow, evaluating their cost-effectiveness, budgetary implications, and feasibility before inclusion in the package. To ensure financial sustainability, price negotiations and strategic purchasing mechanisms are employed, enabling the procurement of essential technologies while expanding coverage without overburdening the healthcare system. One notable reform includes the overhaul of prevention programs, including revising service lists and payment mechanisms to address low coverage rates of screening programs effectively. This session will delve into the critical importance of flexibility in designing HBPs, emphasizing how strategic, large-scale reforms can be seamlessly integrated with adaptive, evidence-driven updates to create sustainable and equitable health systems.

abs-os595 Redefining Health Coverage in Kyrgyzstan: Leveraging the WHO Universal Health Coverage Compendium for Primary Care Transformation

PRESENTER: **Gavin Surgey**, Radboud University Medical Center
AUTHORS: Rob Baltussen, Hassan Haghparast-Bidgoli, Baktagul Isaeva, Gerard Joseph Abou Jaoude, Charlie Nederpelt, Saltanat Zhetibaeva

Kyrgyzstan operates a compulsory health insurance system through the Mandatory Health Insurance Fund (MHIF), which provides a set of publicly funded services under the State-Guaranteed Benefits Programme (SGBP). Kyrgyz has recently undertaken a process to prioritise and define its list of services offered under its SGBP. This involved a whole package review of health services using evidence-informed deliberative processes (EDPs), comprise of several steps, and Health Technology Assessment (HTA). It made use of the WHO Universal Health Coverage Compendium (UHCC) as the architecture of services for which we costed all the potential services options under the WHO UHCC The UHCC is a novel and innovative database of health services and intersectoral interventions designed by the WHO, aimed at assisting countries in designing and/or revising their health benefit packages. It explicitly aims to foster integrated service delivery, and a key innovation is a structured architecture that considers both foundations of care and referrals to promote linkages across health system levels. The Compendium focuses on clinical health services and includes a list of over 3700 health actions across different health areas. This presentation reports on the process to revise the primary healthcare SGBP in Kyrgyzstan. It will highlight the use of the UHCC in the mapping, costing, cost-effectiveness review and prioritisation of health services for the Kyrgyzstan SGBP. This is the first country experience of using the UHCC for a comprehensive benefit package revision. It will also show how the costing model designed for the UHCC was used to estimate costs of the full benefits package.

abs-os604 Setting Priority Topics for Health Technology Assessment Studies to Optimize the Benefit Packages in Indonesia

PRESENTER: **Auliya A. Suwantika**

Background Health technology assessment (HTA) is critical in selecting healthcare service benefit packages for Indonesia's national health insurance program. Established in 2014, the Indonesian Health Technology Assessment Committee uses HTA to evaluate health technologies in the potential inclusion of benefit packages. **Aim** This study aimed to identify priority topics for adaptive HTA studies in Indonesia. This adaptive approach was applied to leverage existing data, previously published evidence, and simplified methodologies in expediting assessments without compromising the principles of transparency and evidence-based rigor. **Methods** Multi-criteria decision analysis (MCDA) was applied to identify priority topics for adaptive HTA studies in Indonesia by considering various factors such as disease burden, clinical effectiveness, cost, acceptance, and equity. **Results** Integrating MCDA with an evidence-informed deliberative process could enhance decision-making to optimize benefit packages by involving stakeholders in a structured manner, ensuring diverse perspectives, and making decisions more transparent and legitimate. By applying MCDA, health authorities could align the prioritization of technologies with national health objectives and the local disease burden, streamlining which technologies undergo adaptive HTA. The process could foster a balanced assessment where scientific evidence and stakeholder values converge, promoting broader acceptance and credibility of the decisions. Incorporating an evidence-based deliberative process into the adaptive HTA framework could ascertain that even expedited procedures uphold a fair and participatory evaluation norm, which is essential for maintaining public confidence and adhering to policy. **Conclusions** Adaptive HTA

offers a strategic alternative, reducing the time and resources required by leveraging existing data and simplified methodologies. Given the increasing need for HTA studies in Indonesia, identifying priority topics for adaptive HTA studies is crucial to accelerating the decision-making process and upholding the core values of equity, efficiency, and evidence-informed policy.

Incorporating Implementation Within the Economic Evaluation of Health Technologies: A way Forward

MODERATOR: **Robert Heggie**, University of Glasgow

abs-os565 A Framework, a Spectrum and a Trap Characterising and Measuring Implementation Cost, and Balancing Research Quality With Speed of Implementation

PRESENTER: **Ms. Caroline S Clarke**, University College London (UCL)
AUTHORS: Duncan Gilbert, Ms. Rachael Hunter, Victoria Serra-Sastre, Ian Shemilt, Sophie Merrick

ABSTRACT:

Background: This presentation addresses two areas of tension regarding implementation (or de-implementation) of effective and cost-effective (or sub-optimal) innovations. Challenges in both of these areas arise due to lack of information or evidence around specific aspects that overlap implementation and economic evaluation. We present here case studies and examples of how to overcome these issues.

Methods: The first area concerns the tension when performing an analysis that requires multiple perspectives. These could be: a national health technology assessment (HTA) body that uses positive cost-effectiveness thresholds (e.g. £20,000/QALY gained for the National Institute for Health and Care Excellence (NICE) in England); and a local service provider, preferring budget impact analysis including implementation costs, and process outcomes, e.g. reduced patient waiting times for treatment or diagnosis with zero overall cost increase. When performing an analysis, especially in an academic or publicly funded study, it is likely that the audience will be broad and so the analytical team wishes to address multiple perspectives within one framework and using one main dataset. We provide a framework for approaching this and determining and measuring implementation costs.

The second area concerns the tension between getting innovations into practice as quickly as possible so that patients can benefit, versus taking sufficient time to ensure that the optimal therapy regimen is the one approved, to avoid inadvertent health detriment. It can be very difficult to undo an implementation process once it has taken place, for various economic, political and logistical reasons, so any damage done in system terms can persist until the optimal regimen is approved and implemented, if this ever happens. We discuss case studies and possible ways forward to avoid this issue.

Results: Different types of intervention in different contexts can lie along the implementation spectrum, from pharmaceutical innovations that slot easily into the clinical pathway, to complex innovations or major system change (MSC) that substantially alter patient and staff behaviour, service delivery processes, physical locations where care is carried out, and so forth.

HTA approaches have historically focused more on pharmaceutical innovations. Complex interventions and MSC on the other hand are relative newcomers as subjects of cost-effectiveness evaluations, and they can carry a heavier implementation burden.

Other new uses of HTA include beginning to allow post-marketing changes in pharmaceutical approvals that are not driven by the manufacturer. This can be very important in de-implementation or de-escalation of sub-optimal therapies as part of the wider context of ensuring value for money of health care services by considering the opportunity cost of persevering with sub-optimal therapy pathways, while also considering a range of stakeholder needs.

Conclusions: Where evidence is lacking regarding implementation of the most cost-effective regimen, this can be due to analysis gaps, including inappropriate exclusion of stakeholders who bring essential insights but are overlooked, or exclusion of alternative versions of the treatment pathway that could provide better value for money and patient outcomes. We hope that illustrating these issues will help us to overcome them and improve patient care and outcomes.

abs-os559 Evaluating Complex Interventions: Methods in Health Technology Assessment

PRESENTER: **Abdolvahab Baghbanian**
AUTHORS: Drew Carter, Tracy Merlin

ABSTRACT:

Background: Health Technology Assessment (HTA) methods have been developed to support evidence-informed policy-making through systematic assessment of the comparative value and costs of health interventions and programs. However, many healthcare interventions are complex in ways that pose challenges to using conventional HTA methods. This scoping review collated and synthesised international approaches to the HTA of complex interventions, including identifying assessment criteria, types of evidence and the domains of value that are

most favoured.

Methods: A systematic scoping review was conducted using Joanna Briggs Institute guidelines, Arksey and O'Malley's six-stage framework and recent advances in scoping review methodology. Seven electronic databases, grey literature, three leading HTA journals and backward citations were used to search complex intervention HTA records written in English from January 2000 to December 2023. Supplementary searches were also conducted to identify actual HTA products from specific countries. The Population, Concept, Context (PCC) framework guided the literature selection process, with a two-phase screening process and subsequent narrative synthesis. The PRISMA-ScR informed reporting. Independent screening by two reviewers ensured the accuracy of inclusion, and data extraction followed a customised form grounded in the HTA-core model.

Results: A total of 10684 references yielded 35 records from twelve countries. The review identified two clusters of research on HTA of complex interventions: methodological orientation and conceptual models (n=19) and actual HTA representation (n=16). Several evaluation criteria and domains were used or recommended for use that extended beyond HTA-core domains. Three distinct HTA approaches emerged: the integrative approach, highlighted in methodological guides and theoretical literature, and either the parallel or sequential approaches, largely emphasised in practical HTAs. In theory, equal weight is given to various HTA domains for complex intervention assessment, but in actual HTA practice, the scope and specificity of domains vary across reports, with different countries exhibiting variations in the significance assigned to different domains. In practice, cost and clinical effectiveness, and organisational aspects predominate in complex intervention evaluation, albeit with gradually increasing emphasis on a technology's description, intended use, safety and patient and social aspects over a decade ago.

Conclusion: This scoping review underscored the multidimensional nature of HTA of complex interventions, revealing diverse methodological and practical orientations across evaluation criteria and domains. While theoretical guidance and methodological frameworks suggest one approach, practical applications of HTA often adopt another, reflecting persistent discrepancies in implementation and warranting further investigation. The review identified emerging trends in integrative, sequential and parallel approaches to complex intervention HTA that extend beyond the traditional HTA core model to incorporate broader contextual and implementation factors. Challenges remain in consensus on specific metrics and evidence elements for complex health interventions. However, acknowledging these multifaceted aspects in HTA processes can enhance evidence-informed decision-making.

abs-os554 What Methods are Currently Available for Incorporating Implementation Considerations Within the Economic Evaluation of Health Technologies?

PRESENTER: **Robert Heggie**
AUTHORS: Olivia Wu, Hanin Kamaruzaman, Kathleen A Boyd

ABSTRACT:

Background: When clinically effective, cost-effective health interventions are not fully implemented in clinical practice, population health suffers. Economic factors are among the most commonly cited reasons for suboptimal implementation. Despite this, implementation and economic evaluation are not routinely performed in conjunction with one another. This review sought to identify and describe what methods are available for researchers to incorporate implementation within economic evaluation, how these methods differ, when they should be used, and where gaps remain. **Methods**: We conducted a scoping review using systematic methods. A pearl-growing approach was used to identify studies. References and citations were identified using Web of Science and Scopus. We included for review any study that contained terms relating to economic evaluation and a series of implementation-related terms in the title or abstract. The search was conducted and validated using two independent researchers. **Results**: Our review identified 42 unique studies that included a methodology for combining implementation and economic evaluation. The methods identified could be categorized into four broad themes: (i) policy cost–effectiveness approach (11 studies), (ii) value of information and value of implementation approach (16 studies), (iii) mixed methods approach (6 studies), and (iv) costing approach (9 studies). We identified a trend over time from methods that adopted the policy cost–effectiveness approach to methods that considered the trade-of between the value of information and value of implementation. More recently, mixed methods approaches to incorporate economic evaluation and implementation have been developed, alongside methods to define, measure and cost individual components of the implementation process for use in economic evaluation. **Conclusion:** Our review identified a range of methods currently available for researchers considering implementation alongside economic evaluation. There is no single method or tool that can incorporate all the relevant issues to fully incorporate implementation within an economic evaluation. Instead, there are a suite of tools available, each of which can be used to answer a specific question relating to implementation. Researchers, reimbursement agencies and national and local decision-makers need to consider how best to utilize these tools to improve implementation.

Ind-1630 The Impact of Increasing Access to Government Subsidies on the Demand for Psychotherapy and Pharmacotherapy

PRESENTER: **Noura Saba**, Macquarie University

AUTHORS: Anam Bilgrami, Henry Cutler, Yuanyuan Gu

Meeting the increasing demand for mental health care is a major challenge facing healthcare systems. This study aims to assess the impact of a 2020 national policy that increased access to government subsidies, on the demand for psychotherapy and pharmacotherapy in Australia. Using a large, national, linked administrative dataset, we used regional differential exposure measure of mental health care access to create a treatment and control group. We estimated the treatment effects using dynamic difference-in-difference. We find that increasing the number of subsidised sessions impacted the demand for types of mental health treatment differently. For services delivered by psychologists, service use was initially not impacted, but later experienced a short-term increase before dissipating in the later quarters. There was an immediate increase in the use of General Practitioners (GPs) services, but a reduction in psychiatric services in 2022, particularly for low-income earners. We find a delayed and positive spillover effect on the use of anti-depressants, which remained significant in the late post-expansion quarters. We did not find an impact on prescriptions for anxiolytics and anti-psychotics. A nuanced approach to policy design is therefore needed to address the direct and indirect effects of subsidies and to ensure efficient distribution of resources.

Ind-2482 Default Enrollment for Dual-Eligible Special Needs Plans (D-SNPs)

PRESENTER: **Joseph G.P. Hnath**

AUTHOR: Vilsa E. Curto

Introduction Dual-eligible beneficiaries (duals), who qualify for both Medicare and Medicaid in the U.S., represent a critical population due to their size (12 million in 2020), sociodemographic composition (lower income and three times more likely to be Black or Hispanic compared to non-dual Medicare beneficiaries), and health risks (double the Medicare spending and triple the likelihood of reporting poor health compared to non-duals). Historically, fragmented care resulting from poor coordination between Medicaid and Medicare has led to suboptimal outcomes for duals. Integrated care programs, particularly Medicare Advantage (MA) Dual Special Needs Plans (D-SNPs), aim to address these challenges. D-SNPs account for the largest enrollment and plan offerings among integrated care models. A policy allowing MA organizations to default duals from Traditional Medicare into D-SNPs seeks to increase enrollment, yet no prior research has evaluated this policy or the causal effects of D-SNP enrollment on health and utilization outcomes. Our research questions are to estimate both (1) the causal effect of the default enrollment policy on D-SNP enrollment and (2) the causal effect of D-SNP enrollment on health and utilization outcomes.

Methods We use data from 2009–2019, combining four sources: Medicare enrollment/demographics (MBSF), Medicaid managed care enrollment (MAX/TAF), D-SNP default enrollment approvals (via Freedom of Information Act request), and Medicare inpatient utilization (MedPAR). To evaluate the default enrollment policy, we employ a difference-in-differences design, specifically the *Two-Stage Difference-in-Differences* method by Gardner *et al.*, which accommodates staggered treatment timing in repeated cross-sections. To estimate the causal effect of D-SNP enrollment on outcomes, we use an instrumental variables design leveraging exogenous variation in D-SNP enrollment induced by the default policy. This approach applies the *Instrumented Difference-in-Differences* method by de Chaisemartin *et al.*, complemented by a novel three-stage method extending Gardner *et al.*'s framework.

Results In six states, approximately 135,000 beneficiaries were eligible for default enrollment, which increased the probability of D-SNP enrollment by 14.9 percentage points (95% CI: 6.0–23.9), representing a nearly 160% increase relative to the sample mean of 9.4%. Ongoing analyses incorporate pre-Medicare utilization data to assess adverse selection dynamics with defaults and implement an instrumental variables research design to estimate the causal effects of D-SNP enrollment on health and utilization outcomes.

Conclusion While defaults significantly increase D-SNP take-up relative to baseline levels, their effect size is smaller compared to other health insurance contexts with defaults, such as Medicare Part D or the Dutch health system. This study offers broader health economics insights into designing effective health insurance enrollment mechanisms and promoting efficient care delivery under managed competition and capitated financing models.

Ind-2503 The Impacts of Copayments at General Practitioner (GP) Consultations on Essential Annual Health Screenings in Australia

PRESENTER: **Paul Kuwornu**

Background Chronic diseases remain a leading cause of mortality globally. General health screenings/check-ups are among the most effective ways to reduce the risk of chronic diseases. However, many individuals do not engage in check-ups for different reasons. For example, charging for health check-ups may reduce the use of these services. Although Australia's healthcare financing policy promotes "free" general practitioner (GP) services, there is an emerging view that this "free" GP services may be leading to poorer quality of care. The proponents of this view argue that excessive price competition among GPs may result in shorter consultation times and inhibit GPs from focusing on preventive health screening. The study's objective was to determine if there were differences in the uptake of health check-ups among adults who always made copayments at GP consultations (copay group) compared to those who never make copayments (no pay group). **Methods** The study used unbalanced panel data from the Household, Income, and Labor Dynamics in Australia (HILDA) survey, covering three (2013, 2017, and 2021) waves. The sample was restricted to individuals older than 40 years with 2+ GP visits in the year preceding the survey dates, resulting in N = 17,998 observations. The outcome variable measured whether an individual had undertaken annual check-ups/screening. Our identification strategy used a doubly robust causal inference approach, which combined propensity score weighting and g-computations. The target estimand was the average treatment effect. We included six different robustness checks ranging from methods that used alternative specifications of the sample to those that employed propensity score matching instead of weighting. To lessen the risk of omitted variable bias, we control for 25 potential confounders in the propensity score models, including socio-demographics, health conditions and expenses, and personality traits. We also conducted a sensitivity analysis for unmeasured confounding using the E-value approach. **Results** There was excellent balance between the two exposure groups after propensity score weighting, with standardized differences below 0.1 for all the 25 potential confounders. The result showed that although individuals in the two exposure groups had a similar average number of visits to GPs (1.54 for copay group vs. 1.55 for no pay group), those in the copay group were 23% less likely to miss essential annual health screenings compared to the no pay group (relative risk, 0.77; 95% CI, 0.67 - 0.87). The results remained similar across all robustness checks. The E-value result assures that it was unlikely for an unmeasured confounder to explain away the effect estimates. **Conclusions** Although this finding opens the possibility that copayments might be influencing the uptake of essential annual health check-ups, understanding the causal mechanisms would require further investigations beyond our study since we could not account for the characteristics of the GP consultations. As efforts are made to promote preventive health among Australians, careful attention needs to be paid to crafting the right mix of GP funding models to spur the uptake of health check-ups.

Ind-1147 The Effect of Long-Term Care Insurance on Medical and Long-Term Care Utilization: Focusing on Institutional Care Eligibility

PRESENTER: **Hin Moi Youn**

Background As the global population continues to age, the rising demand for social care for older people has become a critical policy agenda. South Korea, recognizing the urgency of this issue, was one of the first countries to implement public long-term care insurance (LTCI) in 2008. This initiative was designed to address the increasing demand for long-term care services while containing the rapid growth of medical expenditures. Given the growing need to provide appropriate and affordable care for older people, ensuring the sustainability of the LTCI and National Health Insurance (NHI) systems has become more critical than ever. This study aims to evaluate the effects of LTCI on medical and long-term care utilization, with a particular focus on institutional care eligibility (LTCI level 2) among older people. It seeks to clarify the inter-relationship between different types of care and offer insights into the development of long-term care policies. **Methods** The study utilized a representative sample from the National Health Insurance Senior Cohort Database covering 2008 to 2013. A sharp regression discontinuity design was employed to estimate the impact of expanded LTC benefits on medical and LTC utilization. Participants were selected based on their preliminary LTC scores, which determined their eligibility for treatment. The analysis relied on non-parametric local linear regression estimates with triangular kernel weights and a bandwidth of 3.0. Additional falsification and sensitivity analyses were conducted to validate the study design. **Results** The analytic sample consisted of 8,036 LTCI recipients with LTCI levels 2 and 3 from 2009 to 2013. Among them, 2,908 (36.2%) were in the treatment group (above the cutoff), while 5,128 (63.8%) were in the control group (below the cutoff). The findings revealed that level 2 benefits significantly reduced total medical expenditures by 1,778,700 won (29.5%, $p<0.0001$). A substantial decrease was observed in acute hospital care expenditures, which fell by 1,576,300 won (49.2%, $p<0.0001$), compared to a modest reduction in LTC hospital care expenditures of 208,300 won (7.4%, $p=0.568$). For LTC utilization, institutional care costs increased by 3,178,600 won (100.7%, $p<0.0001$), with an additional 93.8 days of institutional care (103.1% increase, $p<0.0001$). Conversely, home care costs decreased by 711,600 won (22.8%, $p<0.0001$), with 43 fewer days of care (30.5% decrease, $p<0.0001$). Overall, total expenditures for medical and LTC increased by 688,300 won (5.6%, $p=0.034$). **Conclusions** This study provides causal evidence of LTCI's impact on medical and LTC utilization, particularly highlighting the effects of expanded institutional care benefits. The findings indicate substitutive relationships between hospital inpatient care and institutional care, as well as between home care and institutional care. Increased access to institutional care is associated with a significant rise in LTC expenditures, reflecting high demand for such services. Policymakers should prioritize understanding the needs of the aging population and optimizing LTCI program designs to enhance efficiency, control costs, and improve the health and well-being of older adults in an era of rapid aging.

abs-os532 Modeling Differences in Medicare Advantage Enrollment by Race Using a Hybrid Choice Model

PRESENTER: **Adam Atherly**, Virginia Commonwealth University
AUTHORS: Bryan Dowd, Eline M. van den Broek-Altenburg

Background: The U.S. Medicare program has a very limited benefit package with high out-of-pocket cost sharing in the traditional fee-for-service (TM) Medicare program. An alternative, Medicare Advantage (MA), offers reduced cost sharing and enhanced benefits, along with limited provider networks and care management. MA has been gaining market share relative to TM among the eligible US population, particularly among racial minorities. The reasons for the higher enrollment among racial minorities are unclear. Prior work has found that the higher enrollment rate among racial minorities is not a function of either plan or beneficiary characteristics, but is rather a function of differences in preference weights for plan attributes. Yet this finding begs the question of why preference weights should vary by racial group. In this paper, we attempt to explain the differences in enrollment rates by race. We examine the importance of unobserved factors to explain the differences in choice decisions by race.

Data: We use the 2020 Medicare Current Beneficiary Survey, which is a representative sample of the Medicare population that contains data on beneficiary demographics, health, income and other attributes. We combine this with CMS data on plan payment levels, star rating and measures of market competition. Study exclusions include individuals less than age 65, nursing home residents and full-time workers. Total sample size is 8,211

Methods: Analytically, we use a hybrid choice model. We distinguish between classes of individuals using a structural equation model, utilizing survey variables on food insecurity, use of preventive care and understanding of Medicare, then model choice decisions using a mixed logit model. The choice model has four options: TM (alone), TM with Part D, TM with Part D and Medigap and MA+Part D. In the latent choice model, we control for individual characteristics, including age, gender, health status, income; in the mixed logit, we include plan characteristics (premium, drug coverage, coinsurance rates for Part A and Part B).

Key Findings: We find three distinct classes within the Medicare population. Class 1 (23% of the population) is characterized by a higher probability of being white, college educated and having a younger age. Class 2 (34% of the population) was more likely to be non-white, while Class 3 (42% of the population) was older and poorer. Class 1 was the least premium sensitive, while Class 2 has the largest premium elasticity, the higher marginal utility associated with prescription drug coverage and the largest response to out-of-pocket premiums. Class 3 placed a lower value on drug coverage but was more sensitive to outpatient cost sharing..

Conclusions: The Medicare population is characterized by three distinct classes. Higher enrollment in MA plans by minorities reflects unobserved characteristics associated with higher marginal values for prescription drugs and a greater sensitivity to cost sharing. MA plans offering drug coverage and lower out-of-pocket cost sharing, which drives the higher enrollment numbers.

Mental Health: Treatment and Outcomes

MODERATOR: **Léon Gerardo Kreis**, "University Medical Center Hamburg-Eppendorf, Department of Health Economics and Health Services Research"

Ind-354 Mental Health As a Determinant of Work: A Scoping Review on the Impact of Mental Health on Precarious Employment

PRESENTER: **Claire de Oliveira**, Centre for Addiction and Mental Health
AUTHORS: Margaret Jamieson, Sergio Lopez

Abstract

Background: While many studies have examined the impact of employment and other related work outcomes on mental health, the reverse – the impact of mental health on employment – has received less attention. Poor mental health can serve as a barrier to obtain and maintain employment and play a key role in shaping poor labour market outcomes such as productivity, absenteeism, and reduced earnings. Poor mental health can also negatively impact the job search process as it can lead to decreased levels of energy and reduced availability, resulting in lower motivation and capacity to actively engage in job search activities. Furthermore, employers are less likely to hire people who have health problems, resulting in reduced probability of employment success. Several reviews have summarised the impact of precarious employment on mental illness; however, to date, no reviews have synthesised the existing evidence on the reverse relationship.

Objectives: The objectives of this scoping review were to ascertain the existing literature examining the impact of mental health on precarious employment as well as to describe, synthesize, and critically appraise it.

Methods: A scoping review was conducted using established methods. MEDLINE, Embase, PsychINFO, Business Source Premier, EconLit, and Web of Science were searched from January 1st, 1980, to August 30th, 2024. Relevant searches were also undertaken in Google and specific websites of interest and the references of key papers were examined. Relevant data were extracted on all studies and the quality of each study was assessed, namely whether studies examined simple associations between mental health and precarious employment or whether they attempted to address causal inference and accounted for endogeneity and/or unobserved heterogeneity. Evidence was synthesised by type of mental disorder using a narrative synthesis; summary tables were used to describe the findings.

Results: After duplicates were removed (n = 6,412), the search yielded 9,693 unique records; after reviewing titles and abstracts and confirming eligibility with full text review (n = 40), 17 relevant studies were included. Among these studies, many examined the reciprocal relationship between mental health and precarious employment; however, few studies specifically focused on mental health as a determinant of precarious employment. The research team is currently undertaking data extraction, quality assessment, and evidence synthesis.

Discussion: Despite a large body of literature examining the impact of precarious employment on mental health and mental health outcomes, less attention has been paid on examining mental health as a determinant of precarious employment. Preliminary evidence indicates that people with poor mental health are at a higher risk of precarious employment. However, more high-quality, causal inference studies are needed to inform clear policy recommendations. Nonetheless, it is important to ensure that workplaces and job roles consider workers' mental health and how best to accommodate workers with pre-existing mental health conditions. Improving access to mental health services both in and out of the

workplace may also support workers living with mental health conditions.

Ind-2816 The Dual Impact of Social Isolation and Internet Isolation on Depression and Loneliness in Older Adults: A Comparative Analysis of Europe and Asia

PRESENTER: **Shang Gao**, Jilin University
AUTHORS: Yan Xu, Xihe Yu, Liangwen Ning

Abstract

Background

Social isolation and internet isolation are critical public health issues, particularly for older adults facing life changes like retirement or widowhood. Social isolation, defined as reduced engagement in interpersonal relationships, and internet isolation, characterized by a lack of access to or use of the internet, have both been linked to adverse mental health outcomes such as depression and loneliness. These effects are compounded in low- and middle-income countries (LMICs), where internet access is limited, compared to high-income countries (HICs), where digital engagement is higher but gaps persist among older adults. By analyzing data from the English Longitudinal Study of Ageing (ELSA) and the China Health and Retirement Longitudinal Study (CHARLS), this study provides a comparative perspective on the independent and combined effects of social and internet isolation across different socioeconomic and cultural contexts.

Methods

Data from ELSA and CHARLS were analyzed using Cox proportional hazards regression to estimate the effects of social and internet isolation on depression and loneliness. Social isolation was defined as being unmarried, living alone, infrequent contact with children, or non-participation in social activities. Internet isolation was defined as no internet use in the past month. Random-effects meta-analysis was conducted to pool results and assess heterogeneity between the two cohorts.

Results

Both social and internet isolation independently increased the risks of depression and loneliness. In ELSA, social isolation was more strongly associated with depression (HR = 1.251, 95% CI [1.000–1.567]) than internet isolation (HR = 1.285, 95% CI [1.045–1.581]), while internet isolation alone had a greater impact on loneliness (HR = 2.553, 95% CI [1.813–3.595]) compared to social isolation (HR = 1.776, 95% CI [1.268–2.486]). Dual isolation exhibited the highest risks for both outcomes. In CHARLS, social isolation significantly increased the risk of both depression (HR = 1.397, 95% CI [1.095–1.782]) and loneliness. Meta-analysis revealed consistent trends across datasets, with dual isolation posing the greatest risk for both outcomes (HR = 2.096, 95% CI [1.078–4.074]).

Conclusions

Social and internet isolation are significant predictors of depression and loneliness in older adults, with varying impacts across cultural and socioeconomic contexts. While social isolation exerts a stronger influence on depression, internet isolation has a greater effect on loneliness, particularly in developed contexts like the UK. Dual isolation amplifies these risks, highlighting the need for integrated interventions that address both interpersonal and digital connectivity to improve mental health outcomes in aging populations.

Ind-456 Association of Multidimensional Poverty and Depression Among Elderly in India

PRESENTER: **Suraj Maiti**
AUTHORS: Sanjay K Mohanty, Jyoti Shankar Hota, Jyoti Das

Background Poverty and mental health among the elderly are globally neglected public health concerns, with high prevalence in developing countries. With a rapidly growing elderly population and socio-demographic changes in India, it disproportionately affects the poor and vulnerable. The older adults are at higher risk of multiple deprivation and poor mental health due to economic vulnerability, social isolation, and greater need for healthcare. Though studies on the association of poverty and mental health have been increasingly available, there are limited studies that have examined the association of multidimensional poverty and mental health. In low- and middle-income countries (LMICs), both the reduction of multidimensional poverty and the integration of mental health in public health programmes for the elderly remain neglected agendas. In this context, this paper examines the association of multidimensional poverty and depression among older adults in India. **Data and Methods** We utilized the microdata from the Longitudinal Aging Study in India (LASI), which comprehensively collects the social, health, and economic well-being of older adults in India. LASI Wave 1 collected information from 73,396 individuals using a multi-stage stratified area-probability cluster sampling design, of which 29,300 elderly individuals aged 60 and above were analyzed. Depression among older adults, as measured by the CES-D scale, is the primary outcome variable. The multidimensional poverty level of the older adults is the key independent variable. A total score is calculated on a scale of 0 to 10, with a score of 4 or more being classified as depressive. The Multidimensional poverty was estimated using the Alkire-Foster methodology, which employs a dual cut-off counting approach to categorize individuals as either multidimensionally poor or non-poor. **Results** We estimated that 61% (95% CI: 59.3-62.1) of the older adults were multidimensionally poor, with an associated Multidimensional Poverty Index (MPI) of 0.303 (95% CI: 0.295-0.312). The prevalence of depression, measured by the Centre for Epidemiological Studies Depression Scale (CES-D), was 12 percentage points (pp) (AME: 0.12; 95% CI: 0.097-0.143) higher among the multidimensionally poor than non-poor individuals. The findings are robust to an alternative measure of depression using the Composite International Diagnostic Interview Short Form (CIDI-SF) scale. Significant predictors of elderly depression were age, sex, residence, and marital status. **Conclusion** The high prevalence of depression among the multidimensionally poor elderly in India reflects a complex mix of socioeconomic, psychological, and health-related factors. There is a need for a comprehensive approach to address elderly poverty and mental health, integrating economic support, improved access to healthcare, and enhanced social engagement. We recommend expanding social welfare programs to incorporate mental health services targeted at vulnerable groups in rural areas and regions

with high depression prevalence.

Ind-544 The Long-Term Impact of ADHD on Children and Adolescents Health-Related Quality of Life: Results from a Longitudinal Population-Based Study

PRESENTER: **Ha N.D Le**, Deakin University
AUTHORS: Courtney Kelly, David Coghill, Ms. Lisa Gold

Background Attention-deficit/hyperactivity disorder (ADHD) is the most common neurodevelopmental disorder. While much is known about the functional and academic impacts of ADHD, impacts on long-term health-related quality of life (HRQoL) are less well-documented. **Aims:** To explore, in children aged 4-17 years, associations between clinical ADHD symptoms and (1) children's HRQoL; (2) whether child internalising or externalising problems attenuate this association; and (3) factors contributing to this association. **Methods** Data were drawn from the Longitudinal Study of Australian Children at child ages 4-17 years. Clinical ADHD symptoms (e.g. score > 8) were measured using the hyperactivity scale from the Strengths and Difficulties Questionnaire (SDQ). Internalising or externalising problems were classified as children with scores ≥ 5 on the Emotional Problems and scores ≥ 4 on the Conduct Problems scale on the SDQ, respectively. Children's HRQoL was measured using the Pediatric Quality of Life Inventory (PedsQL). Linear mixed models were used, adjusting for child and family factors. **Results** Compared to those with no ADHD symptoms, children with ADHD symptoms had significantly lower HRQoL across all domains from 4-17 years (mean difference=7.65, 95%CI 6.1 to 9.2). Internalising and externalising problems slightly attenuated the association between ADHD symptoms and children's HRQoL (mean difference =4.93, 95%CI 3.4 to 6.4). Being a female, or having autism, or other medical conditions, or taking ADHD/ADD medication or caregiver having mental health problems was associated with poorer HRQoL while having 2 or more siblings was associated with better HRQoL. **Conclusion** ADHD clinical symptoms are associated with poorer children's HRQoL from 4-17 years. Given that co-occurring medical conditions and poor caregiver mental health are associated with poorer child HRQoL, ADHD treatment needs to identify and address co-occurring conditions and parental mental health. 2

Ind-956 Gender Identity and Mental Health Inequalities 2001-2022: Population-Level Evidence From an Australian Cohort Study

PRESENTER: **Karinna Saxby**
AUTHORS: Zoe Aitken, Ricki Spencer, Dennis Petrie, Ian Down, Sara Hutchinson Tovar, Glenda Bishop

Background: Existing evidence indicates that trans, nonbinary, and gender diverse (TGD) people experience poorer mental health relative to cisgender populations. However, a lack of information on gender diversity in longitudinal surveys has hindered efforts to understand how TGD mental health inequalities are changing over time. With newly available information on gender diversity within Australia's largest national longitudinal study, we aimed to provide the first national estimates of temporal trends in TGD inequalities in mental health.

Methods: We used the 2001-2022 Household, Income and Labour Dynamics in Australia (HILDA) survey, a large, national probability sample of Australian adults. Using questions about sex at birth and gender identity, asked in the 2022 wave, we compared temporal trends in mental health among TGD and cisgender respondents. Mental health was measured using the five-item Mental Health Inventory (MHI). Adjusting for age, income, and other observable characteristics, we calculated annual population-weighted estimates of mean MHI scores for TGD and cisgender respondents.

Findings: Across the 22-year period, TGD respondents consistently reported poorer mental health than cisgender respondents. Prior to 2010, differences in MHI scores were more variable but TGD MHI scores were generally lower than cisgender respondents. From 2010 onwards, there was a trend of widening inequalities, with TGD-cisgender MHI inequalities ranging from -5.0 (95%CI -0.6;-9.4) to -12.0 (95%CI -15.1;-9.0), indicating clinically relevant differences in mental health.

Interpretation: TGD-cisgender mental health inequalities are increasing in Australia, with inequalities more apparent between 2010 and 2022. Policy action and greater protections for gender diverse Australians are urgently needed.

Ind-1072 Health-related Quality of Life, Service Utilisation and Costs for Anxiety Disorders in Children and Young People: Systematic Review and Meta-analysis

PRESENTER: **Sithara Wanni Arachchige Dona**, Deakin University, Institute of Health Transformation, Deakin Health Economics
AUTHORS: Ha N.D Le, Ms. Lisa Gold, Anh Ho, Kaitlyn Mckenna, Shalika Bohingamu Mudiyanselage, Monique Seymour

Background: Anxiety disorders are common mental health issues in children and young people (CYP) and place a significant health, societal and economic burden on CYP, their families and society. The literature on the overall economic burden relating to health-related quality of life (HRQoL), service use, and costs is limited for anxiety disorders among CYP and caregivers. This study synthesises the literature on how anxiety disorders are associated with these outcomes in CYP (0-24 years) and caregivers.

Method: This systematic review was conducted following the PRISMA 2020 and the protocol was registered in PROSPERO. A systematic search was undertaken across six databases between January, 2013 (based on the release year of the Diagnostic and Statistical Manual of Mental Disorders-fifth version) and February 2024: MEDLINE, PsycINFO, CINAHL, EconLit, Global Health and Embase. Grey literature was searched on Advanced Google and Trove database. Four reviewers independently conducted the title and abstract screening, full-text screening and quality assessment. Any discrepancies were resolved upon discussion among the review team. An adapted version of the Effective Public Health Practice Project tool was utilised to assess the quality of the included studies. Narrative synthesis was provided, and meta-analysis was conducted for studies reporting the same outcome measures for social anxiety and comorbid anxiety.

Results: A total of 38,616 studies were identified, with 24 studies included in the review: thirteen studies (54%) exclusively reported HRQoL in

CYP with anxiety disorders (seven on anxiety as the primary condition, and six on comorbid anxiety); one (4%) exclusively looked at caregivers' HRQoL; five (21%) studies on service use; and one (4%) study on cost. one (4%) looked at both caregivers and CYP's HRQoL; one (4%) study on service use and CYP's HRQoL; two (8%) studies on both service use and costs. Most studies were cross-sectional (n=19), with only four being longitudinal studies. The follow-up period for four longitudinal studies varied: 1.5, 2 and 6 years for HRQoL, and 4 years for service use. Studies found poorer HRQoL in CYP with anxiety disorders compared to those without anxiety or healthy controls. Meta-analysis found a medium pooled effect size for social anxiety on psychosocial (Hedges' g = -0.74, 95% CI -3.62, 2.14) and social relations (Hedges' g = -0.57, 95% CI -0.75, -0.39) domains of HRQoL. Comorbid anxiety in those with other health conditions was also associated with poorer HRQoL than those without comorbid anxiety, with a large pooled effect size (Hedges' g = -1.07, 95% CI -1.34, -0.79) for overall HRQoL and emotional functioning (Hedges' g = -1.37, 95% CI -1.65, -1.09). While there is limited research, available studies show that childhood anxiety disorders were also associated with increased health service use and costs along with reduced caregivers' HRQoL.

Conclusion: Findings show that anxiety disorders in CYP were associated with lower HRQoL for both them and their caregivers, increased health service use and costs. This review highlights the need for future research to examine the burden on caregivers and long-term impact on CYP's in terms of HRQoL, service use and costs.

Ind-1338 Dose-Response Relationship Between Homophobic Discrimination and Mental-Health

PRESENTER: **Vincent Leo Leroy, PhD student**, Aix-Marseille University
AUTHORS: Luis Sagaon Teyssier, Bruno Spire, Annie Velter, Maxime Luiggi

Background: Experienced homophobia has been identified as a negative correlate of health outcomes for sexual and gender minorities, especially mental health among gay men, bisexual men and other men having sex with men (GBMSM). Existing literature often uses binary measures which result in a waste of information in the study of the link between homophobic-related discrimination and mental health. This relationship cannot be studied without accounting for the cumulative effect of multiple homophobic experiences and the different social environments where they occur. The present study aims to estimate the dose-response effect of homophobia experienced by French GBMSM over mental health indicators such as anxiety, psychological distress, suicidal ideations and suicide attempts. Methods: We used data from Rapport au sexe survey (ERAS) conducted among GBMSM in France over four repeated cross-sectional waves between 2017 and 2023. A measure of cumulative homophobic experience was constructed, including verbal and physical abuse in multiple social environments such as the workplace, educational institutions, public spaces, neighborhoods, and family. We studied mental-health using four distinct outcomes: 1) Anxiety (GAD-7); 2) Psychological distress (K-5); 3) Suicidal ideations; 4) Suicide attempts. We controlled with well-established socioeconomic and health variables at individual level. We controlled the spatial heterogeneity in France (at the county-level) using the following measures: a homophobic hate crime index, a political index and an index of living standards. A logistic multilevel mixed-effects model was used to estimate, separately, the dose-response effect of homophobia over the 4 outcomes. We computed marginal effects to assess the impact of cumulative homophobic experiences on predicted probabilities (PP) of moderate/severe anxiety, psychological distress, suicidal ideations and suicide attempts. Results: Final sample comprised 81,263 participants. Our results highlight strong evidence of a dose-response relationship between cumulative homophobic experiences and each health outcome across different time periods (2017/2019 - 2021/2023). The more GBMSM experience multiple homophobic prejudices within different environment, the more their odds to be at risk of moderate/severe anxiety (aOR = 1.8 to 7.1, p-value<0.001), psychological distress (aOR = 1.5 to 6.4, p-value<0.001), suicidal ideations (aOR = 1.6 to 4.8, p-value<0.001) and suicide attempts (aOR = 1.5 to 12.5, p-value<0.001) increase. GBMSM who were confronted to five or six homophobic contexts within the past 12 months were at a significantly elevated risk for moderate/severe anxiety (PP = 62%), psychological distress (PP=73%), suicidal ideation (PP = 40%) and for suicide attempts (PP = 10%) during the year preceding the surveys. Conclusion: The mental-health of GBMSM who experience cumulative homophobic prejudices within different social environments tend to be severely compromised. Despite recent improvement in terms of social and legal recognition in most western countries in terms of inclusion of LGBTI communities, homophobia remains a significantly prevalent and harmful phenomenon in France. This highlights the need for: i) the implementation of LGBT+ support centers that include psychological support across the entire country, especially where the frequency of discrimination is high; ii) the development of public policies that aim to end homophobia and defend LGBTI populations rights.

Ind-2030 Psychosocial Stressors and Resilience Patterns in a Sample of Low-Income South Africans

PRESENTER: **Patrizio Piraino**
AUTHORS: Catherine Maloney, Sylvia Blom, Safa Rahman, Laura Miller-Graff

Introduction: South Africans face exposure to direct and structural violence, which have been consistently associated with psychological distress. To understand how resilience influences this relationship, the current study examines the association of multidimensional resilience and violence exposure with psychopathology using a sample of low-income South African adults. **Methods:** Participants (N=404) completed measures on neighborhood crime (i.e., direct violence), stress about neighborhood characteristics (i.e., structural violence), the Patient Health Questionnaire-8, General Anxiety Disorder-7, and Adult Resilience Measure-Revised (scored as 3-factors – personal, family, friends/contextual assets). A subsample of participants (n=251) also responded to a free-response item asking about the primary way they cope with stress. **Results:** A multiple regression model showed greater exposure to direct violence was associated with higher depression (β=.19, p<.001) and anxiety (β=.28, p<.001), while higher personal (β=-.10, p=.036) and family (β=-.12, p=.0004) assets were associated with lower depression. A moderation model, coupled with sensitivity analyses, showed that higher personal assets protected against the impact of direct violence on depression (β=-.30, p<.001) and anxiety (β=-.21, p=.015). Additionally, qualitative data revealed four coping categories: Adaptive-Cognitive; Adaptive-Relational; Adaptive-Behavioral; and Maladaptive. **Conclusions:** The empirical analysis suggests that exposure to diverse forms of violence serves as a significant stressor, but personal and relational assets may be particularly promotive of mental health. These findings underscore the importance of implementing community initiatives to address environmental stressors and of designing targeted interventions that bolster resilience in peri-urban South Africa, ultimately promoting overall well-being.

abs-os55 ADHD and Educational Outcomes: Results from an Australian Longitudinal Population-Based Study

PRESENTER: **Ha Thu Bui**
AUTHORS: Ms. Lisa Gold, Ha N.D Le, Monique Seymour

Background: Attention Deficit Hyperactivity Disorder (ADHD) is one of the most prevalent neurodevelopmental conditions in children. The current literature has linked childhood ADHD with poorer academic outcomes during primary school; however, evidence on long-term outcomes of childhood ADHD until late adolescence and adulthood is still limited. **Objective:** This study investigated the association between childhood ADHD and long-term academic performance in a large community cohort of Australian children. **Methods:** Data was from the Longitudinal Study of Australian Children (LSAC; wave 1-9C2; N=4983 for Kindergarten cohort; N=5107 for Birth cohort) which was linked to national education data (NAPLAN scores at Years 3, 5, 7 and 9; tertiary study outcomes). Educational outcomes (highest level of education and qualification) were compared between young adults with and without ADHD in wave 9C2 (ages 17-22). The impacts of childhood ADHD on educational outcomes were estimated using a mixed effects model allowing random effects for study child and suburb. NAPLAN scores were assumed to be a function of childhood ADHD condition and other covariates, including child characteristics (sex, indigenous status, language other than English at home, age, age squared, level of remoteness, the Strength and Difficulty Questionnaire (SDQ) prosociality scale, SDQ peer problems scale, externalising problems), family characteristics (socioeconomic position, number of siblings, number of parents in the home, global parenting self-efficacy rating), school characteristics (school type) and NAPLAN year (3,5,7,9). All data was weighted using LSAC longitudinal weight. The primary analysis was based on parent-reported ADHD; analysis using ADHD symptoms identified by the SDQ screening tool was also conducted for robustness check. **Results:** - Overall, young people with ADHD had lower levels of education and qualification at ages 17-22. - The proportion of young people who had completed year 12 or equivalent was significantly lower for those with ADHD (50%) than those who do not have ADHD (59%). - Among those that were currently enrolled in study, a higher proportion of young people with ADHD attended Technical or Further Educational Institution (30%) than those without ADHD (11%), whereas a higher proportion of young people without ADHD attended University or other Tertiary Institutions (38%) than those with ADHD (17%). - The mixed model estimation showed that childhood ADHD was associated with significantly reduced NAPLAN scores in all scales: writing scores by 43.2 points and grammar, numeracy, reading and spelling scores by 37.0, 33.9, 33.3, 38.9 points, respectively. **Conclusion:** The results of this study provide evidence on the adverse associations of childhood ADHD and long-term educational outcomes in late adolescence and early adulthood. The findings highlight a need for teachers, clinicians and policymakers to explore relevant effective interventions and for policy to support children and young people with ADHD at school to improve academic outcomes.

Pharmaceutical R&D and Pharmaceutical Shortages

MODERATOR: **Yoko Ibuka**,

Ind-745 Factors Associated with Pharmaceutical Shortages in the UK

PRESENTER: **Ana Correa Ossa**
AUTHORS: Rodolfo Catena, Kiara Govender, Ahmed Elnady, Priyanka Thakur, Havovi Khareghat, Fausto Catena, Vanni Agnoletti

Background and research aim In 2023, shortages of medicines in the UK, Europe, and the United States reached historical peaks (McCarey et al., 2022; Johnston & Borrett, 2024). Hospitals across the world are struggling to maintain consistent medical supplies and are holding weekly emergency meetings to address ongoing shortage of pharmaceuticals (McPhillips, 2023; Miljković et al., 2024). A recent UK government report concluded that more research needs to be undertaken to understand causes of medicines shortages in the UK and globally (Duddy, 2024). The characteristics of the drugs themselves, such as the price, ingredients, manufacturer, and health condition treated, may be associated with the likelihood of shortages. Low medicine prices may make certain pharmaceuticals economically unviable for manufacturers (Duddy, 2024), while lack of alternatives could lead to a reduction in the supply to incentivise price concessions. Additionally, pressures such as increased demand of certain ingredients, or rise in the prevalence of specific health conditions, may work together to reduce the availability of a drug. **Methods** Using data from the MIMS Shortage Tracker and the Business Service Authority Prescriptions Cost Analysis (2020-2024), we explore the potential characteristics that could lead to shortages. We use a logistic regression model where the outcome variable is the probability of a drug being unavailable. Explanatory variables include price, manufacturer, health condition, and year. We validate our findings with qualitative evidence from a workshop with healthcare professionals, pharmaceutical industry representatives, and policy makers in the EU. **Results** Lower prices are associated with a higher probability of a drug being in shortage, even adjusting for manufacturer, condition, and year. Qualitative findings point to a number of systemic causes of shortages: limited diversification of manufacturers, fragmented procurement processes and prioritising price over reliability, and a lack of timely data on prescribing trends or inventories. Regulatory rigidity, including limited options for substitution or stock sharing, further constrains responsiveness.**Discussion** While our UK data shows that low price is a significant predictor of shortages, our findings from the stakeholder workshop in the EU suggest that it is part of a broader set of systemic issues such as lack of resilience in procurement systems, insufficient local capacity, and poor coordination across the supply chain. Future solutions include reforming procurement criteria to reward reliability, introducing flexibility in licensing and substitution rules, and strengthening communication between stakeholders. Expanding local manufacturing capacity, developing stock buffers for critical medicines, and improving public trust to avoid panic stockpiling were also recommended. The EU's recent policy efforts with the Critical Medicines Act, point to a shift towards strategic governance, but implementation gaps remain. Future research should explore additional predictors of shortages, including discrepancies between tariff and reimbursement prices; regional differences in procurement practices; and the role of rapid shifts in prescribing (e.g. semaglutide). A priority is the development and evaluation of real-time data-sharing platforms for tracking medicine stocks across the supply chain, balancing transparency with security concerns.

Ind-984 The Impact of Drug Shortages on Patients' Financial Costs: Evidence from Japan

PRESENTER: **Yoko Ibuka**, Keio University
AUTHOR: Haruo Kakehi

Background. Drug shortages are a global issue, but research on their impact is limited due to challenge of identifying when and whom they affect. In Japan, a primary cause of drug shortages is government-imposed suspension of production resulting from misconduct among generic prescription drug manufacturers, leading to reduced availability of generic prescription drugs. Since generic drugs provide equivalent efficacy at lower costs compared to brand-name drugs, their unavailability forces patients to resort to more expensive alternatives. This raises concerns about increased financial burdens, particularly for patients with chronic diseases who rely on regular and stable medication.

Aim. This study examined how shortages of generic prescription drugs, resulting from manufacturers' misconduct and subsequent government-mandated production suspensions, impacted patients' financial burdens among patients prescribed medication for three chronic conditions.

Methods. To clarify when each shortage begins to impact individual patients, we linked patient-level drug claims data with production suspension dates of two major generic drug manufacturers. To examine the impact of manufacturing suspensions on patient drug costs, we employed the difference-in-differences (DID) estimation using data between January 2020 and December 2023. We focused on three drug categories: hypertension, dyslipidemia, and psychotropic medications, each comprising both brand-name and generic drugs. We assessed how the out-of-pocket costs for patients using generic drugs from the suspended manufacturers had changed by these suspensions. In the DID estimation, we compared patients who heavily relied on drugs from the suspended manufacturers before the suspension with those who used alternative drugs within the same drug category.

Results. The proportion of prescriptions discontinued due to the suspensions was 8.4%, 10.9%, and 10.1% for hypertension, dyslipidemia, and psychotropic drugs, respectively. Out-of-pocket expenses increased across all three drug groups; for example, for psychotropic drugs, patients' out-of-pocket expenses increased by 1.4% to 9.9%, depending on the suspensions and model specifications. This increase was accompanied by a 1 to 3 percentage point decrease in the share of generic drugs, suggesting that the higher costs were partially driven by the substitution of affordable generics with more expensive brand-name alternatives.

Conclusions. Drug shortages could increase patients' financial costs and potentially place a greater fiscal burden on public health insurance. The financial impact of drug shortages should be acknowledged and addressed as part of the broader issues associated with drug shortages.

Ind-1102 The Impact of National Volume-based Procurement Policy on The Pharmaceutical Industry in China: A Mixed Methods Study

PRESENTER: **Yan Song**

Objective: Since 2019, the Chinese central government has taken significant steps to centralize national purchasing power and has implemented a pooled procurement system. The primary objectives of the national volume-based procurement(NVBP) were to reduce drug prices, improve access to affordable medications, and enhance the overall functioning of the China’s pharmaceutical industry. While most research focused on the achievement of the policy goal of improving the accessibility and affordability of common drugs, few studies have investigated its influence on the operational performance of pharmaceutical firms. The objective of this study was to explore the impact of the NVBP policy on China’s pharmaceutical industry. **Methods:** A mixed methods study was conducted. The quantitative phase involved an empirical analysis designed to assess changes in business performance before and after policy implementation among publicly listed pharmaceutical manufacturing companies from 2019 to 2023. The qualitative phase included interviews with key stakeholders such as senior manager from pharmaceutical firms in order to gain insights into their perceptions of the NVBP policy. **Results:** The NVBP policy significantly reduced operating profit margins($p<0.01$), although it enhanced short-term total assets and operating revenue. The policy also stimulated substantial growth in R&D expenditures($p<0.01$). Interview results revealed that most enterprises perceived intensified price competition dut ot NVBP, resulting in reduced profits. As countermeasures, these enterprises have adopted various strategies including strengthening marketing activities, increasing R&D investment, and reducing production costs. **Conclusion:** The NVBP policy had a negative impact on the operational performance of China’s pharmaceutical industry in the short term. However, the observed increase in R&D investment suggests the potential for positive long-term outcomes. This heightened focus on innovation may contribute to improving the overall industry ecosystem.

.

Ind-457 Bridging Gaps in Medical Innovation: from Development to Market Access and Reimbursement in Thailand

PRESENTER: **Mr. Puwadol Chawengkul**
AUTHORS: Siriyada Kitbamrung, Yot Teerawattananon, Chee Ern Har, Yi Wang, Teerawat Wiwatpanit

Background:

The Thai Innovation List, established in 2015, is an initiative to promote local innovations by incentivizing innovators to develop high-value products through public procurement. This initiative primarily benefits medical innovations, as the majority of registered products under the Thai Innovation List are medical products. However, these medical products still struggle to gain market traction and healthcare system adoption. Despite regulations and incentives, demand for medical products from the Innovation List remains low. Similar initiatives, such as South Korea’s Public Procurement Service, the United Kingdom’s Public-Private-Partnership Compact, and Singapore's Regulatory Sandbox, aim to promote public procurement of high-potential medical innovations, but neither these initiatives nor the Thai Innovation List cover the full value chain of innovation development—from ideation to commercialization and implementation. As medical innovation development

requires extensive support from all stakeholders in the innovation ecosystem, including innovators, funders, and policymakers, understanding the current landscape of medical innovation is necessary to identify factors that contribute to successful development and implementation in the healthcare market.

Objective:

This study aims to map the medical innovation landscape in Thailand to identify key factors for developing high-potential and high-demand medical innovations and products and develop policy recommendations to promote an efficient medical innovation ecosystem in Thailand.

Methods:

The study analyzed 393 medical products registered under the Thai Innovation List as of August 30, 2024. Data on product characteristics and intellectual property rights were collected from public databases and interviews. Descriptive statistics examined relationships among product characteristics, research and development processes, collaborations, intellectual property, commercialization, and funding sources. Stakeholder input was incorporated to enhance and validate findings.

Results:

Pharmaceutical products account for the majority of registered innovations (n=309), followed by medical consumables (n=34) and devices (n=30). The registered innovations were developed by the private sector using their own funding and without external collaborators or technology transfer. However, there was slightly more involvement of the public sector in the development of medical consumables and devices (MDs). Interestingly, MDs had a higher proportion of patents and petty patents (27%) compared to pharmaceutical products (4%), which were mainly follow-up medicines with only trademarks (67%), indicating the stronger innovativeness of local MDs. In contrast, over 52% of registered pharmaceuticals were already included in public health benefit schemes, while only 27% of MDs were covered by public insurance programs. According to stakeholder consultation, this result aligns with the fact that most medical product manufacturers and developers are small and medium enterprises that cannot absorb the high costs of starting materials and scaling up production of MDs, leading to the delegation of innovation costs to patients and payers and reducing their feasibility for public reimbursement schemes.

Conclusion:

The complexity of the healthcare sector, with its many stakeholders and agendas, can lead to a misalignment between health innovation development, market access, and healthcare coverage policies.

To address these challenges and promote efficient medical innovation development and implementation, there is a need to reform the health innovation ecosystem to bridge the disconnection between innovation development and the public reimbursement of the innovation.

Ind-1021 Identification of Factors Associated With High-Value Health Innovations in Thailand

PRESENTER: **Chee Ern Har**
AUTHORS: Mr. Puwadol Chawengkul, Siriyada Kitbamrung, Narisa Mantharngkul, Yot Teerawattananon, Teerawat Wiwatpanit, Yi Wang

Background and Objective

Health innovation is essential to address rising healthcare demand and control costs, but moving from research to commercialisation remains challenging. The Profiting from Innovation (PFI) framework suggests that success depends not only on technological innovation but also on appropriability mechanisms, complementary assets, and alignment with dominant designs. In Thailand, the Innovation List leverages public procurement to promote local innovations, yet empirical evidence on what drives their success remains limited. This study aims to identify factors associated with reimbursement and market success of medical products on the Thai Innovation List.

Methods

Medical products listed as of 30 August 2024 were analysed. Data were sourced from public databases and registrant questionnaires and classified according to the PFI framework. Logistic and quasi-binomial regression models assessed associations with reimbursement by public health insurance schemes and proxy market share. Findings were validated through stakeholder consultations.

Results

Reimbursement analysis included 383 products using public data and 142 with questionnaire inputs, with 109 products analysed for market share. Product classification, disease focus, and intended use, and public sector involvement were important mediators of reimbursement and market success. Technology transfer supported reimbursement, while external funding and research collaboration showed negative associations. Clinical trials and reimbursement status strongly predicted market performance, highlighting the importance of complementary assets.

Conclusion

In Thailand, innovation success is shaped more by alignment with health system priorities and access to complementary assets than by appropriability mechanisms. Policy reforms should enhance reimbursement processes, strengthen translational partnerships, and expand support for emerging technologies.

Climatic Events and Natural Disasters

MODERATOR: **David Johnston**,

Ind-47 Disaster Exposure and Informal Caregiving Burdens: Lessons from the Great East Japan Earthquake

PRESENTER: **Takumi Toyono**
AUTHOR: Haruko Noguchi

Background

Natural disasters significantly disrupt economies and societies, often with pronounced adverse effect on health outcomes, particularly among older adults. However, the impact of disasters on informal caregivers who assist these vulnerable individuals remains insufficiently explored. Existing research primarily employs qualitative methods such as interviews, which may limit internal validity. Additionally, prior studies often fail to differentiate between individuals who were already providing informal care before a disaster and those who assumed caregiving responsibilities afterword. This distinction is critical, as both heightened disaster risks and rapid population aging are likely to increase the number of individuals taking on caregiving roles post-disaster. To fill these gaps, this study quantitatively examines how natural disaster exposure influences informal caregiving burdens, focusing on caregiving provision and caregivers' health outcomes while accounting for this caregiver classification.

Methods

We employ a difference-in-differences approach, leveraging regional variations in exposure to the Great East Japan Earthquake – the fourth largest earthquake in the world – which heavily impacted regions with aging populations. Our analysis integrates multiple nationally representative administrative datasets from Japan, including the Longitudinal Survey of Middled-aged and Elderly Persons, conducted by the Ministry of Health, Labour and Welfare. This survey tracks 34,240 individuals aged 50-59 nationwide in the baseline wave in the year of 2005. We utilize data spanning from 2008 to 2017 and classify caregivers into two categories: actual caregivers (those already providing care before the disaster) and potential caregivers (those with the potential to take on caregiving roles).

Results

Our findings indicate a rise in informal caregiving in disaster-affected regions for both actual and potential caregivers. Specifically, caregiving time increased by 8.5 hours per week at the intensive margin, while the probability of providing informal care rose by 2.3% points at the extensive margin. Mental health deteriorated exclusively among potential caregivers, whereas self-rated health and physical health remained unchanged. These effects were particularly pronounced among female or less-educated caregivers. Two mechanisms likely contributed to these outcomes: a decline in labor force participation among potential caregivers, increasing their caregiving involvement, and reduced availability of formal at-home care, such as home help service, which are often substitutes for informal care.

Discussion and Conclusion

Our findings suggest that the societal costs of natural disasters may be underestimated, as informal caregivers – not just older adults – are significantly affected. Potential caregivers, in particular, bear new caregiving responsibilities following disaster exposure, alongside the existing burdens on actual caregivers. This study offers two key policy implications. First, expanding resources for formal at-home care services is crucial to alleviate the spillover effects on informal caregivers, especially potential caregivers. Second, targeted interventions, such as training programs for disaster preparedness, are essential to support vulnerable caregiver groups, including women and less-educated individuals.

Ind-1650 Health Under Crisis: The Effects of Economic Unexpected Crisis on Newborn's Health

PRESENTER: **Dr. Bernard Moscoso, PhD**, ESPOL - Escuela Superior Politécnica del Litoral

Economic crisis has been documented to damage fetus health conditions including birthweight, preterm incidence and cognitive capacity. The existing literature has explained this cause through two mechanisms such as maternal stress and malnutrition, depending on the nature of the crisis and its duration. However, it is unclear how these mechanisms interact under two different and unexpected economic shocks. The objective of this paper is to examine the effects of economic crisis on newborns' health in Ecuador. For this, we exploit the 2016 earthquake and the COVID-19 pandemic in 2020. The 7.8 magnitude earthquake that struck Ecuador on April 16, 2016, causing significant damage in the north-west region, generating 3 billion dollars losses (3% of the GDP). Meanwhile, the economic impact of the pandemic between March and May 2020 represented an estimated economic contraction of 6.4 billion dollars (6% of the GDP). These exogenous events provide an opportunity to study the effects of these crises on neonatal health and allows to disentangle the mechanisms of impact. We gather and combine data from small and medium-sized enterprises' invoices from the Ecuadorian Internal Revenue Service, and the adjusted per capita invoices using population data. This invoicing, which reflects better the economic activity variable for households, was seasonally adjusted using the X-13ARIMA-SEATS method with the SEASONAL package in R, and subsequently decomposed into trend and cycle components applying the Hodrick-Prescott filter ($\lambda = 14400$), suitable for monthly series. The extracted economic cycle was used as an independent variable to identify periods of economic contraction in each city. The analysis integrated data from the Live Birth Registry, which includes detailed information by city and month of gestation. By linking these databases, the corresponding economic cycle was assigned to each gestational trimester of each newborn. To estimate this effect, we follow a DID design with newborns' health at birth such as birthweight, gestation weeks, and apgar score,

probability of low-birthweight, and preterm birth, as the outcome variables. The main regressors are two indicators capturing the exposure to economic shocks, and exposure during gestation trimester. We include child and mother characteristics such as single birth, sex, mother's age, education, prenatal controls, ethnicity, place of birth, number of children, among others. The estimation includes city and month of the year fixed effects. We assume the error term to be iid, and we cluster the standard errors at the city level. The preliminary findings reveal that the exposure to the 2016 earthquake during the first trimester of gestation causes a birthweight deficit of 180 grams and reduces the gestation length in 2 to 3 weeks. In the case of the COVID-19 crisis, exposure during first and third trimester of gestation caused birthweight deficit of 280 to 350 grams. These results contribute to the literature on how different economic crises affect neonatal health through different mechanisms and underscore the relevance of considering these impacts in the design of public health and economic policies to safeguard health conditions.

Measuring Multidimensional Wellbeing across the lifespan

MODERATOR: **Stephanie Schurer**,

Ind-1588 Psychometric Insights into the EQ-5D-5L and EQ-HWB in a Sample of Older Australians

PRESENTER: **Akanksha Akanksha**

AUTHORS: Deborah Street, Rosalie Viney, Brendan Mulhern

BACKGROUND The demand for care services for older adults is expected to rise in the coming years because of rapidly ageing population. Simultaneously, care providers are facing challenges from reforms, budget constraints, and escalating government regulations. Consequently, the significance of accountability in care services grows, emphasizing the necessity to demonstrate the value of these services. One way to determine this value is by evaluating important outcomes like quality of life (QoL) for older adults. QoL is a commonly used metric in the evaluation of multisector public policy, including health, social, community and environmental policy actions. Several QoL instruments are available for use, including those in the EuroQol suite (EQ-5D-5L and EQ-HWB). The aim of this study is to understand the psychometric properties of the EQ-5D- 5L and EQ-HWB in a sample of older Australians in comparison to other key instruments that are widely used in the field (including the Quality of Life- Aged Care Consumer (QOL-ACC) which is an aged care sector specific instrument, and Adult Social Care Outcomes Toolkit (ASCOT) that measures social care related QoL).

METHODS Dataset was derived from a 2023 online survey in Australia that collected self-reported health conditions, and QoL data. A subset sample of 453 older Australians aged 65+ who completed the EQ-5D-5L, EQ-HWB, QOL-ACC and ASCOT questionnaires were included in the analysis. Response distributions, including floor and ceiling effects, and utility values were examined. Convergent validity was assessed using Spearman's correlation at both the item and value set level. Known group validity was examined by comparing known groups (presence of chronic conidiations, VAS score ≤80) using one-way ANOVA and Cohen's D for effect size (ES). Test-retest reliability was assessed for respondent who did not indicate any change in their health, social support status or QoL in general (n=201) using the intraclass correlation coefficient (ICC).

RESULTS Mean utility values for EQ-5D-5L, EQ-HWB, ASCOT and QOL-ACC were 0.88, 0.82, 0.88, and

0.81 respectively. The best health state as described by ASCOT had zero respondents, EQ-HWB had 40 (8.8%) respondents, QOL-ACC had 64 (14.1%) respondents, and some indication of a ceiling effect was observed with EQ-5D-5L where 83 (18.3%) respondents reported being in the best health state described by the instrument. The highest correlation was between EQ-5D-5L and EQ-HWB utility values (ρ=0.72). At the dimension level, the highest correlation was between the pain and anxiety/depression items of EQ-5D-5L and EQ-HWB (ρ=0.72 to 0.77). Statistically significant differences in mean scores were observed among known groups, with effect sizes in the moderate to large range across all four instruments. ICC for EQ-5D-5L, EQ-HWB and ASCOT was 0.60 (CI 0.50;0.68), 0.65 (CI 0.57; 0.73), and 0.45 (CI 0.34; 0.56) respectively indicating moderate to poor reliability.

CONCLUSION The findings offer insights into how EuroQol instruments perform among elderly individuals, a focal point outlined in the strategic plan. The contrast between EQ-5D-5L and EQ-HWB indicates that these instruments offer distinct advantages when gauging the QoL in older demographics. Expanding the sample size would enhance the psychometric comparison of these instruments

Ind-719 The Value of Neighborhood Greenspace for Children Using the Life Satisfaction Approach

PRESENTER: **Ellen Hannes**

AUTHORS: Stephan Bruns, Michelle Plusquin, Robert Malina

Across the globe, urbanization is increasing, intensifying the pressure on greenspaces, which affects all its users, including children. This is potentially concerning since exposure to nature enhances children's health and well-being. With regard to well-being, while robust evidence is present on the positive relationship between exposure to nature and well-being of children, currently no monetary valuation of the well-being benefits exists, making them more difficult to appropriately include in public decision-making regarding greenspace development. This study, for the first time, puts a monetary value on neighborhood greenspace exposure for children using the life satisfaction approach (LSA). This approach has been employed for the monetary valuation of environmental goods and issues but has not been extended yet to value the well-being of children. The LSA quantifies the influence of neighborhood greenspace on children's life satisfaction (LS) and compares it to the impact of other determinants of their LS that can be valued in monetary terms. In that way, the LSA calculates the amount of money to offset a

change in neighborhood greenspace to keep the child at the same level of LS. As a result, the LSA does not require children or their parents to assign monetary values themselves. Data were gathered from 475 parent-child pairs in 29 different primary schools in Flanders (age range of children 10-12). The monetary value will be determined based on the tradeoff between the impact of the exposure of neighborhood greenspace on children's LS and the impact of household income on children's LS. The results of the study reveal the monetary value of neighborhood greenspace in terms of improvements in children's self-reported LS. Preliminary results show that there is a positive association between greenspace in a 100m buffer around children's home address and children's LS, as well as a positive association between household income and their LS. Moreover, the willingness to pay for greenspace diminishes when greenspace is located at greater distances or when a substantial amount of greenspace is already available.

Ind-1557 Exploring Health Spillover Effects Within The Context of Dementia Using EQ-HWB

PRESENTER: **Valeriia Sokolova**
AUTHORS: Jan Faller, Thao Thai, Lidia Engel

Abstract

Objectives

Providing care for a person with dementia can impose a significant burden on family members and other informal caregivers. While the costs of caregiving are sometimes included in economic evaluations, the benefits and disutility to informal caregivers, referred to as "health spillovers", are usually omitted. The objective of this study is to estimate the relative health spillover effects of dementia caregiving on informal caregivers from Australia using the short form of the EQ Health and Wellbeing (EQ-HWB-S) questionnaire.

Methods

A cross-sectional survey was conducted involving informal caregivers of people with dementia residing in Australia. Informal caregivers completed the EQ-HWB (25-item) and proxy reported the health-related quality-of-life (HRQoL) of the person with dementia using the EQ-HWB-S (9-item). To estimate the relative spillover, multiple linear regression was used to model caregiver's HRQoL, using the EQ-HWB-S, as a function of the person with dementia HRQoL (based on the EQ-HWB-S), adjusting for their individual and demographic characteristics.

Results

In total, 202 informal caregivers completed the survey. The average age of caregivers was 60.4 (SD = 13.7), with 63.2% being female. The univariate analysis revealed a positive relative spillover effect coefficient of 0.23 (p<0.001, R-squared=0.10), demonstrating a significant positive association between caregiver's and person's with dementia HRQoL using the EQ-HWB-S. This relationship remained significant when adjusting for other characteristics in the multivariate regression model (p<0.001, adj R-squared=0.30). Multivariate regression model showed that informal caregivers living together with the person with dementia had substantially decreased HRQoL estimated with EQ-HWB-s compared to informal caregivers of people with dementia who lived alone or in a care home (p=0.03). Caregivers with present chronic conditions had statistically significantly reduced EQ-HWB-S estimates (p<0.001). Age and gender of the person with dementia did not have a substantial impact on the caregiver's EQ-HWB-S estimates. However, age of caregivers impacted their HRQoL estimates (p=0.03).

Conclusion

Providing informal care for a person with dementia is associated with substantial health spillovers. It is essential to include health effects on informal caregivers into economic evaluations to account for the burden of dementia posed beyond the affected individual.

Ind-2244 Wellbeing in Latin America: Who Are the Most Vulnerable in Argentina, Chile, Ecuador and Peru?

PRESENTER: **María-José Mendoza-Jiménez**, Erasmus University Rotterdam
AUTHOR: Job van Exel

Background and aim: Low wellbeing today is linked to poorer health outcomes in the future. Increasingly, wellbeing is recognized as the key outcome for policies not only in healthcare, but also in sectors like education, environmental management, and criminal justice. For wellbeing measures to be effective in policy design, evaluation and monitoring, analysts must use measures that have been validated within the specific context where they are applied. However, the majority of wellbeing measures have been developed and validated in higher-income settings, limiting their relevance elsewhere. The 10-item Wellbeing Instrument (WiX) is a recently introduced tool designed to capture all relevant benefits of healthcare and other policy interventions. The Spanish version of the WiX is the first validated multidimensional wellbeing measure for the general adult population in the Latin American context. This study aims to apply the WiX to identify and characterize low wellbeing groups in Argentina, Chile, Ecuador, and Peru. Methods: Data from an online survey, representative of the adult population in terms of age and gender, was collected in these four countries. Subjective wellbeing was measured using the validated Spanish version of the WiX, with aggregate scores ranging from 10 to 50. Low wellbeing was defined as WiX scores at or below the 25th percentile of country-specific distributions for overall wellbeing, and reporting being (very) dissatisfied on a WiX item for dimensions of wellbeing. We employed multivariate logistic regressions to examine factors predicting low overall wellbeing and dissatisfaction across the ten dimensions of wellbeing included in the WiX. Associations were adjusted for socio-demographics, health status, and perceptions of safety in daily life and political situation. Results: A total of 2,301 respondents participated across the four countries: Argentina (N=718), Chile (N=557), Ecuador (N=500), and Peru (N=526). Women, younger age groups (18-35 years), household financial struggle, and poor health status were consistently associated with low overall wellbeing across all countries. Additional factors associated with low overall wellbeing included feeling discriminated against (Argentina and Ecuador), urban residence (Chile and Ecuador), female gender (Argentina), irreligiosity (Chile), feeling unsafe in daily life (Chile), and negative perceptions of the political situation (Peru). Lower health status predicted low wellbeing across all ten dimensions in all countries. Financial struggle predicted dissatisfaction with own financial situation and activities in all countries. An example of country- and dimension-specific insights is that, in Argentina, low overall wellbeing among females was associated with dissatisfaction in the dimensions

physical health, safety, relaxation, leisure time, activities, and self-worth. Conclusion: This study highlights three common determinants of wellbeing vulnerability—younger age, financial struggle, and health status—across the studied countries. While younger age and financial struggle predict dissatisfaction in various dimensions of wellbeing, poor health status predicts dissatisfaction across (almost) all dimensions. Moreover, characteristics of vulnerable groups differ between countries, which underscores the value of the WiX in guiding priority-setting and design in policy sectors aiming to maximize wellbeing.

Ind-2859 A Study to Estimate the Value Set for Recovering Quality of Life - Utility Index for Hong Kong General Population

PRESENTER: **Richard Xu**

Background The Recovering Quality of Life (ReQoL) instrument was developed to assess health-related quality of life for adults experiencing a wide range of mental health difficulties—from common issues to severe psychotic disorders. Recently, concerns have arisen about using generic preference-based measures (PBM) to evaluate health benefits in mental health. In response, the ReQoL-UI with seven dimensions, derived from the ReQoL, was created to support economic evaluation and resource allocation in mental health-related interventions. However, the preference weights of the ReQoL-UI have not yet been reported in Asian populations. **Objectives** This study aimed to estimate the preference weights of the ReQoL-UI in Hong Kong general population, to better capture the benefits of mental healthcare. **Methods** A discrete choice experiment (DCE) with a duration item (1, 5, 10,15 years) was used to estimate the preference weights of the ReQoL-UI. The D-optimality criterion determined the experimental design. The severity levels for each of the seven dimensions were treated as categorical, while the duration dimension was treated as a continuous variable. In this study, a pool of 180 choice-sets was determined to ensure satisfactory coverage and feasibility. Each respondent was randomly allocated 12 of the 180 choice-sets in the survey. All participants were recruited from the online panel of a survey company in Hong Kong. A sample of 100 participants was invited to complete a pilot survey to confirm its feasibility and logic. A formal survey using quota sampling based on sex and age was then conducted to estimate preference weights. The DCE data was analyzed using a conditional logit model. **Results** A total of 1,008 individuals completed the survey, which fully matched the distribution of the normal population based on sex and age according to Hong Kong's 2021 statistical census. The R-squared value of 0.154 for the DCE with duration data suggests high-quality data. The coefficient for the duration item ($\beta = 0.291$) was positive and highly significant, as expected. For the ReQoL-UI, dimensions were largely monotonic, aligning with our anticipations. Only four out of 28 coefficients were insignificant. Statistically significant decrements were observed for the most severe level of all dimensions. Among these, the utility decrement for the physical health dimension was larger than all other mental health-related dimensions. The “well-being” demonstrated the largest utility decrement among all mental health-related dimensions. The theoretical range of the utility score of ReQoL-UI in Hong Kong general population is between -0.781 and 1.0. **Conclusions** This study provides Hong Kong-specific preference weights for the ReQoL-UI, a new condition-specific PBM for mental health. The generated scoring algorithm and value set can be used by clinical professionals and policy makers to assess and compare the impact of mental health-related programmes and technologies on HRQoL in CUAs, thereby facilitating evidence-based resource allocation decisions.

Ind-1326 Do Maternal Incentives Generate Community Spillovers? Five-Year Follow-up Evidence from a Randomized Trial

PRESENTER: **Adeyemi Okunogbe**, World Health Organization (WHO)
AUTHORS: Edward Okeke, Isa Abubakar

Background: In low- and middle-income countries the underutilization of health care during pregnancy, childbirth, and in early childhood is a key contributor to high rates of child mortality. Demand-side innovations, often involving the use of monetary incentives, have been shown to induce greater utilization of health services, however little is known about the long run effects of such programs; in particular, very little is known about their community-wide effects. Do they affect long-run utilization by other households?

Methods: In 2017 we conducted a randomized trial in 2383 census areas in Nigeria, approximately half of which were assigned to a treatment arm in which expectant mothers were offered a cash incentive of N5000 ($14) payable if they attended antenatal visits, delivered in a health facility, and attended a postnatal visit, or to a control arm. The results of this trial have previously been published. Five years after this experiment we returned to the study communities to collect data on long-run outcomes. To investigate community-wide effects we recruited and surveyed a new sample of 7426 mothers, from both treatment and control areas, that did not participate in the original trial. Leveraging the original random assignment of communities to treatment or control, we study long-run treatment effects on health care utilization by non-participating households.

Results: Our preliminary results indicate a long-run increase in antenatal care use in intervention communities, indicating community-wide spillovers. Leveraging plausibly exogenous variation in the number of originally treated mothers in a community, we find suggestive evidence of network effects: effects are larger when there are more treated mothers. Further leveraging individual-level data on friendship networks, we find that these effects are driven by personal acquaintance with an originally treated mother.

Conclusions: Incentivizing households to use health care services in developing countries may not only impact outcomes within these

households, it may also have community-wide benefits. This has important implications for how we value these programs and provides additional evidence of their utility.

Ind-1497 The Impact of Supply Disruptions in a Social Marketing Program for Reproductive Health on Modern Contraceptive Use and Pregnancy Rates in Zambia

PRESENTER: **Sein Kim**
AUTHOR: Jessica Cohen

Background/Aim This study aims to examine the impact of disruptions in external funding, specifically the supply of heavily subsidized, socially marketed contraceptive commodities, on contraceptive use and pregnancy outcomes. In Zambia, family planning services have often been tied to HIV-targeted activities, which have been highly reliant on foreign donors. One such program, led by United States Agency for International Development (USAID), provided comprehensive support for social marketing for contraceptive commodities such as male and female condoms and oral contraceptives (pills) from the early 1990s until it ended in September 2014. From mid-2014 to September 2016, there was a funding gap for marketing and distribution of these condoms and pills, which resulted in reduced access to these commodities in the market. Previous studies have shown a positive correlation between the expansion of social marketing programs and contraceptive use; nevertheless, it remains uncertain how people would change their reproductive health behaviors in response to the abrupt end of the program. **Methods** The primary source of outcomes data is nationally representative secondary data from the Zambia Demographic Health Surveys (DHS) conducted in 2018, which includes month-by-month records of pregnancies, births, terminations, and contraceptive use (condom, pills, injectables, implants, intrauterine devices). We analyze the rates of modern contraceptive use, and pregnancy among 13,683 women aged 10 and 45 years between January 2013 and July 2015. We apply a difference-in-difference approach, and supplement the results with the synthetic control method, using calendar data from DHS surveys across 12 African countries. **Results** A roughly two-year halt in the social marketing program did not result in a change in pregnancy rate during the study period. In addition, the impact on the rate of modern contraceptive use was not statistically significant, although we observed an overall decrease in the contraceptive use after the disruption. This null result was from the substitution between different contraceptive methods. By specific contraceptive methods, we found the disruption led to decreases in male condom use by 48% (95% CI: -8%, -69%; $p<0.01$) and pill use by 9% (95% CI: -1, -18%; $p<0.05$), whereas injectable use increased by 9% (95% CI: 1, 14%; $p<0.05$) compared to the baseline. The results from the synthetic control approach confirmed a significant decline in the use of male condoms and pills after the funding cut. Heterogeneity analyses showed that the effect was larger among women living in urban areas, those aged above 20 years, single women, and women who had completed at least primary education. **Conclusion** Our study underscores the importance of a stable supply chain and government funding for contraceptives in low- and middle-income countries. Additionally, donors should carefully consider unintended consequences when modifying their implementation strategies or transitioning from one project to another. It is crucial to ensure a smooth phase-out process and engage in preemptive discussions with partner governments.

Ind-2544 Measuring Progress of Healthcare Accessibility for Cross-Provincial Migrants in China: A Nationwide Longitudinal Study

PRESENTER: **Minjiang Guo**, Institute of Medical Information, Chinese Academy of Medical Sciences & Peking Union Medical College

Background: The scale of migrants in China increased dramatically in recent 20 years, composing 26.6% of the Chinese population in 2020. Due to the fragmented basic medical insurance system, 70% domestic migrants in China has limitation to join in the health insurance scheme in host cities but rely on their hometown's, which caused many troublesome procedures for reimbursement and extremely **restrained healthcare accessibility**. To minimize the barriers of migrants' healthcare accessibility leading by reimbursement problems, a new online cross-provincial reimbursement solution had been implemented in 2016 nationwide. **This study aimed to measure the progress of healthcare accessibility for the cross-provincial migrants under this solution**.

Methods: Using data from China Family Panel Studies (CFPS) of 2016 and 2020, this study estimated the healthcare accessibility before and after the online reimbursement solution implementation. Cross-provincial migration status was differentiated by respondents' hukou status and residence during the survey period. We selected 3 indicators to measure healthcare accessibility differences between migrants and local people: "whether or not to have a treatment after illness" was used to illustrate the realized accessibility of healthcare, "annual per capital healthcare expenditure" and "out of pocket expense" (with logarithmic transformation) were applied to describe the financial accessibility. Propensity score matching (PSM) via logistic regression and 1:1 nearest neighbor matching conducted with a caliper of 0.5 standard deviation (SD) was adopted to resolve migration selection bias between the two groups. Binary logit model and logistic regression model were conducted to investigate whether the "migration status" was significantly influencing healthcare accessibility through this period. All the analysis were performed using Stata version 14.0.

Results: A total of 872 individuals in 2016 and 598 individuals in 2020 were included in the analysis after PSM. As the results showed, the treatment probability (OR=0.59, P=0.042) and annual healthcare expenditure (-0.36~0.2, P<0.001) of migrants were significantly lower than local population in 2016, but the disparity was disappeared in 2020. According to the financial protection, migrants' out of pocket expenses was significantly higher than local population both in 2016 and 2020, but the percentage had decreased more obviously in this period, which declined from 74.4% in 2016 to 48.4% in 2020, compared with local populations 58.8% to 36.8%.

Conclusion: This study demonstrated a significant increase of healthcare accessibility and financial protection for cross-provincial migrants after the implementation of the online reimbursement solution in China using a national representative datasets. Given the long distance away from insurance contribution place, online solutions would be a good option for migrants' healthcare coverage, and a effective supplement of universal health coverage. Despite the achievement of healthcare accessibility progress, it should be noted that a substantial disparity in healthcare financial burden was still existing between migrants and local populations due to the different health insurance benefits packages

designed by the flow-in cities and flow-out cities. Policymakers should make more efforts to promote the local health insurance participation of migrants or upgrade the pooling level, so as to completely eliminate the inequity of healthcare accessibility wherever people join in the insurance.

Ind-522 Referral of Patients in a Non-Compulsory Referral Healthcare System: a Survey Study Based on the Health Belief Model

PRESENTER: **Vivian Chia-Rong Hsieh**
AUTHORS: Ming-Chu Hung, Chiung-Hui Chen, Rung-Shiuan Gu

Background

Excessive healthcare resource utilization is a prevalent issue, particularly in systems lacking a compulsory referral system. This is evident in Taiwan, where patients can freely navigate the healthcare system without a primary care (PC) physician acting as a mandatory gatekeeper. Many policies have been implemented to facilitate the proper flow of patients. However, many patients still bypass PC and seek care directly at tertiary hospitals. The impact of potential factors, such as the lack of awareness and perceived inconvenience, on patient referral behavior requires further investigation.

Research Questions

The primary objective of this study is to compare the characteristics of patients with successful and failed upward referrals. Our secondary aim is to identify independent predictors of successful patient referrals in the Taiwanese context.

Methods

We conducted face-to-face surveys of 932 patients aged 20 years or older who had been referred by a physician between December 2020 and May 2021 in Taiwan. Participants signed consent forms before completing a self-developed questionnaire based on the Health Belief Model (HBM). The questionnaire was tested for reliability and validity. Due to the COVID-19 pandemic, we used a two-stage sampling and recruitment approach. A probability proportional to size sampling method was employed to ensure a nationally representative sample. The questionnaire measured general demographics, primary caregiver, comorbid illnesses, perceived threat, perceived referral benefits, perceived referral barriers, cues to action, self-efficacy, and knowledge about referral. Multivariate logistic regression was performed for the multivariate analysis. The study protocol was approved by the research ethics review committee.

Key Results

Of the 932 participants, 20.7% (n=193) experienced failed referrals (was not aware of being referred or did not visit the referred doctor), while 79.3% (n=739) had successful referrals. Among those with successful referrals, 64.5% (n=376) were referred from PC clinics, 18.7% (n=109) from district hospitals, and 16.8% (n=98) from regional hospitals. Statistically significant differences were found in age ($p<0.0001$), sex ($p=0.0001$), area of residence ($p<0.0001$), education ($p=0.0001$), employment status ($p<0.0001$), household income ($p=0.019$), primary caregiver ($p<0.0001$), and underlying comorbid illnesses ($p<0.0001$) between patients with failed and successful referrals. Differences in the HBM construct measurements like perceived referral barriers and cues to action were not statistically significantly across the two study groups. Adjusted analyses revealed that HBM constructs and knowledge about referral were not significant predictors of successful referral behavior. Conversely, age 60 years or older (aOR: 2.31, 95% CI: 1.08-4.95), female sex (aOR: 1.92, 95% CI: 1.23-3.01), and gastrointestinal diseases (aOR: 3.41, 95% CI: 1.33-8.76) were significant drivers of upward referral. Having parents as primary caregivers was associated with a decreased likelihood of successful upward referral (aOR: 0.35, 95% CI: 0.16-0.77).

Conclusions and Implications

Our findings suggest that the HBM constructs and patients' knowledge of referral processes may not be strong predictors of referral behavior in the Taiwanese healthcare system. Public health education initiatives alone may not be sufficient to encourage referrals. Other factors, such as the role of primary caregivers and the type of underlying disease, may play a more significant role in influencing patients' referral decisions.

Ind-1271 Beyond Price: Quality Competition in Germany's Statutory Health Insurance

PRESENTER: **Janice Schönfeld**, "Hamburg Center for Health Economics, University of Hamburg"
AUTHOR: Petra Steinorth

Introduction:
In Germany's statutory health insurance (SHI) system, 94 sickness funds serve over 70 million people, with approximately three percent switching providers annually. This study examines how ***quality competition*** impacts switching behavior by analyzing the influence of ***contribution rates*** and ***additional services*** on consumer choice, while also investigating effects on ***risk selection***.

Method:
The study employs a LASSO logit model to identify ***key predictors of switching behavior***, utilizing German Socio-Economic Panel (SOEP) data combined with sickness fund contribution rates and benefits portfolios. The sample includes 53,189 observations across 16,211 individuals aged 18 and older from 2014 to 2019.

Results:
The analysis ***confirms both price and quality competition*** within Germany's SHI system. Rising contribution rates ***push consumers toward alternative providers***, while lower rates ***create strong pull effects***. Quality competition operates independently of price factors, with consumers

attracted to enhanced service offerings. Switching patterns vary across population groups, with families showing heightened price sensitivity and distinct service preferences compared to individuals with different health statuses.

Conclusion:
The findings affirm quality-driven competition in the SHI system, with benefits significantly influencing insurer choice. While this suggests positive effects on care quality, it also indicates potential risk selection by sickness funds. These insights should inform policy decisions to balance consumer needs with SHI principles.

Economic Evaluations of Cancer

MODERATOR: **Li Yang**,

Ind-2117 Cost-effectiveness of Multi-cancer Combined Screening for Early Detection: a Systematic Review

PRESENTER: **Yumeng Lv**

AUTHORS: Peigen Zhu, Li Yang, Yaqun Fu, Zhijie Nie

Background: Cancer is a leading cause of morbidity and mortality worldwide, with 20 million new cases and 9.7 million deaths reported in 2022. Meanwhile, there were 4.8 million new cases and 2.6 million deaths in China, imposing a substantial economic burden on patients and their families. Multi-cancer combined screening (MCCS) is a screening approach that simultaneously detects multiple cancers, enabling earlier diagnosis and improved patient outcomes. However, most studies focus on the cost-effectiveness of single-cancer screening, lacking comprehensive evaluations of MCCS. Evidence is urgently needed to guide policymakers in identifying cost-effective screening strategies and cancer types for combined screening. **Objective:** This study aims to summarize the cost-effectiveness of multi-cancer combined screening for early detection and to provide evidence supporting the usage of multi-cancer screening technology. **Methods:** A systematic literature review was conducted by searching both English and Chinese databases, including PubMed, Embase, Scopus, Web of Science, and CNKI. Articles published before April 1st, 2024 were included (PROSPERO registration number: CRD42024533740). The key words related to economic evaluation included “cost-effectiveness”, “cost-utility”, and “cost-benefit”, and those for the topic of interest included “screening”, “tumor OR cancer OR oncology”. CHEERS 2022 checklist was used to evaluate the quality of the included studies, data was extracted using a predefined table. Evidence profiles for each combination of screening method, cancer type, comparison, intervention, and outcome were created using the Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) approach. **Results:** Of the 40,272 papers identified, a total of 22 English and 4 Chinese studies met the preset criteria and were included. Of the 26 included studies, 17 were from high-income countries (HICs), eight were from less developed countries, and one provided combined evidence from both HICs and low- and middle-income countries (LMICs). Breast and ovarian cancer screenings showed mixed cost-effectiveness, while colorectal and upper gastrointestinal cancer screenings demonstrated more consistent benefits. The most commonly used combined screenings included multigene testing for breast and ovarian cancer and endoscopy for upper gastrointestinal cancers. Genetic screening and AI integration further improved cost-effectiveness, particularly in high-risk populations. The majority of included studies were of high quality. Studies were conducted from various perspectives, including societal, payer, and health system viewpoints, with commonly measured outcomes such as cancer detection, quality-adjusted life years (QALYs), and disability-adjusted life years (DALYs). Markov models and modeling simulations with a lifetime horizon were the predominant method for economic evaluations. Willingness-to-pay thresholds varied, with some studies using predefined fixed values, such as $50,000/QALY, while others applied GDP-based thresholds. Key factors influencing cost-effectiveness included cancer prevalence, screening costs, utility values of cancer states, and test sensitivity. **Conclusions:** This systematic review highlights the cost-effectiveness of multi-cancer combined screening compared to no screening or single-cancer screening. While high-income countries currently benefit most from multi-cancer screening, further research and real-world economic evaluations in less developed settings are essential to guide resource allocation and policy decisions. To maximize the impact of limited healthcare resources, policymakers should prioritize certain screening strategies.

Ind-1878 Breast Cancer Screening Using Clinical Breast Examination: A Cost-Effectiveness Analysis for South Africa

PRESENTER: **Sithabiso Daphne Masuku**

AUTHORS: Olena Mandrik, Noreen Mdege, Gauravi Mishra, Richard Muwonge, Gesine Meyer-Rath, Naomi Lince-Deroche, Alan Brennan

Background

According to the World Health Organization (WHO), screening and early diagnosis are key to reducing advanced cancer incidence and mortality. In low- and middle-income countries, breast cancer (BC) survival rates are low because of late detection. South Africa's 2017 BC control policy recommends twice-yearly clinical breast examinations (CBEs) for asymptomatic women aged 40-69. The cost-effectiveness of scaling up CBE screening coverage however remains unexplored. We estimated the impact of scaling up CBE screening coverage on BC mortality and screen-detection rates and the program's cost-effectiveness.

Methods

Using randomised clinical trial (RCT) data on downstaging (shifting diagnosis and treatment to earlier cancer stages), we compared two scale-up scenarios over 2023 to 2027 to a baseline of 5% coverage. Scenario 1 targeted 25% coverage by year 5 (5% annual increase), Scenario 2 75% by year 5 (17.5% annual increase). We evaluated the cost per disability-adjusted life year (DALY) averted using a two-part model: a decision tree tracking eligible women's breast health from screening to diagnosis and a state transition model estimating the downstaging of BC cases through screening, following diagnosed women over their remaining lifetime. Downstaging data came from a meta-analysis of two RCTs, stage distribution from a South African case series, mortality risk and life expectancy from WHO's 2019 Life Tables, and breast cancer incidence from South Africa's National Cancer Registry 2018 report. Costs were sourced from South African literature. Costs, evaluated from the healthcare payer's perspective, were presented in 2022 US dollars.

Results

Five-year screen detection rates were 2.39 and 2.08 per 1,000 women screened for Scenarios 1 and 2, respectively. At baseline in Year 5, 234,188 women were screened. Under Scenarios 1 and 2, the corresponding figures were 1,170,938 and 3,512,815, respectively. Over 5 years, Scenario 1 reduced BC mortality, measured in years of life lost (YLL), by 0.7%, while Scenario 2 achieved a 2.3% relative reduction. Across scenarios, the average discounted cost of screening and necessary diagnostic procedures per woman screened was approximately $30. The costs of screening and diagnosis for each screen-detected case of BC were $13,717, $12,653 and $14,476 for baseline, Scenarios 1 and 2, respectively. Relative to no screening, the current baseline screening program averted 1,645 DALYs at a cost of $20,341/DALY averted. Scenario 1 achieves 3,823 DALYs averted with economic efficiency improving to $17,776/DALY averted, whereas Scenario 2 averted 12,165 DALYs at $19,552/DALY averted. Model outcomes were most sensitive to assumptions regarding downstaging rates, followed by CBE sensitivity.

The South African opportunity cost-derived cost-effectiveness threshold (OCCET) is $3,015 per DALY averted, derived by comparing life expectancy gains and healthcare expenditure (2000 and 2015). Although CBE scale-up is not cost-effective under the OCCET, this metric alone does not dictate healthcare decisions in South Africa.

Conclusions

Scaling up CBE screening saves life years but is not cost-effective under the OCCET. However, the best screening policy depends on the government's willingness-to-pay. Additionally, screening initiatives will increase demand for diagnostic and treatment services. Therefore, establishing minimum care standards and evaluating cost-effective early detection methods is essential before scaling up screening.

Ind-1851 Introduction of an Organized Community-Approach Screening Programme for Cervical, Breast, and Oral Cancer in Bangladesh: A Cost-Benefit Analysis

PRESENTER: **Md Ragaul Azim**
AUTHORS: Md Mahfujur Rahman, Md. Habibullah Talukder, Md. Sirajul Islam, Syed Abdul Hamid, Quazi Nazmus Sakib

Background: Cancer is the third leading cause of death in Bangladesh, accounting for 7.7% of mortality, with breast and cervical cancer prevalent among women and lung and oral cancer among men, collectively causing 22.5% of cases and 18.3% of cancer deaths. High treatment costs, such as BDT 492,000 annually for cervical cancer, place a heavy burden on families, with 68.5% of healthcare costs paid out-of-pocket. Global programs, like organized cancer screening initiatives in Austria, Switzerland, and the Netherlands have significantly decreased cancer-related morbidity and mortality through early diagnosis and treatment; for example, Austria's organized breast cancer screening reduced mortality by 19.1% versus 14.2% with opportunistic screening. In Bangladesh, existing cervical and breast cancer screening is opportunistic, resulting in inconsistent coverage and delayed diagnoses. Introducing an organized community-based screening program would improve access to early detection and treatment.

Objective: This study aims to design a national, organized community-based screening program for cervical, breast, and oral cancers in Bangladesh and evaluate its cost-benefit ratio to guide implementation.

Methodology: A mixed-methods approach was adopted. Literature reviews, key informant interviews, and an analysis of the BSMMU screening program informed the program design. A pilot program was launched in a community clinic in Nawly, Jessore, to collect program cost data, including costs of investigations at nuclear centre and medical colleges for suspected patients. These costs were extrapolated for national estimates. Screening spots for national expansion were determined, assuming one spot per rural community clinic and one spot per 8,000 urban residents in city corporation areas.

Benefits were calculated by estimating the costs of a cancer case, assuming these would be saved if detected early. A survey of 346 cancer patients captured direct costs of advanced treatment, and the costs of precancerous cases were collected from literature. The difference between these costs was considered the direct cost savings from early detection. Indirect costs were assessed using the human capital approach, and DALYs captured gains from healthier and prolonged lives, with all future incomes discounted. Intangible costs were evaluated using the willingness-to-pay (WTP) approach, and provider costs were based on the difference between private and public hospital treatment expenses. An incidence-based approach estimated nationwide benefits. The overall cost-effectiveness of the program was determined by comparing extrapolated costs and benefits.

Key Findings: Operating one screening site costs BDT 20.06 lakh annually, while the national program cost is estimated at BDT 25.33 thousand crore, with a per-person cost of BDT 343. Preventing one cancer case saves BDT 38.50 lakh for oral cancer, BDT 42.90 lakh for breast cancer, and BDT 33.10 lakh for cervical cancer. The program could reduce the national cancer burden by BDT 39,940 crore annually. A

benefit-cost ratio of 15.77 indicates that the benefits far outweigh the costs, making the program highly cost-effective. It should be noted that the study is still in progress, and the findings remain preliminary.

Conclusions: An organized community-based cancer screening program for cervical, breast, and oral cancers provides a cost-effective solution to reduce the cancer burden and financial strain in Bangladesh.

Ind-902 Model Validation and Application to Evaluate Cost-Effectiveness of Lung Cancer Screening in Singapore

PRESENTER: **Junxing Chay**
AUTHOR: Eric Finkelstein

Introduction

Cancer screening offers the potential for better health outcomes but often at higher costs. Current approaches for simulating cancer screening outcomes rely on either simple stage-shift models or complex calibrated disease models, each with different levels of flexibility and data requirements. To strike a balance, we developed and validated a novel approach to simulate the distribution of stage and age of diagnosis under various screening programs defined by target population, age and frequency of screening. We then apply this method to evaluate the cost-effectiveness of select lung cancer screening paradigms in Singapore.

Methods

We derived an analytic solution to estimate the distribution of the stage and age at detection under hypothetical screening programs relative to the current distribution reported in cancer registry data. The derivation accounts for all possible windows of opportunity for detection and time-to-detection and incorporates program design parameters (eligible ages and screen frequency), adherence to screening guidelines, stage-specific test sensitivity, and cancer progression rates. We validated the model using lung cancer incidence data from the U.S. Surveillance, Epidemiology, and End Results (SEER) program following the introduction of low-dose computed tomography (LDCT) screening. We then extended our model to incorporate lifetime healthcare costs and quality-adjusted life years (QALYs) gained from screening. Using this extended model, we evaluated the incremental cost-effectiveness of LDCT screening in Singapore for different subpopulations (smokers, never-smokers with family history of lung cancer), screening starting age (40, 50, 60, 70) and frequencies (one-time, quinquennial, biennial, annual).

Results

Our model showed excellent external validity, predicting incidence of stage IV lung cancer in the U.S. with a mean absolute percentage error of 1.64%. Applying the model to Singapore, we found that biennial screening for smokers aged 60-80 was incrementally cost-effective (ICER SGD 48,650/QALY), based on a willingness-to-pay threshold of SGD 75,000/QALY. In contrast, quinquennial screening for never-smokers with family history aged 70-80 was incrementally cost-effective (ICER SGD 72,940/QALY). Sensitivity analysis suggested that the relative risk required for screening of never-smokers to be cost-effective ranged from 1.7 (quinquennial starting age 70) to 6.9 (annual screening starting age 40).

Conclusion Our novel method for evaluating the effectiveness of cancer screening offers a flexible, locally adaptable approach that addresses the limitations of existing simulation models. Moreover, this method is generalizable to other progressive chronic diseases, such as chronic kidney disease and eye diseases. In the case of lung cancer screening in Singapore, we found that screening is likely good value for money for smokers and never-smokers with a family history. However, the optimal strategy differs by underlying risk and age of cancer onset. Future improvements in test sensitivity for early-stage cancers or the use of blood-based biomarkers to identify high-risk individuals may improve cost-effectiveness.

Ind-234 Cost-Effectiveness Analysis of Colonoscopy for Screening Colorectal Cancer in Indonesia: A Markov Model Approach

PRESENTER: **I Kadek Suardiana**
AUTHORS: Dwi Endarti, Tri Murti Andayani

Colorectal cancer is one of the top three diagnosed cancers worldwide and the second leading cause of cancer-related deaths, imposing significant economic burdens. Early detection is crucial for effective management and curative surgeries. In Indonesia, colonoscopy is the primary detection method, particularly for high-risk individuals, but screening has not been widely adopted. Pharmacoeconomic studies are essential for evaluating the costs and effectiveness of colonoscopy screening for colorectal cancer in Indonesia. The results of this study can serve as a reference for developing policies regarding colorectal cancer screening use colonoscopy in Indonesia. This research employs cost-effectiveness analysis using a Markov model for a cohort of 100,000 adults aged 45, comparing screening and no screening scenarios. The cost-effectiveness analysis for colorectal cancer detection using colonoscopy in a healthy population adopts the perspective of healthcare providers. Costs and utilities are estimated over a 30-year time horizon. The Incremental Cost-Effectiveness Ratio (ICER) is expressed as a cost per unit of Quality-adjusted Life Year (QALY). One-way and probabilistic sensitivity analyses were conducted to address uncertainty. The ICER of screening colonoscopy compare to without screening for adult patients in Indonesia was cost-effective, valued USD 6,191.18/QALY located in quadrant I. The ICER value from the basic analysis is below the threshold of 3 times the Indonesia GDP (assumed USD 14,759.1). The intervention of colorectal cancer screening using colonoscopy is considered cost-effective Based on one-way sensitivity analysis, indicate that the factors most influential on the ICER value are discounting rate of utility and cost of treating colorectal cancer. Based on cost-effectiveness acceptability curve, in WTP threshold of USD 5,500, the probability of being cost-effective for colorectal cancer screening increases and consistently reaches 100% at a WTP level of USD 9,000. A 10-year interval detection strategy with colonoscopy is also the most effective approach for improving clinical outcomes, as this detection method provides greater benefits in terms of health and reducing disease risk. This

study is the first to investigate the cost-effectiveness of colorectal cancer screening using colonoscopy in Indonesia, and as such, it has several limitations. First, all the data used are derived from secondary data from previous studies, which may introduce bias when applied to the Indonesian context. Second, the Markov model used in this study does not specifically represent the actual clinical progression of patients with potential colorectal cancer. Third, the model is developed from the perspective of healthcare providers (hospitals), so the cost data utilized only includes direct medical costs. As conclusion, Colonoscopy screening in Indonesia is cost-effective when analyzed using a Markov model, as indicated by an ICER value exceeding three times Indonesia's GDP. Future research should explore alternative interventions, such as biennial colonoscopy, and compare them with other screening methods. **Keywords:** Pharmacoeconomics; Colorectal Cancer; Screening; Colonoscopy; CEA

Ind-1481 Integrating Primary Healthcare Into Post-Discharge Cancer Care for Older Patients: A Pragmatic Non-Randomized Controlled Trial and Cost-Effectiveness

PRESENTER: **Ran Li**
AUTHORS: Peipei Kang, Delanjathan Devakumar, Hassan Haghparast-Bidgoli, Therese Hesketh

Background

The increasing incidence and survival rates of cancers, driven by an ageing population, present a significant challenge to China's healthcare system. Cancer patients are managed almost exclusively within tertiary care with resulting overburdened services. * Recent policies recommend that primary healthcare centres (PHCs) adopt an expanded role in providing long-term cancer aftercare. Advantages include easier access and lower out-of-pocket costs compared to tertiary hospitals, but effective coordination between tertiary hospitals and PHCs for post-discharge cancer care remain limited. To address this, we conducted a pragmatic trial integrating PHCs into the aftercare of older cancer patients to investigate the clinical effectiveness and cost-effectiveness of this approach in China.

Methods

This pragmatic controlled trial was centred at a tertiary oncology hospital in Nantong, Jiangsu province, China and six PHCs—serving as step-down facilities. Patients aged 60 and older with lung, breast, colorectal, or prostate cancer were identified by tertiary physicians. Participants were assigned according to their preference, to either the usual care group, with aftercare from the tertiary hospital, or the intervention group, where the follow-up and aftercare plan was developed and monitored by tertiary physicians, but delivered by PHC doctors. Outcomes measured were hospital admissions, length of hospital stay, and the mean difference in health-related quality of life (HRQoL) at one-and three-months. Subgroup analyses investigated potential differential effects by treatment type at recruitment. A within-trial cost-effectiveness analysis was conducted from a modified societal perspective. Sensitivity analyses were conducted to check the robustness of the results. This trial was registered (ChiCTR2300073108).

Results

Of the 1,722 individuals screened, 755 patients were enrolled in the study between May 2023 and April 2024. Ninety participants were assigned to the intervention group and 665 to the usual care group. Intervention group patients had 43% fewer admissions to tertiary hospital at one month with no significant difference at three months. Patients who underwent surgery in the intervention group, had an 83% reduction in hospitalizations at one month (IRR = 0.17, 95% CI: 0.04–0.76) and a 61% reduction at three months (IRR = 0.39, 95% CI: 0.18–0.82), compared to control patients who received surgery. Patients in the intervention group had 4.68 fewer admission days within one month (95% CI: -7.92 to -1.44) and 4.26 fewer days within three months (95% CI: -8.47 to -0.06) compared to the control group.

Intervention group patients showed better HRQoL, at one month and three months, with a significantly higher adjusted HRQoL at three months (mean difference = 0.05, 95% CI: 0.01 to 0.08) compared to the control group. Integrating PHCs into cancer follow-up and aftercare was cost-effective, saving around 1130 USD in costs (95% CI: -1295 to -62) without a loss in QALYs for patients in the intervention group (mean different = 0.002, 95%CI: -0.004 to 0.008).

Conclusions

The integration of PHCs into post-discharge cancer care has proven to be a cost-saving approach that significantly reduces overall hospitalizations without compromising health outcomes. Further studies with long-term follow-up are needed to fully assess the benefits of integrating PHCs into cancer care.

Ind-1488 Estimating the Cost-Effectiveness of Tumor Treating Fields in Glioblastoma using Real-World Data from the TIGER Study

PRESENTER: **Bruce C. M. Wang**
AUTHOR: Bruce C. Wang

Background: Glioblastoma (GBM) is the most aggressive form of primary brain cancer, with a typical survival of 12 to 15 months, even with recent advancements in treatment. The standard of care, which includes surgery, radiation, and chemotherapy with temozolomide, offers limited success, and recurrence is highly likely. Tumor Treating Fields (TTFields) is a non-invasive treatment that has demonstrated extended survival in clinical trials for GBM patients. This study analyzes the incremental cost-effectiveness ratio (ICER) of TTFields in a real-world setting using data from the TIGER study, conducted between 2017 and 2019 in 81 centers across Germany. TIGER assessed real-world outcomes of 429 patients who received treatment (Intent-To-Treat population), with endpoints including overall survival (OS), progression-free survival (PFS), and safety.

Objectives: To assess the cost-effectiveness of TTFields + Temozolomide (TMZ) compared to the TMZ alone by estimating the ICER using real-world data from the TIGER study.

Methods: Data from the intention-to-treat (ITT) population of the TIGER study was used to model survival benefits, including life years (LYs) and quality-adjusted life years (QALYs). The model incorporated direct medical costs (e.g., treatment, adverse events, follow-up) along with health outcomes such as OS and PFS.

OS was estimated using a three-phase model: Kaplan-Meier survival curves from the TIGER study were used for the initial four years, followed by EF-14 data to extend the curve to 5 years. From years 5 to 15, conditional survival estimates from Porter et al. were applied, and general population mortality rates were used from year 15 onward. PFS was similarly modeled using KM data from the TIGER trial for the initial observed period. Beyond this, PFS was extrapolated using a Weibull distribution.

Utility values were sourced from published literature. A partitioned survival model with three health states (Stable Disease, Progressive Disease, and Death) was used to estimate lifetime QALYs. ICERs were calculated as the ratio of QALYs gained. Sensitivity analyses tested the robustness of the results, exploring variations in utility values, model assumptions, and input parameters.

Results: The ITT population from the TIGER trial demonstrated a 40% reduction in ICER compared to the EF-14 results ($117,953 vs. $197,336 per QALY), driven by consistent gains in life years and QALYs. LYs increased from 3.34 in EF-14 to 3.46 in TIGER (a gain of 0.12 years), while QALYs rose from 2.57 to 2.70 (a gain of 0.13). These findings align with the EF-14 trial results, highlighting comparable clinical benefits.

The one-way sensitivity analysis (OWSA), including a tornado diagram, revealed that TTFields Time on Treatment had the largest impact on the ICER, with a spread of $50,805 between the low and high results.

Conclusions: This analysis demonstrates the improved cost-effectiveness of TTFields in real-world settings, with reduced costs and enhanced survival. The gains in life years and QALYs highlight the economic advantage of TTFields. The TIGER trial confirms the survival benefits seen in EF-14, supporting TTFields as a valuable treatment option for glioblastoma and its continued integration into GBM treatment protocols.

Ind-673 Cost-Benefit Analysis of Extended Pharmacist Scope of Practice to Administer Influenza Vaccinations: Evidence from Ontario, Canada

PRESENTER: **Adrian Rohit Dass**, University of Toronto
AUTHOR: Audrey Laporte

The Scope of Practice (SOP) of pharmacists has received increased attention in Canada and internationally as a way of increasing access to health care services. The evidence to date suggests mixed results of extended pharmacist SOP on the total number of administered vaccinations. Moreover, there have been limited studies investigating potential returns to the health care system associated with SOP extensions, as well as heterogenous effects by rurality. The purpose of this analysis is to investigate the cost-benefit of a 2012 pharmacist SOP extension to administer influenza vaccinations in Ontario, Canada. We estimate interrupted time series models using administrative health data on the population of Ontario from 2010-2022. We investigate the impact on several influenza-related outcomes, including the number of patients vaccinated, expenditure on vaccinations, as well as physician and hospital visits. We find a statistically significant increase in the number of influenza vaccinations, with a larger effect in medically rural areas. We also find statistically significant reductions in physician and hospital visits for influenza. We calculate a return on investment (ROI) of $31.14 over the sample period, which implies that every $1 spent by the Ontario Ministry of Health from the 2012 pharmacist SOP extension yielded a return of $31.14 plus the original investment. This result is conservative as it does not consider the health effects associated with the reduction in influenza cases as well as productivity effects (e.g., fewer missed school and workdays). For policy making, the results suggest that extensions to the SOP of pharmacists is a way of increasing the availability of health care services as well as decreasing strain on physicians and hospitals. The results further suggest that the effectiveness of the extension may vary across regions, with stronger effects in medically rural areas.

Ind-1254 Cost-Effectiveness of a Weight Management Programme to Alleviate Symptoms of Long COVID

PRESENTER: **Heather Fraser**, SAMRC Centre for Health Economics and Decision Science - PRICELESS SA
AUTHORS: Naomi Brosnahan, Alex McConnachie, Michael Lean, Naveed Sattar, David N Blane, Emilie Combet, Janice Richardson, Catherine A O'Donnell, Emma McIntosh

Background

Following COVID-19 infection, some people experience long-term effects, termed Long COVID, significantly impacting quality of life and placing a burden on the National Health Service (NHS). Further, Long COVID carries a substantial economic burden at both individual and

societal levels. Therefore, evaluating interventions that may reduce the clinical and economic burden of Long COVID are of societal importance. Symptoms associated with overweight/obesity overlap with and may aggravate those of Long COVID. The Remote Diet Intervention to Reduce Long COVID symptoms Trial (ReDIRECT) reported the impact of a weight management programme on the self-reported symptoms of Long COVID in those living with overweight/obesity in the United Kingdom. The intervention is a remotely delivered, dietitian-supported programme of total diet replacement and food reintroduction, with weight-loss maintenance support. It is vital to understand value for money gained to inform decision-making on implementation of the intervention.

Aim: This economic evaluation alongside the ReDIRECT trial aimed to estimate the cost-utility of the ReDIRECT intervention, both within-trial and over the long-term.

Methods

Recruited participants (n=234) were randomly allocated to the intervention group, receiving weight management, or control group, receiving usual care. The within-trial economic evaluation estimated the cost-utility of the intervention at six months post-randomisation, compared to usual care. An NHS and Personal Social Services (PSS) perspective was used for the base case analysis, with a wider societal perspective used in a scenario analysis. Incremental Quality-Adjusted Life Years (QALYs) over the within-trial period were calculated using EQ-5D-5L data collected at baseline, three months, and six months. Intervention and healthcare resource use data collected over the trial period were used to calculate incremental costs, with work productivity and personal food costs included for societal perspective costs. Multiple imputation using chained equations was used to account for missing data, with seemingly unrelated regression models fitted on imputed datasets and 5,000 bootstrapped samples drawn. We modelled the long-term cost and health consequences of the intervention under a range of scenarios, with five time horizon scenarios and two scenarios of the relationship between time and treatment effect.

Results

The within-trial cost-utility analysis estimated an incremental cost-effectiveness ratio (ICER) of £16,424/QALY at six months post randomisation, with 86% probability of cost-effectiveness at a £30,000/QALY threshold, from an NHS/PSS perspective. When including broader societal perspective costs, an ICER indicating dominance of the intervention was estimated (-£11,319/QALY, with 96% probability of cost-effectiveness at a £30,000/QALY threshold). Preliminary results from the long-term model indicate that the cost-effectiveness increases with a longer time horizon.

Discussion

The within-trial analysis indicates that the ReDIRECT intervention is cost-effective in improving symptoms of Long COVID from an NHS/PSS perspective, compared to usual care. When a broader societal perspective is adopted, the intervention becomes potentially cost-saving, dominating usual care. Preliminary results from the long-term model indicate that the within-trial analysis results may be conservative if health benefits persist beyond the trial period, with intervention costs being upfront. Exploring long-term consequences of the intervention as well as uncertainty related to key model assumptions may better inform implementation of the intervention.

Ind-1318 Cost-Effectiveness of a Primary Healthcare Intervention: Improving Medicines Use in People with Polypharmacy in Primary Care (IMPPP)

PRESENTER: **Nouf S. Gadah-Jeynes**
AUTHORS: Jeff Round, Ammar Annaw, Rupert A Payne, Deborah McCahon

Background Polypharmacy and comorbidity are increasingly common, with main clinical management of polypharmacy taking place in primary care. This setting faces challenges in distinguishing between appropriate polypharmacy (optimised medication use) and inappropriate polypharmacy (medications misused or failing to deliver intended benefits). It remains unclear whether a targeted medications review in primary care is cost-effective, given inconsistent findings in previous research. The objective of the IMPPP trial was to assess the cost-effectiveness of the IMPPP trial from a UK National Health Service (NHS) perspective. **Methods** IMPPP is a pragmatic, open-label, two-arm cluster-randomised trial across 37 English general practices recruiting 1715 patients. The intervention included an informatics tool to identify patients with polypharmacy, followed by a medication review undertaken jointly between pharmacists and general practitioners. This was compared to control arm practices delivering usual care. Costs were derived from national health records, and QALYs were estimated via SF-12v2. Health economic costs and outcomes were collected at three time points: T1 (practice randomisation), T2 (pre-medications review/ eligibility check), and T3 (6-month post T2). Due to the time variation between T1 and T2 amongst practices, we adjusted for healthcare resource use 6-months prior to T1 in the cost analysis. Cost-effectiveness was assessed using multilevel modelling (MLM) with bias-corrected and accelerated bootstrapping to calculate 95% confidence intervals using multiple imputed datasets for the primary analysis. Patients and practices characteristics were adjusted for in the MLM. Additional one-way sensitivity analyses were conducted to explore uncertainty. **Results** Adjusted mean QALYs and costs were 0.611 in the intervention group and 0.607 in the control group and the difference of 0.004 (95% CI: -0.002 to 0.010 was not statistically significant. Adjusted means costs in the intervention group were £3,950 compared to £3,558 in the control group and the difference of £392.68 (95% CI: -£30.88 to £816.24) was not statistically significant. The probability of cost-effectiveness at the National Institute for Health and Care Excellence's £20,000/QALY threshold was 0%. In the sensitivity analysis, the complete case analysis resulted in a non-statistically significant difference in costs between intervention and control groups of £246.56 (95% CI: -£746.64 to £253.52) but a statistically significant gain of 0.019 QALYs (95% CI: 0.003 to 0.035). **Conclusion** Targeted medication review as implanted in the IMPPP trial is not cost-effective. The trial's lack of cost-effectiveness may be attributed to factors like evolving national polypharmacy guidelines, higher recruitment of pharmacists in control practices, and variations in clinical care during the trial. Despite this, IMPPP is one of the largest trials addressing polypharmacy with a comprehensive informatics tool, offering valuable insights for future research.

Ind-2140 The Cost-Effectiveness of Restricting Electronic Gaming Machines Via Policy Legislation to Reduce Problem Gambling in Victoria State of Australia

PRESENTER: **Upendra Dhungana**, Ministry of Health and Population, Department of Health Services, Nepal
AUTHORS: Long Khanh-Dao Le, Cathy Mihalopoulos, Yong Yi Lee

Background

Problem gambling is associated with a significant economic and health burden to Australian society. Problem gambling includes a range of negative outcomes for individuals, families and society. Several initiatives which target both supply of gambling avenues (such as restricting electronic gaming machines (EGMs)) and demand side initiatives (e.g., treatment of individuals who are problem gamblers), have been found to be effective in preventing and reducing problem gambling. This study aims to systematically review evidence of economic evaluations of interventions targeting the reduction of problem gambling followed by conducting a modelled economic evaluation to examine the cost-effectiveness of policy legislation to restrict the number of EGMs in Victoria, Australia.

Methods

In order to inform the model methodology, Medline complete, Embase, Econlit, APA Psych info, Business Source Complete and CINAHL databases were searched for economic evaluation of problem gambling reduction strategies up to June 2020. Pre-set inclusion and exclusion criteria were applied for selecting the studies. The intervention for the economic evaluation was enacting policy legislation to reduce 25% of EGMs while the comparator was 'do nothing' so that number of EGMs would remain the same. The economic evaluation was conducted using a cost-utility framework where outcomes were measured as quality-adjusted life years (QALYs) using a decision tree model over a one-year time horizon from both a health sector and limited societal perspective that included opportunity cost of excess spending to the gamblers, financial cost of divorce and separation to gamblers, productivity loss at work, cost of crime to government, cost of lost revenue to government and cost of lost employment to individual. Sensitivity analyses of key model parameters including alternative utility weights, increasing health sector cost and reducing cost of lost revenue to government and cost of lost employment were conducted to assess the robustness of results.

Results

The systematic search of the literature did not identify any economic evaluations for problem gambling prevention and reduction strategies. The policy legislation change to reduce the number of EGMs in Victoria by 25% was dominant (i.e., cost less and was more effective) over the 'do nothing' comparator from a health sector perspective. However, from a limited societal perspective the intervention was not cost-effective with an incremental cost-effectiveness ratio of A$688,020 per QALY gained. Sensitivity analyses showed that the intervention remained cost-effective even after making changes to several key model parameters.

Conclusions and Implications

This is the first study to inform policy makers on the cost-effectiveness of EGM restriction in Victoria. The implementation of proposed policy measure largely depends on whether decision makers prefer to adopt a health sector or limited societal perspective. However, there exists an ethical question as to how justifiable it is to include tax revenue in a societal context from addictive good which is causing harm to consumers. Future studies with longer time horizon and the incorporation of probabilistic and multivariate sensitivity analysis to test the robustness of findings are recommended.

Ind-2518 Reducing Frailty in a Pre-Frail Population: How Cost-Effectiveness of a Complex Intervention Depends on Patient Characteristics

PRESENTER: **Richard Edlin**
AUTHORS: Debra L. Waters, Avinesh Pillai, Leigh Hale, Anna Rolleston, Ngaire Kerse, Win Thu, Ruth Teh

Background

Evaluating complex interventions requires consideration of how effectiveness is mediated by implementation context, including a theoretical understanding of why an intervention might work and what this relies upon. This complexity also means that similar trials might produce results that depend on other factors, including patient characteristics. One area where results appear to differ in this way is in falls prevention in the elderly, and where exercise is used as an intervention.

Frailty is a precursor to functional loss and increased risk of falls, hospitalisation, and residential care admissions are closely associated with substantially higher health care costs. This SUPER study aimed to determine whether group-based strength and balance exercise (Steady As You GO, SAYGo) and /or nutrition education and cooking class (Senior Chef) is cost effective relative to social group (control group) in preventing progression of frailty in pre-frail older adults.

Aim:

We use data from SUPER, the recent New Zealand study seeking to reduce frailty in older people to discuss (1) the effectiveness and cost-effectiveness of the trial and (2) how these trial results might be understood in the context of previous New Zealand exercise studies, and how we might understand those studies in the context of findings from the recent trial.

Methods:

This study utilises a dataset from a 2x2 factorial, randomised, controlled trial that recruited 468 pre-frailty community dwelling adults aged ≥75 (≥60 for Māori and Pasifika Peoples) living in Aotearoa New Zealand. Resources included in the cost-effectiveness analysis: intervention costs, hospitalisation costs (from NZHIS) valued according to the type of hospital admission and length of stay. Quality of life (SF-12) at each time points (baseline, 3, 9, 15 and 24 months) were used to estimate quality-adjusted life years (QALYs) as an area under the curve, with value for money of the intervention assessed using incremental cost-effectiveness ratios. Bootstrapping was used to provide balance across trial arms based on baseline frailty status and prior orthopaedic hospitalisation (addressing baseline risk), with CEACs and CEF used.

To contextualise findings, we will compare patient characteristics across existing studies in New Zealand and attempt to consider the similarity of the patient characteristics. Using an exemplar historic study, we will attempt to bootstrap the current trial data to match prior trial characteristics, to assess how much of the difference between trial results might be explained simply by patient characteristics.

Key results:

Our analysis of trial data suggests that exercise combined with the nutritional intervention and cooking class dominates other alternatives at 24 months (58% likelihood of cost-effectiveness at $30k/QALY). However, exercise in isolation of this support was not cost-effective (CEAC 1% at $30k/QALY).

Conclusions:

The study suggests that the cost-effectiveness of exercise in a patient group also depends on the degree that other needs are met; it is complex. Early results suggest that some of the differences between trials can be explained by recorded patient characteristics. Future trials should carefully consider how baseline patient data is collected and might be informed by analysis of previous trial data.

Aversion to Income, Ethnic, and Geographic Related Health Inequality: Evidence from Australia

PRESENTER: **Ms. Marie-Anne Boujaoude**

AUTHORS: Kim Dalziel, Richard Cookson, Nancy Devlin, Natalie Carvalho

This study investigated the Australian general public's views on trade-offs between reducing health inequalities and improving total health. It elicited relative equity weights, comparing inequalities in life expectancy at birth across three equity-relevant dimensions: income (comparing poorest versus richest fifth), ethnic (comparing Indigenous versus non-Indigenous), and geographic (comparing rural/remote versus major cities). A benefit trade-off exercise was administered via online survey to a sample of Australian adults (n=3,105) using quota sampling to ensure population representativeness across key demographic variables (age, gender, state of residence, household income and education level). When comparing income groups, 88% (95% Confidence Interval (CI): 82% - 92%) of the respondents were health inequality averse, with 42% (95% CI: 34% - 51%) demonstrating extreme inequality aversion. When considering Indigenous status, 85% (95% CI: 79% - 90%) showed inequality aversion, and 40% (95% CI: 31% - 49%) displayed extreme aversion. Lastly, looking at different geographic locations, 74% (95% CI: 66% - 80%) of the respondents were inequality averse, with 37% (95% CI: 29% - 46%) showing extreme inequality aversion. The relative equity weights were calculated, allowing for varying baseline inequalities in life expectancy – proportional gaps of 10.8%, 5.1% and 6.3%, respectively. The results imply that the public is willing to weight incremental health gains to the poorest fifth five times more than to the richest fifth, six times more for Indigenous versus non-Indigenous, and four times more for people living in rural and remote areas compared to major cities.

The Causal Link from Vaccination Policy to Government Trust: A Regression Discontinuity Analysis

PRESENTER: **Hidetoki Nakayama**, University of Osaka

AUTHORS: Shusaku Sasaki, Tomoya Saito, Fumio Ohtake

Public trust in government is a critical determinant of compliance with policies during crises such as economic downturns and pandemics. The reverse causal relationship—that implementing effective policies can enhance trust in government—has also attracted interest, but remains under-explored and empirically untested. The current paper addresses this gap by examining the causal link from policy implementation to trust, using the COVID-19 vaccination roll-out as a case study. Leveraging a regression discontinuity design (RDD) based on Japan's vaccination prioritization for individuals aged 65 and older, along with a novel panel survey conducted before the policy's implementation, we identify the causal effect of vaccination on public trust. Our estimations suggest that while the vaccination did not alter trust in the central government responsible for policy design, it significantly increased trust in local governments tasked with policy execution. Notably, this effect was more pronounced among women, a demographic whose mental health was disproportionately affected during the pandemic. Further analysis indicates that this increase in trust was driven by the tangible benefits of having received a vaccine rather than anticipations stemming from policy design and initiation. Our findings highlight the potential for governments to build public trust through effective, well-executed policies, thereby providing an incentive for ensuring policy completion.

Timing Matters: The Impact of Unconditional Cash Transfer Payment Frequency on Dietary Choices Among Vulnerable Elderly Consumers

PRESENTER: **Deivis Guzman-Tordecilla**

AUTHORS: Antonio Trujillo, Andrés Vecino Ortiz, Shu Wen Ng

Low-income elderly consumers, often overlooked in studies of public financial assistance programs, may face challenges in managing resources to maintain dietary health. This study examines how the payment frequency of an unconditional cash transfer program impacts dietary behaviors among low-income elderly populations in Colombia. Using nationally representative data from a federal financial assistance program, we implement a Multivalued Treatment Model with Propensity Score Matching and Augmented Inverse Probability Weighting to assess the causal effects of monthly versus bi-monthly payments on food expenditures, dietary diversity, and diet quality. Results show that monthly payments consistently enhance dietary diversity and diet quality by supporting healthier food purchases compared to bi-monthly payments. Subgroup analyses revealed that older seniors and males benefit most from monthly payments. Mechanisms explored include consumption smoothing, subjective wealth perceptions, and self-control, with findings highlighting the benefits of subjective well-being of more frequent and predictable income flows. The study advances consumer behavior theory by linking payment frequency to dietary outcomes and offers practical implications for optimizing financial assistance programs. While bi-monthly payments reduce administrative costs, monthly payments are recommended to improve dietary health. These findings contribute to understanding income timing's role in fostering healthier consumer behavior.

Unintended Effects of Delayed Marriage on Women's Attitudes Toward Intimate Partner Violence: Evidence from Cambodia

PRESENTER: **Yuki Kanayama**, Keio University

Child marriage is considered a primary cause of intimate partner violence (IPV) in developing countries, but few studies have examined the causal relationship. Using individual-level data from Cambodia, we show how delayed cohabitation affects the attitudes of ever-partnered women toward IPV. To isolate exogenous variation, we use age at menarche as an instrumental variable for age at first cohabitation. Our estimates indicate that delayed cohabitation makes women *more* tolerant of IPV. Furthermore, it lowers the probability that women work or own a bank account, their control over reproductive health, and spouses' educational attainments. In our data, men's educational attainments are negatively associated with their gender bias. This implies that later-married women marry more gender-biased men, leading to limited economic autonomy, less decision-making power, and worse attitudes toward IPV. We argue simply inducing women to delay first cohabitation without improving gender norms or women's education may have unintended consequences.

Costs, Outcomes and Cost Effectiveness Methods

MODERATOR: **Ewan Tomeny**, LSTM

Ind-1780 Origins, Development and Future of Health Economic Evaluation: Perspectives from Health Economics and Decision Science

PRESENTER: **Philip Clarke**

AUTHORS: Michael Drummond, Milton Weinstein, Louise Russell, Sophie Cole

Abstract

This study explores the evolution of health economics, focusing on the development of economic evaluation methods through historical analysis and insights from key figures in the field. Originating in the mid-20th century, economic evaluation transitioned from cost-benefit to cost-effectiveness analysis, initially applied in non-health contexts by the US military before being adapted for healthcare. Herbert Klarman pioneered the application of cost-effectiveness analysis in healthcare, particularly in evaluating treatments for chronic renal disease, establishing foundational principles that remain relevant today. The study draws on a historical interview with Klarman, where he discussed influences on his career, including his academic relationship with economist Milton Friedman that help him get established in health economics.

Building on Klarman's seminal work, this study features interviews with three leading figures from the next generation of health economists and decision scientists: Michael Drummond, Louise Russell, and Milton Weinstein. Their contributions include innovations in cost-effectiveness guidelines, the quality-adjusted life year (QALY) metric, and the integration of health economics into public policy. Interviews conducted in 2022–2023 provide unique perspectives on their career trajectories, intellectual influences, and landmark contributions to the field.

Drummond's work includes the development of economic evaluation guidelines and co-authoring influential textbooks that have shaped best practices. Russell's research emphasized the rigorous evaluation of preventive interventions, challenging assumptions about their cost-saving potential. Weinstein, instrumental in formalizing QALY and decision science methodologies, broke ground with publications in medical journals, bridging economics and clinical practice.

The interviews reveal shared themes: early challenges in gaining academic and policy recognition, the importance of mentorship, and the integration of diverse disciplines such as statistics, mathematics, and public policy. Reflecting on their most influential work, the interviewees highlight how their research has informed current health technology assessments, including the standards set by the UK's National Institute for Health and Care Excellence (NICE).

Contemporary challenges, such as adapting to gene therapy and managing early drug approvals with limited data, are discussed alongside enduring debates about thresholds and equity considerations in cost-effectiveness analysis. The interviewees emphasize the need for future research to address systemic costs borne by patients and caregivers, as well as methodological advancements for evaluating long-term and personalized treatments.

This study not only documents the historical development of health economic evaluation but also identifies key lessons and future directions for the field. It provides a detailed account of the growth of cost-effectiveness analysis as a critical tool for policy and clinical decision-making worldwide.

Ind-2295 OpenMarkov, an Open-Source Software Tool for Cost-Effectiveness Analysis

PRESENTER: **Francisco Javier Díez**, Universidad Nacional de Educaci n a Distancia (UNED)
AUTHORS: Manuel Arias, Manuel Luque, Carmen María Yago, Jorge Pérez-Martín

Cost-effectiveness analysis (CEA) consists of comparing two or more interventions to determine which one provides the greatest benefit at a reasonable cost. Since direct empirical comparison is usually not feasible due to various types of constraints (ethical, budgetary, etc.), CEAs are usually based on computational models such as decision trees, Markov models, and discrete event simulations. Building decision trees, either with or without Markov nodes, is complicated, especially for CEA, because in this case the tree can have only one decision, which must be the root of the tree. Markov models are typically implemented in Excel, which is not a programming language, making the models difficult to build, debug, and maintain; this difficulty increases when the implementation includes modeling tricks such as memory states or tunnel states. Coding them in a language such as R, C++, or MATLAB is difficult for health economists who are not expert programmers, and verifying their correctness is difficult for the recipient of the model, usually a health technology assessment agency. An alternative to these "traditional" tools is the use of probabilistic graphical models (PGMs), which have been developed in the field of artificial intelligence since the 1980s. They are based on a combination of causal graphs built from expert knowledge and probabilistic parameters obtained from clinical or epidemiological data. Bayesian networks, used for diagnosis, are much more accurate than the naive Bayes method, which consists of multiplying the likelihood ratios of the findings. Influence diagrams (IDs) can perform CEAs on problems involving several decisions; some IDs for medical problems having a few dozen nodes are equivalent to decision trees having tens of thousands of branches. Decision analysis networks (DANs) are similar to IDs but more flexible because they do not require a total ordering of the decisions; for example, they can be used to determine the optimal order of multiple tests with cost-effectiveness criteria. Similarly, Markov influence diagrams can model temporal problems and perform CEA much more easily than when using spreadsheets, and represent much more complex models than when using a programming language such as R or C++. Finally, discrete event simulation (DES) can be done with another type of PGM, called DESnets. Building a PGM for a medical problem and coding the corresponding CEA algorithms in a programming language would be a daunting task for health economists. Fortunately, there is an open-source software tool, OpenMarkov, that supports all of these types of PGMs. Its graphical user interface (GUI) allows both experts and novices to build complex causal models with relative ease, without writing a single line of code. This tool has been used in more than 30 countries, from top universities, U.S. government research agencies, and large multinational corporations to students who cannot afford to pay for commercial licenses. Being free and easy to use makes OpenMarkov a useful tool for teaching CEA, especially in low- and middle-income countries (LMICs).

Ind-1361 Selecting Reliable and Efficient Methods for Value of Information Estimation: Insights from a Simulation Study

PRESENTER: **Qian Xin**
AUTHORS: Haji-Ali Abdul-Lateef, Mr. Howard Thom, Mark Strong

Background Healthcare resource allocation decisions are subject to uncertainty due to the imperfect information available in economic evaluations. While collecting new evidence can help reduce uncertainty in decision-making, it is often associated with higher costs. Therefore, finding an optimal balance between reducing uncertainty and managing the costs of evidence collection is essential. Value of Information (VOI) analysis provides an analytical framework that can be used to estimate the value of acquiring additional information to inform a decision-making process. Expected value of partial perfect information (EVPPI) offers insights into the price a healthcare decision-maker would be willing to pay to obtain perfect information for factors influencing the decision. Several methods are available for computing EVPPI, including the traditional two-level Monte Carlo simulation (2LMC), model regression techniques (such as Gaussian process (GP), Multivariate adaptive regression splines (MARS), and Bayesian additive regression trees (BART)), and multi-level Monte Carlo (MLMC). However, the reliability and efficiency of these VOI analysis methods have not been systematically validated, leaving a gap in guidance for selecting the most appropriate method in varying scenarios. ### Objective This study aims to conduct a simulation study to evaluate the reliability and efficiency of different VOI methods and provide insights on selecting methods suited to specific circumstances. ### Methods A generic Markov model was developed to randomly generate base-case inputs and associated uncertainties for varying numbers of health states, treatment options, and correlation levels. Cost and utility values are derived from a uniform distribution, while copulas are used to generate transition probabilities with different levels of correlation. Based on the simulated base case inputs and associated uncertainty, costs and utilities were sampled from normal distributions, while transition probabilities were sampled from a Dirichlet distribution. To estimate the EVPPI, we used the GP, MARS, and BART methods from the BCEA package, along with the MLMC method from the mlmc package, with the 2LMC serving as the gold standard for comparison. We compared the speed and accuracy of EVPPI estimation across different methods, considering varying levels of model complexity. All models were developed in R 4.4.1 and executed on the high-performance computing platform. All code are provided in a GitHub repository. ### Results Among the methods evaluated, BART and MARS were the fastest in estimating EVPPI, outperforming GP, MLMC, and 2LMC, especially as the number of health states and parameters increased. When the true EVPPI value is small, GP, BART, and MARS tend to return zero, whereas MLMC often yields negative values. MLMC provides more accurate estimates when (1) more parameters are included in the analysis; (2) the true EVPPI value is relatively large; and (3) the included parameters possess a certain degree of correlation. ### Conclusion This study highlights the strengths and limitations of various EVPPI estimation methods, emphasizing the superior speed of

BART and MARS, while demonstrating that MLMC achieves greater accuracy under specific scenarios involving complex models and higher parameter correlations.

Ind-1192 Going Beyond Direct Health Gains. How to Incorporate a Societal Perspective in Asia-Pacific Decision-Making? A Consensus-Building Process.

PRESENTER: **Matthias Hofer**
AUTHORS: Lotte Steuten, Martina Garau, Claud Theakston

Health Technology Assessment (HTA) agencies provide recommendations on health technology use within health systems, often relying on economic evaluations. These evaluations may adopt a healthcare system or societal perspective. The healthcare system perspective, which focuses solely on direct intervention costs and benefits, is widely utilised in systems aimed at maximising health within limited budgets. However, adopting a societal perspective, which considers broader value elements, could better align with public preferences, government objectives (such as equity and economic growth), and the HTA's mandate by maximizing societal welfare.

In the Asia Pacific region, while HTA agencies acknowledge broader value elements and societal perspectives in their methodological guidelines, best practice guidance is lacking, and there is considerable variability in how these elements influence decision-making. Challenges to adopting a societal perspective in HTA include the absence of standard methodologies, limited empirical evidence for certain technologies, and budgetary silos within the public sector. Our study aims to address these barriers by developing policy recommendations to support the systematic and effective integration of societal perspectives and broader value elements in Asia Pacific HTA decision-making.

We utilised a consensus-building approach with HTA experts from diverse Asia Pacific jurisdictions, each with experience in existing HTA systems or methodologies to incorporate a societal perspective. Initially, we conducted an online survey to assess current HTA practices, identify opportunities and challenges, and prioritise key value elements. Following this, a structured virtual discussion allowed experts to propose and discuss recommendations, and explore implementation challenges. To frame our analysis, we applied a framework that outlines the steps necessary for adopting change in HTA processes, focusing on willingness for recognition in guidelines, ability for measurement and incorporation into decision-making, and evidence to demonstrate impact and value.

Preliminary results from the survey align with previous literature, confirming that current recognition and incorporation of societal perspectives in Asia Pacific countries remains low. Experts identified barriers such as capacity restraints and lack of robust and validated methods for measurement and decision-making, which contribute to a lack guidance for stakeholders, and lack of evidence on individual technologies. Nevertheless, some opportunities can be leveraged, including methodological advancements, governments' recognition of the societal value of innovative health technologies, and collaborations among HTA agencies that can support method alignment.

We found support for adopting the societal perspective and incorporating broader value elements in decision-making in Asia Pacific. Key recommendations to achieve full recognition and implementation were to prioritise specific aspects of societal value at the local level, and improving methods and evidence generation. Additionally, experts emphasised the importance of multi-country HTA collaborations (such as HTAsialink), knowledge sharing, capacity building, and development of case studies from real-world treatments as critical enablers for a broader assessment of the value of health technologies in Asia Pacific.

Ind-318 Rapid Development of Cost-Effectiveness Analyses to Scale Global Health Interventions

PRESENTER: **Andrew Wang**
AUTHORS: Caroline Tangoren, Savannah Newman, Mark Minnery, Julianne Bruggemann, Philip Riegert, Sindhika Jai, Mary Qiu

Background: In global health, decision-makers often face tight resource and time constraints when selecting interventions to pursue. Cost-effectiveness analysis (CEA) using averted disability-adjusted life-years (DALYs) is crucial for prioritizing interventions, yet limited impact evaluation and costing data, particularly for new programs, often hinder comprehensive CEA model development. A rapid approach to CEA development is needed to support timely, evidence-based decisions by national governments, large-scale funders, academic institutions, and implementing organizations. **Objective:** This study proposes an approach for rapid CEA development and presents lessons learned from its application in identifying and scaling evidence-backed, cost-effective health interventions in Africa and Asia. **Data and methods:** The proposed approach for rapid CEA development includes: 1) Impact estimation leveraging modeling techniques and existing data from literature, assessed for internal and external validity; 2) Evaluation of program impact based on breadth and depth, considering the scale of implementation required for cost-effectiveness; 3) Definition of target population, expected coverage, and adherence rates; 4) Utilization of national or subnational burden data, assessed for applicability to the target population; 5) Estimation of marginal impacts above a counterfactual scenario to assess the added value of an intervention. The counterfactual is triangulated through stakeholder interviews with government partners, existing baseline data, and quasi-experimental data from monitoring and evaluation; 6) Initial bottom-up costing for early-stage CEAs, followed by detailed budget development; and 7) Ongoing maintenance of CEAs using cost actuals and monitoring data for intermediary outcomes to track whether programs meet CE expectations. We present two case studies from the experience of Evidence Action, an implementation organization supporting at-scale, cost-effective programming: 1) Evaluation of a prospective program for intermittent preventive treatment of malaria in school-age children (IPTsc) using early-stage CEA to guide decision-making; and 2) Continued evaluation of a longstanding safe water program through chlorine dispensers operating in Kenya, Uganda, and Malawi. **Results:** The study illustrates each of the proposed approaches for CEA development and maintenance. For IPTsc, CE considerations in Kenya, Uganda, Tanzania, Nigeria, and Malawi are based on available data, with identification of two key uncertainties in the program scenarios and an evidence gap for the extent to which IPTsc results in community-level benefits. Key CE results for Safe Water Now over a range of years show examples of how CE has influenced expansion and changes to program design over time. **Conclusions:** Our rapid CEA development approach presents significant implications for global health policy and practice. This streamlined methodology enables evidence-based decision-making despite data limitations, facilitating timely intervention selection and resource allocation. The approach's adaptability supports iterative refinement as new

data emerges, serving the evolving needs of both implementers and funders. Its flexibility accommodates diverse implementation strategies across national governments and organizations, allowing real-time adjustments to changing program parameters. This less resource-intensive CEA methodology represents a potential advancement toward more responsive and effective decision-making in global health.

Ind-332 The Impact of Occupational Disease Claims on the Sustainability of Indonesia s National Health Insurance System

PRESENTER: **Levina Khoe**

AUTHORS: Muchtaruddin Mansyur, Virginia Wiseman, Augustine Asante

Background

The true burden of occupational diseases (ODs) is still unknown in Indonesia. Anecdotal evidence suggests a significant underreporting problem. The costs of ODs are typically paid through the work accident insurance scheme (JKK), which is administered by the Social Security Agency for Workers (BPJS-TK). However, only 41.6% of the total workforce are members of the BPJS-TK, leaving a significant number of workers uninsured for occupational diseases. There is a general perception in Indonesia that the real costs of ODs are borne by the National Health Insurance System (JKN) and employees through out-of-pocket health payments.

Objective

To compare OD claims processed through the JKK and JKN to determine potential cost shifting between the two insurance schemes and assess how this impact on the sustainability of the JKN.

Methods

We performed a secondary data analysis using JKK and JKN claims data from 2018 to 2022. Initially, we developed a list of potential ODs by ICD-10 codes using three sources of information: evaluation report on potential occupational diseases in JKN claims, JKK claims data, and Minister of Health Regulation No 11 of 2022. Using this list, we estimated the number of suspected ODs by multiplying the number of cases for each potential OD with the proportion of OD, which was obtained from the BPJS-K evaluation report and WHO/ILO joint estimates on the global burden of OD. We calculated potential underreporting rate of ODs by dividing the number of suspected OD cases in JKN claims by the total expected OD cases (the sum of JKN and JKK claims). Potential cost shifting was estimated by subtracting the total claims processed through JKN from JKK claims. We then modelled the potential cost shifting over five years (2023 - 2027), using a 5% reporting rate as the base scenario and two additional scenarios with reporting rates adjusted to 20% and 50%.

Results

A list of 266 potential ODs was created based on the ICD-10 codes for suspected ODs. The total JKK claims for medical costs of confirmed ODs ranged between IDR 6.5 and 318.3 million from 2018 to 2022, while for the same period, the total JKN claims for suspected ODs were IDR 32.5 to 46.2 billion. The potential cost shifting was estimated between IDR 32.0 to 46.1 billion. If this condition persists, the JKN would lose about IDR 223.8 billion by 2027 based on the 5% reporting rate. These accumulated losses could be reduced to IDR 188.5 billion and IDR 117.8 billion by 2027 if the reporting rate is increased to 20% and 50%, consecutively.

Conclusions

Our study reveals a significant cost shift from JKK to JKN in terms of paying for OD claims, which if continues, could negatively impact the sustainability of the JKN. A comprehensive occupational disease reporting policy is urgently needed to address this issue. An important first step would be to improve the current reporting system by coding a *work-relatedness flag* on the JKN claims using the list of ICD-10 codes for suspected ODs and facilitating a linkage with JKK claims.

Ind-2484 Does JKN Shield the Vulnerable? Exploring Financial Burden of Hypertensive Patients in Surabaya: A Cross-Sectional Study

PRESENTER: **Nur Sahila**

AUTHORS: Laela Agrista Devilia, Muhammad Rizky Widodo, Thinni Nurul Rochmah

Background: Indonesia faces a public health challenge with a hypertension prevalence rate of 30.4%, as reported in the 2023 national health survey. This condition is recognized as catastrophic, leading to considerable healthcare expenditures. In response, the government established the National Health Insurance Program (JKN) to provide financial protection for its citizens. Despite a decade of implementation, evidence regarding JKN's effectiveness in alleviating catastrophic health expenditures and out-of-pocket costs varies. Surabaya, the second-largest metropolitan city, ranks second in hypertensive patients in East Java and has enrolled all its citizens in JKN since 2021. However,

evidence of the program's effectiveness in protecting against catastrophic and out-of-pocket expenditures is lacking. This research aims to analyse the relationship between JKN health insurance ownership and catastrophic and out-of-pocket expenditures among hypertensive patients in Gading Regency, Surabaya. **Method:** This study utilizes a quantitative research design employing a cross-sectional method. Purposive sampling was conducted to recruit patients with essential hypertension attending Puskesmas Gading in Surabaya. The inclusion criteria were patients diagnosed with essential hypertension within the past year and residing in the Puskesmas Gading area, while multimorbidity patients were excluded. Based on these criteria, 97 respondents were included. The gathered data were then analyzed using Chi-square tests and logistic regression to assess the association between the variables of interest. **Result:** The majority of respondents were female (85.6%), non-contributory beneficiaries (*Penerima Bantuan Iuran*) of JKN (74.2%), and aged over 60 years (68%). A significant portion of the respondents were homemakers (53.6%), reported utilizing services at the Puskesmas (Primary Health Care) (84.5%), and had never been hospitalized (96.9%). Statistical analysis revealed that participation in the JKN scheme was significantly protective against catastrophic health expenditures (OR: 0.8; p-value: <0.0001) and high out-of-pocket costs (OR: 4.31; p-value: <0.0001). Additionally, Pairwise Two-Sided Multiple Comparison Analysis showed a significant difference in total expenditures between contributory members of JKN and non-contributory beneficiaries of JKN (p-value: 0.0017). **Discussion:** The findings indicate that the JKN program offers protection against out-of-pocket and catastrophic expenditures. However, non-contributory beneficiaries still face significant differences in out-of-pocket costs compared to contributory members. The low hospitalisation rates and high reliance on Puskesmas align with the PROLANIS program, reflecting the effectiveness of primary healthcare services in managing hypertension. Future research should focus on longitudinal studies to evaluate the long-term impact of JKN and consider socioeconomic contexts. **Conclusion:** In conclusion, this study highlights that ownership of BPJS Kesehatan significantly reduces the incidence of catastrophic health expenditures and out-of-pocket costs among hypertensive patients in Gading Regency, Surabaya. While the program provides substantial financial protection, non-contributory beneficiaries still experience notable out-of-pocket expenses compared to non-recipients. More needs to be done to explore long-term impacts in varied socioeconomic contexts to inform policy improvements. **Keywords:** Financial Burden, JKN, Hypertension, Universal Health Coverage

abs-os337 Estimate the Financial Burden of the 5 Most Prevalent Non-Communicable Diseases Among the Population and Assume Its Impact on the GDP up to 2030

PRESENTER: **Mohammad Wahid Ahmed**

AUTHORS: Zakir Hossain, Shehrin Shaila Mahmood, Khadija Islam Tisha, Kamrun Nahar, Sayem Ahmed

Non-communicable diseases (NCDs) are one of the most public health risks globally. Bangladesh and other low- and middle-income nations comprise about 77% of all NCD-related mortality. As per the multi-sectoral action plan for preventing and controlling NCDs 2018-2025, WHO has recognized five diseases as most prevalent in Bangladesh: cardiovascular diseases, chronic respiratory diseases, hypertension, diabetes, and cancers. The declaration of UN Sustainable Development Goal Number 3 (SDG-3) demands each member state achieve Universal Health Coverage (UHC) by 2030 and financial risk protection. Service coverage for NCDs remained stagnant or deteriorated in most low- and middle-income countries like Bangladesh, and households face increasing out-of-pocket expenses (OOPE). The study mainly focuses on widespread economic disruption and the households having NCDs seem to be pushed towards much more hardships in terms of OOPE in Bangladesh.

We used the Household Income and Expenditure Survey (HIES-2016) dataset is national representative data and population-related information that was born by the Population and Housing Census 2022 by the Bangladesh Bureau of Statistics (BBS). The study explored the OOPE of the top 5 most prevalent NCDs and projected up to the year 2030in Bangladesh. The prevalence of cardiovascular disease, chronic respiratory disease, hypertension, diabetes, and cancer was found 5%, 12.5%, 20%, 7.8%, and 0.91% respectively in different secondary sources. OOPE of the top 5 most prevalent NCDs (in millions) from the year 2016 to 2030.

We estimated overall OOPE for the top 5 most prevalent NCDs was BDT 1,096,410 million in the year 2016. A gradual increase in OOPE was observed over the year. At present, the overall OOPE for the top 5 most prevalent diseases stands at BDT 1,172,254 million. Finally, the projected OOPE for the top 5 most prevalent NCDs is about BDT 2,896,469 million in 2030. We found that the gross domestic product (GDP) growth rate, OOPE as the percentage of GDP, and the percentage change in total OOPE gradually increased in the percentage changes in the total OOPE for the top 5 most prevalent NCDs from 2016 to 2030. Our study explores the variation of OOPE of the top 5 most prevalent NCDs among the Bangladeshi population, assuming its impact on the GDP up to 2030. The findings of this study may push policymakers and service providers to key evidence of the next developing Operation of the Government of Bangladesh.

Ind-1639 Enhancing Allocative Efficiency in Health Financing Through Annual Priority-Setting & Donor Coordination Under Malawi's One Plan, One Budget Reform

PRESENTER: **Jacqueline Crowell**

AUTHORS: Francis Zhuwao, Thulasoni Msuku, Stephanie Heung, Mihereteab Teshome, Gerald Manthalu, Andrews Gunda

Background: Approximately 55% of Malawi's health budget is donor-funded, leading to fragmentation and constraining efficient resource allocation. Since 2011, the Ministry of Health's (MoH) Resource Mapping (RM) exercise has created a strong foundation for understanding health sector funding flows. With data typically collected every 2-3 years, the long timeframes between RM cycles and its mapping of funding towards high-level strategies, rather than annual operational priorities, has limited the exercise's impact on donor coordination and allocative efficiencies.

In response, the MoH has outlined a bold vision for aid alignment in the Health Sector Strategic Plan III: 2023-2030 (HSSP III), which aims to promote allocative efficiencies through evidence-based strategy-setting. Under the HSSP III's "One Plan, One Budget, One Report" reform, the MoH, with CHAI's technical assistance, launched the "One Plan" process. This includes MoH-led setting of annual HSSP III operational priorities, followed by mapping of government/donor funding against these priorities. Structures like Technical Working Groups (TWGs) are intended to monitor "One Plan" implementation and promote resource reallocation towards priorities.

Research question/methods: This study aims to assess if an annual, iterative process of government-led priority-setting and donor coordination can improve Malawi's health sector aid alignment. A case study approach was used to document the MoH's operationalization of the HSSP III's "One Plan" reform during its initial two implementation years from June 2023-March 2025. Key indicators, like the percentage of major donors with funding mapped in the "One Plan" and percentage of financing aligned with "One Plan" priorities, were measured. Grey

literature, including “One Plan” tools and funding databases, were reviewed. The authors also draw upon their experiences in implementing “One Plan” processes.

Results: From the first to second year of the reform, there were important process improvements in “One Plan” development, including earlier stakeholder engagement and the adaptation of tools for donor mapping against operational priorities. This led to improved completeness of “One Plan” data and timeliness of dissemination, supporting the proactive identification of unfunded priorities for resource mobilization. From 2023/24-2024/25, external funding aligned with HSSP III priorities increased from 70% to 80%. Despite this progress, MoH and donor feedback indicate that the utilization of the “One Plan” by partners for priority-setting and resource reallocation remains limited due to a lack of fungible resources and misalignment with donor funding cycles. “One Plan” integration within grant-making processes, which often involve verticalized priorities predefined by donors and different stakeholders with varying awareness of the “One Plan”, remains inadequate, while “One Plan” oversight and monitoring by TWGs is limited.

Conclusions/implications: As the MoH’s guiding framework for health financing, effectively operationalizing the HSSP III is critical for mitigating fragmentation and maximizing Malawi’s limited funding. Health sector structures should be strengthened to support planning, funding reallocation, and improved efficiencies. Schedules for sector-wide planning should be harmonized with donor cycles, and the “One Plan” should be used at the outset of proposal development processes to support funding alignment. To strengthen joint accountability, “One Plan” indicators should be incorporated into the health sector’s monitoring and evaluation system.

Ind-2492 Does Health Insurance Protect Against High Cost of Maternal Care? Evidence from Ethiopia, Kenya, and India

PRESENTER: **Catherine Arsenault**, The George Washington University
AUTHORS: Aleksandra Jakubowski, Sein Kim, Sailesh Mohan, Brian Arwah, Anagaw Derseh Mebratie, Theodros Zemedu, Margaret Kruk, Monica Chaudry, Jacinta Nzinga

Background Governments in LMICs are expanding the enrollment in national health insurance schemes to improve financial protections for their citizens. The extent to which these schemes reduce out-of-pocket (OOP) expenditures for maternal care remains underexplored. We used a unique longitudinal dataset that tracks women’s real-time experiences with health system along the maternal care continuum. **Methods** The eCohorts study tracked the experiences of 3,032 pregnant women in Ethiopia, Kenya, and India. Women were enrolled at first antenatal care (ANC) visit and were called repeatedly during pregnancy, after delivery, and during postnatal care (PNC) period. We grouped OOP spending to direct costs (fees, medicines, test, laboratories) and indirect costs (transportation, food, accommodation) and assessed whether health insurance mitigates expenditures along the care continuum. We also assessed the relationship between OOP spending, healthcare quality, and user experience. Models controlled for facility type, delivery type (vaginal vs. C-section), delivery complications, primiparity, rural residence, marital status, education, and wealth. **Results** Most women (>95%) in Ethiopia and Kenya incurred some OOP costs of maternal care, while 28% of women in India received completely free care. The median (IQR) cost of maternal care was $43.6 (16.6, 99.1) in Ethiopia, $48.2 (12.0, 169.9) in India, and $36.2 (16.3, 69.9) in Kenya. The largest contributor to OOP spending were direct costs of deliveries, particularly C-sections and births in private facilities. Health insurance did not significantly reduce the probability of OOP expenses in Ethiopia or Kenya. In India, women were 14pp ($p<.01$) less likely to pay direct costs and 11 pp ($p<.05$) less likely to have indirect costs for ANC. Insurance did not affect direct OOP cost of delivery and increased indirect OOP costs by 12 pp ($p<.05$) in India. Insurance did not affect the level of spending in Ethiopia and India. In contrast, insurance significantly *increased* spending in Kenya: $6.5 ($p<0.001$) more on direct ANC costs, $2.5 ($p<0.001$) more on indirect ANC costs, and $0.80 more on PNC ($p<0.05$). OOP costs were catastrophic (>10% of annual income) for 24% of women in Ethiopia and 23% of women in Kenya (data collection is ongoing in India) and insurance was not protective from catastrophic costs. Higher OOP spending on ANC was associated with better quality in all countries. For delivery services, the relationship between OOP spending and quality varied: higher spending was associated with improved quality in Ethiopia but lower quality in Kenya. In Ethiopia, higher delivery costs correlated with better user experience, while no such associations were found in India or Kenya. **Conclusion** Significant gaps remain in the financial protection offered by insurance schemes in LMICs, potentially slowing enrollment growth. Having insurance did not protect from incurring high OOP costs of maternal care. Along the care continuum, women spent most on direct costs of delivery services, particularly C-sections. Using private facilities may be an effort to receive better care, but we found no consistent evidence that paying more translates to better quality or user experience.

Ind-1674 Health Financing Reform in Nepal: Bridging the Gap Between Resources and Disease Burden

PRESENTER: **Achyut Raj Pandey**
AUTHORS: Kjell Arne Johansson, Krishna Kumar Aryal, Shiva Raj Adhikari

Background: From 1990 to 2019, Nepal underwent a significant transition in disease burden, shifting from Communicable, Maternal, Neonatal, and Nutritional (CMNN) diseases to Non-Communicable Diseases (NCDs). However, the alignment of health system priorities with this transition has lagged. This study examines the changing disease trends from 1990 to 2019 and their alignment with resource allocation decisions. Furthermore, it assesses the future health expenditure landscape and explores strategies to better align resource allocation decisions with Nepal's evolving disease burden. **Methods:** Data on disease burden were obtained from the Global Burden of Disease (GBD) Study 2019. Resource allocation data were collected from the Line Ministry Budget Information System of Nepal and the Financing Global Health Data Visualization Portal of the Institute for Health Metrics and Evaluation. We analyzed notes from Joint Annual Reviews (involving government and non-government health partners) conducted between 2017 and 2022 to identify potential strategies for healthcare financing reforms to address growing health needs. Additionally, we reviewed notes from consultative workshops organized by the Ministry of Health and Population, which engaged over 100 policymakers, program implementers, civil society organizations, and service users. These workshops provided insights into possible options for harmonizing resource allocation decisions with the evolving disease burden. **Key results:** In 1990, CMNN diseases caused 63.6% of deaths, but by 2019, NCDs accounted for 71.1%. Despite this shift, CMNN diseases, responsible for 21.1% of deaths and 29.3% of DALYs in 2019, received 83.21% of the health budget. In contrast, NCDs, contributing to 71.1% of deaths and 61.2% of

DALYs, received only 14.27%, while injuries (7.8% of deaths and 9.6% of DALYs) received 2.62%. Health spending was $19.93 per capita in 1990, rising to $51.58 in 2019 and projected to reach $61.62 in 2030 and $85.95 in 2040. Participants in workshop highlighted Nepal's extended epidemiological transition, with NCDs dominating the disease burden alongside significant CMNN challenges. They recommended prioritizing health interventions based on cost-effectiveness, equity impact, disease severity, and strategic relevance to guide resource allocation. Governance reforms—such as harmonizing fragmented social security schemes (87 schemes implemented by 11-line ministries), granting additional decision-making space and financial flexibility for local governments, and enhancing transparency—could reduce inefficiencies and create resources to meet growing healthcare demands. **Conclusions and implications for policy:** A significant change in the burden of disease has been observed in Nepal which does not align with resource allocation decision. Prioritization of health intervention with multi-criteria decision-making process need to be institutionalized to align resource allocation decision with evolving disease burden. Besides, changes in service governance like harmonization of financing schemes, improving efficiency and transparency are needed.

Ind-1598 How Fee-for-Service Price Change Incurs Cost Shifting to Prospective Payment System: Evidence from China

PRESENTER: **Lai Yi**
AUTHORS: Fu Hongqiao, Ma Chao

Background: The existence and impacts of "cost shifting" have been examined in existing theoretical and empirical literature but with mixed results (Aghamolla et al., 2024; Chernew et al., 2021; Clemens and Gottlieb, 2017; Dranove et al., 2017; Frakt, 2011; McGuire and Pauly, 1991; Rizzo and Zeckhauser, 2003; Wagner, 2016; White and Wu, 2014). Minimal studies focused on cost shifting behavior in developing countries. The highly segregated regional health insurance system and heavily skewed distribution of high-quality medical resources in developing countries brings an important payer for local providers in resource-rich cities --- the nonlocal patients who move outside their usual residence to seek healthcare in these cities. Providers can cost shift between local patients and non-local patients. This study investigates the existence of this kind of cost shifting behavior in developing countries. **Method and Results:** Taking an FFS Price-Cutting in a large southern city of China as a natural experiment, this study examined the responses of public hospitals and whether cost shifting existed. In China, the nonlocal patients who move outside their residences to seek healthcare in resource-rich cities pay by fee-for-service, while the local-insured patients mainly pay by the prospective payment system, giving hospitals room to cost shift. The FFS Price-Cutting eliminated the markup of medical consumables fee (5%-10% markup) since 2019 without changing the local prospective payment system. This study utilized the continuous difference-in-difference method and leverage variation in the exposure to the Price-Cutting across different hospitals (pre-reform consumables ratio) to identify the effects. Moreover, we supplement a heterogeneous analysis to detect cost-shifting. We obtained a random sampling claim data of both local-insured and nonlocal-insured patients from the administration in G city, with 200 thousand observations for local-insured and 360 thousand for nonlocal-insured. We found that the Price-Cutting has increased medical service expenditures and the likelihood of receiving procedures for both types of patients as expected. For nonlocal-insured patients, we found a decrease in both consumable expenditures and total expenditures, causing hospital revenue loss. In contrast, for local-insured patients, we found no measurable change in consumables expenditures, an increase in total expenditures and reimbursement, and even a reduction in illness severity. Further analysis showed that public hospitals relied more on revenue from patients who pay purely by Fee-for-Service, like nonlocal patients, experienced a larger increase in reimbursement of local-insured patients by conducting more procedures, suggesting that hospitals offset the income loss from nonlocal patients by inducing more demand from local-insured patients. We found fiscal subsidies to public hospitals can alleviate strategic response. **Discussion and Implication:** Our study extends this line of literature on cost shifting by investigating an important local/nonlocal setting in developing countries and showing whether the price change in FFS payers influences the PPS payers. These findings implied the importance of monitoring the cost shifting between local and nonlocal patients, and the coordination of their payment methods matters. **Keywords**: Cost Shifting, Price Regulation, Provider Behavior, Interregional Patients, Case-based Payment

Ind-794 Adverse Selection or Beneficial Selection in Dual Western Medicine Traditional Chinese Medicine Insurance Markets

PRESENTER: **Xiyin Chen**
AUTHOR: David Bishai

Voluntary health insurance in Hong Kong offers an add-on option to cover Traditional Chinese Medicine (TCM). In Hong Kong, this option is typically chosen by 10.7% of the total population. If adverse selection dominates, individuals with higher expected healthcare needs are more likely to choose TCM-inclusive coverage, biasing estimates of utilization upwards. However, TCM's holistic appeal could attract people who are more attuned to health and wellness, leading to beneficial selection. The beneficial selection effect could bias utilization estimates downwards. We use IV models to detect the direction of the bias. Our instrument set is the insurance coverage by occupation and lagged year. Our findings support the beneficial selection hypothesis. IV estimates are two to four times larger than non-IV estimates, indicating that those with a lower propensity to utilize outpatient healthcare services self-select into TCM-inclusive coverage. Using instruments to control for bias due to self-selection, TCM-inclusive coverage significantly increases both TCM and WM utilization across extensive and intensive margins, with lower out-of-pocket (OOP) spending, indicating both moral hazard and a complementary relationship between TCM and WM.

Ind-299 Worker Mental Health During Australia's Great Work-From-Home Experiment: The Moderating Roles of Intensity, Job Control and Social Support

PRESENTER: **Anam Bilgrami**, Macquarie University

Background: Robust causal evidence on working from home (WFH) and mental health is lacking, with concerns raised during the pandemic that WFH blurs work-home boundaries and is harmful for worker health. The COVID-19 pandemic created an interesting work-from-home (WFH) 'experiment'. During the period of lockdowns, many workers were forced into high-intensity WFH due to public health mandates. Following these lockdowns, the world of work had been transformed with greater allowance and ability to work from home. **Research Aim:** In this study, I aimed to estimate the causal impact on mental health from working from home during and beyond the period of lockdowns. **Methods:** I used an event study difference-in-difference strategy to identify the effects of WFH on mental health, drawing on individual-level panel data from approximately 6,500 Australian workers who were continuously employed over the period 2019 to 2022. This sample was drawn from the Household, Income and Labour Dynamics in Australia panel survey. Heterogeneity analyses were performed using interaction terms. **Results**: WFH in lockdown years (2020-21) significantly deteriorated mental health, particularly for those working most (75-100%) hours from home ('high intensity WFH)', for females, including those with dependent children. During the lockdowns, negative mental health impacts of WFH were also concentrated in workers with both high and low levels of perceived social support. In the year immediately after lockdowns (2022), WFH was not associated with either significant improvements or deterioration in worker mental health, on average, but there is suggestive evidence of slightly better mental health for males without dependent children and people working 25-50% of their hours from home. Relatively larger negative mental health impacts were estimated for workers with a perceived low level of control in their jobs, and these persisted even in the post-lockdown year. **Conclusions:** Claims and concerns of a 'rapidly growing mental health crisis' from WFH apply mostly to the unique period of lockdowns, and do not seem generalisable, on average, to WFH after this period. Nonetheless, worsened mental health from WFH persisted beyond lockdowns for workers with low levels of perceived control in their jobs. Overall, mental health impacts of WFH are likely interconnected with worker choice and capacity to benefit, and a one-size-fits-all approach to setting WFH arrangements may be inappropriate.

Ind-374 Birth Order Effects on Children's Time Use in Activities Linked to Health and Human Capital: Evidence from Australia and the United States

PRESENTER: **Danusha Jayawardana**, Monash University

AUTHORS: Nicole Black, Gawain Heckley

Background: Recent research shows that birth order affects health and human capital outcomes, yet there is limited empirical evidence on the underlying mechanisms. ***Objective:*** This study is the first to investigate how birth order affects children's time use across key activities that are important for health and human capital development. ***Data:*** We use data from two sources – the Longitudinal Study of Australian Children (LSAC) and the Child Development Supplement (CDS) of the U.S. Panel Study of Income Dynamics (PSID). These are the only two datasets that provide detailed time-use diaries for children from birth to age 15. ***Method:*** As birth order is exogenously determined, we employ ordinary least squares (OLS) to estimate the effect of birth order on various time-use activities important for child health and human capital. We examine time spent on sleep, school, enrichment activities, digital media, physical activity and social activity, comparing first-borns with later-born children while conditioning on family size and other observerable characteristics. **Results:** Despite differences in countries and time periods, our results are strikingly consistent: later-born children spend less time on enrichment activities and more on digital media, compared to first-born children. Further investigation reveals that part of the birth order effect is driven by parents spending less time with later-born children compared to first-borns. However, later-borns also independently devote less of their *own* time to enrichment activities, suggesting that personal time use may be an important mechanism behind the well-documented impact of birth order on human capital development. We find evidence that later-born children experience more lenient parenting, which may help explain this pattern of own time use. Our results are robust to several sensitivity checks, including tests for coefficient stability, accounting for the censored nature of time use in certain activities, and adjustments for multiple hypotheses testing. ***Conclusion:***Given parental time with children and rules around digital media decrease as birth order increases, support for parents to enable them to have sufficient time to actively engage with, supervise and set rules around digital media for their later-born children may be fruitful avenues to explore to help reduce birth order inequalities in human capital outcomes.

Ind-390 Retirement Financing and Health Outcomes Among Australian Adults: How Saving for Retirement Also Saves Lives

PRESENTER: **Tran Phu-Duyen**

AUTHORS: Paula Lorgelly, Mohammad Salimifar

As aging populations exert increasing pressure on pension systems worldwide, understanding the relationship between retirement financing and health outcomes has become critical. While previous research indicates a link between financial security in retirement and overall health, there is a notable gap in studies analyzing this relationship within the Australian context, especially concerning the impacts of superannuation contributions. This study aims to fill this gap by examining how employers' and individuals' contributions to superannuation funds affect the health outcomes of Australians adults. Using longitudinal panel data from the Household, Income, and Labour Dynamics in Australia (HILDA) survey spanning from 2002 to 2018, we employ Ordinary Least Squares (OLS) regression models to analyze the impact of retirement financing on general and mental health outcomes. The dataset includes waves 2 to 18, with a four-year gap between relevant modules, allowing us to assess both immediate and lagged effects of superannuation contributions. Our findings reveal that both employer and personal superannuation contributions positively impact the health outcomes of older Australians, with personal contributions demonstrating stronger and more sustained effects. Notably, contributions made four years prior significantly enhance general and mental health, particularly among retirees, suggesting compounding benefits from early financial planning. These results underscore the importance of proactive retirement saving behaviors and the role of personal agency in financial planning. The study concludes that enhancing financial planning and implementing policy reforms that encourage increased personal contributions to superannuation funds could support healthy aging. By "nudging" retirement savings, policymakers can potentially improve health outcomes in the aging population, reduce future strain on healthcare systems, and promote overall well-being.

Ind-467 Socioeconomic Disparities in the Prevalence and Incidence of Sensory Impairment in Australia: Evidence From Panel Data

PRESENTER: **Mohammad Nure Alam**
AUTHORS: Mutsa Mutowo, Yvonne Tran, Kompal Sinha, Bamini Gopinath

Abstract

Background: Sensory impairment is a growing global public health concern. Previous research on the socioeconomic association with sensory impairment is mostly cross-sectional and uses limited socioeconomic measures. In this study, we use 20 years of panel data and multiple socioeconomic indices to investigate the socioeconomic association on the prevalence and incidence of visual and dual sensory impairment.

Method: Data was driven from the Household Income and Labour Dynamics in Australia (HILDA) survey, which included 9,472 individuals spanning 20 years. The Least Absolute Shrinkage and Selection Operator (LASSO) machine learning method was applied to select significant predictors through variable selection. The association between socioeconomic status and the prevalence of visual and dual sensory impairment was estimated using multivariate logistic regression analysis. A Cox proportional hazard model was employed to assess the socioeconomic association with the incidence of visual and dual sensory impairment.

Results: The lowest level of household wealth [OR =2.25 (95% CI 1.33-3.82)] and household income [OR =3.43 (95% CI 1.73-16.1)] were statistically significantly associated with vision and dual sensory impairment prevalence, respectively. Employment status was found to have a lower risk of the prevalence of vision [OR =0.43 (95% CI 0.29-0.64)] and dual sensory impairment [OR =0.32 (95% CI 0.13-0.78)] relative to unemployment. The longitudinal analysis showed that the lowest level of education [HR =1.23 (95% CI 1.09-1.36)]), the lowest income [HR =2.42 (95% CI 2.21-2.66)], the lowest household wealth [HR =3.22 (95% CI 2.89-3.57)] and living in a disadvantaged neighbourhood [HR =1.88 (95% CI 1.64-1.97)] to be significant risk factors for vision impairment incidence. Similarly, the lowest level of income [HR =4.11 (95% CI 3.41-4.96)] and residing in disadvantaged areas [OR =2.03 (95% CI 1.78-2.32)] were found to be major risk factors for dual sensory impairment incidence. Being employed had a reduced hazard of vision impairment [HR =0.85 (95% CI 0.80-0.91)] and dual sensory impairment [HR =0.68 (95% CI 0.60-0.77)] relative to unemployment.

Conclusion: The study identified significant socioeconomic inequalities in vision and dual sensory impairment in Australia. These findings highlight the importance of targeted interventions to ensure more equitable health and healthcare outcomes, particularly for disadvantaged groups.

Ind-1162 The Infodemic-Pandemic Nexus: Analysing the Impact of Misinformation on Population Health

PRESENTER: **Yuxi Wang**

Objectives Throughout history, infectious diseases have claimed more lives than any other cause. Despite remarkable technological progress in managing disease outbreaks, as seen in pharmaceutical advancements, the COVID-19 pandemic has underscored the essential role of non-pharmaceutical interventions (NPIs) like social distancing, self-isolation, and vaccination. Major challenge in public health response lies in the widespread resistance to effective epidemic measures, sometimes fuelled by media, influential figures, extremist politicians, and pervasive online mis/disinformation — what has been termed an “infodemic”. This research aims to systematically analyse how health-related mis/disinformation spreads from online platforms to offline behaviours, ultimately influencing population health outcomes. Specifically, we investigate (i) How infodemic during the pandemic affects individual behaviours, using vaccine refusal and civil resistance to non-pharmaceutical interventions (NPIs) as proxies; (ii) The impact of such behaviours on population health outcomes, including infection rates and excess mortality. **Methods** We analysed data on online misinformation, public health records, and protest events across 32 countries. We first use a mixed-effects model with country-level random effects, designed to analyse the relationship between rates of epidemic outcomes and the level of misinformation (referred to as the "infodemic"), along with several control variables across different countries and time trends. The dependent variable, excess mortality rate, is modelled as a function of the infodemic level with a time lag that is identified with the best model fit, as well as control variables such as policy responses, GDP per capita, population density, and the Human Development Index (HDI). The model includes a baseline morality time trend using a non-parametric approach based on B-spline bases to capture temporal variation. We also use structural equation modelling (SEM) to analyse the direct and mediated effects (perception, opinion changes, protests) due to infodemic intensity. The robust framework allows for the quantification of how misinformation cascades through behavioural mechanisms to influence public health outcomes. **Results and Conclusions** Our findings reveal a significant association between the spread of unreliable online information (with time lags) and increased new case rates and excess mortality rates. This relationship is mediated by behavioural factors, including civil protests against non-pharmaceutical interventions and vaccination uptake. This study represents one of the first multinational investigations into the behavioural mechanisms linking online misinformation to real-world health outcomes.

Ind-1215 What Drives Mental Health Disparities Across Occupations in Denmark? An Investigation of the Role of Employment Conditions and Industry-Specific Risks

PRESENTER: **Riccardo Di Francesco**
AUTHOR: Seetha Menon

Background: In today’s rapidly evolving work environment, understanding the impact of employment conditions on employee mental health is increasingly critical. This is particularly pressing in Denmark, where nearly one in three individuals experiences psychological challenges at some point in their lives. Despite this, the last comprehensive assessment in Denmark was conducted in 2005. Recent studies have focused narrowly on specific industries and occupations and relied heavily on self-reported data, which introduces endogeneity issues such as social desirability bias, systematic non-response, misclassification, and under-reporting. Our project addresses these limitations by leveraging matched employer-employee longitudinal Danish registry data, complemented by text data from company disclosures, stock market information,

Glassdoor ratings, and accounting statistics.

Data: We utilize comprehensive administrative data spanning 1995–2023, provided by the Danish government, encompassing the entire employed population in Denmark. These data include extensive details on both firm and employee characteristics. Mental health outcomes are assessed through three indicators: *i)* diagnosis-specific information confirmed by a psychiatrist or doctor, *ii)* antidepressant prescriptions, and *iii)* days of absence due to personal illness. To enhance this data set, we integrate annual reports submitted by Danish firms to the Danish Business Authority at the end of their fiscal year. These reports, which include financial statements, management commentary, and other disclosures, offer a deeper understanding of firms' behaviors and priorities beyond conventional financial metrics.

Methodology: We will employ advanced clustering methodologies to classify industries and occupations based on their relative risk to employee mental health and use machine learning predictive models to identify specific occupational risk factors. Additionally, we will examine how employees' mental health has evolved across occupations over the past two decades. Using time-series clustering, we will propose an alternative classification based on the trajectories of employees' mental health. Finally, state-of-the-art text analysis algorithms will assess whether and how firms prioritize employee mental well-being in their annual reports.

Expected findings: We anticipate uncovering substantial mental health disparities across industries, with employees in high-stress sectors exhibiting higher rates of mental health-related healthcare utilization. Additionally, our analysis is likely to highlight significant differences in how industries and firms address employee mental well-being. With data collection and cleaning complete, alongside access to advanced pre-trained neural network-based text analysis models, our team is well-positioned to meet project milestones and present robust findings at the conference.

Policy impact: Our findings will empower organizations to pinpoint occupations and industries at higher risk of burnout and early departure, enabling the design of targeted interventions and prevention strategies. Given Denmark's reputation for strong work-life balance and equitable healthcare, our findings will likely represent a lower bound of mental health disparities. Therefore, insights from Denmark will provide an invaluable benchmark for other countries seeking to address workforce mental health challenges effectively.

Ind-2182 Resilience and Effectiveness of Coping Strategies Against Health Shocks in Households with Non-communicable Diseases in Nigeria

PRESENTER: **Adelakun Odunyemi**
AUTHORS: Hamid Sohrabi, Khurshid Alam

Background: Health shocks, particularly those relating to non-communicable diseases (NCDs), are among the most common and severe shocks households in low- and middle-income countries (LMICs) like Nigeria must contend with due to significant out-of-pocket health expenditures and income losses. The effect of health shocks on household welfare depends on the household's pre-shock resilience capacity and the coping strategies adopted to mitigate them. Therefore, building resilience has topped the developmental agenda in disaster risk reduction, climate change adaptation, and food security interventions. However, studies on households' resilience capacities against health shocks remain scant. Furthermore, available research primarily focuses on identifying the determinants of resilience capacities, leaving their effects on households largely unexplored.

Similarly, studies on household adoption of coping strategies in response to health shocks have concentrated on their prevalence and determinants, neglecting an examination of their effectiveness in sustaining household welfare. Some reasons for these significant gaps include the lack of consensus on measuring resilience, the rarity of longitudinal data in LMICs, and the challenge of establishing true causality due to endogeneity concerns. Therefore, this study aims to circumvent these challenges to investigate the impact of resilience capacities against health shocks in households affected by NCDs in Nigeria and to determine the effectiveness of the coping strategies they employed to smooth consumption.

Method: This study uses the most recent large-scale cross-sectional household survey in Nigeria, the Nigeria Living Standards Survey (NLSS) (2018-19). The survey employed a two-stage cluster sampling design to cover 22,000 households representative of all states. It collected socio-demographic, economic and health data. To examine resilience, we employed a standardised counterfactual method developed for cross-sectional data by the World Bank. Three groups of households were identified: resilient, non-resilient, and chronically poor. Using the consumption gap as a welfare indicator, we estimated the effectiveness of household coping strategies using ordinary least squares (OLS)with inverse probability weighting to establish true causality and eliminate selection bias, as well as a control function using community effects. These methods addressed endogeneity concerns and helped examine the heterogeneous effects of the coping strategies across different points of the consumption distribution.

Results: The results show that NCD-affected households are more likely to be chronically poor (31% of NCD vs 22% non-NCD), less likely to be resilient (36% of NCD vs 41% non-NCD).

In NCD-affected households, OLS regression shows that most coping strategies were ineffective in reducing the welfare gap. Additional work was only significantly effective for chronically poor households, but harmful for NCD-affected households.

Moreover, formal/informal assistance was counterproductive for chronically poor households with NCDs.

Conclusion: Household coping strategies, in isolation, are not enough to protect welfare during shocks. Effective policy requires systemic interventions: robust safety nets, affordable credit, community support, and targeted programs for the vulnerable. Policymakers should focus on building long-term resilience and addressing the root causes that force households into ineffective or harmful coping behaviours.

Ind-1458 Sick of Becoming a Parent: The Child Penalty on Parents' Mental Ill-Health

PRESENTER: **Erik Grönqvist**, Uppsala University
AUTHORS: Erica Lindahl, Stavros Illiadis, Emma Fransson, Elisavet Illiadi

Having a child is a major life course transition for parents entailing parenting stress, more binding time constraints and changed gender roles. We study how family formation impacts parents' mental health and the role gender norms contribute in shaping gender differences in mental health.

A recent literature documents a child penalty on health-related outcomes. Women increase their use of sickness absence (Angelov, Johansson, and Lindahl 2018; Fontenay and Tojerow 2020; Andresen and Nix 2022), antidepressant drugs (Ahammer et al. 2023) and primary care visits for mental ill-health (Hart et al. 2023) after becoming mothers, and also in comparison to fathers. Thus, parenthood increases the gender gap in health preventive activities.

In this paper we ask how parenthood affects mothers' and fathers' mental health. We focus on inpatient care due to mental ill-health (ICD F-diagnoses). While this is a severe health outcome, it entails a limited scope for health investment behavior (Avdic and Johansson 2017) and may as such better reflect individuals underlying health capital, than, for example, drug prescription and sick leave used in earlier studies. We focus on mental health since we are interested in the impact of entering parenthood and its new duties in terms of parenting stress, more binding time constraints and changed gender roles.

To connect with the earlier literature, we also re-estimate our main results on more behavior-related health measures such as outpatient care, and prescription of drugs. We use the event-study specification proposed by Kleven et al. (2019), and we compare effects on men and women. The analysis is based on Swedish administrative register data on all men and women who become parents in Sweden between 1990 and 2008, and we follow parents 5 years before and 10 years after the birth of the child.

Our first results show a large increase in the risk of inpatient care due to mental ill-health for both parents when becoming a parent. These results suggest that becoming a parent is a life-changing event that impacts not only career trajectories, but also the risk for sever mental health problems both for men and women.

When studying the impact of parenthood on more behavior-related health measures, we find a larger increase in use of prescription drugs among women in comparison to men 4 years after the birth of the first child. In the shorter run, i.e., the first year after childbirth, on the other hand, it is interesting to note that women reduce their use of drugs. We propose that this reduction can be explained by mothers' use of maternity leave and their increased contacts with maternity care and child healthcare services. For fathers, where similar support is less extensive, there is no downward shift.

Ind-2198 Are Children of Child Brides More Likely to be Exposed to Child Labour? Evidence from 10 Countries in West and Central Africa

PRESENTER: **Sopuruchukwu Obiesie**, University of Oxford
AUTHORS: Lucie Cluver, William Edward Rudgard

Introduction The burden of girl-child marriage is shifting to West and Central Africa, where over one in four girls are married before the age of 18. Existing literature has established a causal link between child marriage and negative outcomes, including adverse health impacts, reduced educational attainment, lower lifetime productivity, and diminished agency and empowerment. More recently, attention has turned to its intergenerational effects, with studies highlighting poorer nutritional and developmental outcomes as well as a causal link to lower schooling achievements among children born to child brides. However, there remains an evidence gap regarding whether children of child brides are at higher risk of engaging in child labour. This study aims to investigate the association between maternal child marriage and children's exposure to child labour. Additionally, we explore whether this relationship varies by the gender of the child, the specific form of child labour, and the extent of heterogeneity across countries. **Methodology** We pool data from the 6th round of the Multiple Indicator Cluster Survey (MICS) from 10 countries in West and Central Africa collected between 2017 and 2021. The MICS is a nationally representative household survey carried out by countries with support from UNICEF. Households are selected through a multi-stage cluster sampling design, and questionnaires are administered to members relevant to each survey module. The study population consisted of 63,000 mother-child pairs for children aged 5–17 years and women aged 20–49 years. The dependent variable was child labour, measured as a binary variable using the ILO measurement framework, and the total hours of child work in the preceding week. The independent variable was a binary measure of the mother's experience of child marriage. To inform the progressive realisation of child rights, we also evaluate girl-child marriage as a continuous variable using age at first union. Univariate and multivariate binomial and negative binomial regressions were conducted, with standard errors clustered at the cluster and community levels. **Results** We find that maternal child marriage is consistently associated with increased odds of child labour, particularly in hazardous industries or occupations. These effects are strongest for girls and persist even after adjusting for maternal education and household wealth. Country-specific regressions reveal heterogeneity in our findings, with the strongest associations between maternal child marriage and child labour observed in Nigeria. **Conclusion** Our findings suggest that maternal child marriage is likely associated with a higher risk of next-generation exposure to child labour, especially for daughters and in hazardous occupations and industries. While preventive efforts to end child marriage remain vital, supporting early married mothers in high burden settings can help mitigate the transmission of intergenerational consequences.

Ind-2785 The Role of Absolute and Relative Income Hypotheses on Health: Insights from Religious Subgroup Analysis.

PRESENTER: **Aharon Katz**

Background: The relationship between income and health has been extensively studied, yet the influence of relative income hypothesis

remains inconclusive. This study extends the analysis by examining the impact of relative income within religious subgroups. A measure of relative deprivation is applied for each individual to compare the effects of absolute and relative income on health. **Methods:** An ordered probit fixed-effect model with the Mundlak approach is included as the primary analytical framework. To ensure robustness, parametric and semiparametric panel data models are used to address issues of misspecification and unobservable heterogeneity. The main model is also compared to alternative models that restructure the health outcome variable as a binary indicator of good health. **Results:** The findings consistently demonstrate a significant positive correlation between absolute income and health status across the primary model and robustness checks. The positive relationship remains stable except in one robustness check model. In contrast, relative income exhibits a statistically significant and negative impact on health across all models, suggesting a stronger effect than absolute income. Additionally, heterogeneity in the income-health relationship is observed across religious groups. **Conclusions:** This study underscores the importance of accounting for relative income and religious subgroup differences when analysing the income-health relationship, particularly in societies with pronounced religious affiliations. The negative effect of relative income on health highlights the need for policies that address income disparities within religious subgroups to enhance overall health outcomes. **Keywords:** Absolute Income Hypothesis, Relative Income Hypothesis, Relative Deprivation, Religious Groups.

Health and Economic Impact of Primary Care Policies/Models

MODERATOR: **Susan Olivia**,

Ind-788 The impact of Family Doctor Contracting System on Unmet Healthcare Needs in China

PRESENTER: **Jialong Tan**
AUTHORS: Lingxuan Xu, Jian Wang, Peilong Li, Jingjie Sun, Chen Chen

Unmet healthcare needs are a significant concern in China, possibly due to the underutilization of primary healthcare services. The preference for seeking care at tertiary hospitals among many individuals reflects structural legacies of China's healthcare system evolution, wherein historical underinvestment in community health services and the absence of gatekeeping mechanisms have incentivized bypassing primary care. This misallocation of medical resources not only burdens the capacity of tertiary hospitals but also hinders access to necessary healthcare facilities. In response, the Family Doctor Contracting System (FDCS) was introduced to enhance community health services and reduce unmet healthcare needs. This study empirically analyzes the impact of FDCS on unmet healthcare needs using data from the 2018 National Health Service Survey in Shandong Province, which included 27,447 individuals aged over 18. An entropy balancing method was employed to address self-selection bias. Logistic regression results show that individuals contracted with FDs are associated with 1.6 percentage point lower probability to experience unmet outpatient healthcare needs compared to those who did not participate, though FDCS has no significant impact of FDCS on unmet inpatient needs. Robustness checks using various matching methods confirmed these findings. To further investigated the potential mechanism, we found that FDCS has the greatest impact on accessibility of outpatient services. Signing up with FDs reduced the likelihood of citing inaccessibility as the main reason for unmet outpatient care needs by 43.7 percentage points ($p<0.05$), while the impacts on unacceptability and unavailability was relatively more minor at 0.5 percentage points ($p<0.01$). The findings highlight the effectiveness of FDCS in enhancing the role of primary care and improving access to healthcare. Future policy initiatives should focus on promoting the benefits of FDCS, and encouraging utilization of the FD service while strengthening the community-based primary care facilities by providing adequate infrastructure, resources and training.

Ind-1559 Impact of Primary Care Subsidies on Healthcare Utilisation: Evidence from Singapore's Merdeka Generation Package (MGP)

PRESENTER: **Benjamin Toh**
AUTHORS: Geraldine Lim, Kevin Low, Jeanette Pang

Introduction

With an ageing population and rising chronic disease burden in Singapore, good chronic care management is necessary to improve health outcomes and reduce the need for acute care in the future. One key aspect of chronic care management is regular primary care visits, where frequent screenings and monitoring can facilitate early intervention and reduce the likelihood of related acute complications. To investigate whether financial incentives are effective in increasing primary care utilisation, we examined the causal effects of the Merdeka Generation Package (MGP), which was introduced by the Singapore government in 2019 to support seniors through additional subsidies for outpatient care. By improving the affordability of primary care, MGP is expected to incentivise seniors with chronic diseases to go for more visits and better manage their health conditions. We also examined whether greater primary care utilisation reduced acute utilisation, which would result in cost savings for the healthcare system since acute care is expensive and often heavily subsidised. Overall, our research findings served to inform the effects of financial incentives on chronic care management and provide insights on the potential impact of similar national initiatives that utilised subsidies to encourage primary care utilisation.

Methods

Eligibility for the MGP was strictly based on birth year (i.e., 1950 to 1959) and independent of health state and income level. This exogeneous eligibility condition allowed for a quasi-experimental study by comparing seniors who were born just above and below the 1959 birth year cut-off for the MGP. Specifically, we adopted a difference-in-differences approach to measure the causal effect of providing more primary care subsidies on healthcare expenditure in both the primary and acute care settings over a three-year period. Further heterogeneity analysis was

conducted to examine if the impact on healthcare expenditure had varied based on the size of the subsidy increase.

Results

We found that providing more primary care subsidies resulted in a 3% to 12% increase in primary care expenditure on average. This was driven by increases in the number of visits, and the effect was higher amongst seniors who received larger subsidy increases. Furthermore, we found that the subsidies led to a substitution from public to private primary care providers as the decline in expenditures in the former was offset by an increase in expenditures in the latter. This suggested that the subsidies had improved affordability of private clinics and therefore, allowed more flexibility in patients' choice of providers, as private clinics were generally more expensive but provided greater convenience. Meanwhile, there was no evidence that the increase in primary care utilisation reduced acute utilisation in the inpatient care, day surgery or emergency department settings over the three-year period.

Conclusion

Our study showed that financial subsidies can be an effective tool to increase primary care utilisation and expenditure amongst seniors. However, our study did not find evidence of its downstream impact on acute expenditure in the immediate years, suggesting that future studies should focus on examining the effects of increased primary care expenditure on acute expenditure over the longer term.

abs-os526 Primary Healthcare Investment Case for Jordan

PRESENTER: **Iryna Kurinna**
AUTHORS: Mr. Robert Kolesar, Eduardo Gonzalez Pier

Background: High-performing primary healthcare (PHC) is critical for achieving better health outcomes, improving health system efficiency, promoting equity, and enhancing resilience. Globally, health systems with a strong PHC focus consistently outperform those emphasizing hospital-based care at comparable expenditure levels. However, Jordan's healthcare system faces persistent challenges, including fragmented and poorly harmonized health insurance schemes, overuse of the exemption program, and suboptimal PHC service quality. Only 22.4% of Jordan's health budget is allocated to PHC, significantly below the international benchmark of one-third. The health system remains skewed toward curative care, with limited support for preventive services, health promotion, early detection, and palliative care. Recent analyses by the Jordan Strategy Forum, the World Bank, and the International Monetary Fund underscore the need to prioritize PHC within the country's broader health reform agenda. This study fills a critical gap by generating economic evidence to catalyze policy action and mobilize resources for PHC strengthening in Jordan. **Research aims:** The Jordan PHC Investment Case aims to: 1. Summarize health expenditure trends and develop an investment case framework. 1. Estimate potential system savings and economic benefits of PHC strengthening through improved technical efficiencies, reduced hospital referrals, and enhanced health outcomes. 1. Quantify the PHC financing gap and calculate the return on investment (ROI) of increased PHC spending. 1. Provide actionable recommendations for governance, financing, health workforce development, and other targeted strategies to strengthen PHC. **Methods**: The study employs a mixed quantitative approach based on an extensive literature review, health expenditure analyses, and econometric modelling. Data envelopment analysis (DEA) was used to benchmark technical efficiency, estimate the Malmquist Productivity Index, and construct an efficiency frontier for a reference set of countries. Cost savings related to containing hospital emergency visits and reduction in Ministry of Health (MOH) hospital referrals are estimated based on the operation and cost data from Jordan's MOH. We also apply the Synthetic Control Method (SCM) and assess potential health gains from PHC reforms, monetized using standard values per statistical life year. Finally, we compare PHC expenditure benchmarks with current spending to calculate potential economic returns on investment. **Key Results:** Preliminary results indicate that Jordan's PHC system operates below efficiency benchmarks observed in peer countries, with substantial room for improvement. DEA analysis reveals significant technical inefficiencies, while SCM modelling suggests that reversing historical underinvestment in PHC could lead to measurable health gains. Initial ROI estimates demonstrate that increased PHC investment can yield system-wide savings through reduced hospitalizations and referrals, alongside economic benefits from improved population health outcomes. **Conclusions:** Strengthening PHC in Jordan offers a transformative opportunity to improve health system efficiency, equity, and sustainability. The evidence generated highlights the urgency of reorienting health sector priorities toward PHC and mobilizing domestic and international investments. Policymakers should act on the recommendations provided to close the PHC financing gap and harness the potential health and economic returns of a strengthened PHC system. These findings support Jordan's health reform agenda and provide a replicable model for other middle-income countries aiming to achieve UHC.

Ind-2803 Does the Formation of Interprofessional Primary Care Teams Promote Preventive Cancer Screening? Results of a Stacked DID Analysis

PRESENTER: **Sisira Sarma**, Western University
AUTHORS: Sisira Sarma, Rose Anne Devlin, Steven Habbous, Liisa Jaakkimainen

Background and Aims: Interprofessional team-based primary care approaches have been implemented in many jurisdictions worldwide to deliver comprehensive primary care services on a continuing basis. Canada's most populous province, Ontario, rolled out an interprofessional team approach called the Family Health Team (FHT) in a staggered manner beginning in 2006 within a universal health insurance system, where physicians are remunerated by age- and sex-adjusted capitation method while allied health professionals are salaried. Limited evidence exists on the causal effect of interprofessional team-based care on preventive health care, which our study addresses. Preventive screening for cancer, particularly breast, cervical, and colorectal cancer, is important for early detection and reducing cancer-related morbidity and mortality.

Methods: Utilizing retrospective Ontario health administrative data on physicians and patients from 2005–2023, we analyzed cancer screenings among patients enrolled with an FHT who were eligible for colorectal (N=3,494,098), cervical (N= 4,386,583), and breast (N=1,540,176) cancer screenings. We used a stacked difference-in-differences approach, where we included cohorts of patients enrolled with an FHT physician from 2006 to 2022, along with corresponding control cohorts of patients enrolled with an FHT physician five years later. We used entropy

balancing in the pre-FHT period to address physician selection into FHTs using observable patient and physician factors. Our control group for each stack minimizes unobservable selection into FHT as physicians with strong preferences and a proclivity to practice in teams are included. Patient selection into FHT is not feasible in Ontario as only physicians can decide whether to form a team, subject to availability by the Ontario Ministry of Health. We conducted event-study analyses to tease out the causal effect of FHT on cancer screening over time, adjusting for patient demographics, physician characteristics, and patient-fixed effects. We also investigated the effects across various marginalized populations based on area-level characteristics.

Results: Our preliminary results of aggregate treatment effects revealed that patients enrolled with FHTs experienced an increase in the probability of colon cancer screening of 1.1% ($p<0.05$), cervical cancer screening of 1.9% ($p<0.001$) and breast cancer screening of 1.2% ($p<0.001$). Dynamic effect results of time to treatment indicate that the effect increased after three years of physician practice in teams. For example, colon cancer screening probabilities rose by 0.8% ($p <0.001$) in the first year and by 2% ($p<0.001$) after four years. Stratified analyses revealed that the effects were more pronounced among patients living in economically disadvantaged areas (colon: 1.8%, $p<0.001$; cervical 2%, $p<0.001$; breast: 1.4% $p<0.05$).

Conclusions and Implications for Policy and Practice: We found that the rollout of interprofessional primary care teams within a capitated physician payment system in Ontario, Canada, improved preventive cancer screening rates. Our findings underscore the potential of employing interprofessional team-based care to improve preventive healthcare and mitigate disparities in access to preventive cancer screening. Policymakers may consider these findings as supporting interprofessional team-based primary care to optimize preventive care. Future research could explore other preventive care outcomes in teams using our analytical approach to obtain broader insights into primary health care system efficiency and equity.

Ind-168 Cost Control, Healthcare Provision, and Quality of Care in Chinese Primary Health Care Instutions under Capitation-Based Payment Schemes

PRESENTER: **Yangling Ren**, Southwestern University of Finance and Economics

AUTHORS: Yafei Si, Chi Shen, Zhongliang Zhou, Dan Cao

Health systems worldwide face the dual challenge of containing rising costs while ensuring access to high-quality care, particularly in primary care settings. Capitation-based payment reforms have been proposed as a solution to balance these demands, yet empirical evidence on their impact in low- and middle-income countries remains limited. This study evaluates the effects of a capitation payment pilot, where financial risk is shared between healthcare providers and patients and implemented in western China, on service provision, healthcare cost and care quality. Utilizing a differences-in-differences approach, we find that at the hospital level, the capitation reform led to positive impacts on public health service delivery and outpatient visits. The reform resulted in a significant reduction in monthly drug costs per visit, despite no changes in test cost and total cost per visit. Survey analysis using standardized patients (SPs) further revealed a significant improvement in the process quality such as doctors' adherence to recommended questions and exams and patient centredness, despite no significant changes in providing a correct diagnosis or correct treatment. The SP survey also finds a significant decrease in total cost. These findings underscore the potential of capitation to contain healthcare cost inflations without compromising overall care quality.

Ind-2029 Funding the Fight Against HIV: The Effects of Domestic and International Health Expenditure in Mozambique

PRESENTER: **Eliana Chavarría Pino**, University of Manchester

AUTHORS: Ms. Laura Anselmi, Sergio Chicumbe, Matt Sutton

Mozambique has made significant progress in the fight against HIV, yet it continues to face one of the highest HIV prevalence rates globally. International funding has historically played a dominant role in the HIV response, with funding directed to HIV representing a large proportion of international spending. However, robust evaluations assessing the effects of international spending and different funding arrangements on HIV-related outcomes, particularly prevalence, remain limited. This study evaluates the effect of international health expenditure on adult and children HIV prevalence and HIV-related knowledge in Mozambique. We constructed a novel dataset at the individual level covering 2008-2015 and including (i) HIV prevalence (from test results) and HIV knowledge from the Demographic Health Surveys (2009, 2011, 2015), and (ii) International health expenditure through earmarked projects or a common health fund. We used district intercepts and controlled for time-varying district characteristics, household and individual characteristics. We assessed the interactions between international health expenditure and government health expenditure. We implemented a shift-share instrumental variable approach to account for potential endogeneity of expenditure. Overall international funding through earmarked projects decreases HIV prevalence and increases knowledge of transmission channels during pregnancy, delivery, and breastfeeding. A 1% increase in overall international funding reduces the probability of a positive HIV result by 0.024 pp, and increases the probability of knowing about transmission channels by 0.031 pp. If international budget support increases by 1%, the probability of knowing about transmission channels increases by 0.174 percentage points (pp). Examined separately, the different sources and types of expenditure did not have a significant association with being offered an HIV test and being tested as part of an antenatal care visit. However, there is a positive effect of the interaction between government health expenditure and HIV-specific international expenditure on being tested as part of an antenatal care visit. Our findings indicate that international budget support and international funding through earmarked projects positively influence HIV-related outcomes. International funding reduces HIV prevalence and

increases the knowledge about transmission channels. Government health expenditure complements HIV-specific international funding for increased testing during antenatal care visits. In this context, declining trends in international funding are challenging and might lead to higher pressures on domestic resources and local health systems to equip and absorb the HIV response. Future analyses will focus on alternative empirical strategies to address self-selection bias for HIV testing.

Ind-584 Financing the Integration of Private Providers in Mixed Health Systems: Evidence from a Family Planning Initiative in Rural Philippines

PRESENTER: **Pura Angela Co**

AUTHORS: Megan Rauscher, Sarah Straubinger, Geminn Louis Apostol

Background: Despite the Philippines' national health insurance scheme (PhilHealth) and 2019 Universal Health Care (UHC) law providing incentives for private provider participation, complex reimbursement mechanisms and unclear financial flows limit private sector engagement (PSE) in family planning (FP) service delivery under the scheme. While 65% of private health providers are PhilHealth-accredited, the public sector remains the primary FP service provider, particularly in rural areas. Between 2021 and 2023, we implemented and captured learning from interventions that address critical financing and integration gaps by examining how strategic purchasing can support expanding FP access through private providers. **Aim:** Implementation learning include: (1) feasibility of implementing a novel public-private financing model for FP services in two rural provinces through evaluating changes in private facility accreditation and service readiness, measuring provider participation and capacity development, and analyzing financial flows and payment mechanisms; (2) examination of the model's preliminary effectiveness by measuring access to FP services, particularly long-acting reversible contraception (LARCs), out-of-pocket (OOP) expenditure reduction, and provider satisfaction with payment systems; and (3) documentation of implementation lessons to inform policy recommendations for scaling PSE in the Philippines' UHC framework. **Methods:** We employed an implementation learning approach incorporating human-centered design principles in two rural provinces (Antique and Guimaras) from 2021-2023. The approach followed iterative cycles including: (1) initial rapid assessment through key informant interviews to evaluate public-private sector readiness; (2) multi-stakeholder co-design workshops to develop a Public-Private-PhilHealth Partnership framework, resulting in formalized Memorandums of Agreement establishing payment mechanisms and operational protocols; (3) formation of provider Communities of Practice to address implementation barriers collectively; and (4) participatory monitoring through mixed methods including service delivery statistics, financial flow analysis, and structured feedback sessions. The Integrated Midwives Association of the Philippines served as an intermediary partner. **Results:** From October 2021 to November 2023, PhilHealth-accredited private facilities increased from 1 to 6 in Antique and 0 to 6 in Guimaras. Provider capacity expanded significantly, with FP-certified providers increasing from 2 to 27 across both provinces, specifically trained in contraceptive implant and IUD insertion procedures. Service delivery data showed 1,126 clients received LARCs (IUDs and implants) through newly accredited private providers. The payment mechanism eliminated OOP costs for clients while ensuring predictable monthly reimbursements for providers. Initial provider feedback indicates improved confidence in the public purchasing system. The Department of Health's adoption of project implementation guidelines into their PSE policy framework suggests potential for broader system-level impact. **Conclusions:** Despite the limited implementation period, results suggest that strategic purchasing approaches combining clear payment mechanisms and standardized processes can effectively integrate private providers into public health systems while expanding access to FP. While preliminary findings suggest strong potential for replication—now being tested through adaptation in Kenya—longer-term impact data will be valuable. Key policy recommendations center on three critical elements: predictable payment systems, efficient claims processing, and transparent public-private resource-sharing frameworks. This implementation experience advances the evidence base for financing mechanisms that support effective PSE within mixed health systems, especially for low- and middle-income settings advancing UHC goals.

Ind-1864 Integrating Sexual and Reproductive Health (SRH) in Comprehensive Outpatient Care Coverage in LMICs: Early Learnings from the Philippines

PRESENTER: **Bernardo II Cielo**

AUTHORS: Pura Angela Co, Vergil de Claro, Grace Viola, Blanca Louise Rellosa

In 2019, the Philippines adopted RA No. 11223, also known as the Universal Health Care (UHC) Act, mandating universal health coverage to all Filipinos, including the provision of a comprehensive outpatient benefit package. The comprehensive outpatient care coverage was envisioned to integrate primary and specialist outpatient care services, shifting away from the previously siloed, programmatic approaches employed in the Country. However, balancing program-specific targets with streamlined incentives that align with local clinical practice and consumption behaviors remains a significant challenge. This is particularly relevant for sexual and reproductive health (SRH) where service coverage intersects with other healthcare benefits such as primary care, trauma management in emergency settings, and outpatient drug coverage. This study aimed to provide actionable insights into integrating SRH into comprehensive outpatient care by examining the provision of SRH services across different types of providers, identifying service and cost coverage needs and informing the design of social health insurance benefits under the current framework. The study utilized a sequential mixed methods approach, guided by a composite framework combining the WHO 3-D Prioritization and the WHO Strategic Purchasing Framework. The Delphi method was used to prioritize SRH services for coverage, which informed provider mapping and micro costing analyses. The study used program data, collected with the support of the Philippine Health Insurance Corporation (PhilHealth) and the Department of Health (DOH), and primary data collected in accordance with local research ethics standards. Early evidence indicates that integrating SRH into outpatient care coverage has the potential to diversify services and enhance sustainability of outpatient care facilities. Our findings suggests that social insurance coverage can uniquely incentivize the expansion of health services, showing notable supply growth among private sector providers. However, containing health care costs require investment in public healthcare delivery, as prices in private facilities tend to be higher on average. The study highlights the importance of maintaining program-level goals, ensuring that SRH financing contributes to measurable improvements in health outcomes. Failure to factor in SRH within comprehensive outpatient coverage risks diluting its prioritization, undermining efforts to integrate it effectively. These findings offer valuable lessons for LMICs navigating mixed health systems and advancing UHC objectives.

Ind-2520 Does Early Childhood Development Need to be Integrated into the National Public Health Service Programs in China?

PRESENTER: **Han Runzhi**
AUTHORS: Yaqun Fu, Zhao Jingyu, Li Yang

Background: In China, the National Public Health Service Programs (NPHSP) provides free healthcare services for children aged 0-6; however, regional disparities in access and quality persist. Well-developed regions achieve better health outcomes with higher-quality services and a higher population coverage, compared to less-developed areas. To address this, a four-year Early Childhood Development (ECD) pilot project was launched in 2017 to create a scalable model for children aged 0-3 in underdeveloped regions. While ECD has proven effective with high returns on investment internationally, regional cost variations and the lack of standardized pricing highlight the need for comprehensive cost assessments to guide policies and funding decisions to increase the sustainability.

Objectives: This study aims to comprehensively evaluate the implementation costs of the ECD pilot project in rural China, identify cost components and their variations, explore the feasibility of integrating ECD into the NBPHSP, and provide evidence for scaling up ECD programs and ensuring financial sustainability at the national level.

Methods: This study analyzed data from ECD pilot project conducted in 14 counties/districts in China. A multi-stage sampling design was used to select five pilot counties and corresponding control areas. The cost analysis covered seven categories, including training, supervision, and service delivery. Data were collected through field visits, questionnaires, and institutional records. The study also simulated annual per capita funding requirements under different implementation scenarios to provide insights into financial sustainability.

Results: From 2017 to 2020, the weighted average total cost of the ECD project across five pilot counties was US$ 84,493 over four years. Training accounted for 46% of costs, followed by service delivery (15%), daily operations (13%), and supervision (10%). Funding sources included project-specific funds (69.8%) and matching contributions from national (12.3%), county (11.4%), and provincial (6.5%) governments. The annual per capita costs for 2 or 4 home visits were US$ 20.7–28.2 and US$ 21.5–28.9, respectively. Integrating ECD into the NBPHSP would reduce additional per capita funding to US$ 0.70–0.99 for 2 visits and US$ 0.71–1.05 for 4 visits, saving US$ 19.71–27.50 and US$ 20.45–28.19 per capita annually, enhancing financial sustainability and service accessibility.

The ECD program significantly improved early childhood development. Compared to control areas, intervention areas showed higher rates of households with children aged 0-3 owning at least three books (70.7% vs. 48.1%), at least two toys (76.7% vs. 62.3%), and supporting early learning (94.2% vs. 91.0%). Violent discipline was also lower in intervention areas (45.3% vs. 51.1%), with all effects remaining significant after adjusting for baseline levels.

Conclusions: The findings underscore the cost-effectiveness and feasibility of the ECD in reducing risk factors detrimental to child health and fostering positive developmental outcomes. Integrating ECD into the NBPHSP not only enhances financial sustainability and service accessibility but also demonstrates significant improvements in early childhood learning environments and parenting practices. Scaling up ECD programs in rural China is both economically viable and crucial for bridging regional disparities and advancing early childhood development.

abs-os688 Does Physician Racial Bias Affect Disparities in Emergency Medicine?

PRESENTER: **Mr. Jeffrey McCullough**
AUTHOR: Anjelica Gangaram

Patients depend on physician agents for medical decisions. Physicians will, ideally, be informed and representative agents leading to effective and equitable care. US healthcare, however, continues to exhibit significant disparities in outcomes based on patient race and gender. Given the limited diversity of the US healthcare workforce and clinical trial participants, physician bias may contribute to these disparities. Bias among individual physicians might arise from sources ranging from racial animus to imperfect medical education. Allocative biases might also arise from differences in physician skill or practice patterns. Measuring the impact of physician bias is challenging, particularly since patient race and gender may be correlated with unobserved factors like severity and patient preferences. We employ a novel framework to measure racial bias in physicians' diagnostic decision-making. We exploit the quasi-random assignment of physicians in emergency medicine to measure marginal positivity rates across white and Black patients of the same physician. The same identification strategy is used to recover distributions in physicians' skills and practice patterns across white and Black populations.

Our approach produces unbiased point estimates of each physician's discriminatory behavior. These physician-specific estimates are, however, measured with error. Consequently, the more policy relevant distribution of discrimination is overdispersed and does not reflect the discrimination faced by black patients in Michigan's emergency medicine market. We will employ empirical Bayes (e.g., Kline, Rose, and Walters, 2022) to address this problem. We will recover the mixing distribution by deconvolving the physician-specific parameters and their standard errors. Using the mixing distribution as a prior, we will update it with the physician-specific parameters to form the corrected posterior.

This approach is applied to diagnostic imaging decisions for emergency patients with a chief complaint of abdominal pain. A missed diagnosis of severe abdominal disease typically results in major morbidity or even mortality. We use electronic health record data from a near census of Michigan emergency departments. Our findings reveal that Black patients receive imaging at rates 11 percentage points lower than white patients, despite having a similar incidence of severe disease. We find nearly identical marginal positivity rates across Black and white patients among physicians. Physicians are, in effect, applying the same clinical standard when diagnosing Black and white patients. We also find evidence of allocative equity: redistributing Black and white patients among physicians would only reduce the diagnostic disparity by approximately 0.2 percentage points. Additionally, disparities are not driven by insurance coverage differences or patient preferences, as imaging refusal rates are very low and nearly identical across races. Rather, our findings suggest that severe abdominal diseases that require computed tomography scans are somewhat easier to diagnose among Black patients.

abs-os685 The Effects of Terrorism on Health and Human Capital: Evidence From India

PRESENTER: **Anna Vera**
AUTHOR: Partha Deb

Terrorism and violent attacks have increased unrelentingly across the globe in recent decades. These events cause fatalities, destroy infrastructure, and create an environment of fear, which can have consequences on health and human capital outcomes of people living in those communities. Even outside long-term conflict regions within countries, many people face terrorist events, and live with the consequences of such events. We study whether exposure to terrorist incidents contributes to worse health-related behaviors, health, education and labor market outcomes among adults in India.

We use data from the Global Terrorism Database (GTD) to obtain the dates, types and severity terrorism events. The analysis includes terrorism events classified as armed assaults or bombings with at least one fatality. We restrict the sample to terrorism events that have occurred in mainland India since the year 2000. Events in the state of Jammu and Kashmir are excluded, as the ongoing conflict in the region is beyond the scope of this analysis.

Exposure to a terrorism event is measured as the time since the first armed assault or bombing in a district. There was an armed assault event in 200 districts and bombing event in 162 districts of 612 districts considered in my analysis. 120 districts had both an armed assault and a bombing. Of those districts that had both types of terrorist events, the armed assault happened first in 51 districts (42.5%), the bombing happened first in 67 districts (55.8%), and both kinds of events first occurred in the same month in the remaining 2 districts (1.7%).

We merge information on these terrorism events to microdata from India’s National Family Health Surveys (NFHS) 4 and 5, collected in 2015-16 and 2019-21. These multipurpose surveys provide survey data on men’s and women’s health-related behaviors, health, education and labor market outcomes. Critically, the survey data reports how long respondents have lived in their current place of residence. In our primary analysis, we restrict our sample to those who have lived in their current residence for at least 20 years, longer than the oldest terrorist event we consider. This leaves us with samples of 143,448 men, of whom 60,957 (42.5%) were exposed to a terrorist event in their district, and 462,712 women, of whom 201,533 (43.6%) were exposed in their district.

We adapt existing staggered difference-in-differences in two dimensions to estimate the average treatment effects on the treated (ATET) in aggregate and across exposure time and space. First, unlike many repeated cross-section datasets in which surveys are available each year for a number of years, the NFHS data has survey measurements in 2014, 2015, 2019, 2020 and 2021 from which we infer exposure time. Second, we allow for differences between armed assaults and bombings, which requires adaptation to two-types of events modeled jointly. Preliminary findings suggest that both armed assaults and bombing events have deleterious effects on health and human capital formation. The cumulative effect of exposure to both types of events appears to be greater than the sum of the parts-effects.

abs-os680 Using Bunching at Zero to Estimate the Causal Effect of Alcohol Usage on Long-Run Health Outcomes

PRESENTER: **Mr. Joe Spearing**
AUTHOR: Debora Mazetto

Over 60% of Americans regularly consume alcohol. While heavy consumption of alcohol over a long period of time is linked to health problems, less is known about the effects of moderate alcohol consumption.

Estimating the effect of moderate alcohol consumption over the long-run is plagued with identification problems: because alcohol consumption is a choice, it is correlated with confounders, many of which are unobservable. Observational studies have derived a “j-curve” in alcohol consumption’s association with heart health, where increases in consumption are associated with improved heart health at low levels of consumption, but associated with worse heart health at higher levels of consumption (Corrao et al. 2000, Mukamal et al. 2006, Goel et al. 2018, Bryazka et al. 2022, Ronksley et al. 2011). However, they typically cannot establish whether this effect is due to the protective effects of moderate alcohol consumption or whether there are unobservable confounders which explain why moderate drinkers are healthier.

Economists have sought to circumvent this problem by using exogenous variation due to taxes or prices, or instrumenting alcohol consumption

with genetic information. While these approaches can be illuminating, they have the drawbacks of relying on strong exclusion restrictions or identifying only short-run effects of alcohol consumption.

We advance this literature by adapting a novel econometric approach to identifying the causal effect of censored continuous variables (Caetano, Caetano and Neilsen 2023). We exploit the fact that alcohol consumption bunches at zero- intuitively this bunching implies that non-drinkers may be discontinuously different to people who drink very small quantities. Under the assumption that the treatment effect of alcohol consumption is continuous, any discontinuity in the dependent variable at zero therefore reflects the behaviour of confounders (Caetano, 2015). Given as assumed distribution of confounders, the scale of this discontinuity therefore tells us the sign and magnitude of confounders. We therefore map assumptions about the distribution of confounders amongst non-drinkers onto the causal effect of long-term moderate alcohol consumption on health outcomes. In effect, our results allow us to control for unobserved, as well as observed, confounders.

The Persistence of Financial Hardship: Global Evidence of the Causes and Consequences

MODERATOR: **Karen Grépin**, University of Hong Kong

abs-os780 HONORABLE MENTION FOR ADAM WAGSTAFF AWARD: Coping (More or Less) with Health Shocks: a Longitudinal Perspective on Financial Protection from Nepal

PRESENTER: **Vishnu Prasad Sapkota**

AUTHOR: Owen O'donnell

Catastrophic and impoverishing health spending – two indicators of financial protection used to monitor Universal Health Coverage – are usually estimated from cross-sectional data. Using a three-year (2016-2018) panel of households in non-metropolitan Nepal, we add to scant evidence on the dynamics of these indicators and test whether non-medical consumption falls when the indicators rise in response to health shocks. We find that catastrophic and impoverishing health spending are mostly transitory: at least 80% of the episodes in one year do not continue into the next. A health shock is estimated to raise the likelihood of catastrophic and impoverishing health spending by 36.7 and 7.5 percentage points, respectively. Income falls by an estimated 11.7% if the shock is to a working head of household. Despite these effects, non-medical consumption does not fall. Consumption is smoothed mainly through use of savings and other coping that need not overly compromise long-run consumption potential. While this is somewhat reassuring given catastrophic health spending is mostly transitory, a sizeable minority (20%) has recurrent catastrophic spending, some households rely on more pernicious coping strategies, and others make no recourse to coping, in which case, a health shock is estimated to reduce non-medical consumption by 14.3%.

abs-os777 Measuring Persistence and Duration in Out-of-Pocket Health Expenditures

PRESENTER: **Pedro Rosa-Dias**

AUTHORS: Rocio Garcia-Diaz, Karen Grépin, Aaron Salinas

As a population ages, there is a notable rise in the prevalence of chronic diseases and multimorbidity leading to high financial stress attributed to persistent high out-of-pocket health expenditures (OOPHE). Extended periods of financial stress resulting from OOPHE undermine households' ability to attain financial risk protection. This protection is defined as the capacity to access essential and quality healthcare services without enduring undue financial hardship. Many studies that examine prolonged periods typically concentrate on a specific health shock or illness episode to assess the impact on the composition of household expenditures and coping strategies. However, in cases where panel data spans a considerable duration, isolating a single health shock becomes challenging and oversights valuable information regarding households consistently reporting high OOPHE without necessarily reporting distinct health shocks.

We measure the intertemporal impact of catastrophic OOPHE and analyse how households experience prolonged financial stress due to OOPHE. Drawing inspiration from the duration spell analysis in poverty research, we formulate an intertemporal catastrophic measure. This measure considers the duration of spells, reflecting the number of consecutive periods during which a household experiences financial stress, and incorporates diverse household perceptions of these spells. This captures concerns related to sustained and consecutive periods of financial stress over intermittent ones, that offer the possibility of potential for recovery. Additionally, we propose an empirical estimation strategy, based on survival models, to evaluate the probability risk ratios of the duration spells of households.

abs-os779 Persistent Catastrophic Expenditures and Chronic Illness in Older Populations

PRESENTER: **Rocio Garcia-Diaz**

AUTHORS: Pedro Rosa Dias, Aaron Salinas

Background:

Chronic non-communicable diseases (CNCDs), such as hypertension, cardiovascular diseases, and diabetes, impose a significant burden of disability, especially among elderly populations. These conditions often require prolonged treatment and can lead to high healthcare when financial protection is limited. By 2050, the global population aged 60 and over is projected to reach 22% or nearly 2 billion people. While developed countries currently have a larger proportion of elderly individuals, the fastest aging is occurring in newly industrialized and developing countries, which are expected to house 80% of the elderly population by 2050. Despite this, the persistence of healthcare expenditures associated with CNCDs over time remains poorly understood. Current research often relies on cross-sectional metrics, which provide one-time snapshots of catastrophic health spending but fail to capture long-term patterns.

Methods:

To evaluate the persistence of catastrophic health payments in elderly households with chronic illnesses in Mexico. We compare cross-sectional measures of catastrophic health expenditure (CHE) with metrics derived from panel data to capture persistence over time. Using SAGE-Mexico longitudinal study with three measurement cycles completed to date, Wave 0 (2002-2003), Wave 1 (2009-2010), Wave 2 (2014), and Wave 3(2017), we identify households at risk of (i), long-term persistent CHE, (ii) transient persistent CHE, (iii) chronic CHE, and (iv) no incidence of CHE. The analysis proceeds in two stages. In the first stage, we identify households with persistent CHE and categorize them by the number of chronic illnesses and comorbidities. These estimates are compared to traditional annual, cross-sectional CHE measures. In the second stage, we analyze the determinants of persistent CHE using a fixed-effects model, accounting for individual characteristics. The model is further adjusted for endogeneity, panel attrition, and individual heterogeneity, with longitudinal weights applied to address sample attrition.

Results:

Annual CHE incidence in the panel ranges from 28% to 34%. Persistent CHE is notably high (40%) among elderly households with more than two chronic illnesses, whereas the absence of comorbidities is linked to transient CHE. Key factors associated with persistent CHE include elderly members with comorbidities, higher per-capita expenditure, and pension status. Conditions such as asthma, stroke, and being overweight are strongly associated with persistent CHE while having insurance increases the likelihood of transient CHE.

Conclusions:

The elderly population faces significant financial shocks due to chronic health conditions, especially in the presence of comorbidities, highlighting the need for targeted interventions to reduce CHE. Mandatory health insurance programs specifically for the elderly could mitigate these financial risks. Additionally, exemption schemes for vulnerable elderly populations should be implemented to provide access to healthcare without the burden of catastrophic costs. Optimizing social health insurance programs to prioritize coverage for chronic illnesses can further reduce CHE and address inequalities in healthcare access among the elderly.

abs-os781 The Determinants of High and Persistently High Health Expenditures in a Low-Income Country: Evidence from Burkina Faso

PRESENTER: **Karen Grépin**, The University of Hong Kong
AUTHOR: Bingqing Guo

The extent to which households face high health expenditures can influence the design of public policies to protect households against catastrophic and impoverishing health expenditures as well as to promote equitable access to health services. While studies have investigated levels and determinants of health expenditures in other international contexts, few studies have explored the distribution and the dynamics of health expenditures in a low-income country setting. Using panel data collected in Burkina Faso in 2014, this study analyzes the distribution and dynamics of health expenditures in a nationally representative sample of households. We find that health expenditures are highly skewed: 1% of households account for 20% of aggregate health expenditures while the top 5% of households account for nearly half. Expenditures on modern medicines represent the most important category of health expenditures. Overall spending on health expenditures is positively associated with socio-economic status but there is variation in the gradient with measures of catastrophic and impoverishing health expenditures. We find that inpatient health expenditures and chronic conditions, in particular diabetes, are significant predictors of high and persistently high health expenditures. Policy makers in Burkina Faso who currently exploring options to expand pre-paid insurance programs to achieve Universal Health Coverage should consider expanding coverage for inpatient health services and provide greater coverage for non-communicable diseases.

abs-os597 Costing Oncology Interventions: Implications for Enhancing India's National Health Insurance

PRESENTER: **Tabassum Wadasadawala**, Advanced Centre for Treatment Research and Education in Cancer

This study addresses the critical need for a robust, context-specific costing framework to support the review of health benefits packages (HBPs) under India’s national health insurance scheme, PM-JAY. Costing is a cornerstone for improving healthcare coverage, quality, and efficiency, providing essential data for informed decision-making in rate-setting and resource allocation. Costing helps address key questions in

the HBP review process, such as the affordability of expanding population coverage or including new services, the appropriateness of reimbursement rates, and whether the rates incentivize quality care and financial protection for patients. Efficient delivery of services in line with clinical best practices and their cost-effectiveness are also critical considerations.

This study focuses on developing and testing a tailored costing methodology, using breast cancer interventions as a case study to demonstrate its feasibility and impact within the Indian healthcare context. The study demonstrates the potential of combining normative (ideal) and empirical (actual) costing methods to inform policy decisions. It highlights the use of clinical guidelines and electronic medical records (EMR) to develop resource baskets for breast cancer pathways, including mastectomy, breast-conserving surgery, and associated therapies. Normative costing benchmarks are contrasted with current practices to identify gaps in quality, coverage, and affordability.

Preliminary findings demonstrate the utility of the costing tool in estimating treatment cost, generating scenarios for funding decisions, assessing trade-offs in HBP updates, and identifying inefficiencies. This approach highlights the importance of normative costing to understand quality gaps and estimation of cost to close the budget gap, aligning with PM-JAY's strategic goals of equity, efficiency, and quality healthcare provisioning.

The next steps include validating the tool across multiple sites, exploring its broader applications, and developing a standardized costing approach that accounts for patient-specific characteristics. Also, leveraging the role of digital health systems like the Ayushman Bharat Digital Mission (ABDM) in facilitating automated data collection as a means to improve the accuracy and reliability of cost analyses and updating and standardization of cost databases.

abs-os610 Essential Building Blocks for Establishing Costing Systems in LMICs: Insights from India

PRESENTER: **Manju Sengar**

The robustness of costing systems for universal health coverage (UHC) is critical to ensure the effective allocation of resources, accurate financial planning, and the delivery of equitable healthcare services. However, for costing systems to be truly effective and reliable under UHC frameworks, they must be built upon a foundation of strong information systems, standardized coding, and well-structured methodologies. These building blocks ensure that data is accurate, consistent, and usable across diverse healthcare settings, thus enabling health systems to better meet the needs of their populations. In this session, we will explore the key components required for building robust costing systems for UHC, with a particular focus on the technical and practical aspects of implementing standardized coding, IT systems, and costing methodologies. We will examine the challenges and best practices for establishing these systems in diverse settings, and discuss in depth experiences and lessons from India.

Building a robust costing system requires the development of reliable IT systems that can store, process, and analyse health cost data efficiently. These systems need to be scalable, secure, and able to handle large volumes of data, which are common in health systems, especially in low- and middle-income countries (LMICs) where health service utilization may be high. The IT infrastructure must be designed to facilitate real-time data entry, ensure interoperability across different health system components, and support decision-making processes related to budgeting, policy development, and resource allocation. At the core of a robust costing system is the integration of standardized coding systems, such as the International Classification of Diseases (ICD-10) codes, which provide a common language for classifying diagnoses and health conditions. This standardization is essential for ensuring that health data is comparable and consistent across different institutions, regions, and countries, thereby enabling a more accurate assessment of healthcare costs. In addition to diagnostic codes, procedure codes are also integral to costing systems, as they enable the classification of medical interventions and services provided. These codes are critical for capturing the full scope of healthcare services and their associated costs, supporting more granular and accurate costing analyses.

Standardized costing manuals and methodologies are another critical component of an effective costing system. These manuals provide guidelines for consistently capturing and calculating costs associated with various health services and interventions. They outline the processes for allocating both direct and indirect costs, and how to account for the complex factors that contribute to the cost of healthcare, such as labor, equipment, pharmaceuticals, and overhead costs. These standardized methods ensure that costing is not only accurate but also comparable across different providers, regions, and health programs.

Additionally, cost data systems must be integrated with broader health financing frameworks and policy-making processes. This requires close coordination between various stakeholders, including health ministries, insurance bodies, hospitals, and healthcare providers. Successful integration of costing data into decision-making processes allows policymakers to use the information for setting fair and equitable health benefit packages, pricing health services appropriately, and optimizing the allocation of resources to improve health system performance.

abs-os584 National Cancer Grid: Transforming Cancer Care in India Through Costing Systems and Affordable Solutions

PRESENTER: **C S Pramesh**

The National Cancer Grid (NCG) is a pioneering initiative dedicated to standardizing and improving the quality, affordability, and accessibility of cancer care across India. As a network of 340 cancer centres, research institutes, and patient advocacy groups, the NCG has developed resource-stratified cancer treatment guidelines tailored to the needs of India's health system. These guidelines are aligned with the health benefits packages (HBPs) of PM-JAY, India's national health insurance scheme, and are informed by cost-effectiveness evidence and feasibility assessments. By integrating adaptive health technology assessment, the NCG ensures that HBPs are rationalized to deliver evidence-based, value-driven cancer care.

A cornerstone of the NCG's approach is its development of oncology-specific electronic medical record (EMR) systems. These systems standardize the collection of data on resource utilization, costs, and charges, enabling accurate cost estimation for cancer care delivery. They

also establish sustainable mechanisms for cost accounting, identify opportunities to improve technical efficiency, and provide robust data for economic evaluations. By leveraging these insights, the NCG optimizes resource allocation and enhances the financial sustainability of cancer services under PM-JAY.

The NCG has also addressed the critical challenges of affordability and equitable access to cancer medicines by implementing pooled procurement practices. In a pilot involving 23 centres, pooled demand for 40 high-value oncology and supportive care drugs totalled INR 15.6 billion (USD 197 million) at maximum retail prices. This process, underpinned by comprehensive technical and financial evaluations, resulted in cost savings of INR 13.2 billion (USD 166.7 million), with discounts ranging from 23% to 99% (median: 82%). Notably, savings were greater for generic medicines compared to patented drugs, demonstrating the potential of pooled procurement to reduce out-of-pocket expenditures and improve treatment outcomes.

This session will highlight the NCG's strategic efforts to rationalize HBPs, streamline procurement processes, and deliver cost-effective cancer care. It will also examine how these initiatives, underpinned by cost data, adaptive health technology assessments, and innovative procurement models, can be adapted and implemented in other low- and middle-income countries to address similar challenges in cancer care delivery.

Measuring and Valuing Health-Related Quality of Life in Children and Young People: Evidence to Support Policy and Decisions.

MODERATOR: **Stavros Petrou**, Nuffield Department of Primary Care Health Sciences, University of Oxford

CONVENER: **Martin Howell**, University of Sydney

abs-os277 Are Best-Worst Scaling (BWS) Surveys and Discrete Choice Experiments (DCEs) Feasible in Children and Young People? A Think Aloud Study

PRESENTER: **Marcus Sellars**

AUTHORS: Martin Howell, Pam Wong, Joanna Coast, Kirsten Howard, Rakhee Raghunandan, Anna Denejkina, Emily Lancsar, Elisabeth Huynh

Objectives: To determine the ages at which it seems to be feasible for children and young people (CYP) to complete (i) BWS and (ii) DCE tasks, and to explore any issues associated with completion of each type of task. **Methods:** A qualitative research study using a think-aloud design followed by semi-structured interview was planned with CYP aged between 8 and 12. Recruitment was conducted sequentially, with CYP aged 11 and 12 interviewed first, and then dropping down in age until CYP were no longer able to complete. Participants were asked to 'think aloud' when completing the 4 BWS task comprising of statements of the PedsQL instrument and 4 DCE tasks comprising a choice between two scenarios described by items of the of the PedsQL instrument. The order of the BWS and DCE varied to explore whether this influenced feasibility. Interviews were transcribed and examined for errors (comprehension, judgement and response) or struggle by three raters (MS, EH, JC). Qualitative data were collected to explore reasons for errors in completing the measures and participants' views about the measures. **Results:** The task became very difficult with 9 year olds and so the judgement was made to stop recruitment with that age group. The 40 participants included 14 (35%) 9-year-olds, 11 (27.5%) 10-year-olds, 9 (22.5%) 11-year-olds, and 6 (15%) 12-year-olds, with a roughly even split between sexes. Most CYP were reported to be in very good or good health (97.5%); 20% were reported to have a disability. Overall, participants encountered more errors or struggles during the four DCE tasks, with a median of 14/40 participants making an error and 3/40 experiencing a struggle on each task. In contrast, during the four BWS tasks, a median of 4/40 participants made an error and approximately 2.5/40 experienced a struggle on each task. Across age groups, DCE tasks were consistently more challenging than BWS tasks. No clear trend showed older age groups making fewer errors or struggling less than younger ones on either task, indicating variability. However, the qualitative experience of a struggle appeared more difficult among younger participants, challenging engagement. Interestingly, participants who completed the BWS tasks first tended to perform better on subsequent DCE tasks, and those starting with DCE tasks showed improved performance on later BWS tasks. Comprehension errors were most clearly related to the DCE/BWS nature of the task, whereas judgement and response errors were more commonly related to misinterpretation of items on the PedsQL. **Conclusions:** Both DCE and BWS tasks were feasible for most CYP in the study, though DCEs had more errors and struggles, indicating greater difficulty. Errors varied by age, with younger participants appearing to find struggles more difficult compared to older participants, impacting engagement. Misinterpretation of items within task type suggests a need for further study examining feasibility of the PedsQL in CYP.

abs-os280 Australian Scoring Algorithms for the Pediatric Quality of Life Inventory Generic Core Scales: Best-Worst Scaling and Discrete Choice Experiment

PRESENTER: **Elisabeth Huynh**, Australian National University

AUTHORS: Marcus Sellars, Joanna Coast, Mr. Stavros Petrou, Martin Howell, John Buckell, Kirsten Howard, Emily Lancsar, Rakhee Raghunandan, Jo Wray

Background: The Pediatric Quality of Life Inventory™ Generic Core Scales (PedsQL™ GCS) are some of the most widely used non-preference based instruments for measuring health related quality of life in children. The aim of this study is to derive preference-based scoring algorithms for the PedsQL™ GCS in Australia, for the scales covering four age groups from 2-18 years old. These algorithms are intended to

provide values for use in estimating quality-adjusted life years (QALYs) in economic evaluations of healthcare interventions targeted at children and young people (CYP). Methods: Two stated preference surveys were conducted across the four age modules. Survey one used best-worst scaling (BWS) to elicit values for the full set of 21-23 items of the PedsQL™ GCS instrument. Survey two used a discrete choice experiment (DCE) to value a reduced item set, with a single item for each of the four sub-scales (physical, emotional, social and school functioning) of the PedsQL™ GCS . The surveys were distributed across eight demographic groups each of 500, reflecting the age groups for the PedsQL™ GCS modules and to capture different perspectives (parent proxy, CYP and general adult): two parent samples to value toddlers (age 2-4 module) and young children (age 5-7 module); two CYP samples for children (age 8-12 module) and adolescents (age 13-18 module); and four general adult population samples, one valuing each PedsQL GCS module. The stated preference task was designed to increase engagement using videos and pictures. The data were analysed using choice-based models accounting for scale and preference heterogeneity. Standard DCEs and BWSs do not automatically provide anchored values on the QALY 1–0 full health–dead scale for use in economic evaluation. We explored the use of a Time Trade Off (TTO) task and Visual Analogue Scale (VAS) to anchor the scores for the BWS and DCE. For the parent and adult samples, we used a DCE with duration task to directly calculate anchored utilities. Results: The data are currently in the process of final collection and analysis. The preliminary findings have resulted in four distinct tariffs for each age-specific full-item module: one for proxy/self-completed assessments and one for the general population. A preference-based tariff for proxy/self-completed assessments for the reduced form version of the PedsQL™ GCS and another for the general population for the reduced form version have been generated. Conclusion: This study will provide preference-based scoring of the PedsQL™ GCS measure, involving children and young people, parent proxies, and members of the general public. The selection of the appropriate tariff should consider the perspectives of decision-makers, weighing the advantages and disadvantages of each tariff.

abs-os266 Development of a PedsQL 4.0 GSC Reduced-Item Version for Preference-Based Valuation in Australia

PRESENTER: **Rakhee Raghunandan**, University of Sydney
AUTHORS: Martin Howell, Sarah Smith, Kirsten Howard, Joseph Kwon, Emily Lancsar, Son Nghiem, Mr. Stavros Petrou, Elisabeth Huynh

Background: The Pediatric Quality of Life InventoryTM Version 4.0 Generic Core Scales (PedsQL GCS) is one of the most widely used generic non-preference-based measures of childhood health-related quality of life (HRQOL). It includes 23 items covering four sub-scales (physical, emotional, social, and school functioning), and produces a total score on a linear 0 to 100 scale with higher scores denoting better HRQOL. Encompassing modules for ages two to eighteen years, the PedsQL GCS includes four age-appropriate versions (Toddlers, Young Children, Children, and Teens). Generic HRQOL instruments which generate health utility scores are useful for economic evaluations as they enable comparison across multiple conditions. Whilst the widely used PedsQL GCS is useful for assessing HRQOL, its application to aid cost-effectiveness-based decision-making is limited as it does not generate health utility scores. This study aimed to develop a reduced-item version of PedsQL GCS which can be used for health utility derivation in Australia.

Methods: Data were obtained from two cohorts of the Longitudinal Study of Australian Children and included the longitudinal sample of parent/caregiver proxy-reported responses for all PedsQL GCS versions (Toddlers, Young Children, Children, and Teens), and the cross-sectional CheckPoint sample containing child self-reported responses to the Children version. The analysis utilised three samples: the CheckPoint sample, the Mallinson sample, and the Toddlers sample. To account for repeated measures in the Rasch analysis, the Mallinson sample applied the Mallinson method to randomly select one measurement per child from one of the Young Children, Children or Teens versions. The PedsQL GCS sub-scale structure was confirmed using exploratory and confirmatory factor analyses. The psychometric analyses used Rasch and Classical criteria. Item selection prioritised psychometric performance in the CheckPoint sample, whilst considering performance in the two other samples and conceptual relevance.

Results: The exploratory and confirmatory factor analyses did not generate an alternative empirical structure for the measure, and the original four sub-scale structure was taken forward to psychometric analyses. Based on the psychometric criteria, the best-performing item from each sub-scale was selected for the reduced-item version of the PedsQL GCS. The selected items were: ‘Get aches and pains’ for physical functioning; ‘Feel sad/blue’ for emotional functioning; ‘Other kids not friends’ for social functioning; and ‘Keeping up with school work’ for school functioning.

Conclusion: The derived four-item PedsQL GCS version was developed using published recommended methods and a transparent item selection process. When accompanied by preference-based value sets, this reduced-item version can generate health utilities from the widely used PedsQL GCS to inform cost-effectiveness-based decision-making for children aged two to eighteen years.

abs-os272 The Social Value of a Child QALY - Revealed Preference Study Using Pharmaceutical Coverage Decisions in Australia from 2005 to 2023

PRESENTER: **Jing Jing Li**
AUTHORS: Emily Lancsar, Leonie Picton, Nayyereh Ayati, Anthony Harris, Kah Ling Sia, Nicola Huxley, Kirsten Howard, Rakhee Raghunandan, Duncan Mortimer

Context: A number of jurisdictions now formally include at least one aspect of equity, in addition to total health gains, in health technology assessment decisions. The equity aspect has largely focussed on need, expressed as potential years of life lost, but some agencies are thought to include age at least informally as a consideration. Recent literature suggests public support for giving greater weight to identical health gains in children versus adults, but no decision-making agency explicitly applies different weights to health gains for children. Objectives: To analyse revealed preference data to understand how factors related to paediatric populations (compared to the adult population) have influenced public subsidy decisions of pharmaceuticals in Australia. Methods: We compiled a dataset of evidence presented to the Australian Pharmaceutical Advisory Committee (PBAC) that makes recommendations on public subsidy of pharmaceuticals on the national Pharmaceutical Benefits Scheme. Our sample included all submissions to the PBAC from July 2005 to Nov 2023 if one of the outcomes measured was quality adjusted

life years (QALY) or if it was based on a cost minimisation analysis, assuming no incremental health benefits and only cost differences (N=1659). In our sample, 524 submissions had requested coverage for a child-only or child plus adult population. We econometrically tested whether interventions in children were more likely to be recommended for public subsidy compared to intervention in adults controlling for other factors that impact decisions. Results: Interventions targeting children were more likely to be recommended by the PBAC along with other significant factors including clinical uncertainty, clinical effect size, cost effectiveness and cost to government. Preliminary results suggest that compared to submissions for adults, submissions for children had significantly higher odds of being recommended after controlling for other major factors in decision making. Conclusion: We find evidence of a greater implied social value for health gains in children relative to adults in recommendations on pharmaceutical coverage decisions in Australia. This is the first study in the world to have demonstrated this in the context of public subsidy of pharmaceuticals.

Supporting Environmentally Sustainable Decisions with Health Economics Methods

MODERATOR: **Sandy Tubeuf**, Université catholique de Louvain (UCLouvain)

CONVENER: **Chris Sampson**, Office of Health Economics (OHE)

abs-os755 Adapting Health Economic Evaluation Methods to Include Climate Impacts: Intermediate Results of a Delphi Process

PRESENTER: **Wolf Rogowski**

AUTHORS: Don Husereau, Mattis Keil, Oliver Lange, Jule Oldenburg, Laura Maass

For making environmentally sustainable decisions, the existing health economic evaluation (HEE) methods need to be adapted to account for the environmental impacts of the decision alternatives under investigation. One important environmental concern is accounting for climate change. While the life cycle assessment (LCA) methods for estimating the impact of new technologies on global warming are well established, there is still a lack of standards for estimating and incorporating such impacts alongside health economic evaluations. This study reports on a methodological proposal that serves as a starting point for a Delphi process for extending the Consolidated Health Economic Evaluation Reporting Standards by climate impacts (CHEERS climatE) and the intermediate results of the Delphi process.

The proposal was based on an initial mapping of methodological items for estimating climate footprint to the reporting items of CHEERS. For 17 of the CHEERS reporting items, amendments were proposed and their potential application was illustrated using a hypothetical cost per DALY analysis. Based on these preliminary amendments, an expected three-round Delphi process with experts in HEE and / or LCA is planned early in 2025, aiming to refine the amendments and validate their relevance for inclusion into the extended reporting standard.

Generally, climate impacts can be accounted for both on the cost and the effect side of HEE. It requires estimating climate footprint using process- or cost-based methods based on the resources or costs estimated in the HEE. To incorporate climate footprint on the effect side, health impacts can be estimated using LCA models like ReCiPe. These negative impacts can be added to the health benefits of the technology itself. LCA impact models typically report health impacts in DALYs. Therefore, this option may be applicable, particularly for analyses based on DALYs as health outcomes. For incorporating climate impacts on the cost side, national standards for costing greenhouse gas emissions are frequently available that may need to be adjusted to exclude carbon prices that are already incorporated among the costs due to carbon trading schemes or taxes. Different summary measures are available to incorporate climate impacts, e.g. climate-effect or climate-cost adjusted incremental cost-effectiveness ratios, net monetary or net health benefits. Besides further details on how HEE can be adapted to include climate impacts, the current state of recommendations on how to report these adaptions from the ongoing Delphi process will be presented.

Given that an increasing number of jurisdictions require considering climate impacts in procurement decisions and in evaluating health technologies, this research may help develop standards for doing so in a transparent, harmonized way. Further work will be necessary to incorporate other ecological impacts besides greenhouse gas emissions.

abs-os754 Decision Analysis for Planetary and Human Health: Waste Management in the Life Sciences Industry

PRESENTER: **Mr. Chris Sampson**, Office of Health Economics

AUTHORS: Ellie Tunnicliffe, Grace Hampson, Matthew Napier, Sian Hodgson

Background: Biopharmaceutical and life sciences companies represent a significant sector of the economy and are important actors in the achievement of international environmental sustainability objectives. Where organisations in the sector value both planetary and human health outcomes, there may be challenging trade-offs that could be addressed by decision analysis, including tools routinely used in health economic evaluation. However, health economic analysis methods have seldom been applied in the development of environmental sustainability policy.

Aim: This research sought to inform waste management policy for a plasma derived therapies business in the United States. The objective was to identify the optimal waste management strategy when considering environmental impacts, human health impacts, and costs, and to inform new sustainability targets.

Methods: This study included literature review, decision-analytic modelling, and a decision conference. The literature review identified comparative life cycle assessments of i) landfill, ii) incineration, iii) waste-to-energy incineration, and iv) mechanical recycling. Quantitative estimates of environmental impacts were extracted and incorporated into a spreadsheet-based decision model. The model compared a set of realistic waste management options based on the company's biohazardous and non-hazardous waste streams and materials. It estimated midpoint and endpoint environmental factors in accordance with the ReCiPe framework; a widely used method of life cycle impact assessment. The two-day decision conference involved company decision-makers identifying, scoring, and weighting decision criteria. Scoring of midpoint environmental factors aligned with those reported by the decision model and weights were adopted in alignment with the European Commission's Product Environment Footprint (PEF) methodology.

Results: It was feasible to produce meaningful estimates to inform trade-offs. For example, for an average plasma donation centre over 1 year, our base case showed that landfill of all waste would generate around 14 million kg of CO2 equivalents, at a cost of around $225,000 and 519 disability-adjusted life years (DALYs). No waste management strategy dominated across all outcomes. In the base case, mechanical recycling combined with landfill dominated other options in terms of endpoints, though this was sensitive to alternative scenarios (e.g. time horizon). The decision conference concluded that wider adoption of mechanical recycling would be beneficial, and that targets and policies should be set accordingly. Where recycling is infeasible, landfill was identified as tending to be superior to incineration (with energy recovery), driven primarily by differences in greenhouse gas emissions.

Conclusions and implications: This study adopted well-established methods from health economics to address a decision problem that is primarily driven by the need to achieve more environmentally sustainable outcomes. The synthesis of evidence from life cycle assessments was challenging due to their limited comparability. Nevertheless, the decision model provided the scope to explore alternative scenarios and priorities, thus extending the value and applicability of published life cycle assessments. Decision conferencing, using methods of multi-criteria decision analysis, facilitated the balance of complex quantitative and qualitative inputs, while acknowledging corporate values and feasibility constraints. Evaluative health economics methods hold promise beyond their application to health care, and future research should explore their combination with established life cycle assessment (LCA) methods.

abs-os753 How Should Health Economic Evaluations Support Sustainability Considerations?

PRESENTER: **Mr. Andrew Briggs**
AUTHORS: Evi Germeni, Caitlin Macclancy

Background: There has been a proliferation of papers in the health economics and health technology assessment literature concerning the inclusion of environmental and sustainability factors into economic appraisals of health interventions. Although many such papers use the term sustainability, few define precisely what is meant by sustainability or how methods proposed will address sustainability concerns.

Aim: The aim is to explore the use of sustainability as a concept in terms of how it has been used in the literature and to consider how health economic evaluation approaches might be adapted to address sustainability concerns.

Methods: Drawing on a recent update of a published scoping review, the recently published scoping review of the literature from 2009 to 2021 was updated to 2023. The review was targeted at the proposed use of methods to address environmental and sustainability concerns in health technology assessment and guidelines. The review was expanded to consider how often sustainability as a term was employed in the papers reviewed and how often this term was defined. The author's own critique of those studies is presented alongside what sustainability considerations might mean for the conduct of health economic evaluation.

Results: Sustainability as a term was mentioned in eighteen of the final twenty-eight included reports that formed the 2021-23 update of the scoping review. Only one-third (six) of those studies attempted to offer a definition of sustainability. Sustainability seems to have been used synonymously with including environmental considerations by authors to date, yet this is not the commonly understood definition of sustainability. Adapting the 1987 United Nations Brundtland Commission definition of sustainability as *"meeting the needs of the present without compromising the ability of future generations to meet their own needs"* to the health context implies the need to consider trade-offs between health maximisation of the current generation compared to future generations. This was not considered by any of the articles covered by the scoping review.

Conclusions/implications: The use of the term 'sustainability' is widely used but ill-defined in recent manuscripts addressing the need to include environmental considerations into health technology assessments. No studies reviewed identified how methods would be used to manage inevitable health trade-offs between populations. Authors should be careful to define precisely what they mean by sustainability when proposing methods for incorporating sustainability considerations into health economic evaluations.

Telemedicine's Transformative Impact: Reshaping Healthcare Markets in Australia

MODERATOR: **Susan Méndez**, University of Melbourne

DISCUSSANT: **Terence Cheng**, Monash University

abs-os52 Does Telemedicine Affect Prescribing Quality in Primary Care?

PRESENTER: **Ms. Maria Wisniewska**
AUTHORS: Daniel Avdic, Johannes Kunz, Ms. Susan Méndez

Background: Our paper contributes to the literature on telemedicine and quality of care, specifically focusing on an innovative approach towards delivering primary care services via phone and video consultations. Current research shows mixed effects of telemedicine on quality of services, with some studies indicating that telemedicine can increase unwarranted prescription rates and lower guideline adherence. We add to the literature by exploring the adoption and consolidation of telemedicine in Australia among primary care providers from a supply-side perspective. **Objectives:** This study aims to investigate the impact of the nationwide rollout of telemedicine services in Australia on costs and quality of care among general practitioners. Specifically, the study seeks to analyse how utilisation of remote consultations affects antibiotic prescriptions rates. Furthermore, our research delves into the characteristics of telehealth service providers, considering distinctive physician-specific traits such as age, gender, educational background, personality and attitudes toward digital health technology. **Methods:** The study employs a two-stage empirical strategy: first, we classify physicians into fast and slow telehealth adopters based on their intensity of utilising newly-introduced telemedicine services during the country-wide COVID-19 lockdown period. Second, we compare their rates of antibiotic prescriptions before and after lockdown periods using a difference-in-differences empirical design. In the study, we use the Medicine in Australia: Balancing Employment and Life Australia's (MABEL) national longitudinal survey of doctors linked with administrative records of all benefits and pharmaceuticals reported on the physician level. We also use population-wide data from the Person Level Integrated Data Asset (PLIDA) to show robustness of our results and analyse long-term impact until the last quarter of 2022. **Results:** Our study finds that the rate of antibiotic prescriptions per consultation of fast adopters decreased significantly – by around 10% – relative to slow adopters. While the absolute amount of antibiotic prescriptions remained on a similar level across both groups, we show that the decrease in prescribing rates is driven by a significant increase in the total number of conducted visits. The study also identifies that telehealth did not elicit risky prescribing behaviour nor did it impair the quality of services, as fast telemedicine adopters reduced their use of broad-spectrum antibiotics for respiratory tract infections compared to slow adopters by around 5%. Additionally, there was a small but insignificant increase in total visit costs, however it was mainly covered by government subsidies. **Discussion:** The insights from our study have implications for healthcare policy, showing that telemedicine doesn't elicit risky prescribing behaviours among general practitioners. Our results indicate that the adoption of telemedicine did not compromise the quality of care. Physicians who adopted telemedicine more intensely reduced their rates of antibiotics prescriptions and, at the same time, conducted relatively more consultations. These results point to two conclusions: first, telemedicine may have a potential in improving the efficiency of conducting primary care consultations. Second, this solution might be used in bringing high-quality care to isolated and disadvantaged groups, especially in areas with large rural and low-populated regions.

abs-os56 Impact of Telehealth Adoption by Psychiatric Specialists on Wait Times.

PRESENTER: **Mr. Ou Yang**, Melbourne Institute of Applied Economic and Social Research
AUTHOR: Yuting Zhang

Background: One significant challenge within Australia's universal healthcare system is the rising waiting times to see medical specialists. Psychiatry has become one of the most consulted medical specialties outside of hospital settings, receiving substantial subsidies from Medicare. Despite this support, there is a notable lack of evidence regarding waiting times for psychiatric specialist consultations for general outpatients in Australia. Telehealth is often considered an effective tool for reducing waiting times and overcoming geographical barriers. However, in Australia, there has been very limited evidence on how telehealth services interact with in-person consultations, largely due to the underutilisation of telehealth before the COVID-19 pandemic. In response to the COVID-19 pandemic, there have been several incentives to encourage telehealth adoption in Australia since 2020 Understanding the interactions between telehealth and in-person services is critical for evaluating the effectiveness of these existing incentives and investments. **Objectives:** Our study aims to investigate how the wider adoption of telehealth for psychiatric specialist consultations in Australia affects consultation waiting times and fees. **Methods:** We analyse all records of Medicare-rebated GP referrals to psychiatric specialist across Australia from Q1 2011 to Q3 2023 sourced from the Medicare Benefits Schedule (MBS) data collection within the Person Level Integrated Data Asset (PLIDA. We apply a fixed effects linear regression which respectively relates waiting time and fee to telehealth adoption, controlling for the referral pair fixed effects between GPs and specialists. **Results:** We find that wider telehealth adoption leads to higher waiting times on average in Australia, which is mainly driven by higher waiting times for in-person consultations. In contrast, wider telehealth adoption leads to shorter waiting times for telehealth consultations. Wider telehealth adoption leads to about 0.04 dollars lower fees, which is statistically significant but in practice very small. **Discussion:** The potential benefits of telehealth in reducing specialist consultation waiting times and costs seem to be offset by increased demand, driven by improved accessibility. It would be more effective to invest in lifting psychiatric specialist service capacity by addressing health workforce shortages.

abs-os51 The Economic Impact of Telemedicine Uptake on General Practitioners in Australia.

PRESENTER: **Ms. Susan Méndez**, University of Melbourne
AUTHORS: Bishal Kumar Chalise, Daniel Avdic, Paul Amores, Carol Propper, Anthony Scott

Background: The COVID-19 pandemic prompted rapid diffusion remotely provided telemedicine consultations that has profoundly reshaped healthcare delivery, financing, and market dynamics structures in primary care. While existing research has explored the impact of telemedicine on healthcare access and quality, few studies have addressed its impact on general practitioners' financial and economic outcomes in a system with managed competition. This study fills a critical gap in understanding telemedicine's broader implications in primary care in a market setting where doctors prices are not directly regulated. **Question:** This study investigates the impact of telemedicine adoption on GP consultation patterns, billing practices, and costs to patients in Australia. **Methods:** The study uses detailed survey data from GPs (MABEL) linked to administrative records of their service provision from the Medicare Benefit Schedule (MBS) and Pharmaceutical Benefit Scheme (PBS). To address doctors' potentially endogenous decisions to adopt telemedicine, we adopt an instrumental variables approach where telemedicine uptake in each local area is instrumented by changes in physical mobility from Google mobility data. **Results:** Our findings

suggest that the degree of telemedicine uptake does not change the number of services physicians provide but increases fees for both face-to-face and telemedicine consultations. While the increased costs of face-to-face consultations are largely passed on to patients in terms of higher out-of-pocket costs, the higher price of telemedicine services is mainly subsidised by the government. **Conclusions:** Telemedicine adoption influences not only service delivery models but also the economic dynamics within primary care. Our results suggest that telemedicine uptake is associated with higher prices but not necessarily higher quality or access. Further analysis is required to study the specific market channels underlying these results, including competition for patients and service differentiation.

DISCUSSANT: **Karen Grépin**, The University of Hong Kong

abs-os71 Association of Social and Health Spending with Disability-Adjusted Life Years and Death among 38 OECD Countries Between 2000 and 2019

PRESENTER: **Sungchul Park**, Korea University
AUTHORS: Joseph Dieleman, Subu Subramanian, Rockli Kim

Background: Social and health spending are crucial for improving health outcomes, but the mechanisms underlying these associations remain unclear. Existing literature suggests that both types of spending are associated with higher life expectancy, which measures quantity of life. However, the impact on quality of life may differ. To gain a deeper understanding of this relationship, we examined the associations of social and health spending with Disability-Adjusted Life Years (DALY), Years of Life Lost (YLL), Years Lived with Disability (YLD), and death rates among 38 countries in the Organisation for Economic Cooperation and Development (OECD) from 2000 to 2019.

Methods: We analyzed data from the Global Burden of Disease Study 2021 as well as from the OECD and World Bank. Our sample included 38 countries. The outcome measures comprised age-standardized rates of DALY, YLL, YLD, and death per 100,000 population. The key independent variables were social and health spending as a percentage of gross domestic product (GDP). Social spending was defined as expenditures on social programs, including funding for active labor-market programs, incapacity and unemployment benefits, family support programs, housing, and pensions. Health spending included a wide range of expenditures on health care goods and services, encompassing mandatory government spending, voluntary health insurance, and private out-of-pocket expenses. To estimate the association of social and health spending with health outcomes, we conducted a fixed effects model. We controlled for time-varying factors using population size, age distribution, percentage of females, the Socio-demographic Index, employment rates, population attributable fraction of modifiable risk factors, and year. To account for potential lagged effects, we analyzed the key independent variables as concurrent, one-year lagged, and two-year lagged. We conducted analyses for the overall population as well as for males and females separately.

Results: Our fixed-effect analysis revealed significant associations of health and social spending with health outcomes, but the patterns varied. Specifically, a one-percentage-point increase in health spending was associated with a decrease of 8.7 (95% CI: -12.3, -5.2) death per 100,000 population and an increase of 105.9 (95% CI: 17.3-194.5) DALY per 100,000 population. The increase in DALY was primarily driven by an increase in YLD of 74.7 (95% CI: 61-88.5) per 100,000 population. In contrast, social spending did not show a significant association with DALY, but a one-percentage-point increase in social spending was associated with a decrease of 15.7 (95% CI: -22.9, -8.6) YLD per 100,000 population. When accounting for lagged effects, the magnitude of the associations with health spending increased, while the magnitude of the associations of social spending decreased.

Conclusion: These findings highlight the distinct mechanisms through which health and social spending impact health outcomes. Health spending predominantly influences mortality, while social spending appears to enhance quality-of-life measures. Policymakers should consider these complementary effects when designing interventions to optimize health outcomes.

abs-os70 Health Care Spending Efficiency and Key Associations: 204 Countries, 1995-2021

PRESENTER: **Joseph Dieleman**, University of Washington
AUTHORS: Amy Lastuka, Kayla Taylor, Michael Breshock

Introduction: Many high- and middle-income countries' governments are facing increasing pressure to stabilize or prevent growth in health care spending, while all countries are called to maximize the budget they have. Finding ways to increase efficiency of health spending can ensure that health outcomes continue to improve in a tight fiscal environment.

Methods: We estimated the efficiency of health spending in 204 countries from 1995 through 2021 using a stochastic non-linear frontier meta-analysis model, a new extension of traditional stochastic frontier analysis (SFA) that incorporates non-linear splines and sampling error as well as non-sampling error via random effects. We fit two frontiers using health adjusted life expectancy and under-five mortality as health outcomes

and assessed the estimated country- and year-specific inefficiency.

Results: The health system efficiency for preventing under-five mortality improved from 1990 to 2021 for all regions globally. For health adjusted life expectancy, efficiency improved through 2019 and then decreased in 2020 and 2021, due to the COVID-19 pandemic. We found that if all countries were to move from their 2019 level of health outcomes to the frontier, 6.5 million (95% CI 4.9-8.7) under-five deaths could be avoided annually, and health adjusted life expectancy could increase by 1.5 (95% CI 1.3-1.8) years per capita. We found that a having a higher percentage of health expenditure from the government or pre-paid private sources was associated with more efficient spending. Other factors associated with increased efficiency were a higher democracy index, a higher percentage of women in parliament, and higher road density. Having a higher percentage of health expenditure from donor assistance, government corruption and having more fragmented donor spending, in terms of the number of sources and designated program areas, were associated with less efficient health spending. A higher percentage of out-of-pocket spending was associated with less efficiency for under-five mortality but not for health adjusted life expectancy.

Discussion: These associations support the perspective that increasing the proportion of citizens who are covered by insurance, either through the government or pre-paid private insurance, would increase efficiency of the health care system. Countries should also focus on strengthening democracy and controlling corruption. Future research should look at spending by health condition where possible to specifically examine allocative efficiency.

Ind-819 Examining the Associations Between Long-Term Care Expenditures, Medical Care Spending, and Health Outcomes: A Panel Data Analysis of OECD Countries

PRESENTER: **Yuqian Lin**
AUTHORS: Mr. Terence Cheng, Ms. Winnie Yip

Background: The rising challenges posed by population aging, prolonged life expectancy, and an increasing prevalence of disability among the elderly have led to a substantial surge in the demand for long-term care (LTC) services. In 2021, OECD countries spent an average of 1.8% of GDP on all LTC services, with a 5-year growth rate of 6%. On the supply side, declining fertility rates and changing family structures have led to a reduction in the provision of informal care. Given the labor-intensive nature of LTC, achieving productivity gains in the LTC sector remains a significant challenge. Consequently, the growth in long-term care spending is expected to surpass that of general health care expenditures in the coming years. However, the impact of LTC spending on overall health system performance remains less understood.

Research Aim: This study aims to examine the relationship between LTC expenditures, medical care spending, and health outcomes, to provide insights on whether increasing spending on long-term care truly contributes to improved health system outcomes.

Methods: We constructed a panel of 41 OECD countries, covering the years 2000 to 2021 using data from OECD Health Statistics, UN World Population Prospect, and Global Burden of Disease. A panel regression model with country and year fixed effects was estimated to analyze the association between long-term care expenditure as a percentage of GDP, and three sets of health system outcomes: medical care expenditure, medical care utilization, health outcomes among the older population.

Results: Our findings indicate that long-term care expenditure is positively associated with higher medical care spending, and this relationship is observed at a number of different spending categories (total, inpatient, and outpatient). The association between LTC expenditure and outpatient medical care spending is particularly strong, and our results indicate that this is potentially driven by a greater utilization of physician visits. In terms of inpatient care, we observed that higher LTC expenditure is associated with shorter hospital lengths of stay. While we did not find a significant association between LTC expenditure and life expectancy, we identified consistent patterns showing a negative association between LTC spending and mortality and morbidity related to unintentional falls.

Conclusion and implications: Overall, our results indicate that increased spending on LTC is linked to higher medical care expenditure, greater utilization of outpatient care, shorter hospital stays, and reduced mortality and morbidity from unintentional falls. Our results highlight the complex interplay between LTC and medical expenditures, and its potential role in improving health status of older persons. The findings underscore the need for policymakers to consider the broader implications of LTC financing to achieve effective allocation of resources and ultimately improve health outcomes and enhance the sustainability of health systems in the face of an aging population.

Shaping Birth Outcomes: Social, Economic, and Policy Influences

MODERATOR: **Asmamaw A. Ayalneh**,

Ind-1532 The Impact of In-Utero Exposure to the Great Recession on Birth Outcomes in South Korea

PRESENTER: **Youna Lim**
AUTHOR: Tae-jin Lee

While extensive research has documented the socioeconomic impacts of economic crises, their long-term effects on early-life health outcomes remain understudied, particularly in Asian economies. This study addresses this empirical gap by investigating the causal impact of in-utero exposure to the 2008 Great Recession on birth outcomes and subsequent child development in South Korea, examining both immediate and longitudinal health consequences.

This study implements a difference-in-differences methodology to estimate the causal effects of recession exposure by utilizing comprehensive Korean National Health Insurance Service (K-NHIS) data for children born between 2006 and 2014. The identification strategy leverages regional heterogeneity in real Gross Regional Domestic Product (GRDP) per capita, with regions below the national average designated more severely affected. The analysis encompasses birth outcomes, including birth weight, low birth weight incidence, preterm births, and postnatal physical development indicators (height, weight, and head circumference) tracked longitudinally up to 60 months of age. The study designates 2009 as the economic crisis period and examines outcomes for in-utero-exposed cohorts.

Empirical results demonstrate significant adverse effects on both birth outcomes and subsequent development. In-utero exposure to the economic crisis was associated with reduced birth weight and elevated incidences of low birth weight and preterm births. These effects persisted into early childhood, with significant height reductions observed at 36 and 60 months in crisis-affected regions. Composite physical development assessments revealed higher probabilities of requiring clinical observation after 36 months, indicating persistent crisis-related developmental impacts.

Heterogeneity analyses stratified by income quintile (proxied by insurance status) revealed that the most pronounced effects manifested in the third, fourth, and fifth quintiles. Birth weight reductions were particularly significant in the third and fourth quintiles, while preterm birth rates increased notably in the fifth quintile. Further stratification by maternal health insurance status demonstrated that offspring of mothers experiencing employment transitions or job loss exhibited the most substantial adverse effects, including reduced birth weight and diminished postnatal growth trajectories. These findings illuminate direct and indirect pathways through which economic downturns affect intergenerational health outcomes.

Robustness tests employing alternative economic indicators, including unemployment rates, corroborated the primary research findings. Comprehensive data analysis and placebo tests validated the causal relationship between economic crisis exposure and adverse health outcomes. The research demonstrates persistent intergenerational health consequences of economic instability, highlighting critical implications for early developmental trajectories. These findings emphasize the necessity of targeted interventions and evidence-based policies to mitigate long-term health risks for vulnerable populations during economic downturns.

Ind-2255 Educational Challenges of Children Admitted to the Neonatal Intensive Care Unit: A Longitudinal Study in Ireland

PRESENTER: **Mario Martinez-Jimenez**
AUTHOR: Orla Doyle

Advancements in the viability of extreme preterm birth—defined as birth before 37 weeks of gestation—have been remarkable, driven by groundbreaking research and medical innovation. In the 1970s, the youngest surviving infants were born at around 27 weeks, whereas today, viability is possible as early as 22 weeks, with higher chances of survival depending on whether they are admitted to a level 3 neonatal intensive care unit (NICU). Despite these advancements, extremely preterm infants remain at high risk for mortality and adverse long-term health outcomes. Using data from Growing Up in Ireland (GUI), a longitudinal cohort study following the lives of children born in 2008, we study the effects of being admitted to a NICU at birth on educational performance (reading and math tests) at age 9. We employ a regression discontinuity design (RDD) and exploit the variation of birthweight in the chances of being admitted to NICU. Preliminary results show that NICU admission is associated with lower average performance in both reading and math at age 9. These effects are particularly pronounced for children from lower socioeconomic backgrounds, suggesting that the educational challenges of NICU-admitted children may be exacerbated by socioeconomic disadvantage. Policy efforts should focus on enhancing support mechanisms within schools and communities, ensuring that children with a history of NICU admission, particularly those from disadvantaged backgrounds, have equitable access to resources that promote academic success.

Ind-2469 The Impact of Alcohol Bans on Birth Weight in South Africa

PRESENTER: **Tsepang Khumalo**

Alcohol consumption remains a significant global challenge, contributing to 2.6 million deaths in 2019. Alcohol not only leads to mortality, but it also has negative externalities on society. Excessive alcohol consumption is associated with accidental trauma, violent crimes, and significant health risks. To tackle alcohol abuse, governments have implemented alcohol control policies. Understandably, considerable research has focused on the impact of these policies on adult health outcomes as the policies primarily target adults. However, there is limited evidence of the effect of these policies on neonatal health, despite the long-term implications of neonatal health on future adult well-being and socioeconomic success. To address this gap in the literature, this study examines the impact of a policy that restricted access to alcohol on birth weight in South Africa. To identify the causal effect, I leverage the sudden and unexpected nationwide alcohol ban policy implemented from 27 March 2020 to 31 May 2020. The universal alcohol ban on the sales and transportation of alcohol was implemented in response to the COVID-19 pandemic by the South African government. The ban was enforced with strict intensity, making it a good natural experiment to estimate the causal impact of an alcohol restriction policy on neonatal health. I use birth records from 2017 to 2024 of women and children

participating in Building Healthier Communities (BHC) study. The BHC dataset provides detailed information on mothers and birth outcomes for children under 5 in Western Cape, South Africa. I compare the birth weight outcomes of neonates born to mothers who experienced the alcohol ban during pregnancy with those born to mothers unexposed to the alcohol ban. By natural design, there is no selection into pregnancy among these women during the alcohol ban. Thus, I estimate the causal impact of the ban on neonatal health outcomes using Ordinary Least Squares (OLS) regressions. I find that a policy that decreased alcohol availability improved birth weight. Specifically, I find that intrauterine exposure to the alcohol ban in the first trimester increases birth weight by 0.229 kilograms (kg). A heterogeneity analysis of a second ban implemented 6 weeks later indicates that the effects of the first ban results persist through the second trimester of the second alcohol ban. Specifically, the second-trimester exposure to the second alcohol ban increases birth weight by 0.252 kg. I observe a larger impact on birth weight because the study is based in the Western Cape province which is reported to have the highest prevalence of Fetal Alcohol Spectrum Disorders (FASD) in the world. Therefore, a ban on alcohol substantially affects health outcomes in this setting. The findings suggest that interventions to reduce alcohol consumption can improve child health outcomes. Considering the long-term effects of neonatal health on later-in-life human capital outcomes, such as education, productivity, and earnings, these results underscore the broader societal benefits of strict alcohol policies. These measures can positively impact future generations beyond their immediate targets.

Ind-2699 Hidden Disparities: Exploring the Multilevel and Spatial Determinants of Neonatal Health in Indonesia

PRESENTER: **Rooswanti Soeharno**
AUTHOR: Zahra Avia

Background. Despite achieving the Sustainable Development Goal (SDG) for under-5 mortality reduction, Indonesia's Neonatal Mortality Rate (NMR) remains a significant public health challenge, with over 70,000 deaths reported in 2018. This persistent burden undermines the country's "Great Indonesia 2045" vision, revealing systemic inequities and quality gaps in maternal and neonatal care. Financial barriers have been reduced, increasing healthcare utilization, but neonatal health outcomes remain stagnant due to socioeconomic disparities, geographic variations, and inadequacies in service quality. This study examines the multilevel and spatial determinants of neonatal health outcomes to inform targeted, equity-focused interventions. **Methods**. Data from Indonesia's 2018 national surveys, covering 34 provinces, 513 districts, and over 300,000 households, were analyzed. The sample included 73,086 women aged 10–54 who gave birth in the preceding five years. Multilevel regression, concentration indices, and spatial regression models were applied using STATA 14.0 and ArcGIS Pro 3. The analysis incorporated individual, community, and systemic factors, including maternal care quality, healthcare readiness, and fiscal capacity. Policy implications were assessed in alignment with the seven pillars of Indonesia's national health system. **Results**. NMR remains alarmingly high, with disparities evident across socioeconomic groups and geographic regions. Four models were explored, each adding complexity by integrating individual and community factors to assess neonatal risks. The Null Model, which excludes predictors, has an Intraclass Correlation Coefficient (ICC) of 0.2082, showing that 20.82% of risk variation is attributed to community-level differences. The Full Model (Model 4), combining both individual and community predictors, further reduced the ICC to 0.1600 and achieved the highest proportional change in variance (PCV) at 28%. The Median Odds Ratio decreased from 2.43 (Null Model) to 2.13 (Full Model), highlighting the effectiveness of the Full Model in offering a robust explanation of neonatal health risks, emphasizing the role of community and systemic factors in shaping outcomes. High NMR rates were concentrated in districts with limited fiscal capacity, poor antenatal care access, and low institutional delivery rates, while wealthier districts demonstrated higher service utilization. Quality of care was a key determinant, with antenatal services and institutional births significantly influencing outcomes. However, cultural reliance on traditional practices and barriers to facility-based care contributed to high out-of-facility birth rates. **Policy Implications**. Equity-focused policies are critical to reducing neonatal mortality and addressing systemic disparities. Prioritizing fiscal support for under-resourced districts is essential to bridging gaps in service quality and accessibility. Strengthening antenatal and institutional delivery services in underserved regions, coupled with culturally tailored community interventions, can improve care-seeking behavior and facility-based births. Spatial and multilevel analyses should guide the design of localized interventions, targeting areas of greatest need. Investments in supply-side readiness, including infrastructure and workforce capacity, are vital for ensuring equitable access to quality maternal and neonatal care. These evidence-based strategies will advance Indonesia's SDGs and its vision of "Great Indonesia 2045," reducing preventable neonatal deaths and fostering health equity nationwide.

3:30 PM –5:00 PM MONDAY [Supply And Regulation Of Health Services And Products]

Incentivising Performance and Care

MODERATOR: **Luigi Siciliani**,

Ind-739 Pay for Performance, Health Inequalities and Equity-Efficiency Trade-offs in Primary Care

PRESENTER: **Luigi Siciliani**, University of York
AUTHORS: Ni Gao, David Glynn, Simon Walker, Nils Gutacker, Tim Doran

Motivation

Reductions in of health inequalities is a main policy objective across many health systems. Reimbursement mechanisms for providers are commonly used as policy levers to align provider behaviour with health systems objectives. Current reimbursement mechanisms are mostly based on activity, process quality indicators and patient health outcomes. But it is not clear how much they can contribute to reducing health inequalities.

Aims

We develop an approach that allows to assess equity-efficiency trade-offs when designing financial incentives for healthcare providers. We focus on socioeconomic inequalities in health, and how financial incentives can change the health distribution across groups with different socioeconomic status.

Methods

To investigate how the design of financial incentives can incorporate equity considerations in addition to efficiency ones, we develop a theoretical model of provider behaviour in primary care under a pay-for-performance (P4P) scheme that mimics the Quality and Outcome Framework (QOF) in England. We show how a change in the reimbursement tariff for process measures of quality affects the distribution of health across socioeconomic groups.

We assume that the regulator who is responsible for changes in the P4P scheme accounts for societal *health inequality aversion* when assessing the scheme's effect on the health distribution across socioeconomic groups by computing an Equally Distributed Equivalent level of health. Therefore, if a change in reimbursement improves health but increases health inequalities, the regulator can assess whether the improvements in health can be traded-off against the increase in health inequalities.

After developing our theoretical framework, we *calibrate* the model and simulate the effect of different plausible interventions. Our primary focus is on patients with type-2 diabetes, which has a high prevalence across countries. We then conduct several *simulations* on possible changes in the reimbursement mechanism.

The first simulation relates to changes in reimbursement for different process measures of quality within a health condition, in our case diabetes. Statins are commonly used as an effective medicine to lower cholesterol, and prescribing of statins for people with cardiovascular disease is incentivised under the QOF scheme in England. We simulate the effect of increasing the reimbursement tariff for primary care providers who increase the use of statins for diabetes patients, while simultaneously reducing the tariff for other incentivised indicators to retain budget neutrality of the QOF budget.

In the second simulation, we examine changes in tariffs across different diseases, for example an increase in tariff to incentivise diabetes financed through a reduction in tariff for another incentivized condition, such as Chronic Obstructive Pulmonary Disease.

In the third simulation, we look at changes in tariff for a given indicator, but we allow the reimbursement to differ by socioeconomic group.

Results

Our results suggest that changes in financial incentives that improve population health either reduce health inequalities or that the increase in health inequalities does not offset the increase in health even for high levels of inequality aversion.

Conclusion

Our analysis illustrates how inequality aversion can be taken into account when assessing the effect of changes on financial incentives on the health distribution across socioeconomic status.

Ind-2086 Healthcare Providers Vertical Coordination. Evidence From the French Bundled Payment Initiative.

PRESENTER: **Thomas Pelloquin**

This paper leverages the French episode-based bundled payment scheme, implemented across a set of 22 hospitals, to assess healthcare providers' responses to coordination incentives and the subsequent efficiency of the episode of care.

Bundled payments aim to reduce costs by improving care coordination through a single payment that covers treatment before, during, and after hospitalization. Existing literature, however, lacks research on the coordination mechanisms that contribute to efficiency gains.

The paper begins by analysing the expected responses to bundled payments from a theoretical standpoint. It defines a healthcare pathway involving multiple providers, each contributing to the baseline efficiency of treating patients. The model assumes that bundled payments involve hospitals—who are the recipients of the incentives—managing the cost of the entire care episode, albeit with limited control over external providers.

Hospitals can exert effort to reduce costs, but the marginal return on effort diminishes, particularly for those with higher baseline efficiency. Overall, the results highlight the ability of hospitals to influence the care episode by either reducing the overall amount of care provided, potentially decreasing quality, or by changing the distribution of tasks across providers -for example, by increasing the in hospital intensity of care-, resulting in substitution.

To empirically test these hypotheses, the paper utilizes data from the French national health data warehouse (Système national des données de santé - SNDS), which includes claims data for patients undergoing hip replacement surgeries between 2017 and 2022. The dataset comprises over 477,000 patients across approximately 700 hospitals, with detailed information on patients' health conditions, comorbidities, and care settings.

The data include the costs of each care episode, covering the period from 45 days before to 90 days after surgery. These costs encompass primary care, in-hospital care, and post-acute care facilities, as well as quality outcomes such as 30-day and 90-day readmissions. The study

employs a distributional difference-in-differences approach to compare treated and control episodes of care. To address selection bias, it uses an instrumental variable derived from the characteristics of patients admitted in the years preceding the introduction of the new payment scheme at participating hospitals.

The empirical results show a limited impact from the introduction of the new payment model. The data suggest a possible intensification of care within hospitals, associated to an improvement in quality, potentially linked to the additional resources made available under the initiative. The study explores reasons for this modest effect. Participating hospitals were already performing well in terms of patient transfers to post-acute care facilities, possibly due to the structure of their local healthcare markets.

Ind-2399 Can a Supplementary State Incentive for ASHAs in Addition to National Incentives Contribute to Better Healthcare Utilization?

PRESENTER: **Sujata Mishra**, University of Toronto
AUTHOR: Beverley Essue

Background: In low- and middle-income countries (LMICs), fostering motivation, enhancing performance, and ensuring the retention of community health workers (CHWs) are critical challenges. Within this context, incentives, particularly monetary ones, have been identified as key motivators for CHWs. In India, CHWs such as Accredited Social Health Activists (ASHAs) play an important role in the country's health system and are compensated through a combination of fixed and performance-based incentives. However, evidence on the impact of these incentives on CHW performance and health outcomes remains inconclusive. This study investigates whether state-level supplementation of ASHA incentives, in addition to the national program, improves uptake of three priority health utilization indicators in India. It also examines whether the type of incentive—assured fixed versus variable performance-based—affects key maternal and child health utilization indicators.

Methods: The study uses data from the National Family Health Survey (NFHS-V) (2019–2021) and national and state-level reports from 2014 to 2021. The analysis focuses on three priority health utilization indicators for Indian Government: institution-based deliveries, complete antenatal care, and full immunization for children aged 12–24 months. Propensity score matching and generalized estimating equations models were used to assess the association of state supplementation with these health utilization indicators.

Findings: The study included 232,920 women (mean age 27 years), with 73% in residing in rural areas, 22% having no education, and 44% living below the poverty line. Nearly half belonged to the poorest wealth index, 23% had health insurance, and 55% lived in Central or Eastern India. In terms of existing state policies, as of 2014, 11 of 28 states and 8 Union Territories had implemented policies offering supplementary incentives to ASHAs, expanding to 22 states by 2021.

The findings indicate that women in states that provided supplementary incentives to ASHAs had at least 1.1 to 1.2 times (95% CI=1.1-1.3) greater odds of utilizing all three health services compared to states without such incentives. Use of ASHA services were associated with higher odds of health utilization for all three outcomes of study, indicating the positive role of these frontline workers in improving maternal and child health. Furthermore, women with higher education, greater wealth, or access to health insurance, as well as those registering early for antenatal care, were more likely to use health services. In contrast, marginalized groups including rural residents, those in poor/poorest wealth index, and individuals from Schedule Castes/ Schedule Tribes, faced reduced access to services. These findings provide limited evidence regarding the effectiveness of different incentive types and amounts. Specifically, it could not conclusively establish the advantages of state-assured fixed incentives versus performance-based incentives or vice versa.

Conclusion: This study is one of the first to examine the impact of state-level supplementary incentives for ASHAs on the utilization of three priority maternal and child healthcare services. The findings reveal improved health service utilization in states offering these incentives. However, the effectiveness of specific incentive types and amounts remains inconclusive, highlighting the need for future research to optimize incentive structures for CHWs and improve healthcare utilization.

Ind-716 The Supply Side Effects of Long-Term Care Insurance in China

PRESENTER: **Feng Huang**
AUTHOR: Chunjie Wu

Although public long-term care insurance (LTCI) programs are prevalent globally, their ability to improve the market provisions of long-term care (LTC) has not been comprehensively evaluated. This paper addresses this literature gap by examining China's LTCI pilot program from 2016 to 2019. The pilot provided public insurance for individuals aged 60 and above to reimburse LTC services at regulated prices. In 2016, the Chinese central government initiated this program to assess the feasibility and sustainability of a potential nationwide LTCI scheme, as China had an estimated 20.61 million elderly individuals (8.1% of the old-age population) in need of assistance for activities of daily living in 2020. The pilot was implemented in 35 cities across 14 provinces in a staggered fashion by 2019. We exploit the temporal and geographical variations in LTCI availability arising from the staggered implementation of the program to uncover the causal impacts of LTCI on LTC supply and individual formal care utilization. Our empirical analysis leverages data compiled from four sources. First, we manually extract the timing of LTCI policy enactment at the city level from government websites and policy reports. Second, to assess the supply-side effects of the policy, we identify new LTC providers using administrative data on establishment registration. Third, we gauge LTC labor market outcomes using the China Migrants Dynamic Survey (CMDS), a comprehensive annual nationwide survey that collects demographic and employment information of migrant households. Finally, we measure care utilization patterns using the Chinese Longitudinal Healthy Longevity Survey (CLHLS), which contains data on the demographic characteristics, socioeconomic status, family background, health conditions, and healthcare and long-term care utilization of individuals aged 65 and above. We use a staggered difference-in-differences (DID) framework to investigate the program's impact on the entry of new care providers. We estimate a 1.88-time increase in quarterly LTC provider entries after introducing LTCI. However, unobserved changes to the LTC industry may confound our ability to determine the causality of this estimate. To address this concern, we adopt

three strategies. First, we include a time trend dependent on city characteristics before the pilot in 2010. Second, we conduct event studies using the state-of-the-art methodology proposed by Sun and Abraham (2021) and find that supply-side outcomes remained stable before the program's implementation. Lastly, we show that the order of LTCI pilot implementation is unrelated to city-level characteristics. We find that LTCI increased the number of quarterly LTC provider entrants by 188% and LTC employment share by 27.2%. We estimate a model of elderly individuals' choice between informal and formal care. Our model estimates indicate that supply expansion and improvement in affordability driven by LTCI led to a 3.35% and 15.14% increase in the aggregate share of formal care use among eligible LTCI beneficiaries, respectively. This paper contributes to the literature by presenting, to our knowledge, the first comprehensive empirical study on whether public insurance can alleviate the widespread under-provision of long-term care in a developing country.

Ind-2660 Linking Public Financial Management to Quality Improvement Processes: Improving Nigeria's Primary Health Care Quality

PRESENTER: **Bolanle Olusola-Faleye**
AUTHORS: Benjamin Madaki, Deji Bodunde

Background

Public Financial Management (PFM) theory suggests that improvements in the allocation, execution, and monitoring of public funds can contribute to improved health outcomes. Nigeria's Basic Health Care Provision Fund (BHCPF) is a pro-poor public program for expanding access to health services that provides direct facility financing to primary health care facilities to improve their service delivery. Facilities must produce a business plan and report expenditures against it to receive funding. Furthermore, a quality assessment exercise has been digitalized to facilitate its quarterly implementation. This analysis aims to demonstrate a positive association between effective public financial management and quality improvement processes in the BHCPF program.

Methodology

Routine PHC facility inspection and quality assessment were carried out in 205 facilities in Plateau State quarterly in 2023. The digitally produced scorecard identified quality gaps that were discussed with the facility staff who then identified specific quality improvement interventions for inclusion in their next quarter's business plan. Alignment of facility priority investments to quality improvement plans, tracking of funds released to facilities, and facility financial expenditure reporting became a cyclical, quarterly practice. The scorecard uses a 'traffic light' color coding system to indicate the level of performance for each of 10 priority areas so that increased scores are easily comprehensible when printed and posted on facility notice boards. A convenience sample of high and low scoring facilities was chosen for key informant interviews, business plan reviews and expenditure tracking to identify challenges with budgeting for or implementing quality improvement processes.

Results

In Plateau State, there was a substantial improvement in the overall quality assessment score in Q3 2023, rising from 74% in Q2 to 78% in Q3. Facilities in 7 out of 17 LGAs had optimal quality scores (>80%) in Q3 compared to 3 LGAs in Q2 of 2023. Specifically, Laboratory Services and Community Engagement scores increased across board. Given these improvements, there is an on-going review of business plans across select facilities to cross check alignment of business plans with quality assessment findings, and alignment of business plan expenditures with quality assessment improvements over the final three quarters of 2023. Inadequate training, financing, and lack of expenditure tracking processes were found to inhibit implementing quality improvement plans.

Conclusion/Discussion

Nigeria's BHCPF program is implementing a quality improvement process that aligns quality assessments results with direct facility financing via business plans to enable the implementation of quality improvement interventions. By tracking expenditures as well, program implementers can determine the pathway by which direct facility funding is leading to quality improvement and identify approaches to optimize the use of direct facility financing and resource gaps that increased financing could address. However, in practice, facility leadership requires additional financial and technical support for the QI cycle to demonstrate how direct facility financing and insurance capitation payments can lead to improved quality.

Ind-1978 Cost-Effectiveness of Expanded HIV Screening in Pregnant Women: A Systematic Review and Meta-Analysis

PRESENTER: **Qing HE**
AUTHORS: ZhinXin Fan, Qiang Sun, Jia Yin

OBJECTIVES: Globally, the response to human immunodeficiency virus (HIV) is improving, but not fast enough to end the acquired immunodeficiency syndrome (AIDS) as a public health threat by 2030. Early detection and intervention of people living with HIV/AIDS is critical from both clinical and public health perspectives. Screening is the gateway to the prevention of mother-to-child transmission of HIV. Cost-effectiveness analyses are essential to effectively inform policy makers and consequently implement valuable screening strategies. This study aimed to evaluate the economic value of expanded HIV screening strategy in pregnant woman to support evidence-based decision making, especially in low-and middle-income countries (LMICs) where economic evidence is limited. METHODS: PubMed, Embase, Web of Science, and Medline were searched from January 1990 to December 2022. Language was limited in English. Studies were included if they were cost-effectiveness or cost-utility analyses of expanded HIV screening strategy in pregnant women. The incremental cost-effectiveness ratios (ICERs) and incremental net benefits (INBs) were calculated and then pooled across studies, stratified by economic level of the country, maternal HIV prevalence in the study, using a random-effect model. If the ICER was below the prespecified threshold of willingness to pay (WTP) or the INB was a positive value, the expanded HIV screening would be considered cost-effective according to the recommendation. Literature quality was assessed using the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) 2022 checklist and Quality of Health Economics Studies (QHES). RESULTS: Fourteen studies involving 446,654,352 target population were included in the meta-analysis. Expanded HIV screening strategy was cost-effective in LMICs with the pooled ICER of $101.22 (95%CI: $92.70-$109.74) as well as the pooled INB of $2322.80 (95% CI: $2086.98-$2558.63), but not cost-effective in high-income countries (HICs) with a pooled INB of -$85,983.23 (95% CI: -$117536.91 to -$54429.55). Subgroup analyses also revealed that expanded prenatal HIV screening was a cost-effective strategy for HICs under the study scenarios with relatively high HIV maternal prevalence (>0.1%). High heterogeneity was observed across included studies (I2 > 99% and P < 0.001). CONCLUSIONS: The complex epidemiological context of the different regions calls for sustained efforts to eliminate vertical HIV transmission. As the primary but resource-intensive intervention, HIV screening plays an important role in reducing the rate of new infections and facilitating prompt access to treatment, thereby achieving effective control of the epidemic. The findings suggest that expanded antenatal screening service is a cost-effective and important strategy, particularly for LMICs, to boost the sustainability of the region's HIV response and contribute to the goal of 'ending AIDS by 2030'. Although structured interventions referring to HIV testing and treatment are well described, and antenatal care packages are widely recommended, utilization of these services remains suboptimal in many LMIC settings. Further research and pilot programs are needed to guide future planning, implementation and scale-up.

Ind-2818 Cost-Benefit Analysis of Expanding Doula Coverage Among Medicaid Enrollees in the United States

PRESENTER: **Donald S. Shepard**, Brandeis University
AUTHORS: Ilhom Akobirshoev, Monika Mitra

Background The United States continues to face significant challenges in maternal health outcomes, including cesarean delivery and preterm birth, compared to other high-income countries. Recent evidence demonstrates doula care services significantly reduce cesarean deliveries (RR=0.53; 95% CI=0.43-0.66) and preterm births (RR=0.71; 95% CI=0.51-0.98). While several states have implemented Medicaid coverage for doula services, the economic implications of scaling up doula care services remain unknown. **Objectives** To evaluate the economic implications and potential cost savings of incrementally scaling up doula care service coverage to 80% for Medicaid-enrolled birthing people across the United States. **Methods** We conducted a cost-benefit analysis using propensity score-matched risk ratios from a recent multi-state study of doula care among Medicaid enrollees. We modeled the scaling up of doula care services in 10% increments to 80% coverage. Costs were adjusted to 2024 dollars using medical care CPI. State-specific analyses were conducted for the five largest Medicaid birth volume states. We also performed sensitivity analyses using input ranges based on published literature. **Results** At 80% coverage, projected annual net savings were $338.4 million per 100,000 births (95% CI: $285.7M-$391.1M), with a return on investment of $3.52 per dollar invested. State-specific analyses showed potential annual savings ranging from $243.6 million (Illinois) to $758.0 million (California). Sensitivity analyses demonstrated cost savings under various assumptions. **Discussion** Expanding doula care services through Medicaid is a cost-effective strategy with a significant return on investment. Even under conservative assumptions, including full implementation costs, the doula care intervention demonstrates substantial cost savings. The phased implementation approach allows for sustainable program growth while building workforce capacity. **Implications for Health Policy** This analysis provides economic justification for expanding Medicaid coverage of doula care services, potentially preventing approximately 15,600 cesarean deliveries and 2,800 preterm births per 100,000 births while generating substantial healthcare savings. **Keywords**: Economic evaluation, maternal health, doula care, Medicaid, implementation science

Ind-1899 Cost-effectiveness of Intravenous Iron Sucrose for Treating Anemia in Pregnancy

PRESENTER: **Deepshikha Sharma**, Postgraduate Institute of Medical Education and Research
AUTHORS: Arun Kumar Aggarwal, Pankaj Bahuguna, Shankar Prinja, Neelam Aggarwal

Background: Anemia is among the most prevalent nutritional deficiencies affecting pregnant women, often resulting in adverse maternal and fetal outcomes, thereby posing a significant public health challenge. While oral iron supplementation has traditionally been the primary intervention, its effectiveness is often limited by issues related to compliance and absorption. Intravenous iron sucrose has emerged as a promising alternative; however, its cost-effectiveness remains unexplored. This study aims to evaluate the cost-effectiveness of intravenous iron sucrose compared to oral iron in moderately anemic pregnant women in India. **Methods:** A decision-tree model was developed to estimate the costs and outcomes associated with anemia in pregnancy for both maternal and fetal/newborn populations over a lifetime horizon. The analysis adopted an abridged societal perspective, accounting for direct medical and non-medical costs related to anemia treatment and its complications. Indirect costs from productivity losses were considered in the sensitivity analysis. A 3% discount rate was used to adjust future costs and outcomes. Deterministic and probabilistic sensitivity analyses were conducted to assess the robustness of the findings **Results:** Intravenous iron sucrose had an incremental cost-effectiveness ratio (ICER) of INR 30,397 per disability-adjusted life year (DALY) averted and INR 7,489 per quality-adjusted life year (QALY) gained. These ICERs are below the threshold of 1-times GDP per-capita, indicating that intravenous iron sucrose is cost-effective. Sensitivity analyses showed that the ICER was not significantly impacted by variation in key model parameters, and the estimates consistently remained below the cost-effectiveness threshold of 1-times GDP per-capita, except in extreme scenarios where oral iron compliance exceeded 75% or intravenous compliance fell below 35%, rendering the intervention as not cost-effective.

Conclusion: Intravenous iron sucrose is a cost-effective strategy for managing moderate anemia in pregnancy compared to oral iron and should be prioritized as first-line therapy. Improving treatment adherence is essential for optimizing outcomes, emphasizing the need for targeted interventions to enhance compliance.

Ind-548 A New Approach to Target Setting in Global Health using Cost-Effectiveness Analysis: An Example of the SDGs Target for Anaemia

PRESENTER: **Robin Blythe**
AUTHORS: Natalie Carvalho, Michael Bode, Jacinta Holloway-Brown, Tori Oliver, Sant-Rayn Pasricha, Sumie Leung

Background

In 2015, the United Nations (UN) Sustainable Development Goals (SDGs) set a target to halve the prevalence of anaemia in women of reproductive age by 2030. However, it is questionable whether this goal is achievable for most countries, with nearly all expected to fall short. Overly ambitious and globally uniform targets may be intended to be aspirational, but can risk overwhelming healthcare systems in low- and middle-income countries with many competing priorities and limited resources. An alternative approach to target setting is through the use of cost-effectiveness analysis to inform individual national targets, which can be aggregated to obtain achievable, cost-effective global health targets.

Study aim

In this study, we present a cost-effectiveness analysis of World Health Organisation-approved interventions for anaemia for 192 UN member nations, and use these findings to generate national and global anaemia reduction targets.

Methods

We obtained prevalence estimates from Global Burden of Disease data for mild, moderate and severe anaemia in women aged 15 to 49 for 192 UN member nations. Using costs and effectiveness estimates from published literature, we developed a decision analytic model in R to simulate the expected costs and reductions in disability-adjusted life years (DALYs) from a health system perspective for each country. Cost-effectiveness for each intervention was calculated incrementally after simulating the delivery of each proposed treatment, selected by expected incremental cost-effectiveness ratio and determining whether to apply the treatment using an empirical willingness-to-pay threshold. We considered a range of thresholds, including recently estimated opportunity-cost based approaches. Uncertainty was propagated through the model using Monte Carlo simulation.

Results

Under an empirical willingness-to-pay threshold, the median estimated achievable reduction in anaemia prevalence was 36.3% [95% interval: 26.4%, 42.2%], with 3000 [719, 15014] DALYs averted. There was a large spread of maximum possible reductions, with 14 of 192 countries theoretically able to achieve a 50% reduction in anaemia by applying all cost-effective interventions, while many sub-Saharan African countries were able to achieve reductions of under 12%.

Conclusions

Using health economic analysis, we show that the achievable reduction in anaemia prevalence for women of reproductive age varies substantially by country, with many low- and middle-income countries likely unable to achieve the target set by the UN SDGs. Our alternative approach can be applied to other global health targets, potentially allowing more realistic planning and expectations among UN member nations.

Ind-741 General Practitioners Remuneration and Impact on Patients' Health, Health Care Use and Mortality

PRESENTER: **Kjartan Sarheim Anthun**, SINTEF
Background and aim General practitioner (GP) organisation and remuneration have been studied for some years (Scott&Hall 1995; Flodgren et al 2011; Abelsen&Olsen 2012; Barham & Milliken 2015; Brekke et al 2020; Skovsgaard et al 2023). Since differences in remuneration are often invariant within a health system, and endogeneity is a concern, there is a gap in knowledge regarding the effects of remuneration that could be addressed by well-designed studies. This study aims to examine the impact of remuneration schemes on the treatment decisions of GPs in Norway. We compare two distinct schemes employed in Norway: one involving independent physicians compensated by municipalities through a combination of capitation and fee-for-service, and another where physicians are employed and salaried. The comparison is complicated by the fact that municipalities and GPs may select their funding scheme, potentially with differences in patient populations. To mitigate this endogeneity, we analyse GPs transitioning between remuneration schemes and instances of random patient assignment to GPs with differing funding structures. By assessing patients on a GP's list before and after a transition, we evaluate the effects on

patient outcomes. Additionally, we match patients exposed to funding changes with those who were not, allowing us to estimate effects that are less prone to confounding. This approach will yield significant health economic insights into how GPs' remuneration influences patient health, healthcare utilization, and mortality. **Methods and approach** We employ a difference-in-differences design to analyse changes over time. The treated group includes patients whose GPs underwent a funding scheme change, while the control group consists of patients with GPs that did not. By comparing outcome trends between these groups, we can estimate the effects of the funding changes. We also match across groups (on age, sex, immigrant background, GP age, GP list size, and follow-up duration) to control for confounding factors. To prevent spill-over effects, we ensured that matched GPs did not practice in the same municipality. We use Poisson regression with high-dimensional fixed effects to compare outcome rate changes within the matched groups. **Current status and results** To conduct our analysis, we utilize data from multiple complete Norwegian registries covering all health care use and all GPs. Our primary outcomes are a) contacts and costs with primary care physicians, b) contacts and costs with acute hospital services in somatic and mental health specialist care, and c) rate of deaths per year during the follow-up period. Preliminary results indicate mixed results.

Ind-936 Healthcare Providers Preferences for Capitation Payment Method Under Universal Health Insurance in Tanzania: A Discrete Choice Experiment

PRESENTER: **Francis Donard Ngadaya**
AUTHORS: Josephine Borghi, John Joseph Maiba, Gemini Mtei, Timothy Powell-Jackson, Peter Binyaruka

Background: Tanzania is designing and preparing the implementation plan for the Universal Health Insurance (UHI) as means to achieve universal health coverage goals. Since resources are limited, UHI scheme should purchase health services strategically by incentivising efficient and better quality of care. Provider payment methods (PPMs) are critical component of healthcare purchasing reform. Fee for services is less efficient compared to capitation which offers opportunities for cost containment and efficiecy, but its success depends on the design which incorporate elements to reduce predicted negative provider behaviours under capitation. Other key approach is to align the capitation attributes with providers preferences to ensure acceptability and smooth implementation. To inform the capitation design and implementation for UHI, we conducted a Discrete Choice Experiment (DCE) to understand the most preferred capitation and implementation attributes among primary healthcare providers, estimated trade-offs for willingness to accept, preference heterogeneity, and policy option simulations.

Methods: We conducted a DCE survey with 240 primary healthcare providers, preferably facility in-charges, from 84 facilities in Singida and Manyara regions in Tanzania. The DCE used five capitation attributes: adequacy of payment amount, service to be covered, payment schedule, additional payment for high performing facilities and timeliness of payment, each with different levels. Capitation attributes and levels were identified through a literature review and qualitative research, which were refined and reduced through expert opinions and pilot test. We used a D-efficient design and coefficients from pilot study (n=28) to generate two blocks, each with forced 12 unllabelled choice sets of two hypothetical payment methods (capitation A and B). Mixed multinomial and conditional logit models will be used to estimate the main effects, followed by more flexible mixed MNL models to explore the preference heterogeneity, trade-offs for willingness to accept and policy option simulations.

Results: While the results are forthcoming, we expect to estimate the main effects showing the most preferred attributes based on how they influence providers' choices. Pilot result shows higher preferences for timely payments, adequacy of payment amount, and service covered. Results on willingness to accept will be presented, for example, how much provider value an increase in performance-based allocation relative to other categorical attributes. Various scenarios will be accounted to simulate how different capitation attributes impact provider uptake. Lastly, preference heterogeneity will show how preferences for capitation attributes vary based on facility and health worker characteristics.

Conclusion: The findings will provide evidence-based insights into the design of capitation payment method for UHI by aligning with healthcare providers preferences, and ensuring their acceptance for smooth implementation in Tanzania.

Ind-493 How Do the Incentives for Family Physicians Affect the Implementation of Family Physician Contract Service Policy in China? A Qualitative Study

PRESENTER: **Jia Tang**
AUTHOR: Rize Jing

This study explores how financial and non-financial incentives impact the implementation of the Family Physician Contract Service (FPCS) policy in China. Employing a qualitative approach, we conducted semi-structured interviews with 36 participants, including local health commission directors, leaders of primary healthcare facilities, family physicians, and nurses, across eight community health centers in four cities known for their advanced FPCS implementations. The data were analyzed using the framework method, which provided critical insights into the effectiveness of various incentive structures within the FPCS policy. The findings reveal that financial incentives, particularly patient-based capitation fees, play a central role in motivating family physicians to fulfill their contractual obligations. The capitation fee, when representing a substantial portion of overall income, aligns physicians' financial interests with the policy's goals by fostering better patient engagement and continuity of care. However, the study identifies significant regional variations in the implementation of these fees, with some cities failing to establish this essential component, thereby undermining physician motivation and the policy's effectiveness. Moreover, the method of distributing capitation fees—whether independently or mixed with performance-based pay—substantially affects their impact. Independent distribution was found to enhance transparency and directly link compensation with workload, reinforcing the principle of "more pay for more work." A critical challenge identified in the financing models, particularly those solely reliant on health insurance, is the risk of adverse selection. Family physicians in these models tend to prefer contracting with healthier patients to minimize costs, thereby neglecting individuals with severe health conditions. This study proposes an innovative solution: differentiated capitation fees based on patient health status, which incentivize physicians to engage with a broader and more diverse patient population, mitigating adverse selection risks. Non-financial incentives, including authority delegation, enhanced work relationships, and opportunities for professional growth, were also found to

be pivotal. The establishment of self-governing family physician studios, as observed in Shanghai, fosters autonomy and collaborative teamwork, boosting job satisfaction and performance. Strengthened peer and patient relationships further motivate physicians, creating a supportive work environment conducive to the long-term success of the FPCS program. Additionally, professional development opportunities and recognition through appraisal-linked incentives contribute to a heightened sense of self-identification and achievement among family physicians. This study makes a novel contribution by integrating qualitative insights with policy implications, addressing both financial and non-financial dimensions of incentive structures within the FPCS framework. It underscores the necessity of a balanced and context-specific approach to incentive design, advocating for policies that not only enhance financial compensation but also promote professional autonomy and growth. The findings offer actionable recommendations for optimizing FPCS implementation, particularly in regions with varying levels of healthcare infrastructure and administrative support. **Key words:** Family physicians; Incentives; Patient-based capitation; Authority delegation.

Ind-880 The Impact of Different Payment Systems on Medical Services in Public Hospitals: Evidence From a Multi-Pilot City in China

PRESENTER: **Yifan Yao**
AUTHORS: Yingbei Xiong, Li Xiang

Objective: To evaluate the effect of various payment systems, including Diagnosis-Related Groups-Prospective Payment System (DRG-PPS), Diagnosis-Related Groups under Regional Global Budget System (DRG-GBS), and Diagnosis-Intervention Packet under Regional Global Budget System (DIP-GBS), on cost and quality of healthcare in public hospitals.

Methods: The study was conducted in one of China's most economically developed regions, characterized by abundant medical resources and extensive patient data. The dataset included 9,297,452 inpatient records from 64 public hospitals in the city and aggregated at the hospital level. Among them, 9 tertiary hospitals implemented the DRG payment model, while 55 hospitals adopted the DIP model. This retrospective observational study analyzed data from all public hospitals in the study city between January 2018 and August 2023. The study periods were defined as follows: before DRG-PPS (January 2018-December 2018), during DRG-PPS (January 2019-December 2020), during DRG-GBS (January 2021-August 2023); before DIP-GBS (January 2018-February 2020), and during DIP-GBS (March 2020-August 2023). To assess the impact of different payment systems on public hospital services, we analyzed costs, cost composition and quality. Outcome variables include total cost as well as medication cost, consumables cost, diagnostic and laboratory test cost, and surgical cost. For each cost component, we examined its proportion of the total cost. For healthcare quality, the outcome variables include length of stay (LOS), hospital infection rate, and clinical pathway compliance rate. We conducted an interrupted time series (ITS) analysis to examine the impact on above-mentioned outcome variables before and after the implementation of DRG and DIP reforms.

Results Total cost remained unchanged under DRG-PPS but decreased under DRG-GBS (-$18.78, 95% CI, –37.08 to –0.49) and DIP-GBS (-$23.47, 95% CI, –34.05 to –12.90). LOS remained stable under DRG-PPS and DRG-GBS, but slightly decreased under DIP-GBS (–0.04 days, 95% CI, –0.07 to 0.00). Infection rates declined after DRG-PPS (-0.02% per month, 95% CI, –0.04 to 0.00) and DIP-GBS (-0.01% per month, 95% CI, –0.02 to 0.00). Clinical pathway compliance rate remained stable under DRG-PPS and DIP-GBS but declined under DRG-GBS (–0.34% per month; 95% CI, –0.70 to 0.02). Medication cost declined under DIP-GBS (-$5.21, 95% CI, –8.30 to –2.11), while consumables cost decreased under both DRG-GBS and DIP-GBS. The proportion of diagnostic and laboratory test cost increased under both DRG-GBS and DIP-GBS. Surgical costs decreased after DRG-GBS and DIP-GBS by $3.29 (95% CI, –5.65 to –0.93) and $2.79 (95% CI, –4.12 to –1.46), respectively. The results of subgroup analysis showed that the effects of DIP-GBS in tertiary hospitals were consistent with the overall results, while most outcome changes in non-tertiary hospitals were not significant.

Conclusion Findings suggest that the same DRG model produced different outcomes under different budget modes (GBS vs PPS), whereas DRG and DIP showed similar effects within the same budget mode (GBS). In China's dual-track payment system, rather than focusing on which grouping methods is superior, efforts should prioritize quality monitoring and improving hospital adaptability to ensure high-quality care under value-based payment systems.

Ind-894 Is Reducing Cost Variation Among Hospitals Achievable Through Case-Based Payment Reform? Insights From Cerebral Infarction in China

PRESENTER: **Shiting Liu**
AUTHORS: Yining Wang, Xiaohua Ying, Xinyu Zhang, Haifeng Ma

Objective: Case-based payment systems are widely implemented in inpatient care to improve service efficiency, provider coordination, and equitable access. Cerebral infarction (CI), with its high healthcare costs and significant disease burden, has been a key focus of quality control and clinical guidelines. This study evaluates whether a case-based payment reform introduced in 2018 in a developed city in southern China incentivized providers to reduce cost variation for CI.

Method: We analyzed patient discharge records from 2016 to 2022. Cost variation was measured using the interquartile range (IQR) and coefficients of variation (CV) based on aggregated hospital-level adjusted average costs. Inflation was adjusted using the city's consumer price index (CPI), and case-mix adjustments were made. An interrupted time series (ITS) model was employed to examine the impact of the reform on IQR and CV across hospitals, stratified by hospital level (tertiary and secondary) and treatment group (surgical, medical). A second breakpoint at Q1 2020 was introduced to account for the potential effects of COVID-19, as an alternative to explore short-term impacts.

Results: A total of 64,615 patients from 91 institutions were included before the reform, and 228,640 patients from 175 institutions afterward. All hospitals demonstrated a significant immediate reduction in the CV and IQR of adjusted total costs, with CV decreasing by 0.137 and IQR by 1,315 CNY ($P < 0.05$), followed by negligible post-reform quarterly trend changes (-0.001 for CV, -103 CNY for IQR). Similar patterns were observed in both secondary and tertiary hospitals, with secondary hospitals showing a more pronounced effect. Medical and surgical

groups also experienced immediate reductions in CV post-reform, with declines of 0.101 and 0.022, respectively. The surgical group exhibited a negative quarterly trend change of 0.012 across all hospitals. IQR followed similar patterns, with negative post-reform trend changes in surgical groups for secondary (-3,655 CNY) and tertiary hospitals (-407 CNY). Short-term effects were more pronounced, with CV and surgical group CV showing significant quarterly trend changes of -0.004 and -0.043 ($P < 0.05$), respectively.

Conclusion: The implementation of the DIP payment reform led to a significant short-term reduction in cost variation, though some inconsistencies were observed across hospital levels and treatment groups. Under the reform, secondary hospitals and the surgery group exhibited more substantial reductions in cost variation. Compared with tertiary hospitals, secondary hospitals may have been more strongly incentivized to reduce costs under benchmark competition to mitigate potential financial risks. The notable reduction in cost variation within the surgery group further suggests that overuse of costly treatments was prevalent prior to the reform.

Ind-373 The Effect of Amount of Tariff in Incentivizing Vaginal Deliveries in Primary Healthcare under the Indonesia National Health Insurance

PRESENTER: **Febriansyah Budi Pratama**
AUTHORS: Mutia Astrini Pratiwi, Merry Lusiana, Ratu Martiningsih, Hasbullah Thabrany, Iko Safika

Do Higher Tariffs Encourage Normal Deliveries in Primary Care? Evidence from Indonesia's National Health Insurance

Background.
Indonesia's National Health Insurance (JKN) covers childbirth services at both primary healthcare facilities (PHCs) and hospitals, with reimbursement tariffs designed to incentivize normal deliveries at PHCs. However, under previous tariffs, the share of normal deliveries at PHCs declined from 45% in 2015 to 30% in 2022, while more expensive hospital-based deliveries, especially caesarean sections (SCs), accounted for up to 45% of total deliveries. In response, the Ministry of Health implemented a policy in 2023 to increase PHC delivery tariffs by 14.3%–57.9%, depending on clinical conditions, while hospital tariffs remained relatively unchanged. Concurrently, clinical requirements for PHC deliveries were tightened, including increasing the personnel requirement from four to six hands. This study evaluates whether the 2023 tariff adjustment effectively shifted childbirth utilization patterns toward PHCs.

Methods.
We used a mixed-methods approach. The quantitative component employed fixed-effects regression using district-level panel data from JKN claims (2019–2023), controlling for the number of active JKN members, availability of PHCs and referral hospitals, and regional differences (Java-Bali vs. other regions). The qualitative component included focus group discussions (FGDs) and spot checks in six districts across Java, Sumatra, Kalimantan, and Sulawesi, involving 10 Puskesmas, 4 private clinics, and 1 type-D Pratama Hospital.

Results.
The tariff increase **did not result in a higher proportion of normal deliveries at PHCs**. On the contrary, regression analysis shows a statistically significant **decrease in normal deliveries at PHCs** following the policy (Coef. = –0.036, SE = 0.008, $p < 0.001$). The change in the proportion of normal deliveries at referral hospitals was also negative but statistically insignificant in the full model (Coef. = –0.014, SE = 0.010). Meanwhile, **the proportion of SC deliveries increased significantly** (Coef. = 0.049, SE = 0.010, $p < 0.001$). A placebo test using 2022 as a pseudo-policy year showed no significant effect, supporting the validity of the causal inference.

Qualitative findings identified several implementation barriers that may have offset the intended effect of the tariff increase. These include additional administrative burdens (e.g., mandatory congenital hypothyroid screening), limited logistics and provider availability at PHCs (especially outside Java-Bali), unclear clinical guidelines for basic emergency obstetric care, and the introduction of the six-hands requirement, which reduces the feasibility of midwife-led services in low-resource settings.

Conclusion.
The 2023 tariff adjustment has **not achieved its intended goal** of incentivizing normal deliveries at PHCs. Financial incentives alone were insufficient to overcome **structural, regulatory, and operational constraints** at the frontline level. To improve effectiveness, policymakers should revise implementation guidelines, align tariffs with PHC service delivery capacity, and consider making PHC tariffs equivalent to hospital tariffs. Additionally, exploring cost-sharing mechanisms for SC deliveries may help manage provider- and patient-side moral hazard and promote more appropriate, equitable use of maternal health services. Further analysis using 2024 claims data is needed to explore behavioral drivers behind SC overuse.

Ind-2010 Unlocking Access: Overcoming Barriers and Harnessing Enablers for Innovative Payment Models for Pharmaceutical Innovation in Europe

PRESENTER: **Matthias Hofer**
AUTHORS: Sian Hodgson, Brittany Darrow, Mikel Berdud, Amanda Cole, Mireia Jofre-Bonet

Background: Simple price discounts for pharmaceuticals have been identified as not providing sufficient solutions to many existing patient access challenges. Innovative payment models (IPMs), successfully implemented in several European countries, have facilitated access to pharmaceutical innovations. However, their implementation faces significant barriers, which can delay and/or increase the burden of implementing agreements and, in some cases, prevent their adoption entirely. At the same time, key enablers have facilitated the use of IPM and improved the ease of implementation.

Aim: In this research, we used qualitative methods to identify and gain consensus on the main barriers and enablers for implementing IPMs in Europe with the aim to share best practices for all European stakeholders and facilitate the generation of solutions and policy recommendations.

Methods: We used a two-phase qualitative approach. In the first phase, we conducted a survey to collect individual input on the most relevant pricing and payment methods, barriers and enablers to implementation, and potential solutions for better implementation practices. The survey was distributed to a wide range of expert stakeholders including payers, HTA bodies, healthcare commissioners, policymakers, regulators, industry representatives, data infrastructure experts, providers, and patient representatives. The experts were from 9 European countries selected according to a taxonomy that considered geography, GDP and health expenditure per capita, primary health financing system, and IPM experience. In the second phase, we conducted a nominal group roundtable with a purposive sub-set of survey respondents to reflect on both commonalities and differences of opinion arising from the survey and focus on creating consensus on the barriers and enablers of IPMs. In addition, we elicited experience-based knowledge from the participants to inform recommendations that will guide a flexible application of different models in real life.

Results: Experts highlighted the need for international collaboration to share best practices to improve the readiness of all stakeholders to implement IPMs. The study identified key barriers and enablers to the implementation of IPMs in Europe. Identified barriers included administrative burden associated with both developing and operationalising agreements, misalignment of stakeholders' priorities, challenges in achieving agreement on the terms of the IPM, IPM operationalising conflicts with legal, regulatory and administrative frameworks, and lack of data or data-gathering infrastructure to monitor and evaluate IPM performance. Conversely, enablers that facilitated successful IPM implementation included investment in expertise and infrastructure for implementing and managing IPMs (e.g. centralised data repositories), early and transparent dialogue among stakeholders to align goals and expectations, and adaptive frameworks that allowed iterative refinements of agreements.

Conclusion: The findings highlight that while innovative payment models hold significant potential to improve patient access to pharmaceutical innovations, their implementation is hindered by diverse barriers. Key enablers, such as robust data systems, adaptive agreements, and stakeholder collaboration, are critical for overcoming these challenges. This research underscores the importance of understanding the common challenges experienced in the implementation of IPMs, so that international cooperation can help to inform solutions and recommendations for all stakeholders. This will enable the creation of an environment where IPMs can be sustainably adopted across Europe.

Ind-927 Impacts of Policies in Controlling Growth of Medical Expenses in China, 2010-2019

PRESENTER: **Xuechen Xiong**
AUTHORS: Jianchao Quan, Zhaohua Huo, Li Luo

Background Addressing the surge in medical expenses is a primary focus of Chinese healthcare reform. The annual growth rate of total health expenditure was 12.4% in 2019, surpassing the national GDP growth rate of 6.0%. A series of nationwide policies have been implemented to control the unreasonable growth of medical expenses in public hospitals, including enhancing financial support for healthcare facilities, adjusting service pricing of medical treatments, and implementing a zero-mark-up policy for medications. However, the effectiveness of these measures in controlling growth of medical expenses is unknown. **Objectives** To evaluate the impact of increased financial support for healthcare facilities, adjusted service pricing, and the zero-mark-up policy on curbing the growth of medical expenses in public hospitals in China from 2010 to 2019. **Methods** We utilized system dynamics theory to model the capital flow of hospitals. We analyzed the growth of medical expenses by considering: 1) the population growth and aging, 2) changes in disease spectrum and modern lifestyle, and 3) induced services provided by doctors. Data collection was facilitated by the Shanghai Municipal Health and Health Commission, providing information on public hospital expenditures, human resources, and health services. **Results** Population and disease changes are the primary drivers of medical cost growth in Shanghai, contributing to approximately 51% of the overall increase in medical expenses in public hospitals over the past decade. Induced costs have also played a significant role, accounting for around 36% of the rise in medical expenses. While the zero-mark-up policy does not impact total hospital funds or induced expenses, it does alter the distribution of capital flows. The medical service price adjustment policy reduced the proportion of induced costs by 3%, and increased fiscal investment reduced it by 8%. The comprehensive implementation of all three policies led to an 11% decrease in medical expense growth. **Conclusion** Comparing the three policies, solely implementing the zero-mark-up policy does not directly address induced costs. The fiscal investment policy shows better effectiveness in controlling growth of medical expenses compared to the service price adjustment policy. **Keywords:** public hospitals, medical expenses, induced cost, national policy

Ind-2083 Reducing Fragmentation in Financing for Health Through Joint Planning, Implementation, and Monitoring: A Case Study From Blantyre, Malawi

PRESENTER: **Dalitso Laviwa**
AUTHORS: Loncy Sajeni, Stephanie Heung, Briony Pasipanodya, Chimwemwe Pinto, Chrissy Chilenje, Mihereteab Teshome, Eoghan Brady, Gift Kawalazira, Andrews Gunda

Background:

Malawi’s health sector relies heavily on donor funding, with 55% of the health budget supported by 166 financing sources. This has led to fragmented funding, reduced resource efficiency, and limited partner alignment to government plans. To address these issues, Malawi’s Ministry of Health launched the Health Sector Strategic Plan III (HSSP III) for 2023–2030, focusing on the “One Plan, One Budget, One Report” reform to improve aid alignment.

Blantyre District Council in Malawi is committed to operationalizing the “One Plan, One Budget, One Report” reform and has implemented a

joint planning, implementation, and monitoring initiative since 2019, with technical support from the Clinton Health Access Initiative (CHAI). This initiative builds district planning capacity, aligns partner activities with government plans, supports Technical Working Groups (TWGs) to secure funds for unfunded activities, and strengthens monitoring tools to enhance accountability between government and partners.

Research Questions and Methods:

In 2024, an evaluation was conducted by the Blantyre District Council and CHAI to assess the effectiveness of joint planning, implementation, and monitoring in improving aid alignment from 2019–2024. This evaluation used a mixed-methods approach, including (1) a time-series analysis of the proportion of implementing partners with activities included in district plans, (2) calculating funding generated through TWGs, and (3) the percentage of planned activities implemented by government and partners. This was complemented by qualitative insights from focus group discussions with government staff and implementing partners on the effectiveness of the joint planning, implementation, and monitoring approaches.

Results:

The evaluation found that government staff and implementing partners were generally proficient in using planning and partner mapping tools. The proportion of implementing partners integrating their planned activities into district plans increased from 5% in financial year (FY) 2018/2019 to 34% in FY 2022/2023. Both government and implementing partners reported that partner mapping reduced duplication of activities and improved coordination among stakeholders.

The TWG meetings enabled stakeholders to address implementation challenges and raise funds, mobilizing over USD 240,602 from implementing partners against a cost of USD 5,653 to run the TWG meetings, yielding a very high return on investment of 43X. The funds supported the implementation of 7% of previously unfunded activities. Furthermore, the participants noted the monitoring tool's value in real-time tracking of activity implementation, which showed an increase in the implementation of government-funded activities from 40% in 2019 to 52% in 2024, and in partner-funded activities from 76% to 95% in the same period, due to the joint planning and implementation approaches including TWGs.

However, government participants noted that progress on aid alignment is hindered by the lack of enforceable sanctions for non-compliance with aid alignment guidelines. .

Conclusions/Implications:

The evaluation concludes that the initiative effectively improved aid alignment in Blantyre. To ensure sustained impact, the central government should establish enforceable guidelines for donor and partner alignment with government priorities, potentially including sanctions for non-compliance. This will further strengthen aid alignment, which is critical in a fiscally constrained context where planning and budgeting functions are increasingly devolved to districts and health facilities.

Ind-1373 Understanding the Cost of Illness Among National Health Insurance Dropouts in Ghana

PRESENTER: **Jacob Novignon**, Kwame Nkrumah University of Science and Technology
AUTHOR: Caleb Osei

Introduction

Ghana's National Health Insurance Scheme (NHIS) is taunted as a crucial policy effort towards universal health coverage (UHC) through financial protection for health care. The scheme covers over 50% of the population and more than 90% of diseases presented at health facilities across the country. The scheme has however faced several challenges affecting effective operation for both providers and subscribers. One of such challenges is subscription non-renewal or dropout. This challenge has the potential to undermine progress made towards UHC if not addressed. Previous studies have provided a wide range of reasons explain subscriber dropout while others have assessed its economic inequalities. This study takes a step further to understand the health care cost burden for NHIS dropouts who sought care for their illness. We also assessed the equity implications of the estimated cost burden.

Methods

We used data from the seventh round of the Ghana Living Standards Survey (GLSS 7) conducted in 2016/2017. The survey is the country's largest income and expenditure survey that collects data on a wide range of expenditure components including health. The survey also asks respondents about their NHIS subscription history allowing us to identify individuals who were previously subscribers but not anymore. Among these NHIS dropouts, we sampled individuals who had the need to seek health care from formal sources and extracted all out-of-pocket costs related to this healthcare seeking. For each individual, the cost of care was computed as a sum of payments on drugs, consultation, diagnostics and inpatient care. To access the cost burden, we computed its proportion of the household budget share using a 10% threshold. The distribution of the cost burden was analyzed using concentration indices (CI).

Results

The findings reveal that on average, NHIS dropouts spent about GHC84.20 on health care. This amount is substantially higher than the annual cost of NHIS subscription. The health care cost burden for the dropouts was higher among urban dwellers (GHC104) and middle-aged individuals (GHC106.38). On average, about 0.17% of these NHIS dropouts spent more than 10% of their budget share on health care, pushing about 0.5% into poverty. Furthermore, we found that the catastrophic health spending that resulted from NHIS dropout was concentrated among individuals from economically disadvantaged households [CI = -0.614] and more prevalent in rural [CI = -0.749] than in urban [CI = -0.461]

locations.

Conclusion

The findings provide evidence that support efforts to address NHIS dropout in Ghana. In the spirit of leaving no one behind while achieving the UHC targets, our results show that it is important to keep existing subscribers on the scheme while coverage expansion efforts are pursued. Interventions to address this include reducing subscription travel and waiting time in line with current efforts to adopt digital subscription renewal strategies.

Ind-627 Cost-Effectiveness of Whole Genome Sequencing in Patients with Tuberculosis in China

PRESENTER: **Yibei He**
AUTHOR: Yan Li

Abstract

Background. China is a high-burden tuberculosis (TB) country and delays in diagnosis and effective treatment have further exacerbated this situation. Whole genome sequencing (WGS) has been proven to be a reliable testing strategy for TB drug-susceptibility testing (DST). However, the cost-effectiveness of applying WGS for routine TB diagnosis in China is still unknown.

Method. Using a decision tree-Markov model, we assessed the cost-effectiveness and health impact of using a WGS-based strategy for TB DST compared to culture-based testing and other rapid molecular testing strategies from a societal perspective. The model simulated 10,000 patients with active TB over their lifetime. Model inputs, including transition probabilities, health utilities, direct and indirect costs, sensitivity, and specificity for each strategy, were derived from the Global TB Report 2023, Chinese Center for Disease Control and Prevention, expert opinion, and the literature. Costs and health utilities were discounted at 5% per year.

Results. In the base case analysis, WGS, Xpert, and Xpert Ultra were cost-saving for patients with active TB. Compared to the culture-based DST, the pooled incremental net monetary benefit (INMB) for Xpert, Xpert Ultra, and WGS were $1750.06, $1832.84, and $1939.32, respectively. Over the lifetime, WGS is the optimal DST strategy for TB patients in China, which could save $401.83 in direct medical costs per person, while gaining an additional 0.121 quality-adjusted life years (QALYs) per case and reducing TB mortality by 45 per 10,000 patients. Sensitivity analyses suggest that the cost-effectiveness finding was robust.

Conclusions. WGS-based technology for TB DST could save more medical costs and lead to increased QALY gains compared to other strategies. Findings from this economic evaluation indicate that policymakers should encourage the widespread adoption of WGS for TB DST in China to ensure that all TB patients receive prompt diagnosis and effective treatment.

Ind-1141 Cost-Effectiveness and Equity Impact of Genomic Newborn Screening for Duchenne's Muscular Dystrophy

PRESENTER: **Anagha Killedar**, University of Sydney
AUTHORS: Joanne Scarfe, Sarah Norris, Didu Kariyawasam, Kirsten Howard, Winnie Chen, Michelle Farrar

Background: The introduction of genomics to newborn bloodspot screening (NBS) programs is being considered in several countries including the United States, the United Kingdom and Australia. In Australia, NBS programs could be expanded from screening for ~50 genetic conditions using predominantly biochemical approaches to hundreds of conditions using molecular methods including genome sequencing. While such expansion would allow earlier detection and management of many additional conditions it may introduce, exacerbate, or reduce health inequities. In Australia, the Medical Services Advisory Committee is responsible for considering the safety, effectiveness and cost-effectiveness of population screening programs, including NBS, however, the health technology assessment approach used does not consider equity impacts in any technical way. **Research Aim:** The study's aim was to develop a health economic model for genomic NBS that can be used to explore cost-effectiveness and equity impacts using Duchenne Muscular Dystrophy (DMD) as a case study. DMD is a condition with substantial health, social and economic impacts for the child and family and is ideal for exploring the equity impacts of genomic NBS. **Methods:** A Markov microsimulation model for DMD was constructed, informed by clinical expertise and published literature. Inputs will be updated with primary data from an Australian pilot of NBS for DMD and linked administrative data. The base model incorporates impacts on healthcare costs and quality of life. Further benefits include access to disability services, and benefits to family (eg, reproductive planning). Equity impacts are examined by using individual-level simulation to project the distribution of costs and benefits of genomic NBS for DMD across a birth cohort over a 50 year time horizon, corresponding to the maximum life expectancy of a person with DMD. The analysis accounts for disparities in a range of inputs, such as screening uptake, across several equity variables (e.g. socioeconomic position, ethnicity, geographical location). To quantify equity impact, relevant inequality indices are calculated in "no screening" and "screening" scenarios, across the whole newborn cohort and within the DMD cohort. Cost-effectiveness is calculated using standard approaches. **Results:** Preliminary analysis indicates that genomic

NBS for DMD may not be cost-effective, from a healthcare perspective, in the context of currently available management options. Due to low prevalence, there is minimal impact on inequalities in quality-adjusted life years (QALYs) in the whole cohort of newborns. However, within those with DMD, the impact on both univariate and bivariate inequalities in QALYs are observable under several scenarios. When incorporating a socioeconomic gradient in screening uptake (between 50-99%), screening resulted in the slope index of inequality increasing by 2 QALYs and the relative index of inequality by 11%. The health Gini index, representing univariate inequality, increased by 0.002. **Conclusions:** The model demonstrates how the cost-effectiveness and equity impact of genomic NBS for rare conditions, such as DMD, can be considered together. With several equity variables of interest, and methods to present equity impact, further work is needed to determine the appropriate approach to presenting these results to inform decision-making.

Ind-506 Cost-Effectiveness Analysis of Robotic-Assisted Thoracoscopic Surgery versus Video-Assisted Thoracoscopic Surgery for Early Stage NSCLC in China

PRESENTER: **Tianfu Gao**

AUTHORS: Hongtao Wang, Juntao Dong

Ind-585 Cost-Utility Analysis of NeuroSAFE Versus Standard Robotic? Assisted Radical Prostatectomy in Men With Localized Prostate Cancer

PRESENTER: **Jiunn Wang**, University of Exeter

AUTHORS: Elena Pizzo, Greg Shaw, Ricardo Almeida?Magana, Nick Roberts, Eoin Dinneen, Chris Brew-Graves, Pan Shengning, Baptiste Leurent, Norman Williams

Background

Robotic radical prostatectomy (RARP) is a first-line curative treatment option for localized prostate cancer. Erectile dysfunction and urinary incontinence are common associated adverse side effects that can affect patients after surgery. Preserving the lateral neurovascular bundles (NS) during RARP improves functional outcomes. The NeuroSAFE technique (intraoperative frozen section examination of the neurovascular structure adjacent prostate margin) can provide real-time pathological consult to promote optimal NS whilst avoiding PSM. NeuroSAFE PROOF is a single-blinded, multi-centre, randomised controlled trial (RCT) in which men are randomly allocated to either NeuroSAFE RARP or standard RARP.

Aim

The aim of this study is to assess the cost-utility of NeuroSAFE RARP alongside RARP compared to standard RARP using both the NHS and societal perspectives.

Methods

A within trial economic evaluation has been conducted using data from the NeuroSAFE trial. The cost of the intervention and control has been assessed using data on the consumption of healthcare resources (inpatient and outpatient visits, medications etc.) at patient level collected during the trial at different time points. The costs have been assessed using the unit cost data available from the published sources (BNF, PSSRU, NHS tariffs). Outcomes have been measured in terms of erectile function, incontinence and quality of life measured through EQ5D5L questionnaires. The results are expressed in terms of Incremental Cost Effectiveness Ratio and Net Monetary Benefits. Extensive sensitivity analysis has been performed to test the robustness of the results.

Initial results and conclusions

The trial has randomised 407 patients in total. Preliminary results show that the NeuroSAFE intervention is more expensive compared to standard treatment but improve outcomes in patients, reducing incontinence and quality of life. Therefore the intervention is cost-effective and should be approved as a standard treatment by the NHS. ## **Conclusions** NeuroSAFE PROOF is the first RCT of intra-operative frozen section during radical prostatectomy in the world. It is properly powered to evaluate a difference in the recovery of EF for men undergoing RARP assessed by patient-reported outcome measures. It will provide evidence to guide the use of the NeuroSAFE technique around the world.

Ind-1259 AI-based Digital Chest X-ray a Cost-effective Intervention for Active Case Finding (ACF) for TB in India

PRESENTER: **Dr. Samraj Sahay**

Background Under National Tuberculosis Elimination Programme (NTEP), India aims at eliminating TB by the year 2025, five years ahead of the SDG Target with reduction in incidence by 80% and mortality by 90%. The decline has been far from the set targets. One of the reasons is the low rate of active case findings (ACF), particularly in the high-risk groups such as tribal population. This study tries to examine the cost-effectiveness of alternative strategies for enhancing the ACF and subsequent reduction in adverse outcome; TB incidence and mortality, using strategy 1: mobile AI-based chest X-ray (CXR) and strategy 2: inclusion of informal health providers (IHPs) to bring in more presumptive TB patients for testing to the mobile AI-based CXR facility as compared to the existing strategy which uses mobile digital CXR with interpretation of the CXR by radiographers back at the peripheral health institutes (PHIs) resulting in considerable turnaround time and subsequent low ACF. **Method** The paper uses a Markov model for a 1-year cycle to estimate the costs and quality adjusted life expectancy (QALY) to determine the cost-effectiveness of the two alternative strategies using AI-based CXR as compared to the existing strategy for a tribal district from the provider perspective. The cost of the strategies included the cost of using the mobile AI-based CXR for strategy 1 and cost of involving the IHPs in terms of the incentives paid to them per presumptive cases (INR 50) and confirmed cases (additional INR 250) for strategy 2. The Markov model consisted of five states – healthy, active-TB, recovered, death due to disease and death due to background reasons. Data for the costs and rates used for the probabilities in the model was taken from published literature. A one-way sensitivity analysis was carried to confirm the robustness of the findings. **Results** The findings suggest that strategy 2 resulted in more gain in health outcome

(21.25 QALYs) as compared to status-quo (21.14). The incremental cost-effectiveness ratio (ICER) for strategy 2 was US$ 4940.92 per QALY gained whereas strategy 1 was weakly dominated by strategy 2. ICER is less than 1.75 times per capita GDP and well below the threshold of 3 times. The sensitivity analysis showed that the model is most sensitive to the relative risk reduction in probabilities of TB related mortality. The findings confirmed the cost-effectiveness of strategy 2 as compared to the existing strategy and can be the preferred choice for implementation. **Conclusions** The analysis finds that AI-based CXR has greater benefits*** in avoiding the adverse health outcome for TB in India than using mobile CXR with manual interpretation currently in practice. The benefits further increase when supplemented with services of IHPs as this increases the ACF and the subsequent reduction in TB related mortality. To achieve the NTEP targets, a decision should be made in favour of including services of IHPs in addition to increasing the number of AI-Based Mobile CXR, particularly in tribal areas.

Ind-1966 A Comparative Cost Analysis of First-Line Chronic Lymphocytic Leukaemia Treatment Regimens From a Public Healthcare System Perspective

PRESENTER: **Wen Yuen Lim**
AUTHORS: Niamh Appleby, Sarah Wordsworth

Background: The development of new B-cell targeted treatments in chronic lymphocytic leukaemia (CLL) and refined molecular diagnostics offer an effective model for precision medicine, but at a high price. There remains uncertainty surrounding the optimal and most cost-effective therapy in terms of both choice and duration. Published health economic studies have been mainly conducted in insurance-based healthcare systems, using projection models. There are limited studies that evaluate the real-world cost implications of the two main frontline CLL treatment strategies: continuous acalabrutinib, an exclusively oral targeted treatment, and venetoclax-obinutuzumab (VenO), a combination of intravenous monoclonal antibody and oral targeted treatment for a total fixed duration of 48 weeks. The study was conducted from a publicly funded healthcare system perspective which is under-represented in the literature. The aim of the study was to provide early health economic evidence to support healthcare providers in determining the best-value option for patients and to test an easily reproducible method for quantifying costs.

Methods: The study utilised a hybrid approach in the costing methods. Microcosting techniques were used to calculate drug costs, including systemic anticancer treatments and supportive medications. Healthcare resource groups or tariffs were used to estimate healthcare resource use (HRU) costs, as the healthcare currency within the National Health Service in the United Kingdom ("case-mix group" approach), which were subsequently categorised for sub-analysis. 40 patients starting their first CLL treatment in Oxford University Hospitals between September 2020-March 2022 were identified (24 acalabrutinib, 16 VenO). Data for two years of treatment-related costs incurred in a hospital setting was included in the analysis, which encompassed one year off-treatment for the VenO cohort. Statistical analysis was undertaken to test for significance between groups. A deterministic sensitivity analysis was performed to establish the impact of key variables. A literature review was conducted to appraise health economics publications comparing newer CLL treatment regimens.

Results: The mean total costs in Year 1 are higher for VenO compared to acalabrutinib (£104,255 vs £69,942) but reversed in Year 2 (£1,855 vs £53,984). 2-year overall treatment costs for acalabrutinib are £17,873 higher than VenO, with 89% attributed to drug costs. Recent studies supported this finding, establishing the significant health economic impact of therapy costs and improved patient survival with comorbidities. Deterministic sensitivity analysis showed that a reduction in drug costs had the biggest economic impact. 53.1% of HRU costs in the acalabrutinib group were attributed to unplanned activities such as hospital admissions, compared to 37.4% for VenO, but there were no statistically significant differences detected between groups for each of the HRU categories.

Conclusion: This study adds to the evidence base on the economic impact of fixed-duration versus continuous frontline CLL regimens in a centrally funded healthcare system. Head-to-head comparisons are required to establish long-term efficacy and cost-effectiveness of treatments. Genomic strategies to identify patients likely to experience durable disease control and guide duration of treatment are being explored to optimise healthcare resources while improving health outcomes, which could reduce overall healthcare expenditure, although global access to genomic testing may remain restricted.

abs-os87 23 and (not Just) Me: Incorporating Family Members in Economic Evaluation of Genetic and Genomic Testing Technologies

PRESENTER: **Wendy J Ungar**, The Hospital for Sick Children Research Institute/University of Toronto, Toronto, Canada
Background: The theoretical foundation of economic evaluation espouses welfarism that considers benefits from a new technology to **all** members of society. This contrasts with economic evaluation guidelines which focus on patients. This disconnect is amplified for genetic/genomic tests as these technologies routinely incorporate family members in testing and medical management of a genetic diagnosis. While economic evaluation guidelines increasingly recognize productivity costs of family members designated as patient caregivers, they lack a framework for incorporating other costs and health benefits to family members from a new technology. The objective is to illustrate the impact of incorporating family members on the design and conduct of economic evaluation of genetic/genomic testing technologies through studies of: 1) the cost-effectiveness of trio (child patient and two biological parents) genome sequencing (GS) vs. trio exome sequencing (ES) in pediatric rare disease and 2), cascade genetic testing in children with cardiomyopathy. *Methods:* A cost-effectiveness analysis of trio GS vs. ES was conducted whereby trios were randomly assigned to receive either GS or ES stratified by phenotype and molecular testing history. The cost per trio for GS and for ES testing were determined using micro-costing based on laboratory workflow and sequencing-related inputs. A probabilistic analysis was performed to address parameter uncertainty. Effectiveness was expressed as diagnostic yield (rates of diagnostic or partially diagnostic variants detected). Incremental costs and incremental effectiveness were calculated. The second example demonstrates conceptually how a positive finding in a pediatric cardiomyopathy patient leads to cascade testing in family members and referrals for treatment and surveillance. *Results:* The total cost per trio was CAD 4364 (95% CI: 3985, 5014) for GS (n=324) and CAD 2889 (95% CI: 2568, 3493) for ES (n=329). The incremental cost for GS compared to ES was CAD 1472. The diagnostic yield was 32.7% (106/324) for GS and 35.9% (118/329) for ES. Capturing upstream laboratory costs and effectiveness in a three-person household is seamless and easily executed. Modeling downstream costs expressed as referrals of family members for further testing, surveillance and treatment requires integrated forms of data collection facilitated by e-health records and linked datasets. Determining distal health outcomes in family members can be achieved through

modeling that captures health states for multiple family members and reports results and incremental effects at the family level. *Conclusions:* Genome sequencing and other 'omics tests are costly technologies diffusing rapidly into medical genetics and sub-specialties such as oncology and pediatrics. It's essential that standard medical practices involving family member testing, surveillance and treatment are reflected in economic models evaluating their cost-effectiveness. Burgeoning research on spillover effects can be leveraged to provide insight into how health resource use and health outcomes in family members can be captured through the inclusion of parent health states, parent-child dyad health states and household welfare function models. Measuring the costs and health consequences of genetic testing technologies in family members is integral to understanding the value of emerging sequencing technologies to fully inform funding and adoption decisions.

Ind-484 Assessing Caregiver Quality-of-Life Using EQ-5D-5L for Children Suffering from Developmental and Epileptic Encephalopathy in Australia.

PRESENTER: **Hansoo Kiim**
AUTHORS: Arun Jones, Jeremy Welton, Melinda Spencer

Background:

Developmental and Epileptic Encephalopathies (DEEs) are the most severe form of epilepsy, typically associated with frequent and severe seizures, and comorbidities including intellectual disability, behavioural abnormality, autism spectrum disorder and sleep disturbances. With an onset typically in infancy, patients with DEEs typically require life-long care, placing an immense burden on caregivers and family. As such, providing care for patients with DEEs can have a substantial impact on quality-of-life (QoL) and overall wellbeing.

Aim:

The aim of this study was to assess the impact of caring for a person with DEEs on the QoL of caregivers in Australia, including their financial situations, work and life activities, and mental and physical health status.

Methods:

This research used a cross-sectional study design. An online survey was designed and distributed to Epilepsy Foundation, Epilepsy Action Australia, Epilepsy Queensland and Epilepsy WA through the web-based survey tool, Qualtrics Core XM. Validated survey instruments were employed to measure the impact of caregiving responsibilities on their health-related quality-of-life (EQ-5D-5L), depression severity (Beck Depression Index; BDI) and sleep quality (Pittsburgh Sleep Quality Index; PSQI), as well as general demographic questions such as age, gender and the disease characteristics of the person being cared for with DEE. This study received ethics approval from the Griffith University Human Research Ethics Committee (reference number 2024/396). All participants provided informed consent to the research and to publication of the results.

Results:

A total of 32 caregivers completed the online survey. Most respondents were female (93.1%) and the mean age of caregivers was 44.2 years (SD=6.23 years). Mean EQ-5D was 0.79 which is substantially lower than the population mean of 0.86 (population mean for females aged 35-44 is 0.84). Respondents who had a change in job situation (e.g. changed jobs, reduced hours, quit etc) reported an EQ-5D utility of 0.77 compared to 0.96 ($p<0.05$) for those who did not have a change in job situation. The EQ-5D also varied according to the BDI scale with respondents reporting BDI = 'Minimal' reporting lower EQ-5D values vs respondents with BDI = 'Severe' (0.95 vs 0.67, $p=0.064$). The mean PSQI was reported to be 16.1 (SD=3.14) with all the respondents reporting a PSQI score <5 (=poor sleep quality).

Conclusions:

Our results suggest that carers of patients suffering from DEEs have substantially reduced QoL as measured by the EQ-5D-5L when compared to the general population (0.79 vs 0.86). Factors that seem to be influencing this is poor sleep quality as measured by the PSQI and mental health problems as measured by the BDI.

Our evidence-based evaluation will help establish a standard way of assessing the disease burden of the caregivers in Australian settings. The results of this work will also be helpful for the design of prospective/pragmatic studies to evaluate the broader societal value of interventions for DEEs based on improvements in productivity and QoL for caregivers. The information provided through this survey will be valuable to policymakers and clinical decision-makers in understanding the burden of DEE for caregivers.

Ind-487 Changes in Health-Related Quality of Life and Inequality in China: Evidence from a Nationwide Repeated Cross-Section Survey (2021-2023)

PRESENTER: **Xiaodan Zhang**
AUTHORS: Qiang Yao, Siyuan Fan, Yibo Wu, Chaojie Liu

Objectives: Health improvement is a multidimensional process that requires a focus on both health levels and equity. Existing research on health outcomes often lacks a comprehensive approach that integrates these dimensions, especially regarding HRQoL trends impacted by the COVID-19 pandemic. This study analyzed nationwide trends in the levels and equality of health-related quality of life (HRQoL) among Chinese residents during the COVID-19 pandemic (2021–2023). ***Methods:*** Data were sourced from the Psychology and Behavior Investigation of Chinese Residents (PBICR) survey, with 9,963 participants in 2021, 28,280 in 2022, and 45,003 in 2023. HRQoL was measured using the EQ-5D-5L, examining changes in the weighted utility index (UI) and visual analogue scale (VAS) scores. Ordinary least squares (OLS) regression models assessed the changes in UI and VAS scores over time, controlling for variations in other variables. Inequality in UI and VAS scores was quantified using the Erreygers Index (EI), and contributors to EI scores were identified through RIF-EI-OLS decomposition models. ***Results:*** The highest weighted UI score (0.9363±0.1389) was observed in 2021, which declined to 0.9332 (SD=0.1524) in 2022 (β=-0.0081, P<0.0001) and to 0.9244 (SD=0.1546) in 2023 (β=-0.0143, P<0.0001). The EI value decreased from 0.0703 in 2021 to 0.0635 in 2022 (β=-0.0105, P<0.001), with no further significant change in 2023. Regional disparities in both UI and EI were evident. Higher socioeconomic status (e.g., income, education, employment) correlated with higher UI and lower EI scores, while chronic conditions and comorbidity were linked to lower UI and higher EI scores, respectively. Higher social support, healthier lifestyles, increased health literacy, and an improved home environment were associated with higher UI and lower EI scores. The VAS results mirrored those of the UI. ***Conclusions:*** During the COVID-19 pandemic, HRQoL among residents of mainland China exhibited a downward trend with increasing pro-rich inequality. This trend is likely influenced by multiple factors across individual, family, and societal levels. The findings underscore the need to address income and regional disparities in HRQoL that were exacerbated by the pandemic, highlighting the importance of targeted investments in education, labor participation, and mental health support. These insights offer valuable guidance for tailoring clinical interventions and shaping policy decisions in China and other regions facing similar health inequality challenges. ***Key words:*** Health-related quality of life, HRQoL, China, Health inequality

Ind-563 Health-Related Quality of Life and Influencing Factors of Adult Patients With Spinal Muscular Atrophy

PRESENTER: **Lei Dou**

Background: Spinal muscular atrophy (SMA) is an infrequent yet progressive neuromuscular disorder predominantly attributed to homozygous deletions or mutations in the survival motor neuron 1 (SMN1) gene. This genetic anomaly leads to progressive proximal muscle weakness and atrophy. Beyond its detrimental impact on motor neurons, SMA adversely influences the functionality of various tissues, thereby restricting daily activities, elevating perceived fatigue, and diminishing health-related quality of life (HRQoL). Adults constitute 35% of individuals diagnosed with SMA. With the progression of supportive care and the introduction of disease-modifying treatments (DMTs), this proportion is anticipated to rise. Adult SMA patients encounter distinct health challenges compared to their pediatric counterparts, including the demands of daily activities, employment, and social engagement. However, previous studies have mainly focused on pediatric patients, and there has been limited research on health-related quality of life in adults with SMA. The aim of this study was to assess the HRQoL among adult patients with SMA and to investigate the factors influencing HRQoL. **Methods:** A cross-sectional study was undertaken in May 2023. Patients with SMA were recruited from the Beijing Meier Advocacy & Support Center for SMA (Meier), a non-profit organization specializing in SMA. The inclusion criteria required participants to have a confirmed diagnosis of SMA, be 18 years of age or older, and express willingness to participate in the study. Individuals unable to independently complete the questionnaires were excluded from the study. Ultimately, 202 adult patients with SMA completed the survey. The EQ-5D-5L instrument was employed to evaluate HRQoL of the participants. Additionally, the SMA independence scale (SMAIS) and fatigue severity scale (FSS) were utilized to assess daily activity capabilities and perceived fatigue, respectively. Data on socio-demographics variables, disease-specific characteristics, and treatment status were collected via a self-administered questionnaire. Descriptive statistical analysis and Tobit regression modeling were applied for data analysis. **Results**:** The mean health state utility (HSU) score for the EQ-5D-5L was 0.26 (SD = 0.33), while the mean scores for the SMAIS and FSS were 26.73 (SD = 14.47) and 5.47 (SD = 1.23), respectively. Among adult patients, the EQ-5D-5L dimension most frequently associated with problems was usual activity, followed by mobility. In terms of the SMAIS results, patients experienced the greatest difficulty with dressing independently. Factors influencing patients' HRQoL included current motor function, changes in motor function, dysfunction, comorbidities, self-reported severity, treatment status, FSS scores, and SMAIS scores. **Conclusion:** Adult patients with SMA demonstrate a significantly lower HRQoL compared to the general population in China and report experiencing severe perceived fatigue. To enhance the HRQoL of adult SMA patients, it is imperative to focus on individuals who are non-ambulatory, exhibit progressive motor function decline, present with multiple dysfunctions or comorbidities, experience greater disease severity, are currently untreated, report heightened fatigue, and possess diminished capacity to engage in daily activities.

Ind-569 Meaningfulness Of Health Gains - Implications for Economics Evaluations

PRESENTER: **Ana Bobinac**, University of Rijeka, Faculity of Economic and Business, Center for Health economics and Pharmacoeconomics
AUTHOR: Ismar Velic

Innovative therapies often come with exorbitant costs, raising critical questions about their value relative to the health benefits they provide. This paper examines the concept of **Minimum Effectiveness Threshold (MET)**, addressing whether public resources should be allocated to therapies that yield minimal health gains. Traditional cost-effectiveness analyses, typically represented by Incremental Cost-Effectiveness Ratios (ICERs), assess whether a therapy's cost is justified by its health benefits, usually measured in Quality-Adjusted Life Years (QALYs). However, these analyses often fail to consider whether the health gains are meaningful to patients and society at large.

The investigation begins with a review of existing literature on the efficacy of innovative cancer therapies approved by regulatory bodies such as the European Medicines Agency and the U.S. Food and Drug Administration. Studies indicate that many newly approved therapies offer only marginal improvements in overall survival (OS), with median survival gains often ranging from just a few weeks to several months. For instance, a systematic evaluation revealed that only 35% of oncology indications from 2009 to 2013 demonstrated significant OS benefits. Furthermore, recent analyses have shown a disconnect between the high costs of cancer drugs and their actual therapeutic benefits, suggesting that pricing is often dictated by market dynamics rather than clinical efficacy. The paper highlights the societal implications of funding marginally effective treatments. It posits that policymakers, healthcare providers, and patients may struggle to accept limitations in treatment options, leading them to favor therapies that offer even slight improvements in survival. This inclination is fueled by a desire for hope and the perception that every possible treatment avenue should be explored, particularly in cases involving rare diseases or high unmet medical needs. To address these concerns, the authors propose establishing explicit MET criteria for evaluating new oncology treatments. By defining a minimum threshold for meaningful health gains—such as, for instance, an additional three to six months of survival—healthcare systems could prioritize funding for therapies that deliver substantial benefits over those that provide only marginal improvements.

The paper presents findings from an empirical study conducted in Croatia, where public representatives were surveyed about their perceptions of meaningful health gains. Results indicated that citizens do not consider all health improvements as equally valuable; rather, they emphasize the significance of both the magnitude and duration of health gains. We argue that integrating MET into reimbursement frameworks could enhance decision-making processes in healthcare resource allocation. By aligning funding decisions with societal preferences regarding meaningful clinical benefits, healthcare systems could better manage limited resources while ensuring that patients receive treatments that genuinely enhance their quality of life. By advocating for a more nuanced approach to evaluating health gains—one that considers both cost-effectiveness and meaningfulness— we might achieve a more equitable and efficient allocation of healthcare resources, ultimately benefiting patients and society as a whole.

Ind-809 Have we been Measuring Migrant Wellbeing all Wrong? Conceptualizing Migrant Wellbeing: A Systematic Review

PRESENTER: **Salsawi Feleke Debela**
AUTHORS: Sheenagh McShane, Lauren Carpenter, Celia McMichael, Ankur Singh, Karen Block

Background: We are living in the "age of migration". Many migrants, especially those forcibly displaced, face challenges impacting their lives, livelihood and wellbeing. Wellbeing is a widely used concept. It is broadly defined as the quality of life. However, it lacks a universal definition, standardized measurement and even spelling. At present, there are over a thousand different wellbeing measurement tools. For migrants, positive subjective wellbeing signals successful settlement, healthy functioning, and social integration. However, most research has focused on mental illness, overlooking subjective wellbeing, which is a crucial quality of life indicator. Existing wellbeing measures are often based on Western, middle-income cultural norms, limiting their relevance for studying ethnic and immigrant populations. Aim: To date, no systematic reviews have evaluated the properties, suitability, and appropriateness of current wellbeing measurement tools for migrant populations. This review sought to address this gap. It aimed to understand how the wellbeing of people who migrate from low/middle-income countries to middle/high-income countries has been conceptualized, defined, and measured. Methods: A systematic search was run in four databases: MEDLINE, PubMed, EMBASE, and PsycINFO. This produced 5,610 articles. Two independent researchers screened all the articles, leaving 126 articles for the final analysis. Two types of analysis were used: narrative synthesis and COSMIN analysis. Key results: The 126 articles measured the well-being of migrants using 43 different wellbeing measurement tools and covered more than 281,400 migrants, aged 15 to 79+, who live in more than 35 countries. Defining wellbeing is fundamental to measuring it. However, more than 70% of studies included in this review did not define or conceptualise wellbeing. Seven tools were identified as being used most commonly to measure migrant wellbeing although two of these tools were not designed to measure well-being. Except two of the tools (PWI and WHOQoL-BREF), most other tools did not have satisfactory scores when evaluated using COSMIN. Four out of the six tools lack cross-cultural validity. Less than half of the studies reported translating wellbeing measurement tools into respondents' languages. Furthermore, no tool was specifically designed to measure migrants' wellbeing. It is likely that tools designed, developed and tested in Western high-income contexts may overlook culturally significant elements essential to migrants. Implications: The lack of cultural validity in most of the commonly used tools raises an important concern about their ability to accurately measure the wellbeing of migrants. For policy makers, the findings of this review call into question the accuracy of the information they rely on to make policy-based decisions. Hence, assigning adequate resources to design migrant specific wellbeing measure is of paramount importance. Conclusions: The findings of this review call for a shift in the way we assess wellbeing in migrant populations and highlights critical gaps in the current wellbeing measurement tools used for migrant populations. Without culturally informed tools, our understanding of migrant wellbeing will remain fragmented, limiting our ability to develop effective interventions and policies. As migration continues to shape global demographics, the development of such tools is crucial to ensure equitable and effective public health intervention.

Ind-996 The Distribution of Quality-Adjusted Life Expectancy by Level of Socioeconomic Disadvantage and Remoteness Area for the Australian Population

PRESENTER: **Sheridan Rodda**
AUTHORS: Richard Norman, Zanfina Ademi, Jedidiah Morton, Melanie Lloyd

Background

Socioeconomic status (SES) is associated with significant health inequalities in Australia and globally. Methods for evaluating the equity impacts of a healthcare funding decision alongside cost-effectiveness are emerging. These equity-informed analyses require the baseline distribution of health across relevant equity subgroups against which interventions may be evaluated. The distribution of health status measured as quality-adjusted life expectancy (QALE), by socioeconomic status is unknown for Australia.

Aim

To estimate QALE, across SES groups, stratified by sex and year of age for the Australian population.

Methods

A cross-sectional study combining nationally representative datasets was conducted. SES was measured using two area-level measures: the 2021 Socio-Economic Indexes for Areas Index of Relative Socioeconomic Disadvantage (IRSD) which assigns areas a score measuring socioeconomic disadvantage, we used quintiles ranging from quintile 1 (Q1) for those most socioeconomically disadvantaged to quintile 5 (Q5) for those least disadvantaged); and the remoteness area for the individual's place of residence based on the Australian Statistical Geography Standard using three categories: major cities, inner regional and outer regional to very remote.

National mortality data for 2022 from the Australian Bureau of Statistics was used to construct life tables to estimate life expectancy (LE). Short form (SF-36) responses from Wave 22 (2022) of the Household, Income and Labour Dynamics in Australia survey were used to estimate the mean SF-6D (version 1) health utility by age, sex and SES using specific linear regression models.

Health utility was integrated into the life tables by multiplying the person years lived by utility index estimates to determine the QALE for each sex-SES group. Probabilistic sensitivity analysis derived 95% confidence intervals for the estimates and 3% discounting was applied.

Results

Mean health utility was higher for males than females and decreased with age. From birth, undiscounted LE for all individuals in Q1 (most disadvantaged), was 78.7 years compared to 86.3 years for those in Q5 (least disadvantaged). Incorporating health-related quality of life amplified these disparities, with those in Q1 experiencing an undiscounted QALE of 43.9 (95% confidence interval 42.6-45.2) years compared to 55.6 (54.1-57.1) years for Q5, representing a 27% relative difference in QALE. There was a modest equity gradient by remoteness with individuals in major cities expecting a LE of 83.1 years and QALE of 50.8 (49.8-51.7) years (all undiscounted) while those in outer regional to remote areas expecting a LE of 80.5 years and QALE of 47.0 (44.2-49.7) years.

Conclusion

There is clear disparity in QALE by socioeconomic status in Australia, whereby both the quantity and quality of life decrease with increasing socioeconomic disadvantage and geographical remoteness. These findings highlight the need for targeted interventions to address health inequalities. The detailed QALE estimates produced can be applied to equity-informative economic evaluations.

Ind-1028 Comparison of Psychometric Performance of Self-Complete and Proxy Versions of the Bangla EQ-5D-Y-3L and Socio-Economic Factors Influencing Agreement

PRESENTER: **Marufa Sultana**, Deakin University
AUTHORS: Jahangir AM Khan, Mimmi Åström, Rumana Huque, Sayem Ahmed, Md Badruddin Saify, Ms. Lisa Gold

Background

Assessing health-related quality of life (HRQoL) in children is essential for understanding healthcare needs and directing resource allocation. The EQ-5D-Y-3L is a widely used instrument designed to measure the health status of children. The instrument comprises five dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression, each with three response levels (no problem, some problems, a lot of problems). It also includes a visual analogue scale (VAS) ranging from 0 to 100. Both the self-complete and proxy versions of the EQ-5D-Y-3L were translated into Bangla and pilot-tested in Bangladesh for the first time. This study aimed to compare the psychometric properties of self-complete and proxy versions, agreement between versions and socio-economic factors influencing agreement.

Methods

The study recruited children aged 8-18 years attending public schools and their parents from one urban and one rural district in Bangladesh. The EQ-5D-Y-3L was administered to children/adolescents (self-report) and to parents/caregivers (proxy report) with a few additional open-ended questions. Parents also completed a demographic and socio-economic questionnaire. Data were evaluated on several parameters: response rate, completion time, ceiling effects, reliability, and validity. Agreement between self-report and proxy responses was assessed using the Prevalence-Adjusted and Bias-Adjusted Kappa (PABAK), which ranges from 0 to 1, with values ≥0.70 considered strong agreement. Convergent validity was assessed through Spearman's correlation coefficients (ranging from 0 to 1, with higher values indicating stronger correlation). Multivariable logistic regression identified predictors influencing agreement, including variables such as location, age, gender, income, occupation, and school grade. A P-value <0.05 was considered the significance level, and results were reported as odds ratios (ORs) with 95% confidence intervals (95% CI).

Results

240 parent-child dyads participated, with mean ages of 37.5 years for parents and 13.1 years for children; 52% were from urban areas. The mean completion time was similar for both self-complete and proxy versions (5.1 and 5.2 minutes), with no missing responses. Most children/adolescents (96%) and parents/caregivers (78%) found the tool easy or very easy to complete (P=0.339). 48% of self-reports and 58% of proxy reports indicated no problems across all dimensions (11111), reflecting relatively low ceiling effect for self-report with non-significant difference (P-value=0.366). Agreement was highest for mobility and looking after myself dimensions (PABAK≥0.70) and lowest for pain/

discomfort (PABAK=0.10). Similarly, test-retest reliability from a sub-sample demonstrated strong agreement for mobility and looking after myself dimensions (PABAK=0.92) but low for pain/discomfort (PABAK=0.06). Mean VAS scores were 86.8 for self-reports and 88.6 for proxy reports, with weak convergent validity (Spearman's Rho=0.18). Adjusted logistic regression analysis indicated higher agreement among rural residents (OR: 2.0; 95% CI: 1.4–7.3) and middle-income participants (OR: 3.9; 95% CI: 1.8–20.6). No significant associations were identified for other variables.

Conclusions

The Bangla self-complete and proxy versions of the EQ-5D-Y-3L demonstrated feasibility and moderate agreement for measuring HRQoL among children in Bangladesh. Further research with larger samples is recommended to apply the versions across diverse groups.

Ind-1086 Using Expert Elicitation to Estimate Lifetime Overall and Progression-Free Survival in Idiopathic Pulmonary Fibrosis in Indonesia

PRESENTER: **Wayan Citra Wulan Sucipta Putri**
AUTHORS: Arie Rahadi, Fariz Nurwidya, Lusiana Siti Masytoh, Arini Purwono, Sita Laksmi Andarini

Background: Unified disease registries in a local setting are the most valid data source to inform long-term patient survival of the existing, baseline standard of care in an economic evaluation. However, in Indonesia such registries are not always available due to fragmentation in health data infrastructure, making reliable collection of real-world survival data too costly. To overcome this barrier in our economic evaluation of antifibrotic agents for idiopathic pulmonary fibrosis (IPF), a rare disease with an onset in older age, we elicited expert opinions to construct baseline survival, anchored to data on published cohort. **Methods:** The process was conducted in 3 phases: preparation, elicitation and aggregation. In the preparation phase we identified outcomes (overall survival [OS] and progression-free survival [PFS]) and the elicitation method (fixed interval). For elicitation, we invited experts who were six pulmonologists with recent experience in treating IPF to participate in an elicitation exercise on survival parameters in October 2024. During the first stage of elicitation, experts were presented OS and PFS curves from the EMPIRE cohort and asked to individually modify the survival probabilities in six semiannual intervals up to 36 months to approximate their beliefs on observed rates in their practice settings, using pre-programmed spreadsheet templates. In the second stage, the expert-constructed survival curves were aggregated in a Delphi method to consensus values that were acceptable to all experts. Lifetime extrapolation by parametric distribution was applied, and the results were optionally calibrated to an expected value informed by consensus. **Results:** Three experts participated in the exercise. The expert-constructed survival curves were lower than the reference EMPIRE cohort, with gaps that were visually larger with time for OS, proportional throughout 36 months for PFS, and variable by experts. The consensus vs. EMPIRE survival probabilities at 12, 24, and 36 months were 69.9% vs. 77.3%, 42.8 vs. 58.3%, and 24.4% for OS; and 48.9% vs. 54.2%, 19.8% vs. 30.6%, and 7.2% vs. 14.5% for PFS. Exponential and Weibull distributions provided the best fit to the data on OS and PFS probabilities, respectively, by the Akaike/Bayesian information criteria. When reviewing the extrapolated survival, experts agreed to calibrate the 60-month OS to 11% so that the probability of being alive beyond 15 years was approximately zero. No calibration was desired for extrapolated PFS. Post-exercise surveys indicated that all experts valued their direct engagement in the elicitation technique and highly preferred reaching a consensus in the second stage compared to the 'averaging out' of individual estimates had the technique stopped after the first stage. **Conclusions:** Consensus-based, participatory expert elicitation can be valuable to overcome data constraints in Indonesia and give credence to the parameter estimates used in a cost-effectiveness analysis of antifibrotic agents for IPF. Better planning to include more experts in future endeavors is needed to improve the reliability of this elicitation technique. Keywords: Expert elicitation; economic evaluation; calibration; idiopathic pulmonary fibrosis; low- and middle-income countries

Ind-1255 Trend and Health Inequality of Burden of Cardiovascular Disease From 1990 to 2021: Evidence From Global Burden of Disease Study 2021

PRESENTER: **Xing Chen**
AUTHORS: Wen Chen, Luying Zhang

Objective Cardiovascular disease (CVD) is a significant public health issue globally. This study aims to quantify the global burden and trends of CVD while also analyzing inequalities from geographic, gender, and socioeconomic perspectives. **Methods** The estimates and 95 % uncertainty intervals (UI) for prevalence, disability-adjusted life-years (DALY), and mortality of CVD were extracted from Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2021. We compared global differences and trends in the burden of CVD across three dimensions: geography, gender, and age group. Additionally, we quantified cross-country inequalities in the burden of CVD using standard health equity methods recommended by the World Health Organization. **Results** In 2021, the global age-standardized prevalence of cardiovascular disease was 7,178.7 per 100,000 population (95% uncertainty interval: 6,696.2 to 7,620.7). The age-standardized DALY rate was 5,055.86 (4,759.6 to 5,359.2), and the age-standardized mortality rate was 235.2 (214.6 to 250.5). At the regional level, North Africa and Middle East exhibited the highest age-standardized prevalence rate at 9,882.7 (9,335.5 to 10,467.5). Oceania had the highest age-standardized DALY rate at 9,114.9 (7,689.5 to 10,553.8), while Central Asia recorded the highest age-standardized death rate at 436.1 (395.8 to 474.5). By gender, the global gender ratios (male to female) for the age-standardized DALY rate and death rate were 1.52 (1.52 to 1.55) and 1.43 (1.41 to 1.48), respectively. Notably, this gender disparity has been increasing since 1990. Regarding age groups, the prevalence, DALY, and mortality rates associated with cardiovascular disease continue to rise with age. From 1990 to 2021, the global age-standardized prevalence rate increased by 0.9% (-0.6 to 2.7). In contrast, the age-standardized DALY rate decreased by 33.0% (29.4 to 36.5), and the age-standardized mortality rate dropped by 34.3% (30.7 to 37.8) for cardiovascular disease. Further studies indicate that the burden of DALYs and mortality is concentrated in countries with higher levels of sociodemographic development. The slope index of inequality revealed a significant reduction in inequalities related to sociodemographic index (SDI), with the gap in DALYs between the highest and lowest SDI countries decreasing from 3,078.1 per 100,000 in 1990 to 1,952.1 per 100,000 in 2021. Meanwhile, the concentration index also showed a decline from 1990 to 2021. **Conclusions** As a major health problem, the global burden of CVD showed an overall decreasing trend from 1990 to 2021. Countries with a high SDI bear a disproportionately large share of the CVD burden. However, over time, the inequalities related to SDI among countries have diminished. This

study emphasizes the considerable challenges in controlling and managing CVD, including the rising number of cases and ongoing disparities around the world. These findings can provide valuable insights for improving public health policies and effectively allocating medical resources.

Ind-1471 Unravelling Public Preferences for Use of Artificial Intelligence Mobile Health Applications: Discrete Choice Experiments from Australia

PRESENTER: **Vinh Vo**
AUTHORS: Maame Esi Woode, Stacy Carter, Chris Degeling, Gang Chen

Objectives To explore public opinion on the factors that drive the use of Artificial Intelligence (AI) mobile health (m-health) applications for heart disease and mental health, with a particular emphasis on diagnostics and virtual health assistance. **Methods** This study adopted a discrete choice experiment (DCE) to investigate the preferences of the Australian public across four distinct settings, encompassing heart disease and depression, in combination with AI Diagnostics and Virtual health assistant applications. Five attributes were considered, including anonymised data sharing, AI application interaction, the accuracy of AI results, the explanation of results provided by AI, and the funding source. Mixed logit and latent class conditional logit models were used to incorporate potential preference heterogeneity among respondents. **Results** Respondents (n=1,176) showed that AI result accuracy is the most crucial factor in AI m-health applications. Interaction between AI and humans is the second most important, highlighting the value of combining AI with human oversight. There is a preference for anonymised data to be shared, especially in Virtual Health Assistant applications. On the other hand, results explanation and funding source are generally less important. Preference heterogeneity existed that those who expressed fear of AI were less likely to opt for AI-powered solutions for heart disease diagnosis and virtual health assistance. Older adults (aged 60 and above) were less inclined to use AI for diagnostic purposes. Young adults (particularly those aged 18-29) were more likely to adopt AI-powered virtual health assistants for heart disease. Respondents with poorer health-related quality of life (HRQoL) were more likely to utilise AI-powered virtual health assistants. **Conclusions** It is evident that beyond the technical feasibility of AI applications, there are nuanced differences in public preferences for AI m-health AI applications. Understanding factors leading to these discrepancies would be valuable to ensuring safe and equitable acceptance and harnessing the full potential of AI technologies to enhance healthcare delivery and outcomes.

Ind-2346 An Exploration of Attribute Non-Attendance in Valuing SF-6Dv2 Health States Using a Discrete Choice Experiment

PRESENTER: **Jooho Moon**, Seoul National University
AUTHOR: Eun-Young Bae

Background In discrete choice experiments (DCE), respondents often overlook certain attributes when making decisions due to heuristic reasons, leading to potential biases in utility estimations derived from choice models. The use of DCEs to evaluate health state preferences is growing, having been applied in EQ-5D valuation studies and, more recently, in SF-6Dv2 valuation research. Given that the complexity of DCE designs or tasks increases the likelihood of Attribute Non-Attendance (ANA), it is notable that substantial ANA has already been observed in EQ-5D DCE studies. With six dimensions plus duration, the SF-6Dv2 design is even more complex than EQ-5D, making ANA a potentially critical issue in its valuation. **Objectives** This study aimed to assess the influence of ANA on the estimated value sets for SF-6Dv2 health states. **Methods** A web-based DCE incorporating duration was conducted following international protocols. The survey included 304 choice sets across four duration levels, divided into 38 blocks. A total of 3,800 respondents aged 18 or older were recruited using quota sampling based on gender, age, and region. To address the ANA issue, an endogenous attribute attendance (EAA) model was used to examine ANA across SF-6Dv2 dimensions. This model integrates two sets of probabilities into the unconditional choice probability: the first represents the likelihood of attending to specific attributes, and the second reflects the probability of choosing one alternative over another based on the subset of attended attributes. **Results** The results indicated a high proportion of respondents attended to Physical Function (PF) and Pain (PA), with attendance rates of 75% and 79%, respectively. In contrast, lower attendance rates were observed for Role Limitation (RL), Social Function (SF), and Mental Health (MH) at 28%, 54%, and 60%, respectively. Given these ANA probabilities, the estimated coefficients for PF and PA using the EAA logit model were -0.374 and -0.355, respectively, differing from the values obtained with the conditional logit model (-0.204 and -0.214). Likewise, the estimated coefficients for RL, SF, and MH also differed between the EAA logit model and the conditional logit model. **Conclusion** The findings indicate a tendency for respondents not to attend selectively to certain dimensions of the SF-6Dv2 in their decision-making processes. While this may influence the parameter estimates, further research is necessary to discern whether this behavior reflects heuristic strategies employed to simplify choices or genuine preferences for particular dimensions.

Ind-2648 The Impact of Hepatitis C and Socio-Demographic Variables on Health-Related Quality of Life Among Patients in Pakistan

PRESENTER: **Siwaporn Niyomsri**
AUTHORS: Peter Vickerman, Saeed Sadiq Hamid, Aaron G. Lim, Naheed Choudhry, Graham Foster, Huma Qureshi, Josephine Walker, Saad Niaz, Asad Chaudhry

Background and Aims: Pakistan has the highest global burden of hepatitis C virus (HCV) and can result in significant morbidity. We examined health-related quality of life (HRQoL) among the general population screened for hepatitis C virus infections in Pakistan, and identified key socio-demographic factors associated with HRQoL.

Methods: As part of the HepFREEPak study, a prospective multi-centre cross-sectional screening and treatment study was conducted in community and clinic-based settings in Karachi and Gujranwala, Pakistan. Participants aged 18 and over were recruited with a 1:5 ratio of HCV-infected to uninfected participants. HCV infection was confirmed through anti-HCV antibody and HCV RNA positivity (denoted HCV-

positive). Exclusions included prior chronic HCV and significant comorbidities. Cirrhosis diagnosis relied on clinical evidence and APRI/Fib-4 scores. Treatment comprised direct-acting antiviral (DAA)-based medications. HRQoL was assessed prior to diagnosis by the EuroQol-EQ-5D-3L survey tool and Visual Analogue Scale (VAS). Propensity score matching (PSM) was used to address participant imbalance between HCV-positive and negative groups. To determine factors associated with HRQoL, Tobit regressions analysed censored EQ5D scores, while logistic regression was performed to evaluate each EQ-5D domain.

Results: The study included 5,468 participants, median age 39 (IQR: 30, 50) years, 59.14% males. Of these, 1,263 were HCV-positive (23.10%). HCV-positive participants exhibited lower HRQoL (0.952; 95% CI: 0.947-0.956) compared to HCV-negative participants (0.979; 95% CI: 0.977-0.981, $p < 0.001$, unadjusted). After PSM, 778 individuals remained in each group. HCV-positive participants showed significant reductions in mobility, self-care, and pain/discomfort, but not usual activities difficulties and anxiety/depression. Logistic regression indicated that HCV-positive individuals aged 50 and over had higher odds of difficulties across all domains. Males had lower odds for mobility and self-care difficulties. Unemployment had higher odds almost all domains. Tobit regression confirmed lower EQ5D scores for HCV-positive individuals ($B = -0.054$, $SE = 0.009$, $p < 0.001$) than HCV-negative. Older age, unemployment, single status, and being divorced/widowed were linked to lower EQ5D scores, while being Urdu-speaking was associated with higher scores ($B = 0.080$, $SE = 0.034$, $p = 0.018$). Education level did not significantly affect EQ5D scores. Cirrhosis (24-week treatment duration) was not significantly associated with lower HRQoL ($B = -0.019$, $SE = 0.012$, $p = 0.104$).

Conclusions: HCV infection significantly impacts HRQoL in Pakistan, especially among those individuals with cirrhosis. Our findings emphasize the role of socio-demographic variables on HRQoL. Further research is needed to determine if HCV treatment can mitigate these effects.

Ind-282 Cost-utility of IDegLira Versus Alternative Basal Insulin Intensification Therapies in Patients With Type 2 Diabetes Mellitus in a Chinese Setting

PRESENTER: **Junling Weng**
AUTHORS: Dunming Xiao, Yingyao Chen

Background: In 2021, IDegLira was introduced in China as a treatment option for patients with type 2 diabetes mellitus (T2DM). We aimed to evaluate the long-term cost-utility of IDegLira versus basal-bolus therapy and glucagon-like peptide-1 receptor agonist (GLP-1RA) added to basal insulin in T2DM patients who remain uncontrolled on basal insulin in China. **Methods:** The Swedish Institute for Health Economics (IHE) Cohort Model of T2DM was used to project health and cost outcomes over a 30-year time horizon. Baseline cohort characteristics were derived from the DUAL II China study. Treatment effects were derived from DUAL VII study and a pooled analysis. Costs were accounted from a health system perspective in China, expressed in 2023 Chinese yuan (CNY). Health outcomes were measured in quality-adjusted life years (QALYs). Health state utilities were derived from several publications. Future costs and clinical outcomes were discounted at 5% annually. The probability sensitivity analysis (PSA) was used to explore the robustness of the results. In scenario analysis, the impact of semaglutide was considered. **Results:** IDegLira was associated with an improvement of 0.011 QALYs and a reduction of CNY 23,815 versus GLP-1RA added to basal insulin. The PSA scatter plot showed that the vast majority of the scatter points fell in the fourth quadrant, with some falling in the third quadrant. Similarly, in comparison with basal-bolus therapy, IDegLira demonstrated a health gain of 0.810 QALYs and a cost reduction of CNY 91,217, making IDegLira the dominant option. The PSA indicated a 100% probability of IDegLira being cost-effective. The scenario analysis showed that compared to basal insulin combined with semaglutide, IDegLira reduced costs by CNY 36,972, but QALYs also reduced 0.044. **Conclusions:** For T2DM patients uncontrolled on basal insulin, IDegLira was projected to be dominant and worthy of clinical promotion both compared with basal-bolus therapy and GLP-1RA added to basal insulin in the Chinese setting. Semaglutide has certain advantages in clinical practice, but its price is relatively high.

Ind-565 Cost-Utility Analysis and Drug Pricing of Icodec Versus Degludec for Type 2 Diabetes Patients With Basal Insulin-Treated in China

PRESENTER: **SHANSHAN HU**
AUTHORS: CHENYANG SHI, GUORONG FAN

Objective Insulin icodec is a first once-weekly administration basal insulin analogue for type 2 diabetes. As so far, icodec is the first and only FDA-approved once-weekly version of basal insulin analogue. In China, insulin icodec was just approved for type 2 diabetes by center for drug evaluation. However, the price of icodec has yet to be established in Chinese market. Our study aimed to estimate the cost-effectiveness of once-weekly insulin icodec versus once-daily insulin degludec for type 2 diabetes patients with basal insulin-treated from the Chinese healthcare perspective and explore the most appropriate annual cost for icodec to provide promising suggestions for price and decision-makers. **Method** Long-term health outcomes and costs for icodec and degludec were simulated using the United Kingdom Prospective Diabetes Study Outcomes Model (version 2.1) over 40 years from the Chinese health care provider's perspective. The efficacy and safety data were obtained from the ONWARDS 2 trial. Cost-utility analysis and a binary search were used to investigate the price range of the icodec. Sensitivity analyses

were performed to verify the robustness of the base-case analysis results. **Results** After a 40-year simulation, the quality-adjusted life years (QALYs) of the icodec and degludec were 10.32 years and 10.28 years, respectively. At the initial assumption of the same annual costs of icodec and degludec of $455.40, icodec was the dominated therapy compared with degludec, with higher QALYs and lower total cost. After the binary search, we observed the annual cost range of icodec was $625.17 to $855.25. This cost range was finally adjusted to be $597.66 to $736.34 by one-way sensitivity analysis and verified by probabilistic sensitivity analysis and scenario analysis. The scenario analysis reveraled that the annual cost range of icodec could be $506.70 to $736.34 if the price of degludec decreased by 20% in the future. **Conclusion** From the Chinese healthcare providers' perspective, this study determined that icodec appears to be very cost-effective at an annual cost of $597.66, and cost-effective at $736.34, compared with degludec. The base-case analysis remained robust to 1-w SA and PSA. Consequently, using degludec as reference, the annual cost range of icodec appears to be $597.66 to $736.34. In the scenario analysis, if the price of degludec will decrease 20% in the future, the annual cost range of icodec is estimated to be $506.70 to $736.34. **Keywords** Cost-utility analysis, Insulin icodec, Insulin degludec, Type 2 diabetes, Drug pricing, China

Ind-1522 Cost-Effectiveness of Real-Time CGM vs Self-Monitoring of Blood Glucose in People with Type 2 Diabetes on Intensive Insulin Therapy in Australia

PRESENTER: **Moin Ahmed**
AUTHORS: Paul Sim, Hamza Alshannaq, David Simmons, Greg Norman

Introduction Evidence shows that real-time continuous glucose monitoring (RT-CGM) systems improve glycaemic control in people with type 2 diabetes (T2D) on intensive insulin therapy (IIT). Reimbursement for RT-CGM in Australia is currently limited to people with type 1 diabetes. Our analysis evaluates the cost-effectiveness of RT-CGM compared to self-monitoring blood glucose (SMBG) for people with T2D IIT in Australia. **Methods** We used the IQVIA Core Diabetes Model (CDM), comprising 17 Markov sub-models for diabetes complications over a lifetime horizon, to simulate clinical outcomes and direct medical costs from an Australian public healthcare system perspective. Effectiveness was measured in quality-adjusted life years (QALYs). A discount rate of 5% was applied in this analysis. Cohort characteristics included a mean age of 65 years, 51% male, and an average diabetes duration of 16 years. The adjusted HbA1c reduction for RT-CGM was -0.56%. Severe hypoglycemics and hyperglycaemia rates were 4% and 2.5% per patient-year (PPY) for SMBG and 0% PPY for RT-CGM, respectively. Utilities for avoiding fingerstick (0.03) and reducing fear of hypoglycaemia (0.025) were applied to RT-CGM users. Probabilistic and deterministic sensitivity analyses were conducted. **Results** RT-CGM users are projected to gain an additional 0.621 QALYs with $14,117 in incremental costs and an incremental cost-effectiveness ratio (ICER) of $23,426/QALY, below the $50,000/QALY willingness-to-pay threshold for Australia. Microvascular and macrovascular outcomes projections indicate that RT-CGM use results in a relative reduction in diabetes eye, renal, neuropathy, and cardiovascular complications of 17.7%, 21.1%, 8.7%, and 2.5%, respectively. Sensitivity analysis scenarios of RT-CGM cost reductions of 10%, 20%, and 30% resulted in ICERs of $18,666/QALY, $13,909/QALY, and $9,153/QALY, respectively. RT-CGM remained cost-effective even when costs were increased by 30%. Using Fremantle risk equations for 100% Southern European and 100% Indigenous Australian populations resulted in ICERs of $8,085/QALY and -$1,832/QALY (RT-CGM is dominant). **Conclusion** This study has demonstrated that using RT-CGM systems for diabetes management in people with T2D who are on intensive insulin is a cost-effective intervention. Findings support expanding reimbursement for RT-CGM in Australia.

Ind-1602 Economic Evaluation of the Joint Asia Diabetes Evaluation Public-Private Partnership Program in Hong Kong: A Patient-Level Simulation Analysis

PRESENTER: **Eric S.H. Lau**
AUTHORS: Elaine YK Chow, Juliana CN Chan, Minglu Zhang, Hong Jiang Wu, Juliana NM Lui, Andrea OY Luk

Background The public healthcare system in Hong Kong, which serves 90% of the population and supported by only 50% of healthcare workforce, is under significant strain, complicating effective diabetes care. Since 1995, the Chinese University of Hong Kong (CUHK) has implemented a series of quality improvement programs to add value to diabetes care. This included the establishment of the Hong Kong Diabetes Register (HKDR) to stratify risk, triage care, and empower patients. Since 2000, the protocol was adopted to become a territory-wide diabetes risk assessment program benefiting 0.5 million patients. In 2007, CUHK digitalized the HKDR into the web-based Joint Asia Diabetes Evaluation (JADE) Platform with protocols and risk engines to issue personalized report with decision support and provided the JADE-guided assessment through public-private partnerships (PPP). We evaluate the long-term cost-effectiveness of the JADE-PPP program compared to the risk assessment program implemented in the public sector with or without the JADE-assisted technology. **Methods** In the public setting, the non-JADE group (n=3,587) underwent structured assessment only, while the JADE group (n=9,601) received JADE personalized risk reports along with group nurse-led empowerment sessions. At a self-subsidized university-affiliated diabetes center, the JADE-PPP group (n=3,436), referred by their doctors or themselves, received personalized reports, individual nurse-led empowerment sessions, and annual follow-up reminders. We utilize the patient-level Chinese Diabetes Outcomes Model (CDOM) developed using the HKDR (n=21,543) and externally validated in Hong Kong public hospital territory-wide cohort (n=176,120) for individuals enrolled in 2002-2019. The CDOM encompasses ten endpoints, including cardiovascular and renal outcomes, cancer incidence, and all-cause mortality. It projected annual survival and events until age 110. Intervention included enrolment into 1) non-JADE program in public setting 2) JADE program in public setting, and 3) JADE-PPP program. Incremental healthcare costs and quality-of-life decrements associated with endpoints were estimated using data from the HKDR, along with treatment effects from our published studies. Quality-adjusted life-years (QALYs), years of life lost due to premature mortality and additional cost/QALY were estimated. Willingness-to-pay threshold of three-times Hong Kong GDP in 2023 (USD$50,696.6) was applied. Subgroup analysis were carried out by JADE risk levels, sex and age groups. **Results** The JADE-PPP and JADE groups experienced substantial increases in survival, with the JADE-PPP group achieving an additional 1.64 years (1.25 QALYs) compared to the non-JADE group with the JADE group having an increase of 0.44 years (0.37 QALYs). Both intervention groups demonstrated long-term cost-effectiveness, with ICERs (incremental cost-effectiveness ratio) of $10,317 for JADE-PPP and -$6,387 for JADE group. Across all JADE risk levels 1-4, enrolment in JADE was cost-saving (ICER range: -5,850 – -3,109) while JADE-PPP was cost-effective (ICER range: 12,831 – 14,155). Notably, JADE was most cost-saving for men with young-onset diabetes (age of diagnosis <40 years old) (ICER: -17,765) and JADE-PPP program was most cost-effective in men aged 60 and older (ICER: $9,580). **Conclusion** The JADE and JADE-PPP programs

substantially enhanced survival rates with long-term cost-effectiveness in diabetes management across all JADE risk categories, as well as diverse age and sex subgroups in Hong Kong.

Ind-2354 The Cost-Effectiveness of Continuous Glucose Monitoring (CGM) for Adults With Type 1 Diabetes in Ireland

PRESENTER: **Gintare Valentelyte**

AUTHORS: Edward W. Gregg, Jonathan Briody

Introduction Continuous Glucose Monitoring (CGM) improves glucose control in adults with type 1 diabetes. In 2024 CGM was nationally rolled out for all individuals living with type 1 diabetes in Ireland. We estimated the lifetime cost-effectiveness of CGM for adults with type 1 diabetes in Ireland, using a validated diabetes cost-effectiveness model. **Methods** We adapted the U.S. Centers for Disease Control and Prevention-RTI Diabetes Cost-Effectiveness Model to an Irish cohort living with type 1 diabetes. In this microsimulation model, we estimated the costs, quality-adjusted life-years (QALYs) and cost-effectiveness of CGM as an intervention relative to usual diabetes care i.e. self-monitoring of blood glucose (SMBG). In this microsimulation model, CGM may lead to reductions in other related complications, which we also modelled. Costs were considered from the Irish health care system's perspective. An annual discount rate of 4% was applied to future costs and outcomes. Uncertainty was evaluated using probabilistic sensitivity analysis. **Results** CGM was cost-effective relative to SMBG at the incremental cost-effectiveness ratio (ICER) of -€1,331 per QALY gained. Most simulations were below the commonly accepted willingness-to-pay threshold of €45,000 per QALY gained in Ireland. Additionally, CGM led to an average reduction in the share of patients with the associated complications and reduced incidence of many type 1 diabetes-related complications, compared to SMBG. Sensitivity analyses indicated that base-case results were robust. **Conclusion** This study provides evidence to support that nationally subsidised roll-out of CGM for the entire population living with type 1 diabetes in Ireland is cost-effective.

abs-os352 Subnational Health Sector Financial Resource Prioritization and Management in Ghana

PRESENTER: **Mustapha Adams Hamidu**

AUTHORS: Ms. Zohra Balsara, Mark Akanko Achaw, Caesar Kogoziga, Afua N. Aggrey

Background

Ghana's fiscal decentralization in the late 1980s excluded the health sector to enable a more agile response to the rapidly changing needs of the healthcare system. However, this exception has continued to weaken the public financial management (PFM) system, exposing the health sector to fiscal and fiduciary risks. For example, the 2018 Ghana Public Expenditure and Financial Accountability (PEFA) Assessment identified several financial management challenges within the health sector, including a lack of mechanisms to ensure cost-effective resource use; unreported extra-budgetary operations; and insufficient controls in payroll, procurement, and asset management—resulting in mismanagement and waste.

To address these challenges, developing partners are strengthening the financial management capacities of Ghana Health Services (GHS), including expanding the use of the Ghana Integrated Financial Management Information System (GIFMIS) across all GHS budget management centers including health facilities, many of which operate at the subnational level.

Aim

This study aims to assess the effectiveness of the approaches implemented by USAID to enhance the financial management capacities of subnational GHS budget management centers. It also seeks to document lessons learned and best practices to inform the government's PFM strategy, which is focused on strengthening the planning process at all levels and ensuring better alignment of budgets with government strategies and priorities.

Methods

The study will analyse budget data from selected project districts to assess the accuracy and effectiveness of budget execution, as well as examine the alignment of spending with priority programs and the medium-term expenditure framework. Adapting the Organizational Capacity Assessment Suite of Tools and the PEFA methodology, the study evaluates the financial management capacities of GHS subnational departments and facilities.

Key Results

Budget execution rates in Ghana's health sector are generally low, particularly for donor-funded programs, with rates of 80% in 2022 and 87% in 2023. This has been largely associated to low budget releases and poor budget management, especially in allocations for capital investments. The study results will present a comparative analysis of expenditures by funding sources and economic classifications, along with capacity scores on key PFM service delivery objectives, including budgeting process quality and accountability, as well as key policy recommendations.

Conclusions

Investments in strengthening subnational PFM systems are often underprioritized, which systematically undermines the core objectives of PFM and service delivery goals. Well-functioning subnational PFM systems have the potential to better align health sector resources with community needs and ensure the efficient use of the limited resources. The USAID interventions offer an opportunity to mobilize increased investments to strengthen and reinforce PFM systems at all levels to ensure a transparent and efficient health system. 2 / 2

Ind-1765 Effect of Government-to-Government Financing Mechanisms on Subnational Public Financial Management and Service Delivery: Experience from Malawi

PRESENTER: **Mark Akanko Achaw**
AUTHORS: Dominic Albert Nkhoma, ATAMANDIKE CHINGWANDA, John Limited

Background

As in many low-income countries, Malawi's health system is characterized by fragmented and poorly coordinated donor funded vertical health programs. Much of this donor support is provided through off-budget projects, which can limit the effectiveness, transparency, and national ownership of priority health areas. In Malawi, a weak public financial management (PFM) system which often delays or restricts funds reaching last mile health facilities is often cited as the reason donors opt for off-budget financing support. However, this approach can be counterproductive, as off-budget funding may further weaken the PFM system. In 2022, the United States Agency for International Development (USAID) initiated a government-to-government (G2G) financing mechanism in the Mangochi and Zomba districts of Malawi. The mechanism, which provides direct funding to district councils aims to improve service delivery outcomes including maternal and child health. The support is accompanied by technical assistance to strengthen the districts' PFM systems.

Aim

As part of a broader public expenditure review, this study aimed to assess how donor resources can be efficiently channelled to the subnational level on-budget rather than off-budget to achieve better health outcomes while preserving the principles and service delivery goals of the PFM system.

Methods

The study employed a mixed-methods approach, combining policy document reviews, budget data analysis, and key informant interviews with district officials and community representatives. The sample included 28 health facilities across the Mangochi and Zomba districts. PFM service delivery goals and budget credibility were assessed using the Public Expenditure and Financial Accountability methodology and indicators. The study also analyzed health sector budget trends from 2016/17 to 2020/21 and evaluated the effectiveness of PFM in the health sector at G2G district councils and facility levels, comparing these findings with national-level data.

Key Results

The study found that the G2G financing mechanism strengthened the PFM system by improving the availability, timeliness, and predictability of on-budget funding at the district level. However, it has not impacted sub-district facility funding, highlighting the need for more direct funding to those facilities. The implementation of the G2G mechanism has also been associated with improvements in equitable access to essential primary healthcare services (including family planning, maternal and child health, HIV, and tuberculosis services), increased accountability in health services, performance-based resource financing, and evidence-based programming.

For example, during the implementation period, Mangochi saw a 59% increase in the uptake of tubal ligations from 2022 to 2023, along with a 15.6% increase in general family planning services. Accountability in service delivery was also enhanced through the introduction of community oversight in service provision. Additionally, the institutional maternal mortality ratio decreased in both districts, from 460 to 62 deaths per 1,000 live births between 2021 and 2023 in Zomba and from 200 to 147 deaths per 1,000 live births in Mangochi.

Conclusion

The G2G mechanism demonstrated that when donor funds are well-coordinated and aligned with government priorities, they can be effectively channelled through on-budget government support to achieve impactful health outcomes at the subnational level. 2 / 2

Ind-1238 Strengthening Budget Credibility at Subnational Levels: Lessons from Nepal's Health Sector

PRESENTER: **Hema Bhatt**

Background: Public Financial Management (PFM) in Nepal faces significant challenges, particularly in the health sector, where budget credibility remains low. This is evidenced by persistent underspending, frequent downward revisions, and discrepancies between allocated budgets and actual funds received by subnational governments (SNGs). Between 2018 and 2020, the health sector experienced substantial deviations in budget execution, with conditional grants comprising a large portion of expenditures. Existing financial management information systems (FMIS) at local levels are limited to economic-level data, making it difficult to track specific programs like health, education, and agriculture. These challenges hinder the tracking of progress against national and international indicators, including SDGs. This study examines budget credibility in Nepal's health sector in the context of federalism and explores solutions to improve service delivery.

Methods: A mixed-methods approach was used to assess budget credibility in Nepal's health sector post-federalism. Quantitative data were gathered by analyzing health expenditure deviations at the federal, provincial, and local levels using a health sector budget analysis dataset detailing fiscal transfers and local revenue contributions. Qualitative data were collected through interviews with health managers, account officers, and other stakeholders from three provinces and 38 municipalities. The study also explored the institutionalization of a budget credibility framework and associated training programs aimed at improving local-level financial management.

Findings: Budget credibility issues in Nepal's health sector were primarily driven by discrepancies between allocated budgets and actual expenditures at the local level. Conditional grants, which account for 77% of health expenditure at the local level, showed the largest deviation. Federal government contributions made up 58% of the total health budget, while subnational levels contributed 28% from internal revenues. Health expenditures funded by internal revenue had a higher deviation (35%) compared to those funded by fiscal transfers (15%). Key contributing factors to these deviations included the de-prioritization of health, inaccurate revenue forecasting, delayed fund releases, and procurement delays.

Training programs for local health managers and account officers improved understanding of the Public Financial Management (PFM) cycle and the importance of budget credibility. However, challenges persist in disaggregating budgets by sector and inconsistencies in financial reporting across government levels, which hinder effective budget utilization in health. While there have been positive impacts from training, the systems still lack the necessary granularity to track expenditure by program type, such as health, education, and agriculture, which further impedes progress on national and international goals.

Conclusion: Improving budget credibility in Nepal's health sector requires systemic changes at both the federal and subnational levels. The lack of accurate, disaggregated data and outdated, incompatible FMIS create significant challenges in tracking and reporting health expenditures, undermining efforts to meet national and international health targets. The institutionalization of a comprehensive budget credibility framework and local-level training programs have led to improvements in budget execution and monitoring. However, continued efforts are needed to standardize practices, improve data management systems, and integrate budgeting and financial reporting across all levels of government. Strengthening budget credibility is essential for better resource allocation, improved health outcomes, and achieving SDG targets.

Ind-1169 Assessing Optimal Principal-Agency Arrangements for Devolved Funds at Health Facility Level in Malawi

PRESENTER: **Dominic Albert Nkhoma**
AUTHORS: Joe Zonda, Gerald Manthalu, Moritz Piatti-Fuenfkirchen, Dayo Obure

1) Introduction

Achieving Universal Health Coverage (UHC) in environments with severe fiscal constraints requires effective provider management to improve efficiency in service delivery. In Malawi, the Direct Facility Financing (DFF) reform is being implemented and aims to transfer financial management responsibility from the central district administration to primary and secondary facilities in the public health sector. However, delegating autonomy of the budget process to providers without effective oversight can lead to serious misalignment of incentives. This paper examines the principle-agency arrangements that yield optimal oversight by the principle (community) and increase the likelihood of agent (provider) delivering optimal PFM outcomes.

2) Methods and Data

We examine variations in the setup and functioning of facility boards in Christian Health Association of Malawi (CHAM) owned facilities, comparing them with the common use of health facility management committes (HFMCs) in both Government and CHAM facilities. Additionally, we compare PFM outcomes across CHAM and government facilities, differentiating between health centres and hospitals. The Public Expenditure and Financial Accountability (PEFA) framework was used to assess and score (from lowest (1 or D) to highest (4 or A)) PFM stages of budget planning, execution and monitoring as well as facility performance with respect to efficiency, quality, equity and accountability. To gain deeper insights into differences in oversight between government and CHAM facilities, as well as across different levels of care, we conduct key informant interviews and focus group discussions with relevant stakeholders.

3) Findings

The analysis of PFM performance using the PEFA methodology reveals stronger alignment and better PFM outcomes among providers with active facility board governance structure. Specifically, CHAM hospitals achieved high PEFA scores, averaging an "A," compared to government hospitals, which scored "D." At the primary facility level, both CHAM and government-owned health centers performed poorly, with average score of "D," though government facilities slightly outperforming their CHAM counterparts. Despite similar ownership, CHAM health centres underperformed relative to CHAM hospitals, suggesting that ownership alone does explain the observed performance variations. Qualitative findings indicate that while HFMCs are common across both CHAM and government facilities, a key distinction lies in the presence of facility boards. CHAM hospitals benefit from facility boards overseeing budget planning, execution, and monitoring — governance structure absent in government facilities, and CHAM health centres. This distinction underscores the limitations of HFMCs, which primarily function in an advisory capacity. The findings suggest that enhancing community governance structures from mere advisory roles to exercising greater control over the PFM cycle could significantly improve provider management and, ultimately, service delivery outcomes.

4) Conclusions

These findings highlight the critical role of structured board oversight in enhancing PFM at provider level, emphasizing the importance of

board-level governance in aligning facility operations with UHC objectives. As Malawi scales up DFF, establishing robust board governance structures across both government and CHAM health facilities will be critical to improving performance. Ongoing research is further exploring variations in oversight arrangements across different CHAM proprietors to evaluate how these governance differences impact service delivery outcomes, including access, quality, and efficiency.

Ind-449 The Vicious Cycle of Bullying: Evidence from South Korean Children

PRESENTER: **Elcin Tuzel**

AUTHOR: Kam Ki Tang

Abstract Research has shown that victims of bullying can also become bullies (known as bully-victims). A substantial body of literature examines the similarities and differences between bullies, victims, and bully-victims in terms of contributing factors and their mental health outcomes. However, these studies overlook the quantitative and causal relationship between victimisation and the likelihood of later becoming a bully. This study addresses this gap by quantifying the impact of victimisation on a child's likelihood of engaging in bullying behaviour using longitudinal data from the Korean Youth Panel Survey, which follows students over five years. Our dataset of 26259 observations shows that about 9% of students report experiencing bullying. We follow the staggered difference and differences design which accounts for lagged treatment effects, potential treatment attrition, and varying treatment intensities over time. Our results show that peer maltreatment, most likely by schoolmates, increases the likelihood of a victim becoming a bully in the following year by 19 percentage points. In mathematical terms, the 19 percentage point increase in the probability of a child becoming a bully in the year after bullying alone implies a social multiplier of 1.21 (=1/(1-0.19)). This finding, that the social multiplier is noticeably greater than one, suggests an alarming possibility: bullying is a self-perpetuating phenomenon, at least within the related population subgroup. Our results also suggest that any policy intervention aimed at breaking the bully-victim cycle and reducing the negative impact of bullying on children should focus primarily on changing the toxic environment in schools.

Ind-338 COVID-19 Socioeconomic Inequalities in Individual Well-Being in Switzerland

PRESENTER: **Jeanne Berche**

AUTHORS: Mauricio Avendano, Joachim Marti

Background: Despite Switzerland's high standard of living and healthcare capacity, the COVID-19 pandemic exposed and deepened social and economic disparities within its population. Existing research has largely overlooked the interplay of individual and environmental factors in shaping well-being outcomes. This study addresses this gap by assessing the impact of the pandemic on socio-economic inequalities in well-being, incorporating not only individual sociodemographic factors but also environmental variables, such as green space density and neighborhood characteristics. **Aim:** We investigate the impact of COVID-19 on socioeconomic disparities in well-being in Switzerland. **Methods:** Using the equality of opportunity framework (Roemer, 1998), we classify determinants of well-being into "circumstances" (beyond individual control) and "efforts" (reflecting personal actions). We analyze inequalities by applying a counterfactual approach to isolate inequality rooted in circumstances, measured through transformed well-being distributions. Data from the Swiss Household Panel (SHP), covering 2018 to 2022, and a dedicated COVID-19 survey conducted in 2020, allow for an analysis of changes in life satisfaction, social relationships, and financial status before, during, and after the pandemic. The Shapley-Shorrocks decomposition technique, based on cooperative game theory, quantifies the contribution of each factor to inequality dynamics over time. **Data:** The SHP provides comprehensive longitudinal data across domains such as employment, education, and social relationships. Our sample includes 4,197 individuals who responded consistently across all waves. Additionally, environmental data from geographical databases complement the analysis by capturing neighborhood characteristics relevant to well-being disparities. **Key Results:** Well-being declined significantly during the pandemic, with increased socioeconomic inequality in life and relationship satisfaction, while financial inequalities temporarily narrowed. Although life satisfaction disparities returned to baseline, inequalities in personal relationships persisted, indicating lingering impacts of the crisis. Shapley decomposition results show that individual factors became more significant drivers of inequality during COVID-19, while environmental variables, such as neighborhood density and green space access, regained importance post-pandemic. **Conclusions and Implications:** These findings underscore the uneven impact of the pandemic on well-being and the necessity for policies that address both socioeconomic and environmental inequalities to build resilience for future crises. Supporting equitable access to quality housing and community resources may mitigate adverse effects on well-being during restrictive periods, while robust financial support mechanisms can help alleviate temporary financial inequalities and support recovery in overall well-being.

Ind-2774 Socioeconomic Inequality in Hypertension Care Continuum in Southern States of India: Analysis of Nationally Representative Data

PRESENTER: **Susmita Dutta**

AUTHORS: Pijush Kanti Khan, Atanu Ghosh, Suraj Maiti

Background

Hypertension is a major contributor to non-communicable disease burden and poses a significant public health challenge in the southern states

of India. Understanding the prevalence, awareness, treatment, and control (ATC) rates of hypertension, as well as associated socioeconomic inequalities, is crucial for developing effective interventions and policies. This study aimed to analyze hypertension prevalence and ATC among individuals aged 15 years and above in South India.

Methods

Utilizing the data from the recent National Family Health Survey (NFHS) (2019-21), we analyzed hypertension prevalence and awareness, treatment, and control (ATC) rates among 285,728 individuals aged 15 years and above in the southern states of India. Hypertension was defined as systolic BP ≥140 mm Hg, diastolic BP ≥90 mm Hg, or self-reported use of antihypertensive medication. Awareness, treatment, and control were assessed among those with hypertension. Multivariable logistic regression and concentration indices and curves were employed to assess socioeconomic inequalities in hypertension management.

Findings

Hypertension prevalence was estimated at 29.8% (29.4, 30.1%). While awareness was relatively high (44.3% (43.5, 45.2%)), treatment-seeking (35.5% (34.8, 36.1%)) and control rates (26.0% (25.5, 26.6%)) were suboptimal. Pro-rich socioeconomic inequalities were evident across the hypertension care continuum, with wealthier individuals exhibiting better ATC outcomes. The difference in awareness between the lowest and highest wealth quintiles was 22 percentage points (pp), while treatment and control rates differed by 21 and 18 pp, respectively. Urban residence and higher education levels were associated with improved hypertension care. Females were more likely than males to be aware of having hypertension, receiving treatment, and maintaining control. Among the southern states, Telangana had the highest prevalence of hypertension (31.7%), while Kerala showed the highest rates of awareness, treatment, and control (54.9%).

Conclusion and Recommendations

There is a significantly high burden of hypertension in southern India, with nearly one in three adults affected. While awareness rates are relatively high, treatment and control rates remain suboptimal. Substantial socioeconomic inequalities exist across the hypertension care continuum, with disadvantaged groups experiencing poorer outcomes. Strategies such as expanding access to primary healthcare, enhancing health literacy, and strengthening community-based interventions could help mitigate disparities and reduce the burden of hypertension in the region. Future research should focus on longitudinal studies to capture changing trends in hypertension care and evaluate the effectiveness of interventions aimed at reducing socioeconomic inequalities.

Keywords: Hypertension, Care cascade, inequality, pro rich, India

Ind-2813 The Impact of Uber on Traffic Fatalities in Mexico: Evidence from Three Quasi-natural Experiments

PRESENTER: **Jorge Morales Alfaro**

Background: The introduction of ridesharing services, such as Uber, has been linked to reductions in traffic fatalities in high-income countries like the U.S., but their impact in middle-income contexts remains understudied. In countries with lower car ownership rates and less reliable public transit or taxicab options, the dynamics of ridesharing adoption and mortality effects may differ substantially. My study extends the analysis to Mexico, examining the impact of Uber on traffic fatalities, particularly those related to alcohol consumption, through three quasi-natural experiments exploiting the introduction and political regulation of cash payments. In 2016, Uber began accepting cash payments in 13 Mexican cities, sharply increasing utilization, particularly in low-income areas. In three cities, cash acceptance was politically restricted, creating natural experiments. In Mexico City and Querétaro, cash was banned from 2016 until a Supreme Court ruling in 2018; in Puebla, cash payments were accepted in 2016 but banned in 2017 after media concerns about safety. These events generate exogenous variation in Uber ridership, enabling robust causal inference. **Methods:** Three identification strategies are employed. First, an event study evaluates traffic fatalities across 15 cities with staggered cash acceptance dates, using Mexico City and Querétaro as controls. Second, a regression discontinuity design (RDD) analyzes ridership effects near the State of Mexico-Mexico City border, leveraging the discrepancy in cash payment policies between 2016 and 2018. Third, a synthetic control approach estimates the effects of Uber's adoption and subsequent ban in Puebla. Further specifications include restricting the analysis to nighttime fatalities as a proxy for drunk driving. **Preliminary Results:** My event study results show no statistical effect on the reduction of overall traffic fatalities. Further robustness and sensitivity analysis are needed to be sure that this result holds, as the trends in raw data in some cities show clear decreases in the trends after the ban. Analysis using nighttime data is pending to infer avoidance of alcohol related deaths. Analysis of Puebla's adoption-ban experiment and the RDD framework remains ongoing, the latter contingent upon the acquisition of granular georeferenced data from the statistical bureau of Mexico or local governments. **Discussion:** This research will offer evidence on the health effects of ridesharing in middle-income countries. By leveraging natural experiments, it contributes to understanding ridesharing's public health outcomes and allows to better estimate the potential benefits of expanding public transportation and the value of alternative solutions that face regulations challenges. Avoiding drunk driving is usually signaled as one of the most important effects of ridesharing, this research will provide evidence to support this claim.

abs-os624 Income Inequality and Crime Rates: Their Role in Police Fatal Shootings Across U.S. Counties (2015-2022)

PRESENTER: **Hossein Zare**, JHU

AUTHORS: Khushbu Balsara, Mojgan Azadi, Danielle Gilmore, Darrell Gaskin, Shervin Assari

IMPORTANCE: Income inequality, crime rates, and racial composition are critical factors influencing fatal police encounters, with significant racial disparities observed. Addressing these disparities is vital for promoting equality and justice within law enforcement practices.

OBJECTIVE: To examine the impact of income inequality (Gini Coefficient), crime rates, and racial composition on fatal police shootings across U.S. counties from 2015 to 2022.

DATA & METHODS: We analyzed data from Mapping Police Violence and the Washington Post, which documented 7,082 fatal police shootings across 3,144 counties. This data was integrated with demographic and socioeconomic variables from the American Community Survey. Negative binomial regression models were used to assess the association between income inequality and fatal shootings by race/ethnicity, accounting for population density, age distribution, racial composition, and crime rates. Interaction terms were incorporated to explore how high-crime areas and population factors modified these relationships. State and year fixed effects were included to control local and regional variation.
RESULTS: Higher income inequality (Gini Coefficient) was significantly associated with increased fatal police shootings. The greatest disparities were observed among Black individuals (incident rate ratio [IRR]: 7.058, 95% CI: 4.389–9.726), compared to White (IRR: 3.170, 95% CI: 1.536–4.804) and Hispanic populations (IRR: 3.057, 95% CI: -0.206–6.320). Interaction analyses showed that high-crime areas amplified these effects, with Black populations experiencing the most significant disparities (IRR: 1.291, 95% CI: 1.095–1.486). Additionally, population density and age distribution played modifying roles, further illustrating the intersectionality of geographic and social factors.
CONCLUSIONS: The study highlights the profound impact of income inequality, racial demographics, and geographic disparities on fatal police shootings. While legislative and community efforts have sought to address policing disparities, significant gaps persist. Policymakers must prioritize structural reforms, including equitable resource allocation, institutional transparency, and community-police relationship building, to combat systemic racism and reduce fatal encounters.

Ind-946 Drivers of Unexpected Health Expenses and Their Association with Healthcare Access: Evidence from 19 European Countries

PRESENTER: **Jean Pierre Uwitonze**
AUTHORS: Clément Meier, Irene Papanicolas

With growing global concern about out-of-pocket (OOP) health expenses, research has highlighted their disproportionate burden on certain populations. However, most studies treat OOPs as a uniform phenomenon, overlooking key dimensions such as their unpredictability and differing perceptions of what constitutes a “large” expense across health systems. Using data from Waves 6 and 8 of the Survey on Health, Ageing, and Retirement in Europe (SHARE), we introduce the notion of predictability into OOP cross country comparative research and provide novel evidence on unexpected health expenses across European countries. We examined how perceptions of “large” OOPs vary across European countries and examine individual/household, and system-level factors associations with large, unexpected health expenses (UHEs). Switzerland and Luxembourg reported the highest average OOP payments, while Slovenia and Croatia had the lowest, revealing diverse national thresholds for "large" expenses. Households with prior UHEs consistently reported higher OOP amounts and OOP-to-income ratios. Individual/household level factors such as gender, financial hardship, and poor health were significantly associated with UHE encounters. At system level, households in social health insurance and specialist-oriented health systems were more likely to have ever encountered large UHEs. Household level factors explained more variation in households’ UHE encounters compared to system level factors. Our findings imply that it is important to consider the predictability of OOPs, to contextualize what constitutes a “large” OOP health expense within local norms and to target household-level interventions in health financing policy.

Ind-2694 A Threshold-Agnostic Measure of Catastrophic Health Expenditure and Catastrophic Health Expenditure Sensitivity Curves across 131 Countries, 1995-2018

PRESENTER: **Jacopo Gabani**, University of York
AUTHOR: Marc Suhrcke

BACKGROUND: Universal health coverage (UHC) is a priority for many governments around the world. Governments use catastrophic health expenditure (CHE) incidence to monitor progress toward UHC, which is also part of the Sustainable Development Goals framework (SDG 3.8.2). However, the debate on how to measure financial risk protection across countries is ongoing. One critical point in estimating CHE incidence is that a threshold must be chosen to derive it. For example, SDG 3.8.2 uses 10% and 25% as thresholds. This raises two issues. First, country rankings and trends based on CHE are sensitive to threshold changes, which may hinder deriving consistent conclusions about UHC progress when CHE trends vary by threshold. Second, any threshold chosen reflects an arbitrary choice. Therefore, developing a threshold-agnostic CHE measure would be a desirable aspiration. **METHODS and RESULTS**: In this theoretical and methodological paper, we first define threshold-agnostic CHE as the area under the CHE incidence sensitivity curve, which has been widely used to analyse CHE across different thresholds. Then, we prove mathematically a perhaps unappreciated property of the widely used out-of-pocket (OOP) health expenditure budget share (i.e., OOP health expenditures as a percentage of total household expenditures): the OOP health expenditure budget share is equivalent to the area under the CHE incidence sensitivity curve, and therefore it is a threshold-agnostic measure of CHE. To address potential concerns with the OOP budget share not being representative in case where the distribution of OOP health expenditure is highly concentrated in very few households, we provide CHE sensitivity curves derived from 504 household surveys, across 131 countries (period: 1995-2018). **DISCUSSION**: This paper underscores the value of the OOP health expenditure budget share as a threshold-agnostic measure of catastrophic health expenditure. While it does not replace threshold-based measures like CHE-10% or CHE-25%, its simplicity, accessibility, and robustness make it a valuable complementary tool for monitoring financial risk protection. By avoiding the arbitrariness of threshold selection, the OOP budget share offers consistent cross-country comparisons and highlights financial burdens even when they fall below commonly used thresholds. However, it is not without limitations – such as its inability to capture extreme variations in expenditure concentration – reinforcing the need to use it alongside other tools like CHE sensitivity curves and traditional incidence measures. Together,

these measures provide a more comprehensive understanding of financial risk protection, equipping policymakers and analysts with the insights needed to design effective interventions and track progress toward universal health coverage.

Ind-1506 Financial Protection Against Catastrophic Health Expenditure in Burkina Faso: Evidence From National Surveys Conducted in 2014 and 2018

PRESENTER: **Offosse Marie-Jeanne Ngbesso**
AUTHORS: Jean Edouard Doamba, Aduragbemi Banke-Thomas, Nirmala Ravishankar, Pierre S. Yaméogo

Background Several African countries, including Burkina Faso, have introduced various health financing mechanisms ranging from user fee removal, social health insurance, and performance-based financing to protect households from financial hardships while seeking health services. However, evidence of the effectiveness of such interventions in minimising financial hardship remains limited. In this study, we investigate the degree and patterns of financial protection achieved in Burkina Faso amid the series of health financing mechanisms implemented in the country since 2010. **Method** Our analysis draws on two national surveys in Burkina Faso which collected data on the living conditions of households in 2014 and 2018 - the 2014 Continuous Multi-sector Survey on the Living Conditions of Households (EMC) and the 2018 Harmonized Survey on Household Living Conditions (EHCVM). We set a threshold of 40% of household expenditure after subsistence needs have been met as the cut-off for catastrophic health expenditure and below the World Bank's extreme poverty line of US$1.9 per day in non-poor households as impoverishment due to health. We calculated and compared the incidence and intensity of catastrophic health expenditure based on household expenditure and poverty-level data. We employed the z test to compare the proportions of catastrophic health expenditure and impoverishment observed in the EMC 2014 with the EHCVM 2018 surveys. We also analysed the frequency of occurrence based on the location of residence (rural versus urban) and the income distribution between the two time periods. The Chi-square test for independence was used to ascertain any statistically significant association between groups and periods, with a significance level of 0.05. **Results** The proportion of households facing catastrophic health expenditure fell from 3.5% to 1.0%, and impoverishment due to health decreased from 4.7% to 2.5%. However, data shows significant inequalities between socio-economic groups persist. First, the decline in the incidence of catastrophic health expenditures from 2014 to 2018 is more noticeable within the richer quintiles, 3.5% for the fourth quintile and 3.0% for the fifth quintile, while the other quintiles recorded a drop between 1.5% and 2.5% ($p<0.05$). Impoverishment is more pronounced for the poor (8.9% for quintile 2) and decreased by 0.2% and 0.1%, respectively, for rich quintiles 4 and 5 ($p<0.05$). Considering the place of residence, although catastrophic health expenditure was less pronounced in rural areas in 2018, impoverishment due to health expenditure was more prevalent in rural areas (61.5%) as compared to urban settings (15.1%) ($p<0.05$). **Conclusion** In the context of pluralistic health financing reforms being implemented in the country, catastrophic health expenditure and impoverishment due to healthcare expenses have decreased in Burkina Faso. However, not all socio-economic groups are equally impacted, especially the poorest and most rural families. Policymakers can further mitigate the financial burden of healthcare costs for vulnerable populations by specifically targeting them with bespoke policies that ensure that no one is left behind.

Ind-65 Out-of-Pocket Expenditure on Maternal Health Service Utilization in India: An Analysis of National Family Health Survey (NFHS-5) Data

PRESENTER: **Ajay Kumar Singh**, The Asia Foundation
AUTHORS: Ruchi Jain, Tamal Reja

Background: In India, maternal health services have received increasing attention in policy circles, especially with programs like Janani Suraksha Yojana (JSY) and Pradhan Mantri Jan Arogya Yojana (PMJAY) aiming to reduce maternal mortality and improve access to healthcare. However, despite these efforts, significant out-of-pocket expenditure (OOPE) continues to pose a financial burden for households. This study utilizes data from the National Family Health Survey (NFHS-5, 2019-21) to assess the OOPE associated with maternal health service utilization, with a focus on gender differences in expenditure patterns and state-wise variations and also to examine the state-wise variation in OOPE for maternal health, identifying both high and low-expenditure states. **Methods:** This study utilizes data from the NFHS-5,to analyze the out-of-pocket expenditure (OOPE) incurred for maternal health services in India. The NFHS-5 data includes responses from 636,699 households, which provides comprehensive information on healthcare utilization and expenditure across India. The focus is on OOPE related to key maternal health services, including antenatal care (ANC), delivery services, postnatal care (PNC), and institutional deliveries. The analysis separates expenditures for women and men, recognizing that men often bear indirect costs (e.g., transportation, informal fees) while women bear direct healthcare costs. Descriptive statistics were used to calculate the average OOPE, with the data segregated by gender, state, and type of healthcare facility (public or private). State-wise variations are presented, and special attention is given to aspirational districts, where access to healthcare services remains limited. **Results:** The analysis of NFHS-5 data reveals significant out-of-pocket expenditure (OOPE) on maternal health services, with women incurring an average of ₹6,800 ($82 USD), higher in private facilities (₹11,200 or $135 USD) than in public ones (₹3,500 or $42 USD). Men typically contribute ₹1,800 ($22 USD) in indirect costs like transportation. Urban areas exhibit higher OOPE, averaging ₹8,500 ($103 USD) for women due to greater reliance on private healthcare, whereas rural women average ₹4,500 ($54 USD), often utilizing public services. State-wise, Kerala and Tamil Nadu reported lower OOPE, while Uttar Pradesh and Bihar showed higher costs, exceeding ₹8,500 ($103 USD). In aspirational districts like Dantewada (Chhattisgarh) and Nuh (Haryana), OOPE surpassed ₹10,000 ($121 USD), highlighting limited healthcare access. Women bear most direct costs, while men cover logistics, underscoring the need for targeted policies to reduce financial burdens in high-cost regions. **Conclusion:** The NFHS-5 data highlights substantial OOPE on maternal health services in India, with significant variation across states and aspirational districts. Women, despite benefiting from government schemes, continue to bear considerable direct healthcare costs, while men often cover indirect costs. States like Kerala and Tamil Nadu perform better in reducing OOPE, while Uttar Pradesh, Bihar, and many aspirational districts experience disproportionately high expenditures. These findings underscore the need for targeted policy interventions, particularly in high-burden regions, to reduce OOPE and ensure equitable access to maternal health services.

Ind-2459 Projecting Public Health Impact and Cost-effectiveness of Interventions Against Mosquito-borne Diseases Using Optimal Control

PRESENTER: **Alex Perkins**

Mosquito-borne diseases, such as malaria and dengue, impose a persistent burden on the health of billions of people throughout the Global South. Although vaccines were recently approved for use against these diseases, no currently available vaccine is alone sufficient to achieve public health goals for control of these diseases. This means that continued use of interventions that target mosquitoes is necessary. At the same time, interventions against mosquitoes have imperfect effectiveness, exert temporary effects, and are often labor-intensive to implement correctly. In addition, a variety of novel interventions against mosquitoes are under evaluation or in the early stages of adoption, which makes the evaluation of the public health impact and cost-effectiveness of mosquito interventions a timely topic. In this presentation, I will describe a new approach for projecting the public health impact and cost-effectiveness of mosquito interventions, which simultaneously identifies the optimal use of these vaccines. This latter feature solves the challenging problem of specifying coverage scenarios for these interventions, which necessitate careful and locally tailored targeting over time with respect to mosquito-borne disease transmission seasons. This feature also generates outputs that can be used to guide the use pattern of the intervention in a given context or to project potential future demand, assuming optimal use. In addition to the general capabilities of this approach, I will give a technical overview in two parts. First, I will describe the development and application of dynamic transmission models for malaria and dengue in any local context where globally available products on temperature, mosquito occurrence, and other inputs are available (generally at 5 km x 5 km spatial resolution). Second, I will describe the formulation of an optimal control problem, which uses Pontryagin's maximum principle together with published estimates of costs associated with the health burden of malaria and dengue and the costs of interventions. After describing the approach, I will present illustrative results of this approach for both malaria and dengue. For malaria, results indicate that the cost-effectiveness of novel interventions to reduce mosquito blood-feeding on humans depends on a combination of local epidemiology and use of long-lasting insecticide-treated nets. For dengue, results indicate that conventional mosquito interventions could lead to short-term reductions in disease burden but will be counteracted over time as short-term reductions in transmission allow for the buildup of population susceptibility. Overall, this approach to projecting the public health impact and cost-effectiveness of optimally deployed mosquito interventions provides needed information to abate the burden of mosquito-borne diseases while the world awaits the development of improved long-term approaches to control of these diseases.

Ind-130 Prioritising Resource Allocation Between and Within Heterogeneous Countries: A Tool to Support Decision-Making for Perennial Malaria Chemoprevention

PRESENTER: **Catherine Pitt**, London School of Hygeine and Tropical Medicine
AUTHOR: Plus Project

Introduction

Evidence on cost-effectiveness is increasingly used to inform prioritisation of health interventions within countries and within international donor institutions. In the World Health Organization (WHO) Africa Region, 233 million malaria cases and 580,000 deaths occurred in 2022, primarily in young children. International donors provided two-thirds of the region's $3.3 billion annual investment in malaria interventions, but funding remains far below need. Prioritisation of these scarce resources is particularly complex because of the growing number of available malaria interventions; heterogeneity in malaria transmission, deaths, drug and insecticide resistance, intervention coverage, and costs; and the multiplicity of stakeholders involved in international and sub-national malaria resource allocation processes. We developed a tool to support prioritisation of delivery models and geographies for perennial malaria chemoprevention (PMC), a WHO-recommended preventive intervention for young children.

Methods

In consultation with stakeholders, we modelled the potential impact and costs of PMC implementation across eligible countries, defined as those with moderate to high perennial transmission in sub-Saharan Africa. Estimates were modelled at the upper-administrative level within each country. We combined secondary analyses of empirical evidence from the Plus Project multidisciplinary evaluations with publicly available secondary data and estimates available across the continent. We modelled variation across geographies and other factors in the protective efficacy of sulphadoxine-pyrimethamine; malaria incidence in the absence of PMC; expected PMC coverage; and in unit costs per PMC dose and malaria case treated. Incidence and deaths were modelled using the individual-based malariasimulation model, adapted to generate age-based estimates. We identified expansion pathways based on the incremental economic cost to the public provider (domestic government and donor combined) per disability-adjusted life-year averted.

Results

We find that >27 million children under 2 years of age in 25 countries live in areas eligible for PMC. We present an interactive web-based PMC decision tool coded in R-shiny, with options for user data input. Users can choose to view country-specific or continent-wide rankings of PMC delivery models and geographies based on cost-effectiveness. Country-specific cost-effectiveness thresholds are presented along with thresholds

to reflect the opportunity costs of donor investments. Ranking tables include estimates of cumulative financial costs of programme implementation to allow comparison with programme budgets, as well as cumulative estimates of cases and deaths averted and economic costs. Maps illustrate main findings.

Conclusion

We offer new evidence to support prioritisation of alternative PMC delivery models within and between countries across the continent. PMC has the potential to reduce substantially the numbers of malaria cases and deaths in young children across Africa. The expected impact of PMC varies substantially with the expected variation in coverage, efficacy, and malaria incidence in the absence of PMC, as well as with the chosen delivery schedule, but PMC can still improve health in contexts where either expected coverage or efficacy are not high. Cost-effectiveness – and thus the specific geographies and delivery models to prioritise – varies both with impact and the projected heterogenous costs of PMC implementation and malaria treatment. Our approach may serve as a framework for wider malaria prioritisation processes.

Ind-1032 Cost-effectiveness of Iron Supplementation With Malaria Chemoprevention for Malawian Children (IRMA Trial): Evidence From a Randomised Control Trial

PRESENTER: **Patrick Abraham**, University of Melbourne
AUTHORS: Natalie Carvalho, Martin Mwangi, Mayamiko Kapulula, Glory Mzembe, Sabine Braat, Ricardo Ataide, Kamija Phiri, Maclean Vokhiwa, Chikondi Ngwira, Sant-Rayn Pasricha, Alistair Maclean, Ernest Moya

Background/Objectives

The World Health Organization recommends universal iron supplements (e.g. syrup) or iron-containing Multiple Micronutrient Powders (MNPs) to all infants living where anaemia is prevalent, to alleviate negative functional effects on child development and health, however, effectiveness and cost-effectiveness evidence are limited. Additionally, iron supplementation in malaria-endemic settings is thought to increase clinical malaria incidence, raising challenges in determining optimum health policies in these settings. We aimed to determine the cost-effectiveness of iron supplementation under malaria prophylaxis for infants in a malaria endemic setting.

Methods IRMA was a four-arm, double-blind, triple-dummy placebo-controlled randomised controlled trial set in southern Malawi. Children of 6 months of age were randomised to 6 months of a) placebo anti-malarials monthly + daily placebo syrup + daily placebo MNPs; b) Dihydroartemisinin-Piperaquine (active DP) monthly for 6 months + daily placebo syrup + daily placebo MNPs; c) active DP + daily iron syrup (10mg elemental iron) + daily placebo MNPs; or d) active DP + daily placebo syrup + daily MNPs (10mg elemental iron + 13 other micronutrients), and followed up 6 months post intervention. We conducted a within-trial cost-utility analysis using individual patient level data from a partial societal perspective, including direct medical costs to the health system and out-of-pocket costs. Disability-adjusted life-years (DALYs) due to anaemia and malaria were used as primary outcomes in the cost-effectiveness analysis, using disability weights from the Global Burden of Disease (2019) and duration of illness from trial data. Incremental Cost-Effectiveness Ratios (ICERs) were compared to 0.5 and 1x GDP based thresholds, with one-way and probabilistic sensitivity analysis using non-parametric bootstrapping performed to determine the likelihood of the iron interventions being cost-effective.

Results We recruited 2168 infants to the trial (71% anaemic; Hb <105 g/L) at baseline, with 90% of participants assessed at the primary outcome timepoint. Compared to children receiving DP alone, moderate and severe anaemia was reduced in children receiving iron syrup or MNPs. Malaria incidence wasn't significantly affected by iron and was mitigated by chemoprevention compared to placebo during the treatment period. There were no significant differences in cognition scores, motor development, length, or weight across the study arms during treatment. Despite the relatively small intervention cost per child (less than US$7.5), universal iron syrups and MNPs administered alongside malaria chemoprevention are unlikely to be cost-effective in this setting, as minor sustained-clinical benefit resulted in minimal DALYs averted. Results will be presented using probabilistic sensitivity analysis and cost-effectiveness acceptability curves.

Conclusion These findings do not support the use of universal iron supplementation with malaria chemoprevention as a cost-effective public health strategy for young children in Malawi. Global recommendations need to consider the cost-effectiveness of health policies, particularly for universally applied interventions with potentially limited clinical benefit. Results of this economic evaluation indicate the need for updates to global nutrition policy, particularly in highly resource constrained settings.

abs-os440 Extended Cost-Effectiveness Analysis of Decentralized TB testing Versus Hub-and-Spoke in Mozambique and Tanzania

PRESENTER: **Saima Arif**
AUTHORS: Lelisa Fekadu, Akash Malhotra, David Dowdy, Ms. Manuela De Allegri, Claudia Denkinger

Background: In low- and middle-income countries (LMICs), tuberculosis (TB) regained its status as a leading cause of death from a single infectious agent in 2023, surpassing COVID-19 Rapid diagnosis is key for effective TB management, requiring access to fast, accurate tests. Decentralized diagnostic algorithms for detection of TB and rifampicin-resistance offer new possibilities. As part of a multicentre real-world cluster-randomized controlled trial (cRCT) evaluating a novel decentralized diagnostic strategy, we analysed both implementation costs and participants' out-of-pocket (OOP) expenditures (including direct and indirect costs) across different socioeconomic groups (SES) from a societal perspective. **Methods:** This** cRCT compared decentralized point-of-care TB testing using the Molbio Truenat platform with MTB Plus and MTB-RIF Dx assays (intervention arm) versus hub-and-spoke Xpert MTB/RIF Ultra testing (control arm) in Tanzania and Mozambique. Economic data were collected as part of the trial along with asset ownership information using an equity tool. Multiple Correspondence Analysis (MCA) was employed to create an asset index for each country based on ownership data. We conducted an Extended cost-effectiveness analysis (ECEA) to estimate incremental participant costs for TB diagnosis and health outcomes, measured by number of TB

treatment initiated within seven and sixty days across SES groups. A Distributional Cost-Effectiveness Analysis (DCEA) assessed the incremental facility-based diagnostic cost per participant initiating TB treatment within seven and sixty days, from a societal perspective, across SES groups. Regression analyses further explored the intervention's impact on direct, indirect, and total costs for participants. **Results** In the intervention group, 82% of individuals with microbiologically confirmed TB initiated treatment within seven days of enrolment, compared to 3.3% in the control group. Average OOP costs were lower in the intervention group (USD 8.82) than in the control group (USD 13.61). Regression analysis further confirmed that the intervention significantly reduced overall OOP costs. Participants in the higher SES group (rich) experienced greater cost savings (USD -6.36 vs. USD -2.83), while those in lower SES group (poor) had a higher number of individuals initiating TB treatment within seven days of diagnosis (poor vs. rich: 36 vs. 10. Additionally,, the Incremental Cost-Effectiveness Ratio (ICER) per TB treatment initiated within seven days was more favourable for the lower SES group (ICER: 0.32) compared to the higher SES group (ICER: 0.81). **Conclusion:** The pooled results from both countries indicate that the intervention arm is associated with lower costs and improved health outcomes across all SES groups.* *Although many countries have implemented policies providing free access to TB services, patients in LMICs continue to face a substantial burden of OOP expenses associated with TB care. Decentralized TB testing has the potential to significantly reduce the time to diagnosis and to facilitate faster linkage to treatment, with many patients beginning TB treatment within seven days of diagnosis.* We discuss not only the results and implications of our findings, but also the challenges of collecting data in real-world clinical setting in rural Mozambique and Tanzania.

Ind-2432 The Cost of Human Immunodeficiency Virus (HIV) Viral Load Test in Indonesia

PRESENTER: **Mutia Astrini Pratiwi**, ThinkWell, LLC/USAID Health Financing Activity
AUTHORS: Diah Eva Sari Husnul Khotimah, Hasbullah Thabrany, Tri Indah Budiarty, Anastasia Susanto, Iko Safika, Nurhalina Afriana, Dini Kurniawati, Amalia Zulfah Wijaya, Endang Lukitosari

Background.

The Government of Indonesia (GOI) and the HIV community support efforts to achieve HIV/AIDS elimination agreed at the global level by 2030 to reach 95-95-95 targets. These targets – 95% of persons living with HIV (PLHIV) knowing their status, 95% of those diagnosed receiving antiretroviral treatment (ART), and 95% of those on treatment having suppressed viral loads (VL) - are pivotal in ending the epidemic by 2030. However, as of July 2024, these targets were 70%, 62%, and 42%, respectively. Currently, VL test administration is funded by a mixture of funding sources: the Global Fund, the Government (National and Subnational), and out-of-pocket payment. In anticipation of a decreasing international donor funding, the Government of Indonesia is preparing to cover VL test. Therefore, information on the VL test unit cost is needed to estimate the total budget to cover VL test for all PLHIV. Previous studies have limited generalizability due to small sample size and limited geographical areas representativeness. This study aims to estimate the unit cost of HIV viral load test with more representative samples, enabling more accurate result.

Method

We used a cross-sectional design focusing on the facility perspective. Primary data was collected through a survey of 41 health-care facilities across the 34 provinces in Indonesia, which is categorized as region 1 to 5. Activity-based costing (ABC) was utilized to calculate the unit cost per VL test. This approach considers costs associated with each step or activity involved in providing VL tests to patients. This includes patient registration, specimen collection, specimen processing, specimen testing, and results delivery. The survey took place in August – September 2023.

Results

12 (36%) facilities use high-capacity (HC) machines, and 29 (64%) facilities use small-capacity (SC) machines. SC machines were used in all types of healthcare facilities: private PHC facilities (3), private hospitals (5), public PHC facilities (10), public hospitals (9), and stand-alone public laboratories (2). HC machines were used in public hospitals (8) and stand-alone public laboratories (4) only. The average unit cost of VL test by HC machine was almost double the unit cost of VL test by SC machines at IDR 1,682,465, - and IDR 889,332, -; respectively. The lowest unit cost using the SC machine (IDR 797,687, -) was in region 3. While the lowest unit cost using a HC machine (IDR 1,355,963) was in region 1. Two main cost drivers for VL tests conducted by both machines were consumables and equipment.

Conclusion and recommendations

Our findings indicate that VL cost varies according to the type of machine, regional division, and type of healthcare facilities. This information helps determine the amount of reimbursement rate from the payer so that providers can be paid at cost. However, the ABC method tends to overestimate cost and therefore future studies using other method such as the double-distribution may be helpful to determine the most accurate unit cost. Adequate payment to provider based on the accurate unit cost will incentivize access expansion to VL test and eventually increase its coverage among the PLHIV.

Ind-605 Trends in Utilization of Mechanical Support During Percutaneous Coronary Interventions in the United States, United Kingdom, and Canada

PRESENTER: **Bruce Landon**, Harvard University
AUTHORS: Feng Qui, Olivia Haldenby, Dennis Ko, Peter Cram, Sharon Aroyo, Christina Fu, Mamas Mamas

Background: International comparisons can provide insights into how the financing of new medical technologies impacts their adoption and use over time. Microaxial flow pump (MAFP) and intra-aortic balloon pump (IABP) are costly technologies that are commonly used during percutaneous coronary interventions (PCI). Data supporting their effectiveness have been limited except for a recent trial demonstrating that MAFP is beneficial patients with ST-segment elevation myocardial infarction (STEMI) accompanied by cardiogenic shock. Information on the utilization of MAFP and IABP across different health systems and how use has changed over time since the introduction of MAFP is scarce.

Objective: To evaluate the adoption MAFP and the de-adoption of MAFP IABP in patients undergoing PCI in the United States (US), United Kingdom (UK), and Canada.

Methods: We performed a retrospective serial cross-sectional cohort study utilizing administrative and clinical data from the US, the UK (England and Wales), and Canada (Ontario). We studied adults aged ≥ 65 years who underwent PCI from January 1, 2012 to December 31, 2021 using population-level administrative data that captures all hospitalizations including diagnosis and procedure codes in the US and Canada; for the UK we used a clinical registry of all PCIs that we aligned with the administrative data from the other two countries. The primary outcomes were the utilization rates of MAFP and IABP over the study period, standardized by the annual number of PCI performed in each country. Device utilization was also examined in prespecified cohorts based on the main diagnosis.

Results: The median age of patients who received both types of mechanical support was ~75 years across all countries. There were higher utilization rates of both types of mechanical support in patients presenting with STEMI and cardiogenic shock in all countries. During the study period, the use of MAFP increased more than 7-fold in the US, from 60/10,000 PCI in 2012 to 443/10,000, while utilization in the UK and Canada remained low (< 10/10,000 PCI). While there was a substantial reduction in IABP use of 68% in the UK (from 206/100,000 to 66/100,000) and 29% in Canada (261/100,000 to 185/100,000) over the study period, the US had a slight increase in the utilization of IABP from 328/10,000 PCI in 2012 to 356/10,000 in 2021. Overall rates of mechanical support during PCI increased in the US from 388/10,000 to 799/10/000 while rates decreased in the UK (206/10,000 to 75/10,000) and Canada (149/10,000 to 99/10,000).

Conclusions and Implications for policy: The adoption and de-adoption patterns for two costly, highly-invasive cardiac devices differed substantially in the US relative to Canada and the UK. Current utilization of MAFP in the US was 40 times higher than in the UK and Canada. In addition, IABP use continued to increase in the US, sharply contrasting to the significant decline observed in other countries. Our results suggest that non-clinical factors related to incentives for use at both the hospital and physician level drive excess use in the US as compared to the UK and Canada.

Ind-667 Did Primary Care Teams Minimize the Impact of the COVID-19 Pandemic on Quality of Care? Evidence from Cancer Screenings in Ontario, Canada

PRESENTER: **Mehdi Ammi**
AUTHORS: Li Bai, Kim McGrail, Erin Strumpf, Walter Wodchis

Background: There is mixed evidence on the impacts of primary care teams (PCT), teams of interprofessional healthcare providers, in the health economics literature. Only some studies show improvement in the quality of care. Quality of care can be measured on different metrics, with preventive services delivery such as appropriate vaccination and screenings often used. Existing literature on the impacts of the COVID-19 pandemic suggests that disruptions in health care led to reduction in preventive services. It remains to be seen if PCT minimized the negative impact of the pandemic on these services.

Research question: Did primary care teams minimize the impact of the COVID-19 pandemic on cancer screenings?

Methods: We focused on the province of Ontario in Canada, the most populous province in the country. This province has a universal healthcare system and has largely implemented PCT models. We linked multiple Ontario health administrative databases to create a monthly panel dataset from January 2018 to December 2021. We selected a 25% random sample of all adult Ontarians, with a sample size of about 2.9 million individuals. We centered the analysis on the three main cancer screenings (colorectal, breast and cervical) and their eligible population. Furthermore, we focused only on those individuals who remained rostered with their PCT throughout to minimize confounding. We estimated difference-in-differences linear probability model regressions for each of these three outcomes to assess the impact of being enrolled in a PCT during the pandemic (starting March 2020). We extended this before-after model to allow for differential effects across the four COVID-19 waves covered in our timeframe. We furthermore explored heterogeneity across subgroups and assessed the reliability of a causal interpretation with event-study and placebo tests.

Results: PCT patients had higher cancer screening rates before the pandemic (from 10% to 13% more depending on screening) compared to non-PCT, however, being enrolled in a PCT during the pandemic led to a reduction in cancer screenings: from a 0.6% reduction in cervical and colorectal cancer screenings to a 1.1% reduction in breast cancer screening. There was no large variation in findings across COVID-19 waves, with an across-the-board relative reduction in screenings among eligible PCT patients for each wave. Subgroups analysis did not reveal any major difference in patterns – they were all negative with one exception: patients with multiple chronic conditions benefited from the PCT enrolment during the pandemic (+0.2% and +0.8% for colorectal and for cervical cancer screenings respectively). Event-study analyses confirmed the existence of common trends while placebo tests led to null results, both supporting the reliability of a causal interpretation of our findings.

Conclusion: Focusing on one aspect of quality of care (timely cancer screenings), we found that PCTs did not minimize the negative impacts of the pandemic, except for those with multiple chronic conditions. However, the size of the effect was small. Understanding whether PCT performed better during the pandemic than non-PCTs on other areas of quality of care, such as accessibility of care, is an important area for future investigations.

Ind-247 How Does Cooperation Among Outpatient Physicians Affect the Quality of Chronic Care?

PRESENTER: **Sophia Cordes**

AUTHOR: Tom Stargardt

Objectives: Existing literature shows, that inter-professional relationships between physicians can enhance health-related outcomes, in particular for chronically ill patients, who require complex treatment and interact frequently with multiple (outpatient) providers. These relationships (e.g. formalized as referrals) facilitate the exchange of information and the diffusion of innovation. However, studies on the link between the extent of cooperation and outcomes are still scarce. Against this background, this study addresses the research question: How does cooperation among outpatient physicians affect the quality of chronic care?

Methods: A social network analysis was conducted using claims data from the second largest sickness fund in Germany, the BARMER, between 2007 and 2019 for a large region (Berlin and Brandenburg). Based on referrals, we created physician networks weighted by the count of physicians' interactions (referrals). We computed network centrality measures on practice (node) level to describe cooperation, coordination and collaboration behaviour. In the analysis the mean interaction frequency of a general practitioner with other physicians (specialists) is used as a predictor for their patients' health outcomes. We addressed endogeneity of network measures to outcomes by employing a two-stage residual inclusion (2SRI) approach. A hurdle model was used for the outcome of hospitalization and a Cox proportional hazards model was applied for mortality, and an GLM for costs of care, combining these models with the instrumental variable strategy. In our sample we included newly diagnosed patients with congestive heart failure (CHF) and did a two-year follow-up. We controlled for patient morbidity using the Ontario Acute Myocardial Infarction Prediction Rules in combination with Elixhauser index. Also, we included several further patient characteristics (e.g. NYHA level and participation in DMP) and practice characteristics (e.g. experience and capacity) as covariates in the model.

Results: In the Berlin region, we did a follow-up of 23,367 CHF patients with a main GP assigned within our sample. Within the regression models we observe the behaviour of 2,176 main GPs in an dense outpatient provider network. Our results from the hurdle model show, that patients whose GPs show intensive cooperation and coordination effort are less likely to be hospitalised ($p=0.0016$). Furthermore, using Cox regression models, we also observe lower mortality rates ($p<0.0001$) for those GPs. In terms of costs, these coordinating and cooperating GPs show higher pharma costs ($p=0.056$), while at the same time reducing outpatient costs ($p<0.0001$). With focus on GP-cardiologist collaboration we see adverse outcomes here.

Discussion: The evidence from claims data suggest, that GP's network position, serving as a proxy for cooperation, coordination and collaboration behaviour, impact the health outcomes of patients with chronic diseases like CHF. Also, it is relevant to consider in terms of care efficiency. As one possible policy implication, we see a need to promote provider-led, primary care-based organizations and to evaluate financial incentive structures for collaborative efforts.

Ind-1890 Targeted Strategies to Reduce Readmission: Clustering Older Patients Combining Machine Learning and Expert Insights

PRESENTER: **Evora Hailin Zhu**

AUTHORS: Chuncheung Ching, April Yushan WU, Eng-kiong Yeoh, Susan Zi-may Yau, Lucy Xiaolu Wang

Background: Hospital readmissions among older patients are common and costly. Despite various intervention programs to reduce readmissions, effectiveness varied widely, partly due to delivering uniform care to patients with different health needs.

Aim: To classify older patients at risk of readmission into distinct clusters using machine learning and clinical expert evaluation, enabling more targeted intervention strategies. Effective readmissions management is crucial not only for improving patient outcomes but also for reducing healthcare spending by minimizing unnecessary costs.

Method: We conducted a retrospective cohort study using electronic health records (EHRs) from the public healthcare system in Hong Kong, covering all patients aged 65+ hospitalized between 2010-2018. Machine learning and clinical evaluation were combined to identify patient clusters that were clinically interpretable and recognized by clinical experts. We applied a two-stage hierarchical clustering algorithm to identify patient clusters among those with 30-day readmission, cross-validated by a different partitional clustering algorithm. Clustering characteristics included demographics, health conditions, healthcare utilization, and socio-economic factors. Clinicians assessed the clinical relevance of each cluster by reviewing key characteristics and comparing outcomes—including 90-, and 180-day readmission rates and mortality— across clusters and against non-readmitted patients. Then, clinicians validated and contextualized each cluster based on unique key characteristics and provided tailored recommendations.

Results: Among 537,125 older patients, 81,125 (15.10%) experienced readmissions within 30 days. Eight mutually exclusive patient clusters were identified and validated by clinical experts. The largest cluster (36,584; 45%) had fewer comorbidities than the non-readmitted but showed higher readmission and mortality at 90 and 180 days post-discharge. Clinicians attributed this to "hidden health risks" potentially not captured in the current risk factor data. Improved primary care was recommended for better detection of these risks. The second largest cluster (15,153; 19%) comprised elderly home residents with high rates of dementia and cerebral vascular accident (CVA), highlighting the need to address cognitive and physical care simultaneously. Other clusters include those with cardiopulmonary disease (10,856; 13%), diabetes with renal

diseases (7,197; 9%), liver diseases (4,341; 5%), advanced malignancy (3,160; 4%), and CVA with hemiplegia (2,759; 3%). Clinicians recommended tailored multimorbidity management for these five clusters with specific chronic conditions. The last cluster contains “frail elders” (1,075; 1%), who are heavy utilizers of inpatient care, had the longest average hospital stays and a high proportion of patients approaching end-of-life. Clinicians suggested palliative care instead of readmission reduction interventions for patients near end of life.

Implications: By integrating machine learning and clinical evaluation, we identified distinct patient clusters at risk of readmission, including those with hidden risks, elderly home residents requiring cognitive and physical care simultaneously, patients with multimorbidity, and frail elders approaching end of life. Targeted interventions tailored to the unique needs of each cluster have the potentials to significantly improve health outcomes while reducing unnecessary costs via readmission reduction. The next step of this research will involve designing and piloting targeted interventions for large patient clusters to evaluate their effectiveness in real-world clinical settings, where we plan to design cost diaries for a comprehensive cost-benefit analysis to inform policy.

abs-os186 Adjustments in Health Financing Policy to Contribute to Climate Mitigation and Adaptation in the Health Sector.

PRESENTER: **Maarten Oranje**, Cordaid
AUTHOR: Ms. Inke Mathauer

Background and objectives

The role of health financing policy to contribute to climate mitigation and adaptation in the health sector is slowly but increasingly being recognized and more and more development partners are integrating this perspective in their health financing work. Likewise, country policy makers also shift attention to the health financing domain. Yet, their health financing policy measures are hardly documented and assessed. At the same time, there is conceptual confusion between climate finance for the health sector and health financing policy for climate mitigation and adaptation.

This paper provides a conceptualization of the role of health financing policy for climate mitigation and adaptation as one specific area within climate financing for health. The objective is to identify and assess the core policy measures in the three health financing functions of revenue raising, pooling and purchasing that can contribute to climate mitigation and adaptation. Various examples from low-, middle- and high-income countries are provided to illustrate these measures.

Method

Building on the WHO health financing progress matrix, we used a deductive approach exploring how health financing policy instruments can be modified to contribute to climate mitigation and adaptation. This was combined with a rapid literature review to sharpen this conceptualization and to identify country practices.

Results

The analysis shows that all the health financing functions can be adjusted in such a way that they contribute to low carbon health systems. However, most measures are found within the purchasing function. Provider payments, contracting and accreditation serve to set financial incentives for providers to adapt service provision and prescription behaviour as well as procurement processes. So far there are few country experiences of health financing policy for climate mitigation and adaptation that are documented and assessed.

Likewise, for the health sector to be able to cope with climate stress and shocks, health financing instruments can be modified to support health sector adaptation. While this calls for new revenue raising approaches and revised pooling arrangements (including the use of flexible risk equalization or risk adjustment mechanisms), again many of the necessary adjustments concern the purchasing function, such as revisions in benefit package and cost-sharing mechanisms to cater to changing health needs under climate stress and shock situations. In various cases, health financing measures for adaptation equally have a mitigating effect.

Conclusion

This conceptualization and country practice demonstrate that health financing policy instruments can be designed in such a way, by setting appropriate incentives and disincentives, that negative effects on the climate and environment are minimized, while positive contributions to climate resilient health systems are optimized. Importantly, all health financing measures for climate mitigation and adaptation are in line with and further underline existing UHC oriented policy guidance.

It is critical for countries to start with the low-hanging fruit, i.e. measures that can be implemented without large investments. Awareness and political will are decisive to leverage the role of health financing policy for climate mitigation and adaptation. More research and country assessments will be needed to promote peer learning in this field.

abs-os188 Climate Finance Opportunities for Health Systems Financing.

PRESENTER: **Ms. Josephine Borghi**
AUTHORS: Agnes Soucat, Giulia Gasparri, Blanca Anton, Soledad Cuevas Garcia-Dorado, Domenico Gerardo, Mark Hanson, Flavia Bustreo, Etienne Langlois

Background: Climate finance can offer opportunities for the health sector as a source of funds and a means of risk reduction. Climate finance refers to finance activities and instruments originating outside of the health sector for mitigation - reducing carbon emissions, or adaptation - investments to reduce vulnerability to climate change, or to address climate loss and damage. This presentation reviews existing climate finance mechanisms and their potential to support health systems, exploring their capacity to generate resources, enhance sustainability, and build resilience in health systems. We also examine the challenges of integrating climate and health financing instruments.

Methods: We conducted a narrative review, focusing on climate finance mechanisms including multilateral funds, voluntary market-based mechanisms, taxes, fossil fuel subsidy removal, microlevies, and adaptive social protection. A search of the literature from 2013-2023, including PubMed, Web of Science, and grey literature, identified 40 studies. The review synthesized evidence on financing arrangements, health system potential, and implementation challenges.

Results:

Multilateral funds support climate mitigation and adaptation but have limited allocation to health. Between 2009-2019, only 5.7% of multilateral adaptation finance (US$ 522 million) went to health, far less than sectors like energy or agriculture. Barriers to accessing these funds include the lack of accredited health institutions and the need for more targeted funding for vulnerable countries. The Climate Loss and Damage Fund may address health impacts from climate hazards, but uncertainties about its operationalization remain.

Carbon credits fund health-related projects like clean cookstoves, water treatment, and forest fire management by monetizing avoided emissions. While carbon credits can mobilize private sector funding, challenges such as market volatility, transparency, and alignment with health goals (e.g., unsafe water treatment for carbon credit income) require careful design and monitoring.

Taxes (such as on carbon emissions) and microlevies (e.g., airline taxes) can generate revenue for health and contribute to emissions reductions. However, there are concerns about stability of revenues from taxes on carbon emissions and the potential perverse incentives for emission reduction in the longer term. Microlevies offer predictable and long term funding, but funds generated tend to be limited and are vulnerable to economic fluctuations. Adaptive social protection can mitigate climate risks by improving healthcare access for displaced populations and incentivizing mitigation actions (e.g., installing solar panels). These mechanisms can be crucial for reducing the health impacts of climate hazards at the local level, but this needs to be weighed against the risk of prematurely burdening new and developing programs with multiple objectives. We found few empirical examples of integrative health and climate co-financing. To be effective, information systems need to be linked, and dependencies between health and climate risks quantified.

Conclusion: Leveraging climate finance for health is vital to addressing the funding gap for health sector mitigation and adaptation, aligning with global climate funding pledges from the recent COP. Our review highlights the potential and limitations of various climate finance mechanisms and underscores the need for more research to optimize their impact on health systems.

abs-os183 The Effect of Extreme Weather Events on Financial Protection in Zambia.

PRESENTER: **Chitalu Chama Chiliba**
AUTHORS: Cherie Part, Dell Saulnier, Richard Bwalya, Moses Chisola, Ms. Josephine Borghi

Background: Extreme weather events are increasingly frequent due to climate change, posing risks to health financing, particularly in resource-poor settings still progressing toward universal health coverage. These events can impact income and livelihoods, reducing the affordability of healthcare. Severe floods may displace populations to areas lacking financial protection. Disruptions to roads, transport and medical supply chains can also affect the costs of care-seeking. Facility operations may suffer, prompting patients to seek alternative, more expensive, care. While extreme weather events likely affect financial protection, few studies have examined these impacts.

Aim: This study examines how floods and heatwaves affect healthcare costs and financial protection in Zambia, assessing catastrophic health expenditure and impoverishment impacts using secondary data.

Methods: We use Zambia Living Conditions Monitoring Survey data from 2010, 2015, and 2022, to measure household health and total consumption expenditure. Outcomes for the analysis include: total health expenditure; incidence of catastrophic expenditure at 10% and 25% thresholds of household consumption; and impoverishment (based on Zambia's poverty line, international poverty lines of USD 1.90, 2.15, and 3.20, and relative poverty at 60% of median per capita consumption). Household data are linked to climate exposure data based on survey cluster geo-coordinates. A household is considered to be flood-exposed if water is present within a 2 km² radius of the household, or within a 2km (urban) or 5km (rural) catchment area of its nearest health facility, with flood intensity measured by extent of water coverage. Floods are identified by comparing satellite data and water reference maps via NASA's MODIS Global Flood Product and the Global Surface Water

database. Heatwave exposure, identified using ERA5-Land re-analysis data, is defined as three or more consecutive days above the 90th, 95th, and 99th percentiles of daily maximum temperatures during the three hottest months of the year (reference period: 1990-2019), with annual heatwave frequency also recorded. We analyse the effects of floods and heat on outcomes using linear fixed effects panel regression models with time and district/cluster fixed effects controlling for household characteristics. We assess heterogeneity in exposure effects by distance to urban centers, socio-economic and health insurance status. We also explore whether effects are mediated by changes in income, household displacement, injury, or care seeking for flood/heat-sensitive conditions.

Key Results: We present relationships between flood/heatwave exposure and healthcare costs, catastrophic expenditure, and impoverishment in Zambia, identifying temperature and flood intensity thresholds for these effects. We also show differential effects across subgroups, identifying those most at risk, and explore mediators of effect.

Conclusions: Understanding how weather extremes affect household financial protection can guide adaptations to health financing arrangements, to ensure services remain affordable in the wake of extreme weather events, through targeted waivers or benefit package adjustments.

The Use and Usefulness of Discrete Choice Experiments in Shaping Healthcare Policy: A Global Perspective

MODERATOR: **Jason J. Ong**, Melbourne Sexual Health Centre, Alfred Health, The School of Translational Medicine, Monash University, Melbourne

CONVENER: **Yuanyuan Gu**, Macquarie University, Sydney

abs-os318 Eliciting Practitioner Preferences when Selecting Infection Prevention and Control Practices for the Prevention of Healthcare Associated Infections

PRESENTER: **Shalini Elangovan**

AUTHORS: Sameera Senanayake, Nicholas Graves, Sanjeewa Kularatna

Background

Hospital acquired infections worsen patient outcomes and increase healthcare costs. Infection prevention and control professionals must select practices to keep hospital acquired infections to a minimum, but this decision-making process is not well-described.

Aim

This study aims to use a discrete choice experiment to evaluate practitioner preferences when selecting infection prevention and control practices for hospital acquired infections.

Methods

A discrete choice experiment consisting of four phases was conducted. Firstly, attributes of infection prevention and control practices were established using literature reviews and expert opinion. Secondly, choice tasks were generated using a Bayesian *d*-efficient design and were combined with screening and demographic questions to structure the discrete choice experiment. Pre- and pilot tests were conducted to ensure understandability of the choice tasks and to generate prior values to inform the final design. Thirdly, the discrete choice experiment was administered online to infection prevention and control professionals. Lastly, a mixed multinomial logit model and a latent class model, followed by the relative importance of attributes and a scenario analysis, were estimated.

Results

Four attributes with three levels each were used: the quality of clinical evidence supporting an infection prevention and control practice, the amount of time it will take to implement the practice, economic costs and benefits associated with the practice, and the additional amount of time it will take healthcare professionals per patient to carry out the practice. 256 infection prevention and control professionals completed the discrete choice experiment. The mixed multinomial logit model revealed the following attribute levels to be preferred by respondents in general: systematic reviews and RCTs as clinical evidence, 3 months to implement, small investment with large health returns, and an additional 5 minutes per patient. A latent class analysis revealed 2 distinct classes. The first class, termed Evidence Seekers, was more likely to comprise respondents from low- and middle-income countries with a research-focused role who participate more in decision-making, while the second class, coined Efficiency Seekers, was more likely to consist of respondents from high-income countries with a more clinical role who participate less in decision-making. In a relative attribute importance analysis, Evidence Seekers valued the quality of clinical evidence the most, while Efficiency Seekers valued the economic costs and benefits of the IPC practice the most. In scenario analyses, Evidence Seekers demonstrated consistently high uptake probabiltities of real-world infection prevention and control practices regardless of attribute level combinations compared to Efficiency Seekers.

Conclusion

Distinct priorities among infection prevention and control professionals from low- and middle-income and high-income countries highlight the need to support incorporation of economic evidence in decision-making across settings to maximise health outcomes and resource use.

abs-os306 Medical Brain Drain - Assessing the Role of Job Attributes and Individual Traits

PRESENTER: **Marco Bertoni**
AUTHORS: Yuanyuan Gu, Debdeep Chattopadhyay

Background: Economic research has extensively examined the "brain drain" from low- to high-income countries, but less attention has been paid to the movement of skilled workers between high-income nations. This study contributes to this area by exploring the migration intentions of Italian medical students, with a particular focus on their preferences for domestic versus foreign job opportunities. The emigration of physicians from Italy affects healthcare quality and imposes fiscal costs, as their training is publicly funded.

Aim: We explore three questions: (1) Do future doctors prefer domestic jobs over comparable jobs abroad? (2) Do these preferences vary based on personal characteristics? (3) How do job preferences differ between domestic and international jobs?

Methods: We designed a Discrete Choice Experiment where Italian medical students chose between pairs of hypothetical job offers, differing by six attributes: professional development opportunities, income, job security, working conditions, skill match, and the country of the job. The study's challenge was isolating job market-related attributes from country location. In the survey, students were initially asked to name their preferred foreign European country. When thinking about this country, we prompted students to focus on non-labor aspects that attract them. We then presented students with job options located either in Italy or their preferred foreign country. Data were collected from 2020 to 2021 through an online survey of 527 senior medical students at 12 Italian universities. The survey also included questions on students' backgrounds and personality traits. Using mixed logit models (main effects, interaction between attributes, interactions with covariates) and adjusting for sample representativeness through entropy balancing, we analyzed students' willingness to pay (WTP) for job attributes.

Results: We found that students are willing to forgo €13,515 in annual income to work in Italy, although preferences vary significantly. Roughly one-sixth of students would sacrifice an average of €7,841 to work abroad. Students with higher levels of cognitive skills, altruism, risk tolerance, and competitiveness are more inclined to move abroad. These findings suggest that medical migration negatively impacts the quality of the remaining pool of doctors. We found notable differences in WTP for job features between domestic and international jobs. Students showed a high WTP for permanent contracts in Italy but were more open to temporary contracts abroad. They also placed a greater value on professional development and skill alignment in foreign jobs, likely due to the challenges of adapting to a new institutional environment.

Policy implications These results have significant implications for understanding the drivers of medical migration and for designing job contracts that help retain doctors in countries facing potential shortages. As most young Italian doctors are willing to trade higher pay for better working conditions and development opportunities at home, this suggests that Italy's medical brain drain is driven largely by unmet job quality expectations rather than salary alone. Furthermore, the preference for temporary migration suggests policies such as tax incentives for returnees could encourage the re-entry of Italian doctors trained abroad.

abs-os321 Men Under the Radar : Understanding Their Preferences for Suicide Prevention Services to Increase Uptake and Effectiveness

PRESENTER: **Yuanyuan Gu**, Macquarie University
AUTHORS: Alexis Whitton, Katherine Boydell, Anam Bilgrami, Helen Christensen, Fiona Shand, Noura Saba, Aimy Slade, Henry Cutler, Dandan Yu

Background: Suicide is a critical public health issue in Australia, claiming 8.6 lives daily - twice the number lost to road accidents. Men are disproportionately affected, representing three out of every four suicides. Despite this high prevalence, 58% of men experiencing suicidality do not seek formal support, leaving them 'under the radar'. Existing studies on men's engagement with suicide prevention services have largely focused on attitudes and stigma, but little is known about their needs and preferences for specific service attributes.

Aims: This study quantifies the preferences of men who remain 'under the radar' for suicide prevention services, identifying pathways to enhance service uptake. The target group was defined as men aged 18 or older, fluent in English, residing in Australia, who had experienced suicidality in the past six months but had no contact with formal mental health care services.

Methods: A discrete choice experiment (DCE) was used to elicit preferences. Service attributes and levels were developed through a literature review and refined by interviews with men with lived experience (N=7). Final attributes included out-of-pocket cost (first session), service type (online self-help, peer support, formal mental health care/support), service mode (online, phone, face-to-face), waiting time, availability, service environment (individual or group), and service linkage (e.g., to support with employment, finances, housing, or relationships). A D-efficient design generated 12 choice sets per respondent, with each set containing two hypothetical service plans and an opt-out option. Data were collected from July 2023 to November 2024 through an online survey using purposive sampling, with participants recruited via university and social media platforms. Analysis was conducted using mixed logit models to derive Willingness to Pay and Relative Importance (RI) estimates, supplemented with scenario analysis to evaluate pathways for improving service uptake.

Results: After assessing data quality, responses from 398 participants (mean age 42.4; 57.8% urban; 33.2% single) were retained for analysis. Results indicate that all attributes significantly influenced choice. Cost was the most impactful factor (RI: 47), followed by waiting time (RI: 18), with respondents willing to pay around 300 AUD to reduce waiting time from 3 months to zero. Service type and environment were also important (RI: 15 and 11), with a preference for professional, one-on-one services. Respondents favoured services that are face-to-face,

available 24/7, and linked with additional supporting services; however, service mode, availablity, and linkage were relatively less important drivers of choice (RI: 5, 3, and 2). Preference heterogeneity was significant; for example, those seeking help with emotional regulation were more likely to engage with services, while lower-income respondents were more cost-sensitive. Scenario analysis indicated a near-zero probability of uptake for a service with the least preferred attribute levels, which increased to 99% with the most preferred attribute levels.

Policy Implications: This study highlights how aligning suicide prevention services with men's preferences can improve their uptake and effectiveness. Incorporating these insights into service design can help policymakers enhance engagement and optimise resource allocation in suicide prevention.

abs-os314 Preferences of Adolescents and Young Adults for Sexual and Reproductive Health Services in Ethiopia: A Discrete Choice Experiment

PRESENTER: **Melaku Birhanu Alemu**
AUTHORS: Richard Norman, Yuanyuan Gu, Tigest Tamrat, Daniel Gashaneh Belay, Jaya Dantas, Gavin Pereira, Gizachew A. Tessema

Background: Adolescents and young adults (AYAs) face significant sexual and reproductive health (SRH) challenges, including unintended pregnancy, unsafe abortion, and sexually transmitted infections in Ethiopia. However, SRH service utilisation remains low. One of the potential reasons could be the misalignment of SRH services with AYA needs. There is limited evidence on AYAs preference for SRH services in Ethiopia. **Aim**: We aimed to assess the preferences of AYAs (aged 15 to 24) for SRH services in Ethiopia. **Methods**: We conducted three distinct but interrelated discrete choice experiments (DCEs) on contraceptive services, abortion care, and sexually transmitted infection (STI) services between February and April 2024. A literature review, focus group discussions with a ranking exercise among AYAs, and expert discussion were conducted to identify six attributes (privacy, cost, distance, health provider attitude, service quality and cleanliness). A D-efficient design with two blocks, each containing 12 choice tasks, was constructed using Ngene software. Stratified sampling methods were used to select participants. The survey was collected electronically using REDCap. A mixed logit model was used to estimate attribute importance, willingness to pay, choice probabilities, and preference heterogeneity. Analyses were weighted to improve representativeness and comparability. **Results**: A total of 984, 990, and 990 participants completed the contraceptive, abortion care, and STI DCEs, respectively. Privacy was the most important attribute for contraceptive and abortion care, while quality of care dominated in STI services. There were preference variations among sociodemographic characteristics. Respondents from rural and regional areas prioritised privacy, whereas participants from urban and metropolitan areas valued high-quality care. Under optimal service conditions, the predicted uptake of SRH services could reach as high as 95%. In contrast, under unfavourable conditions, the uptake rate could decline substantially, falling to as low as 10%. Participants were willing to pay an additional US$54 to avoid receiving low-quality STI services. Likewise, respondents were willing to pay (2,302 ETB/US$42) to protect privacy for STI services, followed by contraceptive services (2,031 ETB/US$38) and abortion care (1,870 ETB/US$34). **Conclusions and policy implications**: AYAs have significant preferences for the attributes (privacy, cost, distance, health provider attitude, health service quality and cleanliness of the facility), with privacy and service quality emerging as the most important attributes for all SRH services. Privacy was particularly prioritised for abortion care, while service quality was most important for STI services. Notable variations in preferences were observed across different sociodemographic groups, highlighting the need for context-specific interventions to maximise service utilisation.

DISCUSSANT: **Siti Nadia Tarmizi**, Director of Non-Communicable Disease Prevention and Control, Ministry of Health RI

abs-os383 Budget Impact Analysis for Initiating Insulin Therapy for Type 2 Diabetes Mellitus Patients Under the National Health Insurance Program in Indonesia

PRESENTER: **Zahrina Laborahima**
AUTHORS: Gemala Chairunnisa Puteri, Dhia Ticha Pertiwi, Royasia Viki Ramadani, Budi Hidayat, Ketut Suastika, Soebagijo Adi Soelistijo, Tri Juli Edi Tarigan

Background: Type 2 Diabetes Mellitus (T2DM) is a leading global health concern, affecting approximately 536.6 million individuals worldwide and imposing significant healthcare costs. In Indonesia, the prevalence of T2DM among adults was 19.5 million in 2021 and is expected to rise by 46% by 2045. This study aims to assess the financial impact of shifting insulin initiation from hospitals to PHC within the NHI system, considering the potential for reduced costs and improved patient outcomes.

Objective: This study seeks to quantify the cost implications of transitioning insulin therapy for T2DM patients from a hospital-based approach to a primary healthcare (PHC)-based approach and evaluate its potential for improving both the financial sustainability of the NHI system and the quality of care for T2DM patients in Indonesia. The research question is: *What is the budget impact of initiating insulin therapy for T2DM patients at PHC compared to the current hospital-based approach under Indonesia's NHI program?*

Methods: A prevalence-based Budget Impact Analysis (BIA) model was developed to estimate the costs associated with insulin initiation using basal and premix insulin modalities at PHC versus hospitals. The model incorporates data from Indonesia's NHI claims database, including T2DM patient records, treatment protocols, insulin usage patterns, and related healthcare expenditures. The model assumes that insulin initiation at PHC would only apply to patients without complications and that insulin would be prescribed based on HbA1c ≥7.5%. Costs were derived from 2019 NHI data, adjusted for inflation to 2024 figures, and converted to USD for clarity. Direct medical costs were analyzed from the perspective of the NHI, considering both capitation and fee-for-service payment structures at PHC and hospital settings.

Results: Findings suggest that shifting insulin initiation to PHC could reduce the total medical costs for T2DM patients significantly. Over a 5-year period (2024-2028), the total cost for basal insulin initiation in hospitals is estimated at US $3.674 billion, while transitioning insulin initiation to PHC could reduce this to US $3.308 billion, resulting in savings of US $367 million. Similarly, for premix insulin, the cost decreases from US $3.901 billion to US $3.535 billion with a potential savings of US $367 million. Sensitivity analyses confirm the robustness of these results, showing that the shift to PHC remains cost-effective even with variations in key assumptions, such as patient volume and complication rates.

Conclusions: The study concludes that transitioning insulin initiation to PHC is both a financially sound and clinically beneficial strategy. The shift would reduce hospital-related costs and improve access to timely insulin therapy, potentially enhancing clinical outcomes by reducing HbA1c levels and preventing complications. The findings have important policy implications, suggesting that Indonesia's healthcare system could benefit from reallocating resources to PHC, improving diabetes management, and aligning with the country's health transformation agenda. This shift may also support broader efforts to integrate non-communicable disease (NCD) management into primary care and reduce the burden on hospital services.

abs-os366 Direct Medical Cost of Type 2 Diabetes Mellitus and Its Associated Complications in Indonesia

PRESENTER: **Budi Hidayat**, Universitas Indonesia
AUTHORS: Ketut Suastika, Pradana Soewondo, Achmad Rudijanto, Junice Ng, Royasia Viki Ramadani

Background: Diabetes, particularly Type 2 Diabetes Mellitus (T2DM), is a major public health issue globally, with Indonesia experiencing one of the highest prevalences worldwide. In 2019, an estimated 10.7 million people in Indonesia were diagnosed with diabetes, a number projected to rise to 16.6 million by 2045. Uncontrolled T2DM leads to various complications, increasing morbidity, mortality, and healthcare costs. While previous studies have highlighted the burden of diabetes-related complications, there is a lack of comprehensive data on the direct medical costs of T2DM and its complications within Indonesia's national health insurance system, Jaminan Kesehatan Nasional (JKN). This study aims to fill that gap by analyzing the direct medical costs associated with T2DM and its complications across Indonesia.

Objective: The primary objective of this study was to estimate the direct medical costs of managing T2DM and its complications in Indonesia, using data from the JKN database. Specifically, the study sought to assess the costs incurred by individuals with diabetes-related complications and identify the key drivers of healthcare expenditure.

Methods: A retrospective cohort study was conducted using 2016 data from the JKN database. The study included individuals aged 30 years and older diagnosed with T2DM (ICD-10 codes). Seven diabetes-related complications were considered: cardiovascular disease, nephropathy, neuropathy, retinopathy, cerebrovascular disease, peripheral vascular disease, and iatrogenic hypoglycemia. Direct medical costs—encompassing inpatient hospitalizations, outpatient specialist visits, and medications under the non-capitated fee-for-service payment model—were calculated from a payer's perspective. A prevalence-based approach was used to estimate the total costs for the year. Statistical analyses were performed using Stata version 15.

Results: Of the 18.9 million JKN members who accessed secondary and tertiary healthcare services, 812,204 (4%) were diagnosed with T2DM. Among these, 57% had at least one complication. The mean annual direct medical cost per person was US $708, with those having complications incurring significantly higher costs (US $930) compared to those without complications (US $421). The most common complications were cardiovascular diseases (24%), neuropathy (14%), and nephropathy (7%). Inpatient hospitalization was the largest cost driver, accounting for 55% of the total costs. The total direct medical cost for managing T2DM and its complications in 2016 was estimated at US $576 million, with 74% of these costs attributed to individuals with complications. Cardiovascular diseases and nephropathy were the most-costly complications, accounting for US $236 million and US $129 million, respectively.

Conclusions: This study highlights the significant economic burden of T2DM and its complications on Indonesia's healthcare system. Individuals with complications incur substantially higher healthcare costs, particularly due to inpatient care. Early detection and effective management of T2DM, especially at the primary care level, are essential to reduce long-term healthcare expenditures. Strengthening primary care infrastructure, including empowering healthcare providers to initiate insulin therapy and manage complications more effectively, is critical. Policymakers should use these findings to inform healthcare resource allocation, reforms, and strategies aimed at improving diabetes care and control across the population.

abs-os396 Estimating the Direct Medical and Indirect Costs of Non-Communicable Diseases in Indonesia

PRESENTER: **Septiara Putri**
AUTHORS: Afra Inayah Dhyaniputri, Royasia Viki Ramadani, Budi Hidayat

Background: Non-communicable diseases (NCDs), including cardiovascular diseases, cancer, and diabetes, account for 63% of all deaths in Indonesia. Despite their significant health and economic impact, there is limited data on the economic burden of NCDs in the country, particularly in terms of healthcare costs and their consequences on financial sustainability of the national health insurance system (JKN). This gap in knowledge impedes effective policy development aimed at managing the rising burden of NCDs. This study addresses this critical gap by

estimating the direct and indirect costs of NCDs in Indonesia, using data from the 2023 JKN claims database; or use sample data and apply longitudinal, focus on Direct medical cost only).

Objective: The main objectives of this study are to assess the prevalence of Non-Communicable Diseases (NCDs) among claimants under Indonesia's JKN program, and to examine the rates of complications associated with these diseases and their impact on healthcare costs within the system. Additionally, the study aims to analyze how demographic and clinical factors influence medical expenditures for NCD patients in the JKN program. Finally, the research seeks to quantify both the direct and indirect costs associated with NCDs, providing valuable insights into the overall financial burden of these diseases on the JKN system.

Methods: The study employs a retrospective analysis of 2023 JKN claims data for individuals aged 18 and older. The data includes information on NCD diagnoses (cardiovascular diseases, cancer, diabetes), complications, comorbidities, medications, medical costs (outpatient and inpatient), length of stay, and mortality-related costs. Descriptive statistics will be used to summarize patient demographics and resource utilization, while multivariate regression analysis will explore associations between demographic and clinical variables and medical expenditures. To estimate indirect costs, including productivity losses due to absenteeism, permanent disability, and premature mortality, a human capital approach is applied, incorporating data on lost workdays, income levels, and mortality rates.

Results: Preliminary results indicate that NCD complications significantly increase healthcare costs, with NCDs representing 22% of the total claims under the INA-CBG payment system, despite comprising only 7.3% of the JKN patient population. Additionally, the indirect costs of NCDs—due to productivity losses and premature mortality—add a substantial economic burden that is often underreported in conventional cost-of-illness studies. These findings suggest that the true economic impact of NCDs is far greater than traditional estimates, emphasizing the need for more comprehensive cost assessments.

Implications: The study's findings have important implications for policy and practice. The rising financial burden of NCDs on the JKN system necessitates a reevaluation of resource allocation and funding strategies. By quantifying both direct and indirect costs, this research provides essential evidence for policymakers to improve health financing, optimize resource use, and address the growing burden of NCDs. The results highlight the importance of integrating NCD-related costs into health policy and planning, promoting preventive measures, and ensuring equitable access to healthcare services, especially for populations at higher risk.

abs-os403 The Impact of Multimorbidity Among Adults with Cardiovascular Diseases on Healthcare Costs in Indonesia

PRESENTER: **Royasia Viki Ramadani**
AUTHORS: Mikael Svensson, Sven Hassler, Nawi Ng, Budi Hidayat

Background: Cardiovascular diseases (CVDs) are the leading cause of death in Indonesia, accounting for 38% of the total mortality in 2019. Moreover, healthcare spending on CVDs has been at the top of the spending under the National Health Insurance (NHI) implementation. This study analyzed the association between the presence of CVDs with or without other chronic disease comorbidities and healthcare costs among adults (> 30 years old) and if the association differed between NHI members in the subsidized group (poorer) and non-subsidized households group (better-off) in Indonesia.

Methods: This retrospective cohort study analyzed the NHI database from 2016–2018 for individuals with chronic diseases (n = 271,065) ascertained based on ICD-10 codes. The outcome was measured as healthcare costs in USD value for 2018. We employed a three-level multilevel linear regression, with individuals at the first level, households at the second level, and districts at the third level. The outcome of healthcare costs was transformed with an inverse hyperbolic sine to account for observations with zero costs and skewed data. We conducted a cross-level interaction analysis to analyze if the association between individuals with different diagnosis groups and healthcare costs differed between those who lived in subsidized and non-subsidized households.

Results: The mean healthcare out- and inpatient costs were higher among patients diagnosed with CVDs and multimorbidity than patients with other diagnosis groups. The predicted mean outpatient costs for patients with CVDs and multimorbidity were more than double compared to those with CVDs but no comorbidity (USD 119.5 vs USD 49.1, respectively for non-subsidized households and USD 79.9 vs USD 36.7, respectively for subsidized households). The NHI household subsidy status modified relationship between group of diagnosis and healthcare costs which indicated a weaker effect in the subsidized household group (β = -0.24, 95% CI -0.29, -0.19 for outpatient costs in patients with CVDs and multimorbidity). At the household level, higher out- and inpatient costs were associated with the number of household members with multimorbidity. At the district level, higher healthcare costs was associated with the availability of primary healthcare centres.

Conclusions: CVDs and multimorbidity are associated with higher healthcare costs, and the association is stronger in non-subsidized NHI households. Households' subsidy status can be construed as indirect socioeconomic inequality that hampers access to healthcare facilities. Efforts to combat cardiovascular diseases (CVDs) and multimorbidity should consider their distinct impacts on subsidized households. The effort includes affirmative action on non-communicable disease (NCD) management programs that target subsidized households from the early stage of the disease.

abs-os509 Association Between Hospital Leadership Characteristics and Engagement in Online Dual Practice for Physicians in China

PRESENTER: **Mr. Zhuo Chen**, University of Georgia
AUTHORS: Qing-Ping Ma, Duo Xu, Xuyan Lou, Lina Song, Hongqiao Fu, Xuening Cheng

A rising number of online healthcare platforms have emerged in China, facilitating health professional especially public hospital doctors to provide patients with on-demand remote health care primarily via telephone and video-conferencing software. This combination of public hospital doctors serving on privately funded online health platforms creates the **online dual practice** for public hospital doctors. This new practice might be encouraged or discouraged by public hospital leaders since it may generate distinct unintended consequences for public hospitals and there may exists a conflict of interests between doctors and hospitals. Given the important role of hospital leaders highlighted by the Upper Echelons Theory (UET) and the context of Chinese health system, this study addresses the research question on how hospital leadership characteristics affect online dual practice adoption and online health service provision among doctors. It explores the association between public hospital leader's characteristics and doctor's engaging in online dual practice. This study integrates unique database at three levels: leadership characteristics of hospital CEOs, information on doctors providing outpatient services, and on doctors providing telemedicine service through online health platforms. Logistic regression models are used to investigate the association between hospital CEOs' background and doctor's engagement in online dual practice at doctor's level, and linear regression models are used to test the effect of hospital leadership on the extent of online service provision at hospital level. Results showed that hospital leaders' age, seniority and educational level can positively affect doctor's adoption of online dual practice and their provision of online service. However, a long tenure of leaders worked in this hospital is unfavourable to the promotion of online dual practice, but can encourage those online doctors to provide more online consultations. Leaders who having overseas experience and management background are less encouraged to doctor's adoption of online dual practice, but become more supportive to online doctors rendering online services. In addition, a large heterogeneity effects are found across different clinical departments. Our findings offer important policy implications for designing appropriate policies and training programs for public hospital leaders to promote the adoption of online dual practice and mitigate potential adverse consequences of it.

abs-os446 Impacts of Platform Endorsement in Online Healthcare: Evidence from China

PRESENTER: **Hongqiao Fu**
AUTHORS: Xu Zhang, Jiajia Zhan

Impacts of platform endorsement in online healthcare: Evidence from China

Abstract:

Online healthcare platforms enhance healthcare access and equity by removing geographic barriers and facilitating doctors to serve underprivileged patients. However, they exacerbate information asymmetry due to the vast number of doctors available online. To mitigate this and to motivate leading doctors to improve their practices, platforms have introduced endorsements, awarding select doctors badges for exceptional performance. This study investigates the impact of platform endorsement on both patients' demand and doctors' decisions on pricing, quantity, the mix between free and paid services, and quality by exploiting a leading Chinese platform's "Good Doctor of the Year" endorsement program. Using the Generalized Synthetic Control method, we find that endorsement boosts demand for endorsed doctors, who respond by increasing prices and provision of paid services while maintaining service quality. However, we find that endorsement leads to an unintended consequence of a decrease in free services provided by endorsed doctors, thereby disadvantaging underprivileged patients. Notably, this reduction in free services is more pronounced among "pro-social" doctors due to their reluctance to raise prices and limited capacity. These findings highlight the need for platforms and policymakers to understand the nuanced impacts of information disclosure on doctors' decisions and the potential unequal effects across different groups of patients in online healthcare, a sector with significant societal implications.

Keywords: online healthcare, platform endorsement, doctor consultations, paid services, free services

abs-os502 Social Determinants of Telemedicine Use: Evidence from Georgia Fee for Service Medicare Beneficiaries, 2018-2019

Telemedicine has played a critical role in providing much-needed services to hard-to-reach patients in remote areas and vulnerable populations during the pandemic. However, telemedicine utilization is limited by factors including access to high-speed internet, preference, access, and perception of privacy protection and convenience associated with telemedicine provision. This study aims to examine the disparities in telemedicine utilization and associated social determinants of health. We linked claims data for fee-for-service Medicare beneficiaries in the state of Georgia in 2018-2019 with the zipcode-level social determinants of health indicators constructed by the Agency for Healthcare Research and Quality. We excluded beneficiaries eligible for Medicare due to reasons other than old age. A total of 808,141 beneficiaries were

included, with 54.4% of them being women, 80.5% living in an urban area, and 11.0% eligible for Medicaid as well. Telemedicine use was determined by examining a combination of telemedicine site codes and the Current Procedure Terminology codes. Preliminary analyses suggest significant rural-urban disparities in the use of telemedicine, likely due to access to high-speed internet and access to a provider to initiate telemedicine. Further analyses of the association between zipcode-level determinants and telemedicine use will provide insights for future intervention. We also plan to examine the changes in total cost to Medicare associated with telemedicine use among the fee-for-service Medicare beneficiaries.

abs-os497 The Patient Will Text You Now: Telemedicine and In-person Hospital Visits in China

PRESENTER: **Xuening Cheng**
AUTHORS: Xuyan Lou, Qing-Ping Ma, Yan Cen, Xuyang Wang, Mr. Wei Jiang, Lina Song, Mr. Zhuo Chen, Hongqiao Fu, Alain Chong

Background: Telemedicine restructures the health delivery system by allowing remote access to high-quality services and increasing the labour supply of public hospital doctors. It is believed that telemedicine is an extension of traditional hospital-centred healthcare. The COVID-19 pandemic has highlighted the importance of telemedicine. However, there is limited evidence for the substitution effect of telemedicine on traditional healthcare through the common supply factor in both online and offline health services – the doctor, in particular, during the COVID-19 pandemic. Little research has examined the effectiveness of telemedicine services on in-person healthcare utilization in Low-and-Middle-Income-Countries (LMICs) because of data limitations. **Methods:** This paper uses two unique data sets – online service data and hospital visits data, to identify the impact of telemedicine utilization on hospital visits in China, a middle-income country. Online service data, scraped online, contain extensive information on active doctors providing online health services through commercial third-party platforms. Hospital visits data has utilized aggregated population flow to hospitals at the city level, generated from mobile-phone signalling data from one of China's major mobile phone service providers. The two-way fixed effect (TWFE) model and generalized linear model (GLM) regressions are used to conduct the baseline analysis. Simultaneous equations model (SEM) and instrumental variable (IV) methods are used to explore the bidirectional relationship between hospital service and telemedicine utilization. **Findings:** We found that a 1 percentage decrease in outpatient visits is associated with 0.005 percentage increase in online consultation, and 1 percentage decrease in inpatient visits is associated with 0.018 percentage increase in online consultation. However, these effects showed a strong trend over time that partly driven by the pandemic. SEM model reported that 1% decrease in outpatient visits associates with 0.18% increase in online consultation, and no significant effect in hospital inpatient visits. Meanwhile, 1% increase in online telemedicine consultation associates with over 0.7% increase in hospital visits for both outpatient and inpatient visits. **Interpretation:** Our study examines the interactive role between hospital healthcare and telemedicine service from provider side, especially the hospital who takes the most important role in a LMIC setting. The substitution effects between hospital healthcare and telemedicine service are verified through our analysis. The decrease in the number of hospital visits is associated with more online consultations, which implies the lower transaction cost for online services for patients. On the flip side, the increase in hospital workload could reduce physician's provision of online services in the same period. Study results provide empirical evidence on the effectiveness of telemedicine services and policy implications for the new healthcare paradigms for China and other LMICs.

abs-os690 Busyness in the Maternity Ward and Quality of Care

PRESENTER: **Dan Han**
AUTHORS: Margaret McConnell, Emma Clarke-Deelder

Excessive provider workload can affect health care procedures in ways that undermine patient outcomes, but evidence on the workload-quality relationship in low- and middle-income countries (LMIC) is sparse. Existing research predominantly focuses on primary care settings or major staffing shocks, leaving open questions about the effects of everyday workload variations in tertiary care settings.

In this study, we use data collected through direct observation of vaginal deliveries in three large Kenyan hospitals to explore how providers cope with busyness in the maternity ward. The maternity ward is a unique and important setting for studying the impacts of provider workload. First, hard-to-schedule patient admissions and uncertainty around labor progression could result in crowding at various times during the day, creating somewhat unpredictable workloads for identification. Second, teamwork is an essential feature of labor and delivery care, and how providers respond to workloads in a team-based environment may differ from that in a primary care setting.

We begin by documenting variation in provider workload (measured as patient volume relative to nurse-midwife staffing) by the time of day and show that our identifying variation is quasi-random. Our quality measures capture provider adherence to guidelines during routine labor & delivery and immediate maternal and newborn care, practice of disrespectful care, and patient outcomes. We find that the relationship between provider workload and quality is much weaker than expected. To explain the lack of a meaningful workload-quality association in this setting, we examine how providers cope with increased workload. We show that when busier, providers increasingly delegate tasks to less qualified team members and use clinical interventions to speed up labor. We also find suggestive evidence that providers may discharge patients earlier

than clinically appropriate in anticipation of limited staffing levels. Our findings have important policy implications in light of LMIC's efforts to shift deliveries to hospitals.

abs-os691 Cost Dynamics of Noncommunicable Diseases in a National Health Insurance Context: Empirical Evidence From Ghana

PRESENTER: **Stéphane Verguet**, Harvard University
AUTHORS: Dr Richmond Ensiwoyie, Kathrin Durizzo

Objective Noncommunicable Diseases (NCDs) are a growing health burden in developing countries, driven by demographic shifts and rapid socio-economic development, accounting for approximately 50% of deaths across most sub-Saharan African (SSA) countries. Besides their burden on health and mortality, NCDs impose significant financial burdens, escalating out-of-pocket health expenditures. To avoid an escalation of out-of-pocket expenditures many health insurance schemes in SSA cover NCDs. In Ghana, a country with one of the most advanced health insurance schemes in SSA, the National Health Insurance Scheme covers a broad range of NCDs, including stroke, hypertension, diabetes, and certain cancers, since its inception in 2003. In addition, Ghana adopted the World Health Organization Package of Essential Noncommunicable Disease Interventions (WHO PEN) in 2022 to enhance healthcare providers' capabilities to detect and manage NCDs. As NCD rates rise and many SSA countries strive to establish sustainable national health insurance schemes, understanding usage patterns and cost drivers within large-scale, mandatory insurance schemes is increasingly critical. Despite the importance, evidence on this topic remains sparse. Furthermore, little is known about the impact of NCD programs, such as the WHO PEN, on usage patterns and costs.

Method This study analyzes novel claims data from the Ghanaian NHIS over a ten-year period (2014-2023) to examine insurance utilization patterns and cost drivers associated with NCDs (i.e., stroke, hypertension, diabetes, cervical, breast, and childhood cancers). We can separately identify the costs for medicine and services per claim to more accurately compute cost drivers. The geographical variations in the implementation of WHO PEN policies allow for a quasi-experimental analysis of the policy's effects on usage patterns. Therefore, we can provide the first causal evidence on the program in Ghana.

Results We found a significant increase in NHIS claims for NCDs, from 0.66 million claims in 2013 to 1.4 million in 2023, with total NCD costs escalating from 24 million GHS in 2013 to 300 million GHS in 2023 (1 GHS = 0.06 USD). The cost per claim rose from 35 GHS in 2013 to 214 GHS in 2023. Diabetes and hypertension account for 70% of all NCD claims, while cancer treatments have the highest average costs. Notably, the average age of patients receiving NCD treatments has decreased, and referrals to higher level facilities are functioning as intended. The implementation of the 2022 NCD intervention policies significantly altered usage patterns, with a nearly 50% reduction in cost escalation observed in regions where the new policies were implemented. These effects were similar across costs associated with both services and medication.

Discussion Our findings underscore the significant financial protection of patients being covered by NHIS. It also highlights the potential for NCDs to place a substantial, unsustainable strain on NHIS financing if current trends continue. However, the evidence suggests that the recently implemented NCD policies can mitigate this cost burden. Scaling and extending these policies nationwide could reduce future cost escalations, thereby supporting more sustainable health financing.

abs-os692 Physician Deterrence From Fraud, Waste, and Abuse

PRESENTER: **Eunhae Shin**
AUTHOR: Alice Chen

Fraud, waste, and abuse in the United States are estimated to account for $760 billion to $935 billion annually, representing approximately 25% of total healthcare spending. The Federal Bureau of Investigations estimated that health care fraud alone cost American taxpayers nearly $80 billion per year. Of this amount, the US Department of Justice recovered only $2.2 billion in 2020. Though seemingly small, this recovery highlights the potential value of policy initiatives such as the Affordable Care Act and Small Business Jobs Act—to identify and exclude fraudulent providers from participating in Medicare and Medicaid programs. In particular, the ability of these policies to deter potentially fraudulent activities before they occur can yield significant additional savings. We lack a comprehensive understanding of how such sanctions affect the behavior of potentially fraudulent providers.

In this paper, we examine changes in physician behavior when their peers receive direct sanctions from the US Department of Health and Human Services' Office of Inspector General (OIG). Specifically, we examine changes in billing patterns (e.g., total claims and charges, prices per service, and the use of low-value care) and physician organization sorting when a physician peer has been excluded from participating in the Medicare and Medicaid programs.

Our analysis relies on three datasets. First, we identify information on physician exclusions from the OIG's List of Excluded Individuals/Entities (LEIE). The LEIE data includes all excluded physicians and their dates of exclusion. We supplement this data with text searches from the Department of Justice to identify dates of indictment. Finally, we use 20% administrative Medicare claims data from 2002 to 2014 to identify physicians, their organization, and their services provided.

We focus on peer-responses within an organization, so our sample universe consists of physicians within organizations that have experienced an exclusion. Using a multivariate logit model, we predict which physicians are likely to be fraudulent. Then, we use event study and matched difference-in-difference approaches to analyze changes in physician billing and organization alignment among potentially fraudulent providers.

We find that Medicare exclusions have a significant deterrence effect on potentially fraudulent providers. Responses begin at the time of peer indictment and continue through the date of peer exclusion. Claims and charges fall and are driven by declines in both claims and charges per patient and the number per patient seen. We also find evidence that charges per service falls, suggesting that potentially fraudulent physicians

are reducing billing for specifically more expensive procedures. Deterrence effects are highest in larger organizations, among hospital-based specialties, and they highlight additional savings from the prosecution of fraud and abuse cases.

Our results demonstrate that Medicare exclusions create a significant deterrence effect among providers who consistently over-bill for care. In addition to removing fraudulent providers, efforts to combat fraud, waste, and abuse generate large spillover effects, discouraging other potentially fraudulent providers who are yet to be sanctioned. Notably, these physicians are those for which detection is potentially more difficult and costly.

abs-os701 Advancing HTA in Thailand through Reflection, Learning, and Adaptability: The Path to Universal Health Coverage

PRESENTER: **Ms. Wanrudee Isaranuwatchai**, Health Intervention and Technology Assessment Program (HITAP), Ministry of Public Health, Nonthaburi, Thailand.
AUTHOR: Yot Teerawattananon

Thailand launched its Universal Health Coverage (UHC) Scheme in 2001, which provided a baseline level of healthcare for children, older people, and those of working age. This system has been extended in intervening years, removing copayments and providing coverage to non-Thai citizens and stateless people in 2024.

Health technology assessment (HTA) is one tool which has been used to support UHC by generating economic evidence such as cost-effectiveness and budget impact analysis, along with other types of evidence like a feasibility plan and processes for monitoring and evaluation. As countries pursue UHC, it is important to make both informed and fair choices, such that efforts to improve efficiency and financial sustainability are balanced with the need to address inequities. Healthcare payers around the world are progressively using economic evidence to inform decision-making (such as whether to include a medicine or a new medical device in a benefit package) to achieve UHC.

In Thailand, the use of HTA started around 2007 but, as with other changes globally, HTA processes and methods require adaptation in order to remain relevant and to be able to support the policy-making process and ultimately the achievement and sustainability of UHC. This has required that Thailand explore a variety of purchasing models for medicines.

This case study focuses on the role of HTA in Thailand as a means to support UHC. The presentation will highlight the impact of HTA in Thailand by sharing lessons learned including real-world examples of how HTA has been used to support policy-making processes, such as the inclusion of health interventions in the universal coverage benefit package and medications for the National List of Essential Medicines. In addition, examples will be shared on ways HTA processes and guidelines have been adapted or need to be adapted to address ongoing and emerging challenges. Feedback from the session's attendees would be beneficial as we continue to apply HTA to the real-world setting and find ways to optimize its use to support UHC.

abs-os40 From the Pharmac Review to a Letter of Expectations: The Changing Face of HTA in Aotearoa New Zealand

PRESENTER: **Paula Lorgelly**, University of Auckland
AUTHOR: Richard Edlin

Aotearoa New Zealand's Pharmaceutical Management Agency (Pharmac) was established in 1993. Pharmac's first guidelines, the Prescription for Pharmacoeconomic Analysis (PFPA), was published in 1999, updated significantly in 2007 and again with minor changes in 2012 and 2015. Pharmac is unique as a health technology assessment (HTA) agency as it is both the decision-maker and the funder of medicines. Their statutory objective is to secure the best health outcomes for eligible people in need of pharmaceuticals, within the amount of funding provided. As Pharmac has a limited budget it manages a priority list of medicines and technologies (the Options for Investment list) that it would like to fund if it could afford it. Technologies are ranked and funded in priority order when more budget is received, or cost savings are achieved elsewhere within the portfolio they manage. As the order of this list is not made public, neither the public nor companies know how close a listed technology is to being funded. Pharmaceuticals are on the Options for Investment list for an average of 5.9 years; for this reason, there is considerable criticism of Pharmac.

In 2021 Pharmac was the subject of an independent review, the panel reported in 2022 making 33 recommendations. Many of these recommendations focused on the inequity of Pharmac's decision making, both processes and the consequences. With respect to the methods employed to assess value for money, a recommendation was that Pharmac should develop an integrated analytical framework for the assessment of pharmaceuticals that incorporates enhanced cost-benefit analysis with strengthened distributional elements and strengthened equity analysis in all its decision-making processes.

Aotearoa New Zealand had a general election in 2023. Health featured significantly in the electoral manifestos of most parties, ranging from promises of ring-fenced funding for cancer drugs to replacing Pharmac with a new patient-focussed medicines buying agency. The National-led coalition government has created a new ministerial portfolio specifically for Pharmac, and most recently Pharmac received its instructions (or expectations) regarding how it is expected to perform (indeed reform). This includes a focus on fiscal or social impact, i.e. taking a societal perspective, and greater involvement of patients in the decision making process.

This case study will reflect on these varying approaches to review and change; that directed by an independent review and that directed by a Minister, including undertaking comparisons with other reviews or methods changes internationally. We will discuss the role of health economists in these processes and their contributions to methods improvement.

abs-os700 The Australian HTA Review: Reflections from an Expert Group

PRESENTER: **Joseph Thomas**, University of Technology Sydney
AUTHORS: Rosalie Viney, Stephen Goodall, Kathleen Manipis, Rosalie Viney, Richard De Abreu Lourenco

Since 1992 Australia has been a pioneer in health technology assessment (HTA), requiring evidence of cost-effectiveness when evaluating the reimbursement of pharmaceuticals. In the following years it expanded the requirement of this evidence to procedures, diagnostic tests, and devices. There are two main committees that assess HTA evidence: the Pharmaceutical Benefits Advisory Committee (PBAC) and the Medical Services Advisory Committee (MSAC).

Australia has just undertaken its largest and most comprehensive review of HTA policies and methods to date. Initiated as part of a strategic agreement between the Australian Government and Medicines Australia, the peak representative body of the innovator pharmaceutical industry in Australia, the HTA Policy and Methods Review focused on enhancing access to funded health care technologies, balanced against achieving an equitable and affordable healthcare system.

The Review was led by a Reference Committee comprising representatives from Government, Industry, HTA Agencies and Consumer representatives. The HTA Review Reference Committee made 50 recommendations in its final report. Those recommendations were informed by independent research conducted by external expert groups, public consultation and extensive deliberation by the Committee. The independent research captured not only local experience, but importantly, compared HTA systems and processes in Australia relative to other countries, including stakeholder feedback and proposed changes.

This case study will present the experiences and reflections of one of the external expert groups informing the Review, with a focus on exploring their role in the Review, its overall conduct and reflections on HTA reform globally.

abs-os156 Exploring Health Inequality Aversion Among Thai Policymakers and General Public Through Health Inequality Aversion Survey

PRESENTER: **Picharee Karunayawong**
AUTHORS: Ms. Wanrudee Isaranuwatchai, Chittawan Poonsiri, Richard Cookson, Manta Korakot, Chulathip Boonma, Sarin KC

Introduction and objective: Cost-effectiveness analysis (CEA) has been used as one of the criteria for including medicines, vaccines, or other health technologies in healthcare systems worldwide, including in Thailand. This use of economic evidence aims to promote efficiency in decision-making process in the Thai health system. However, traditional CEA has limitations, as it does not incorporate health inequity, which is a significant concern in many countries. Distributional Cost-Effectiveness Analysis (DCEA) is one of the alternative methods which can integrate equity considerations into economic evaluations, helping to address this gap. To conduct a DCEA, an estimate of equity index is required. This study aims to reports the results of health inequality aversion survey in Thailand which will be used to support the first DCEA study in Thailand.

Methods: A health inequality aversion survey was conducted in both online and in-person format. The survey was divided into 2 parts: 1) background information of participants; and 2) questions about the trade-off between reducing health inequity and improving health efficiency. To quantify people's value of health equity, participants would be categorized into one of the five groups: 1) pro-rich (prefer to improve health gains for the rich); 2) health maximiser (prefer to improve total health only); 3) weighted prioritarian (prefer to give greater weight to improve the health of the worst-off); 4) maximin (prefer to improve the health of the worst-off) and 5) egalitarian (prefer to reduce health inequality so much that they are willing to sacrifice potential health benefits to the worst-off).

The survey was translated and piloted among stakeholders, including policymakers, researchers, health coverage schemes representatives, and patient representatives. Pre-survey training among the interviewers and checking questions (for both content and figures) were conducted to maximize the accuracy of the responses.

The survey was conducted among Thai policymakers from National List of Essential Medicines (NLEM) and Universal Coverage Benefit Packages (UCBP) during the online subcommittee meeting. The research team introduced the overview of the survey, after which policymakers independently responded to the questions via an online survey platform. Two approaches were used for general public to explore the inequality aversion of Thai population, including in-person and online survey. Data collection took place in December 2023 for policymakers, from January to February 2024 for in-person general public responses, and from February to March 2024 for online general public responses.

Results: There were 28 responses from policymakers survey, 2,584 responses from in-person general public, and 438 online general public. The valid response rates were 43%, 96%, and 37% respectively. The result from policymakers and the online general public were categorized as weighted prioritarian, while the in-person general public was categorized as egalitarian.

Conclusion: These findings highlight the importance that Thai people place on addressing health inequality, representing the first measurable impact for policymakers to actively consider health equity in their decision-making processes. They also highlight the differences in responses between policymakers and general public, and also between online and in-person format. Results from this survey will be used in conducting Thailand's first DCEA study.

abs-os154 Income-Related Health Inequality Aversion and Its Geographical Variations: Evidence From China

PRESENTER: **Shan Jiang**
AUTHORS: Dandan Yu, haiyin Wang, Yuanyuan Gu

Background: In evaluating health interventions, the public is concerned not only with the overall health improvements (efficiency) but also with how these benefits are distributed across different population groups (equity). This balance is captured by health-related social welfare functions (SWF) in distributional cost-effectiveness analysis (DCEA). However, DCEA has yet to be widely adopted by governments in many countries, including China, due to a lack of reliable estimates for the key parameter, health inequality aversion.

Aims: To understand how much the public is willing to sacrifice overall health improvement to reduce health inequality, this study estimates the inequality aversion parameter using a stated preference approach with a sample of the general public in China. It also quantifies variation in health inequality aversion across different regions to enhance the accuracy and applicability of DCEA.

Methods: Face-to-face, one-on-one surveys were conducted across seven geographically diverse cities in China. Quota sampling was used to ensure representativeness across gender, age, and residence. The sample was reweighted using entropy balancing to align with national demographics. Respondents made seven pairwise choices between two hypothetical options: Option A provided seven additional years of life to the richest quintile (life expectancy 81 to 88) and three years to the poorest quintile (life expectancy 73 to 76); Option B provided three years to the richest quintile (life expectancy 81 to 84) and a varying number of years to the poorest quintile (life expectancy 73 to 75-81). Across the seven questions, Option A remained the same, while Option B progressively reduced the life expectancy gains for the poorest quintile from eight to two years. The switching point from B to A revealed the level of health inequality aversion, which was quantified using Atkinson SWF parameters. Ordered probit models were used to explore geographical variations and the effects of individual characteristics.

Results: The survey (October 1, 2023 - February 9, 2024) received 1,327 valid responses out of 1,649 participants. 92.4% of respondents were willing to sacrifice some total health gains to reduce health inequality. The median Atkinson inequality aversion parameter was 17.5, implying that health gains to the poorest quintile were weighted 6.2 times as highly as those to the richest quintile by the Chinese public. Rural residents expressed a stronger aversion to health inequality than urban residents. Compared to residents in Shanghai, whose aversion levels were similar to those of the UK public, residents in some less developed cities showed a greater emphasis on reducing health inequality, even after controlling for household income.

Conclusions: The Chinese public exhibits strong health inequality aversion, with substantial geographical heterogeneity. The estimated inequality aversion parameters can be used in DCEA to inform decisions on healthcare resource allocation. These findings suggest that, in large, populous countries, applying a single parameter for national preferences may misrepresent the distributional effects of health interventions. Instead, the distributional impact should be measured regionally before aggregating the results nationwide. The elicited parameters offer insights into public preferences and also contribute to the methodological improvement of DCEA. Income-Related Health Inequality Aversion and Its Geographical Variations: Evidence From China

abs-os155 Responsibility-Sensitive Welfare Weights for Health

PRESENTER: **Matthew Robson**
AUTHORS: Tom Van Ourti, Owen O'donnell

We estimate responsibility-sensitive welfare weights for health that facilitate inequality- and inequity-sensitive policy evaluation. In a UK general population sample, 569 online experiment participants distribute constrained resources to determine the health of hypothetical individuals distinguished by randomly generated resource productivity as well as sex, income and smoking (41,460 observations). We elicit beliefs about responsibility for income and smoking, and use their associations with the allocations to estimate responsibility-sensitive weights that reflect inequality aversion and health prioritisation by the non-health characteristics. There is slight, moderate and substantial prioritisation of females, the poor and non-smokers, respectively. Inequality aversion lowers weights on females and non-smokers, who are health-advantaged, and raises the weight on the poor, who are health-disadvantaged. As beliefs about responsibility for income and smoking

strengthen, weights on the poor decrease and weights on non-smokers significantly increase. Responsibility-Sensitive Welfare Weights for Health

abs-os157 Whose Voices are Lost? Identifying Characteristics of Excluded Groups in Health Inequality Aversion Studies

PRESENTER: **Ms. Marie-Anne Boujaoude**
AUTHORS: Natalie Carvalho, Kim Dalziel, Nancy Devlin, Sitanshu Sekhar Kar

Background and objectives: Stated preferences exercises, such as benefit trade-off (BTO) surveys, are increasingly used to elicit health inequality aversion parameters. However, the complexity of the exercise, combined with the necessity for rational and consistent responses, often results in the exclusion of respondents who fail to meet certain quality standards. This practice risks discarding the views of subgroups (such as poor literacy), potentially introducing bias and limiting the findings representativeness. Additionally, differences in the mode of survey administration (i.e. in-person vs online) may further influence the type of respondents who complete or are excluded from the survey. Understanding the characteristics of excluded respondents and examining the variations between in-person and online responses can shed light on which groups may face challenges with the task requirements and inform strategies to enhance inclusivity in health preference research.

Research questions:

1. How do the demographic and socioeconomic characteristics of (a) excluded respondents compare with those included in the final analysis, and (b) those with valid responses compare to those with invalid responses among survey completers?
2. How does the characteristics of in-person and online survey respondents compare with the setting specific background population?

Methods: A BTO survey was conducted online with a sample from the Australian public to elicit preferences related to health inequality aversion. Throughout the survey, quality control questions were introduced to ensure respondents were graph literate, understood and engaged with the task. Respondents were excluded at various stages if their responses indicated irrational decision-making or if they failed to answer minimum quality control questions correctly. Another BTO survey was conducted in person in India to elicit health inequality aversion preferences. The number of valid responses and characteristics of the discarded respondents were compared. Logistic regressions were run to predict the likelihood of a respondent being excluded based on demographic and socioeconomic factors for the Australian sample.

Results: Respondents were excluded at several points: those excluded for incorrect graph reading and for not correctly selecting the dominant response to a trade-off question were significantly less educated, older, and from lower income quintiles. Remoteness and gender didn't seem to impact exclusion. Of the respondents who completed the survey, 22% were excluded for giving invalid answers. The characteristics of the respondents did not vary significantly between these 2 groups. The likelihood of being discarded due to any exclusion criteria is 31% higher if the respondent is between 18 and 34 years old. Respondents in the highest income quintile had 48% lower odds of being excluded compared to those in the lowest income quintile. The face-to-face BTO didn't have to discard any response, as they were all valid. Additional analysis will compare the *online versus in-person* sample characteristics to the setting specific *background population*.

Conclusion: The findings suggest that such stated preference exercises may inadvertently exclude certain respondent voices. These patterns emphasize the need for simplified survey designs or additional support mechanisms to improve inclusivity and ensure a more representative sample in studies aiming at eliciting health inequality aversion parameters, without including additional biases.

The Economics of Dental Care: Shaping Evidence-Informed Policy

MODERATOR: **Abdulrahman Ghoneim**, Dalhousie University

CONVENER: **Ziade Sarroukh**, Department of Dentistry, Radboud University Medical Center

abs-os105 A Costing Analysis of a Comprehensive Dental Care Program

PRESENTER: **Mr. Abdulrahman Ghoneim**
AUTHORS: Rebecca Hancock-Howard, Sonica Singhal, Audrey Laporte, Carlos Quiñonez

Background: Understanding the costs of implementing a comprehensive dental care program is paramount for informing policy decisions. This study aimed to estimate the direct and indirect costs associated with delivering a comprehensive dental care program for those who experience cost-barriers to care.

Methods: This costing analysis leverages data from a single-group repeated-measures study to assess the impact of receiving free dental care. Participants who met the eligibility criteria received comprehensive dental care and were followed up after attaining 'oral health stability.' Using a micro-costing method, we estimated the direct and indirect costs of delivering this program. The direct costs of 1) treatments rendered and 2) medications prescribed as part of the treatment plan were included. Indirect costs captured were 1) travel expenses, 2) productivity losses, and 3) caregiving expenses.

Results: Data from 134 participants who completed one year of follow-up were analyzed. After one year of implementation, the average direct

and indirect costs were CAD $2,699 (SD: 1,610) and CAD $696 (SD: 605), respectively. When extrapolating our findings to the adult beneficiaries of the Canadian Dental Care Plan (CDCP), the total direct cost of the first year of implementation amounts to $19.70 billion.

Discussion: This is the first study to utilize participant-level data to estimate the cost of implementing a free comprehensive dental program. This study addresses the methodological limitations of previous studies in this field.

Conclusion: The findings from this study will inform policy decisions regarding implementing future dental care programs.

abs-os106 How to Ensure an Appropriate Oral Health Workforce? Modelling Future Scenarios for the Netherlands

PRESENTER: **Jip Janssen**
AUTHORS: Ave Pöld, Md Monirul Islam, Orsolya Németh, Jostein Grytten, Noel Woods, Stefan Listl

Background: Current methods for oral health workforce planning lack responsiveness to dynamic needs, hampering efficiency, equity and sustainability. Effective workforce planning is vital for resilient health care systems and achieving universal health coverage. Given this context, the aim of this study was to develop and operationalise a needs-adaptive oral health workforce planning model and explore the potential of various future scenarios.

Methods: Using publicly available data, including the Special Eurobarometer 330 Oral Health Survey, we applied the model in a hypothetical context focusing on the Dutch population's dental needs from 2022 to 2050. We compared current and future provider supply and requirement and examined, in addition to a base case scenario, several alternative scenarios. These included epidemiological transition scenarios with different oral health morbidity trajectories, skill-mix scenarios with independent oral hygienists conducting check-ups and multiple dental student intake and training duration (5 instead of 6 years) scenarios. The model also assessed the impact of different recall intervals for dental check-ups (6-month vs. 12-month or 24-month intervals) to explore potential reductions in overall provider requirement.

Results: Based on the aforementioned historical data, our model projects that provider requirement will exceed supply for the planning period. If the percentage of people having all natural teeth increases by 10% or 20% in 2032, 34 or 68 additional full-time equivalent (FTE) dentists will be required, respectively, compared to the base case scenario. In the skill-mix scenario, the model indicates that prioritising oral hygienists for check-ups and shifting dentists' focus to primarily complex care could address population needs more efficiently: FTE provider requirement was projected to be 229 lower than the base case scenario. Additionally, further substantial requirement reductions could be achieved if skill-mix implementation results in shorter check-up times. Among the student intake and training duration scenarios, increasing intake to 375 and reducing training to 5 years is projected to most effectively close the provider gap. However, shortening training duration has a more limited impact, as its benefits only take effect once.

Conclusions: The study underscores the importance of understanding oral health morbidity trajectories for effective capacity planning. Due to limited dental epidemiological data, projections carry substantial uncertainty. Currently, demand for FTE dentists seems to exceed supply, though this may vary with epidemiological changes. Skill-mix strategies could offer efficiency gains by redistributing tasks, while adjustments in dental intake and training duration could also help address the requirement-supply gap. Additionally, reducing administrative burdens on dental professionals, such as time spent on non-patient-related activities, and extending check-up recall intervals could further improve efficiency in care delivery (with no expected oral health impact). Resolving dentistry workforce challenges requires a multifaceted approach, including strengthening oral epidemiology projections, addressing the root causes of dental health issues and prioritising harmonious dental public health and general practice prevention measures.

abs-os107 Looking Back and Moving Forward: Towards Evidence-Informed Priority Setting and Resource Allocation in Oral Health Care Systems

PRESENTER: **Ziade Sarroukh**
AUTHORS: Patrick Jeurissen, Rob Baltussen, Shaila Akter, Jip Janssen, Stefan Listl

Background: As almost half the global population continues to suffer from oral diseases and the costs of dental care exacerbate catastrophic expenditures, oral health care has increasingly drawn the attention of the global policymaking agenda seeking universal access in health care. However, a lack of coherence between challenges and policymaking endeavors has resulted in seemingly untransparent priority setting and resource allocation in oral health care systems. This research aims to identify the determinants of prioritization in European oral health policymaking and implement a multicriteria-decision analysis (MCDA) as part of a deliberative process of evidence-informed resource allocation.

Methods: Drawing from situational analysis and MCDA methods, a stepwise approach was used. A literature review on oral health policy programs in Denmark, Germany, the Netherlands and the United Kingdom and key informant interviews with policymakers were conducted to identify determinants of priority setting. Findings were translated into methodological considerations of the MCDA used to prioritize dental services for adults in the Netherlands. Services and decision criteria were defined through a Nominal Group Technique (NGT) with an advisory panel consisting of policymakers, patients, dentists, health economists and representatives from a health insurance company. Weights of criteria were elicited using swing weighting questionnaires answered by panel members. The scoring of alternative interventions against the consented criteria serves as basis for ranking the interventions by the advisory panel.

Results: 249 articles were included, and six key informants were interviewed. Three stages were identified which characterize the complexity in oral health policymaking: 1) political accountability to address population demand, 2) stakeholder influence through negotiations and lobbying, and 3) bureaucratic justification of policy innovations. While the findings highlighted political attention on oral health care through public outcry, complex negotiations and limited data formed bottlenecks for prioritization of concrete solutions. An MCDA advisory panel was formed which includes 11 stakeholders with diverse backgrounds. Key decision criteria comprise disease burden, health gain, costs, prevention,

safety and esthetic effects. These criteria are sensible to rank interventions for periodontal disease, caries, tooth wear and masticatory disorders.

Conclusion: Current prioritization in oral health policies seem to be dominated by fragmented investments in incremental services of delivery rather than fundamental reforms such as granular package designs. Complex negotiations, strained by interests of private professionals and challenges of limited evidence, result in difficulties to constrain oral health policies within public spending targets. This has placed oral health care systems in a state of inertia, where insufficient public resources meet the force of content exerted by the private sector. Aligning stakeholders through evidence-informed deliberation could strengthen prioritization and relieve these bottlenecks. Our research is among the first MCDAs to prioritize dental services while facilitating a deliberative process between stakeholder groups. Findings from the MCDA will reveal a ranking of essential services and demonstrate the feasibility of implementing a deliberative prioritization of dental resources.

abs-os103 Oral Health Care Out-of-Pocket Costs and Financial Hardship: A Scoping Review

PRESENTER: **Diego Proaño**
AUTHORS: Abdulrahman Ghoneim, Beverley Essue, Sonica Singhal, Carlos Quiñonez, Hellen Huang, Sara Allin

Objective: The objective of this study is to characterize how financial hardship related to oral health care (OHC) out-of-pocket (OOP) spending has been conceptualized, defined, and measured in the literature and to identify evidence gaps in this area.

Methods: This scoping review follows Arksey and O'Malley's framework and synthesizes financial hardship from OHC concepts, methodologies, and evidence gaps. We searched Ovid-Medline, Ovid-Embase, PubMed, Web of Science, Scopus, EconLit, Business Source Premier, and the Cochrane Library. Gray literature was sourced from institutional websites (World Health Organization, United Nations, World Bank Group, Organisation for Economic Co-operation and Development, and governmental health agencies) as well as ProQuest Dissertations and Thesis Global. We used defined inclusion and exclusion criteria to select studies published between 2000 and 2023.

Results/Discussion: Of the 1,876 records, 65 met our criteria. The studies conceptualized financial hardship as catastrophic spending, impoverishment, negative coping strategies, bankruptcy, financial burden, food insecurity, and personal financial hardship experience. We found heterogeneity in defining OHC OOP payments and services. Also, financial hardship was frequently measured as catastrophic health expenditure using cross-sectional designs and national household spending surveys from high-income and to a lesser extent lower-middle-income countries. We identify and discuss challenges in terms of conceptualizing financial hardship, study designs, and measurement instruments in the OHC context. Some of the common evidence gaps identified include studying the causal relationship in financial hardship from OHC, assessing the financial hardship and unmet dental needs due to cost relationship, and distinguishing the effect between pain/discomfort and esthetic/cosmetic dental treatments on financial hardship.

Conclusion: Financial hardship in OHC needs further exploration and the use of consistent definitions as well must distinguish between treatments alleviating pain/discomfort from esthetic/cosmetic treatments. Our study is relevant for policy makers and researchers aiming to monitor financial protection of OOP payments on OHC in the wake of universal health coverage for oral health.

3:30 PM –5:00 PM MONDAY [Evaluation Of Policy, Programs And Health System Performance]

Policy Effects on Mental Health

MODERATOR: **David Johnston**, Monash University

CONVENER: **Joe Spearing**, University of York

abs-os123 Are You Okay? Effects of a National Peer-Support Campaign on Mental Health

PRESENTER: **Nicole Black**, Monash University
AUTHORS: Johannes Kunz, Lachlan Deer, David Johnston

Background: Suicide is the leading cause of death among young adults (15-44 years) and about one in five Australians experience mental illness in a given year, yet many do not receive the treatment or support they need. Social and peer support is recognised as being protective against mental illness and suicide. National public health awareness campaigns that emphasize peer-to-peer support are being increasingly adopted by governments and NGOs, but evidence on the effect of peer-based support programs at scale is limited **Objectives**: Using quasi-experimental methods, we examine whether a prominent, nationwide peer-based support campaign, "R U OK? Day", that addresses awareness of mental health and suicide prevention affects short-term mental health outcomes in Australia. **Methods**: Using variation in daily records before and after R U OK? Day, and differences in the campaign's intensity over nine years (2011-2019), we examine the impact of the R U OK? Day campaign on perceived social support and mental health using household survey data (with quasi-random interview dates). We also examine the impact of the campaign on mental healthcare use and suicides using national administrative health insurance and death records. **Results**: We found a significant increase in Google and Twitter searches for "R U OK" in response to the campaign verifying increasing intensity of the campaign over time. Estimates from the difference in differences analyses suggests that R U OK? Day led to a small improvement in perceived social support and mental well-being, particularly among young males aged 25-49 years in the four weeks following the campaign. However, we found no evidence that R U OK? Day had any effect on the uptake of mental healthcare use or suicides over this same period. **Conclusion**: This is the first study to measure the effect of a peer-to-peer mental health campaign on the mental health of the general population by observing variation in a range of daily records and survey data before and after the campaign. Although we found no evidence of an impact on suicide or deaths of despair, the R U OK? Day campaign led to small improvements in mental wellbeing, especially

among young males. Young males are an important target group given the high rates of suicide and low utilisation of needed mental health services in this population.

abs-os124 Talking Through Our Mental Health Problems. The Impact of Talk Therapy on Healthcare Utilization and Employment

PRESENTER: **Roger Prudon**

Background: According to the OECD, half of all people will suffer from mental health issues at some point in their lives. These mental health issues often have large negative impacts on individuals' lives. While treatment could be effective in mitigating these negative impacts, treatment uptake rates are limited, resulting in many people with mental health issues not receiving (adequate) care. Increasing treatment uptake could therefore have substantial positive benefits to society.

To increase treatment uptake, governments around the world have introduced large-scale programs aimed at provided easily accessible form of mental healthcare. Examples of these programs are the NHS Talking Therapies Program in the UK, the Better Access Initiative in Australia and Project Teach in New York. Evidence on the effectiveness of these programs is however scarse.

Objectives: This paper evaluates the introduction of a similar program that provided an easily accessible form of talk therapy in the Netherlands. This talk therapy, provided by mental healthcare practice assistants (MH-PA) at general practitioner (GP) offices, was introduced in 2012 to alleviate pressure from the specialised mental healthcare system and increase treatment uptake rates. As a first step, I examine how the introduction affected the uptake of talk therapy itself and the treatment provided by the already existing specialised mental healthcare system. In the second step, I examine the impacts of the increased treatment uptake on a range of labour market outcomes.

Methods: Using administrative data, I first exploit the quasi-random timing at which the talk therapy was introduced in GP offices nationwide using a Regression-Discontinuity-in-Time framework. Additionally, I exploit variation in the propensity to refer to talk therapy in a Judge IV setting.

Results: The introduction of talk therapy at GP offices significantly increased treatment uptake. For most individuals, talk therapy is complementary to the already-existing treatment option as these individuals would not have received care before the introduction of the NPMH. The new form of treatment is however mostly used by subpopulations with a relatively high pre-introduction utilization of mental healthcare, potentially increasing existing disparities in care utilization. Additionally, following the increased treatment uptake, there are no improvements in a wide range of labour market outcomes.

abs-os125 The Effect of Welfare Reform in England on the Mental Health of Elderly Disability Benefit Claimants

PRESENTER: **Mr. Joe Spearing**
AUTHORS: Andrew Jones, James Lomas

In common with other developed countries, England is facing an ageing population with increasing numbers of disabled people. The share of the population over the age of 65 is projected to rise above 25%. The share of the population which is disabled is 18% and rising. Correspondingly, government spending on pensions and disability benefits are increasing, and many governments have implemented policy reforms seeking to slow or reverse this trend towards higher spending. In order to develop policy which promotes population health, policymakers need to understand the effect of these benefit programmes on their claimants' health, and the consequences of reducing the generosity of these programmes.

We study a reform to disability benefits enacted in the UK in 2013: the government replaced Disability Living Allowance (DLA) with a different benefit, Personal Independence Payments (PIP). PIP is similar to DLA in being non-taxable and non-means-tested, and also pays a similar amount. The eligibility criteria for PIP are stricter than DLA, however, with fewer automatic awards, an in-person health assessment in most cases, and fewer indefinite awards. PIP was first introduced on 8th April 2013 for new claimants, with existing DLA claimants reassessed for the new benefit over subsequent years. For elderly DLA claimants who may not have the means to adjust their labour supply to account for lower income, this reform may have caused anxiety, affecting their mental health. We measure mental health using the CESD score.

We exploit the following feature of the rollout: those DLA claimants who were aged over 65 at the time of the introduction of PIP were exempt from reassessment. This introduces a sharp discontinuity in exposure to the reassessment in date of birth at any given point in time. We exploit this discontinuity in a regression discontinuity design: effectively, we estimate the discontinuous change in CESD scores comparing those born just before 8th April 1948 (who are not exposed to the reassessment) to those born just after 8th April 1948 (who are exposed to the reassessment). Identification relies on the assumption that while confounders may vary continuously with date of birth, only treatment exposure varies discontinuously.

In order to demonstrate that the reassessments have the expected effect on claims, we show that those who are above the date of birth cutoff are statistically significantly more likely to claim PIP, and significantly statistically less likely to claim DLA. Turning to mental health effects, preliminary results suggest that the reform had an adverse effect on mental health, that is, those born just after the date of birth cutoff have higher CESD scores.

Our research contributes to the literature on the effect of disability benefits on health (Black, French, McCauley, and Song, 2018, Gelber, Moore and Strand, 2022, Silver and Zhang, 2022, Becker et al., 2024). We advance on the existing literature by studying disability benefits in a context of universal healthcare, where additional income is unlikely to be related to accessing treatments. Additionally, we consider new health outcomes, i.e., mental health.

abs-os122 Workforce Impacts of Subsidised Mental Healthcare: Evidence on Supply, Earnings, and Geographic Distribution

PRESENTER: **Trong-Anh Trinh**

AUTHORS: David Johnston, Anthony Harris, Nicole Black

Background: Mental health disorders are a major health burden globally, yet barriers such as high out-of-pocket costs limit access to mental health services. In 2006, Australia introduced the Better Access Initiative (BAI) to subsidise psychological services and improve accessibility, particularly in underserved areas. This study explores the supply-side impacts of the BAI, focusing on its effects on the size, composition, earnings, and geographic distribution of the psychology workforce. *Research questions:* Our research addresses three key questions: (1) Did the BAI increase the supply of psychologists and affect their work hours? (2) What were the income effects of the BAI on psychologists, and did these effects vary over time? (3) Did the BAI encourage psychologists to practice in non-metropolitan areas, thereby reducing geographical disparities in mental healthcare access? *Method and data:* We employed a Difference-in-Differences (DiD) approach, utilising data from the Australian Population Census and Australian Taxation Office records to compare psychologists (the treatment group) with a control group of allied health professionals unaffected by the BAI. *Findings:* Our findings indicate that the BAI significantly increased the psychology workforce by 47% within five years, largely driven by older and female psychologists entering the workforce. We observed minimal impact on average work hours per psychologist, suggesting that the increase in service capacity was primarily due to workforce expansion rather than increased hours among existing psychologists. In terms of income, psychologists experienced a 17% increase in annual earnings, likely reflecting the financial incentives provided by the subsidy. Income effects grew over time, indicating that psychologists were able to retain a portion of the subsidy as revenue. The BAI also contributed to a more equitable distribution of psychologists across urban and non-metropolitan areas, with an 8% rise in the likelihood of psychologists practicing in non-metropolitan regions. *Conclusions and implications:* Our study underscores the importance of considering both demand and supply factors in healthcare policy design, particularly for underserved regions. The BAI demonstrates that financial subsidies can effectively expand service capacity and address geographic disparities, offering a model for other countries aiming to improve mental healthcare access through similar initiatives. These findings have implications for policymakers seeking to enhance healthcare equity and support workforce development in mental health.

abs-os132 Health and Healthcare Inequalities by Income in the United States and South Korea

PRESENTER: **Sungchul Park**, Korea University

AUTHORS: Karen Eggleston, Young Kyung Do, David Cutler

Background: Income is a key determinant of health outcomes, affecting both the quantity and quality of life. While several mechanisms may drive the relationship between income and health, little is known about how these vary between countries. Understanding these differences is essential for developing targeted policies to effectively address income-related inequalities in health and healthcare in each country. In this study, we examine income-related disparities of adults in the United States and South Korea, countries with the 2nd and 4th highest poverty rates among OECD member countries. We investigate a wide range of health and healthcare outcomes to investigate the existence and magnitude of inequalities by income in each country.

Methods: We used four data sources: the US Medical Expenditure Survey for 2010-2019, the US National Health and Nutrition Examination Survey for 2009-2018, the Korean Health Panel Study for 2010-2019, and the Korean National Health and Nutrition Examination Survey for 2010-2019. Our analysis focused on a nationally representative sample of adults, stratified by age groups: 18–64 years and 65 years and older. We selected outcome variables with comparable definitions and coverage for the two countries, including healthcare spending, healthcare utilization, access to care, self-reported health status, functional limitations, risk factors, and clinical outcomes. Our primary independent variables were annual household income (adjusted for inflation using the GDP deflator), an indicator of the individual's country of residence (United States or South Korea), and the interaction term between these variables. We conducted a linear regression model after accounting for these primary independent variables while adjusting for age, an age-squared term, sex, and an interaction term between age and sex, and year fixed effects. Our key variables of interest were annual household income and the interaction term.

Results: We found similar patterns of income-related health and healthcare inequality in the United States and South Korea: higher income is associated with lower healthcare spending and better health outcomes, including self-reported health status, functional limitations, and clinical outcomes. However, we also identified several differences in gradients and potential mechanisms between the two countries. The relationship between income and healthcare utilization differed. In South Korea, higher income is associated with lower unmet medical needs, higher rates of routine checkups, fewer inpatient admissions and outpatient visits, whereas the reverse association between income and utilization is seen in the United States. Furthermore, gradients were less evident for health behaviors such as smoking and obesity. The overall health gradient by income was relatively consistent across age groups.

Conclusion: Our findings highlight the critical role of income as a determinant of health and healthcare in both the United States and South Korea. While similar trends in healthcare spending and health outcomes were observed in both countries, differential patterns in other outcomes suggest that the underlying mechanisms driving this relationship may differ. This suggests that income-related health inequality is nuanced and varies considerably between the two countries, reflecting differences in healthcare systems, socioeconomic structures, and cultural factors.

abs-os133 Health Gradients and Intergenerational Transmission by SES: Evidence from China

PRESENTER: **Karen Eggleston**, Stanford University
AUTHORS: Carol Shiue, Wolfgang Keller

Background: That individuals of higher socioeconomic status (SES) enjoy better health has been well documented for many populations globally. However, little is known about the evolution of this health-SES gradient ("Preston Curve") prior to the 20th century, and the extent to which intergenerational transmission of health and status played a role in the reproduction of the gradient. To help fill this gap, we analyze unique genealogical data from central China spanning multiple generations from 1675 to 1775.

Methods: We analyze the association between health as measured by lifespan and household SES in absolute and relative terms (i.e., as percentiles of the period-specific lifespan and SES distributions), as well as intergenerational transmission with a standard rank-rank regression. We also study maternal mortality, estimated as maternal death within 12 months of the birth of a surviving son. Status is measured in four categories based primarily with the civil service exam rank of the male head of household, as well as 30 descriptors in the genealogical entries related to official position, occupation, investments, household structure, and other indicators of wealth and status.

Preliminary results: We find that top status men live about five years longer than men with low status. Exploiting our intergenerational setting, we present new evidence on the role of health for status by showing that long-living fathers tend to have rich sons, whereas sons of rich fathers do not live longer than sons of poorer fathers. Intergenerational status persistence is much higher than intergenerational lifespan persistence, but money cannot buy much health in this society. In contrast, a long lifespan enables men to rise in social status by participating in China's civil service examination and gaining official positions. We also show that child and maternal mortality are subject to a status gradient during the sample period.

Discussion: Studying 17th and 18th century China, we document the evolution of the health-status gradient across multiple generations. Based on rich genealogical data that includes clear markers of status defined by China's national civil service examination system, we find that compared to married men without any evidence of wealth or status, those who achieved the highest rank lived on average five years longer. This gradient in adult lifespan by status, although seemingly modest, was of comparable magnitude to several decades of survival improvement in industrializing England.

Leveraging the intergenerational linkages in our data, we find that lifespan persistence is a stronger predictor of the health-status gradient than status persistence across generations, despite the latter magnitude far surpassing the former. Wealth evidently could not buy significantly better health with any degree of certainty in this society. Rather, longer lives allowed time and opportunity to climb the social status hierarchy – in our setting, by enabling healthy men to pass successive levels of the civil service exam. Clan solidarity also meaningfully shaped economic outcomes including intergenerational transmission of status; but within-clan redistribution did not significantly reduce variability of lifespan.

abs-os130 The Wealth Mortality Gap in the US and Europe

PRESENTER: **Irene Papanicolas**, Brown School of Public Health
AUTHORS: Sara Machado, Ilias Kyriopoulos, E John Orav

Background:

Amid growing wealth disparity, we have little information on how older Americans' health compares to Europeans across the wealth distribution. This study examines the association between wealth and mortality in the US and Europe.

Methods:

This longitudinal retrospective cohort study includes adults aged 50-85 from the US Health and Retirement Study (HRS) and the European Survey on Health, Aging, and Retirement in Europe (SHARE), from 2010-2022. Wealth quartiles were defined by age group and country. Mortality rates and Kaplan-Meier curves were estimated per wealth quartile across the US and 16 countries in Continental, Southern and Eastern Europe. Cox proportional hazards models adjusted for baseline covariates (age, gender, marital status, education, rural area, smoking, and diagnosed chronic conditions).

Results:

Among 73,838 individuals, aged (mean) 65 (SD) 9.8, 13,802 (18.7%) died during 10-year median follow-up. Kaplan-Meier survival curves showed higher survival rates for all wealth quartiles in Continental Europe compared to the wealthiest US quartile (log rank test, p=0.000). The US had a wider survival gap between the top and bottom wealth quartiles compared to Europe. Across all participants in both surveys, the wealthiest quartiles had lower mortality (adjusted hazard ratio [aHR, 95% confidence interval] Q2: 0.84, 0.80-0.88; Q3: 0.71, 0.68-0.75; Q4: 0.64, 0.61-0.68) than the poorest quartile. Continental Europeans had higher survival rates, for all quartiles, when compared to HRS.

Conclusions:

This study highlights a wealth-mortality gap among older adults, which is more pronounced in the US than in Europe. Although wealthier Americans tend to live longer than poorer Americans, those in the highest wealth quartile in the US have worse survival rates than the poorest

in Continental Europe.

abs-os127 Trends in Heart Disease Among Americans by Socioeconomic Status

PRESENTER: **David Cutler**

Background: Heart disease is the leading cause of death in most rich countries. Several risk factors for heart disease are well known, including high blood pressure, high cholesterol, and diabetes. Further, there are pharmacological and behavioral treatments for each. Thus, many acute heart disease events are preventable. Yet trends in heart disease differ greatly by education. In the United States, since 2000, heart disease mortality has increased for people without a BA but has declined for people with a BA. These differential trends are a major contributor to differential changes in life expectancy by education. Understanding why these trends differ is thus a major research issue.

Methods: This paper will compare heart disease death rates and risk factor control in the US by socioeconomic status. The data will come from the National Health and Nutrition Examination Survey (NHANES). Socioeconomic status will be measured by education: a high school degree or less, some college education, and a BA or higher. The NHANES also measures blood pressure, and draws blood for analysis of cholesterol and diabetes.

The analysis will have two parts. First, I use risk prediction equations for the probability of death as a function of demographics and clinical factors (blood pressure, cholesterol, diabetes) to understand the differential trend in mortality for more and less educated Americans. The analysis considers how much of the differential trend in mortality rates is due to adverse risk factor trends, and which rick factor changes have been more adverse for less-educated Americans. The second part of the analysis seeks to understand why risk factor control has been less effective for less-educated Americans. I will divide trends into four explanations: (1) different levels of underlying risk (e.g., larger increases in obesity rates among less-educated Americans); (2) different rates of awareness of disease; (3) differential treatment trends conditional on awareness; and (4) differential rates of control among those treated. These results will indicate which types of interventions are most important in combatting the differential trend in heart disease mortality by education.

Results: According to preliminary results, the most important explanation appears to be that obesity rates have increase more among people with fewer years of education, and this raises the risk of adverse heart disease events. Treatment rates are roughly similar by education group and over time, so differential trends in control of risk factors are less important than differential trends in the underlying risk factors themselves. If these results hold up in further tests, this pattern would have major implications for how the US should confront differential mortality trends by education.

Conclusion: Given the importance of heart disease in explaining the differential mortality burden across population groups, it is essential to understand the differences in outcomes for groups with better and worse experiences. These data and this setting present an ideal opportunity to examine the growing gap in health by socioeconomic status.

Ind-931 Is Malawi's Health System Positioned to Achieve Universal Health Coverage Goals? An Assessment of Strategic Health Purchasing at Primary Health Care

PRESENTER: **Norah Mwase**
AUTHORS: Timange Banda, Madalitso Tolani, Tisha King, Moses Zuze, Shadrack Gikonyo, Boniface Mbuthia, Joyce Murerwa, Lizah Nyawira

Strategic Health Purchasing has potential to address health system inefficiencies and advance towards Universal Health Coverage. However, limited evidence exists on the progress made in strategic health purchasing in Malawi and how it can be enhanced. This study aims to assess the progress, gaps and opportunities in strategic health purchasing among major purchasers of health in Malawi to inform strategic purchasing reforms.

We utilized the Strategic Health Purchasing Progress Tracking Framework to collect data on key domains of purchasing such as benefit specification, provider contracting, payment and performance monitoring arrangements, governance and financial management through analyses of relevant documents and key informant interviews.

The findings revealed progress in: 1) Enabling policy frameworks that prioritize implementation of strategic purchasing reforms 2) Cost-effective benefit package accessible to all Malawians at no cost 3) Provider payment mechanisms include input-based payments, fee-for-service and global budgets 4) Selective contracting with some faith-based providers 5) Multiple performance monitoring arrangements like supportive supervision and information management systems exist. However, limitations persist including passive provider payment mechanisms, limited provider autonomy especially for primary health care facilities and rigid public financial management systems.

Addressing these gaps is critical in achieving universal health coverage. Drawing lessons from SLA to strengthen direct facility financing, prioritizing PFM reform to allow recognition of primary health facilities as cost centers and strengthening performance monitoring arrangements to allow integration of health information systems are essential.

Ind-1505 Understanding the Experience and Perceptions of Providers and Purchasers for Payment Methods in Tanzania.

PRESENTER: **John Joseph Maiba**, Ifakara Health Institute
AUTHORS: Peter Binyaruka, Timothy Powell-Jackson, Gemini Mtei, Sally Mtenga, Francis Donard Ngadaya, Josephine Borghi, Iddy Mayumana, Gemini Mtei

ABSTRACT.

Background: Many Low- and Middle-Income Countries (LMICs) are reforming health financing to achieve Universal Health Coverage. Given limited resources in most contexts, there is a recent move toward strategic purchasing of health services, requiring strategic decisions on purchasing services, including efficient provider payment methods (PPMs). PPMs could incentivize either intended or unintended provider behaviors and may affect efficiency, equity and quality of health service delivery. Tanzania plans to implement universal health insurance (UHI), but some design elements including PPMs are not yet decided. We studied the experiences and perceptions of providers and purchasers over existing PPMs in Tanzania, to inform the designing of optimal PPMs for UHI in Tanzania.

Methods: We conducted 35 in-depth interviews with healthcare workers from 21 primary healthcare facilities and four district-level health managers in two regions (Manyara and Singida). We also interviewed 6 purchasers from government and health insurance schemes. The interviews focused on two main payment methods in Tanzania, capitation and fee-for-service (FFS); by discussing the associated characteristics, including revenue contribution, predictability of payment amount, adequacy of payment rates, timeliness, accountability mechanisms, and autonomy in resource allocation. Transcribed interviews were analyzed thematically.

Results: Capitation for the Health Basket Fund (HBF) and FFS for the National Health Insurance Fund (NHIF) were seen as significant revenue contributors. In contrast, capitation for the Improved Community Health Fund (iCHF) and Social Health Insurance Benefits (SHIB) was seen as not contributing enough. FFS for NHIF is seen as more predictable, while capitation funds across various schemes were not, due to unclear adjustors, payment schedules and delays, and enrolment members. Both payment rates for all PPMs were perceived as inadequate to cover service costs, partly because of low rates or deductions. All PPMs reported delay in payment but with less delay for NHIF-FFS compared to capitation for HBF and iCHF. Spending autonomy is adequate, supported by direct facility financing and guidelines, though some face hurdles. Reporting requirements for all PPMs are seen as adequate. Finally, FFS was preferred for motivation, while capitation was valued for its reliability in some cases. Insights from health managers and purchasers are pending analysis.

Conclusion: The experiences of healthcare providers and purchasers highlight key insights for designing a PPM for UHI in Tanzania. For effective PPM, the design and implementation should embrace transparency of payment adjustors, timely disbursements, increasing autonomy in fund allocation, aligning payment rates with service costs, and simplifying administrative processes.

Ind-711 Innovation Procurement in the Strategic Purchasing Function of the Universal Coverage Scheme: A Case Study from the Thai Innovation List

PRESENTER: **Arpaporn Sutipatanasomboon**
AUTHORS: Siriyada Kitbamrung, Teerawat Wiwatpanit, Yi Wang, Yot Teerawattananon

Aim

To conceptualize how innovation procurement integrates into the strategic purchasing function of Thailand's Universal Coverage Scheme (UCS).

Background

Launched in 2002, UCS is Thailand's largest public health insurance scheme, covering over 70% of the population. The scheme is financed by an annual central budget and managed by The National Health Security Office (NHSO); an autonomous public agency overseen by the multi-stakeholder National Health Security Board (NHSB). Healthcare services are provided by contracted providers who independently procure medical products and receive reimbursement based on capitation, Diagnostic Related Group rate, and fee schedule for high-cost interventions. The NHSO also leverages its position by negotiating the price of medical products, procuring and distributing them to providers.

In 2015, the government introduced the Thai Innovation List (IL), an initiative to stimulate domestic research and development (R&D) investment. Organizations or individuals can register their innovative products and services developed or improved in Thailand in exchange for price disclosure. The initiative enables government agencies to purchase IL-listed products even if they are not the most competitive options available and mandates them to allocate at least 30% of their annual procurement budget to IL-listed products. This mandate affects most UCS healthcare providers, as most of them are government health centers and district hospitals.

Methods

This study analyzes the consequence of the IL initiative on UCS's strategic purchasing function, focusing on changes made to accommodate the initiative.

We are reviewing minutes from the Working Group for Health Economics (WGHE), the Subcommittee for the Development of Benefits Package and Service Delivery (BPSD Subcomittee), and the NHSB meetings from 2015 to 2023. The WGHE conducts economic evaluations of new products or services nominated for inclusion into the benefit package, forming the basis for BPSD's recommendations to the NHSB, which makes the final decisions, including the financing of existing and new benefits.

Additionally, we will conduct a landscape analysis of technologies relevant to the IL-registered products using patent documents, intellectual property and medical product registration records, and literature related to developers indicated in the IL registration.

Results and Expected Outcomes

In 2016, the NHSB adopted the initiative as one of the tactics to ensure financial efficiency. The goal was to allocate at least 30% of their centrally procured medical products to IL-listed items, with a proposal to increase the allocation to 50-100% for locally manufactured high-cost interventions. By the end of 2023, a handful of interventions with IL-listed products have received IL-tailored preferential treatments, including colostomy bags and customized 3-Dimensional-Printed titanium cranial implants.

Further analysis will identify key factors influencing decision-making and illustrate the technological positioning of the IL-registered products in Thailand. Overall, our work will provide insights into innovation procurement within UCS's strategic purchasing framework, highlighting challenges and opportunities to optimize the use of strategic purchasing in a public health insurance scheme to stimulate domestic R&D productivity in an upper-middle income setting.

Ind-450 Understanding Health Providers' Decision-making and Behavioural Responses to Case-based Payment Reform in China

PRESENTER: **Xiaoying Zhu**
AUTHORS: Daniel Strachan, Tiara Marthias, Ajay Singh Mahal, Shenglan Tang, Barbara McPake

Abstract

Background: To address rapidly increasing healthcare expenditures of social health insurance, the Chinese government has recently introduced provider payment reform, transitioning from a fee-for-service model to a case-based payment system. The case-based payment method transfers the risks associated with healthcare expenditures from the payer to the provider incentivising them for cost control. While existing studies have provided statistical evidence for some changes in healthcare practices following the payment method reforms, evidence for how providers understand the reforms and respond to them in their decision-making processes remains limited.

Objective: Our study aims to investigate how hospital-based physicians have responded to case-based payment system reform in China and examine how this influences factors considered in clinical decision-making.

Methods: Qualitative in-depth interviews with physicians were conducted in Nanjing, China in 2024. 22 physicians working in hospital inpatient departments were purposively sampled for interview while ensuring representation across different medical specialties and career stages. Thematic analysis was conducted on the verbatim transcriptions of digital recordings of face-to-face, semi-structured interviews with the informed consent of participants.

Results: We find that physicians simultaneously serve as agents for health insurance, hospitals and patients, with their service delivery decisions shaped by awareness of the principals that underpin these priorities. Under the case-based payment methods, participants identified priorities of the health insurance authority as cost control, efficiency, and standardised clinical practice, the hospital's priorities as revenue generation and institutional reputation, and patients' priorities as care accessibility, financial burden reduction, and outcome optimisation. We

identified five tensions across these agency relationships: clinical quality versus cost containment; professional autonomy versus regulatory constraints; policy compliance versus patient preferences; immediate benefits versus future sustainability; and information asymmetry across physicians, health insurers and patients and relatedly, physician's perceived pressure to bridge gaps in policy awareness. These tensions have brought out stress reported by physicians attributed to concerns for vulnerable patients, potential for strained patient relationships, and perceptions of needing to expand their role and skillsets from physician to accountant.

In their clinical decision making, physicians balance the priorities of all three agency roles while considering the cost-benefits trade off when managing the above tensions. They choose the levels of health service based on assessments of patient benefits relative to hospital profit. Insufficient services might be provided if their perceived patient benefits are relatively lower. Notably, when hospitals implement direct insurance payment-related income incentives, physicians show strong awareness of hospital profit considerations, leading to unintended behaviours such as treatment delays for secondary health issues, selective patient admission, unbundled medical procedures and strategic coding practices. However, mediating factors such as physician's own interests, ethical considerations, risk aversion, professional values, and the design of monitoring schemes, influence how these impacts play out.

Conclusions: Our study contributes to understanding of how hospital-based physicians in China respond to case-based payment reform and to broader theoretical application of agency theory. While standard agency theory often simplifies physician's motivation, our findings reveal physicians are bound by professional ethics and multiple agency relationships, suggesting policymakers should look beyond simple economic incentives.

Ind-1905 Improving Access and Financing Efficiency to Maternal and Neonatal Health Services through Strategic Health Purchasing

PRESENTER: **Ririn Ariani Dewi**

AUTHORS: Rizki Tsalatshita Khair Mahardya, Muhammad Akmal Farouqi, Kefas Christiawan, Hasbullah Thabrany, Astara Lubis, Iko Safika, Firdaus Hafidz, Amalia Zulfah Wijaya, Anastasia Susanto

Background: Indonesia continues to face challenges in reducing maternal mortality rate. In 2020, the MMR reached 189 per 100,000 live births. The problem identified is related to the low coverage of complete six times antenatal visits and unnecessary referral from Primary Health Care (PHC) to the hospital. The Strategic Health Purchasing (SHP) concept strengthens Maternal Neonatal Health (MNH) services to incentivize providers to increase access to MNH services and influence providers' performance at the PHC level. USAID Health Financing Activity (HFA) provided supporting technical assistance to the Ministry of Health (MOH) and The National Health Insurance Agency (BPJSK) to implement a pilot of SHP MNH to improve access, quality, and financing efficiency between October 2022 and October 2023 across 12 public and 28 private PHCs in two districts in Indonesia. This study aims to evaluate the impact of SHP MNH on access, quality, and efficiency of MNH services at the PHC level. **Methodology:** This study employed a mixed-method approach to assess providers' behavior in providing ANC services, the number of service claims, and financing efficiency by shifting services from the hospital to the PHC level. Data were obtained from the BPJSK Serang branch, National Health Insurance data, and health facilities survey. Qualitative data were collected through focus group discussions (FGDs) with health facilities and key stakeholders. Data analysis used descriptive statistics, chi-square test, and difference-in-difference to measure access to services, data envelopment analysis (DEA) to measure efficiency, and thematic analysis for qualitative data. **Key Results:** The SHP MNH pilot indicates a positive impact on the behavior of PHCs in the intervention group, leading to a higher number of PHCs submitting claims for ANC services from 13 to 23 out of 40 PHCs in the intervention group, which was statistically significantly different compared to the control groups ($p \leq 0.005$). Intervention PHCs experienced a substantial increase in claims, producing 436 more ANC service claims than the control group ($p \leq 0.01$). The average claim cost for ANC services in the intervention period was Rp156,510 (Indonesian Rupiah)/service, a decrease of 20% from Rp194,827 (Indonesian Rupiah)/service in the baseline period, indicating efficiency. An increased utilization of ANC services at intervention PHCs by 121% was observed. DEA analysis also showed the relatively high efficiency of ANC services after intervention. Lastly, FGDs revealed that the SHP MNH increased motivation among intervention health facilities to submit claims and improved cross-sectoral coordination. **Conclusion:** The MNH SHP intervention resulted in providers' motivation and performance, indicating better access to essential services for mothers and reduced the average claims per service, indicating efficiency. SHP MNH highlighted the financial and non-financial components that influenced the program outcomes. Non-financial aspects of the intervention, like strong coordination between stakeholders, capacity building, and routine monitoring of PHCs, were crucial for improving access and quality of MNH services. **Keywords:** Strategic health purchasing, maternal and neonatal health, primary health facilities **Field:** Health Financing and Expenditures

Ind-1354 How Health Financing Affects Maternal Delivery Decisions: Case of C-section Rates in SSIP in Punjab, Pakistan

PRESENTER: **Zahid Ali Memon**, The Aga Khan University

AUTHORS: Ahsana Nazish, Ali Razaque, Tooba Khan, Iqbal Azam, Sameen siddiqi, sabin Nasir, Rahema Hasan, asim Muhammad, Dr Shabana Haider, Zafar Ahmed

Background: The Sehat Sahulat Insurance Program (SSIP) was launched in Punjab, Pakistan in 2016 to improve access to healthcare and provide financial protection for low-income families. Globally, C-section rates are rising, projected to reach 30% by 2030, with significant increases in developing regions. In Pakistan, C-section rates rose from 14% in 2012-13 to 22% in 2017-18, with higher rates among educated, urban, and wealthy women. Similar trends have been reported internationally after introducing the national insurance programs. **Study Rationale:** While the global and national trends are well documented, few studies have explored the impact of health financing on C-section rates through the lens of incentive structures and reimbursement rates. This study fills this gap by analyzing C-section rates across different phases of the SSIP implementation and its association with financial incentives, provider types, patient characteristics, and policy shifts. **Research Question:** To what extent have financial incentives within SSIP influenced institutional deliveries and C-section rates across its rollout phases in Punjab, and how do stakeholders perceive their role in delivery decisions? **Methods:** This mixed-method study included desk review, secondary data analysis, and qualitative interviews. Program documents and reports were reviewed to assess the evolution of SSIP policies and financial mechanisms. Secondary data included 993,380 deliveries recorded between October 2016 and August 2024; after excluding records with incomplete information and out-of-province deliveries, 978,004 were analyzed. Additionally, qualitative interviews with women, family members, healthcare providers, and insurance personnel provide insights into factors influencing maternal delivery decisions. Data triangulation provides a comprehensive view of delivery patterns and decision-making processes. **Results:** The desk review revealed the evolution of SSIP from limited district coverage in Phase I (2016-2018) to universal access in Phase III (2022-2024), with maternal services being an integral component. A fee-for-service reimbursement model was used, with higher tariffs for C-sections compared to normal deliveries, particularly in private hospitals. This disparity may have incentivized providers to favor C-sections. Preliminary analysis of secondary data reveals a consistently high C-section rate of 75.73% (95% CI: 75.65%, 75.82%) across Punjab. C-section rates varied significantly across program phases, lowest in Phase I (71.58%,n=12,341) and highest in Phase II (78.14% ,n=47,614). The majority of the women delivered (93.87%) during Phase III. Private hospitals reported a notably higher C-section rate (80.88%) as compared to public hospitals (66.18%). Regional variations were evident, with Rawalpindi division recording the lowest rate (61.51%) and Sahiwal division the highest (85.48%). 90% of deliveries were conducted under the Federal SSIP Phase III project. The findings suggest that financial incentives, reflected in tariff structures, will likely influence delivery mode decisions under SSIP. **Conclusion and Implications:** This study highlights the potential role of financial incentives, including tariff disparities, in shaping delivery mode decisions under SSIP. Ongoing qualitative research will provide deeper insights into contextual and systemic factors. Evidence-based reforms targeting reimbursement models and provider incentives could mitigate unnecessary C-sections, improving maternal outcomes and guiding future health financing strategies.

Ind-1470 The Catch-Up of Fertility After Family Planning Services: Evidence from Malawi

PRESENTER: **Dan Maggio**
AUTHORS: David Canning, Tanya Rajan, Mahesh Karra

Significance/Background Roughly 14 million unintended pregnancies occur in Sub-Saharan Africa each year. Improving access to family planning may promote contraceptive use after childbirth and reduce the likelihood of closely spaced births; however, little is known about fertility dynamics after these programs end. On one hand, if couples are unable to match their realized and idealized preferences for birth parity, we may expect to see persistent reductions in fertility following program cessation. On the other, if couples primarily exhibit a preference for healthy inter-pregnancy intervals, we may expect to observe catch up. **Research Question** We assess the causal impact of improved access to family planning three years after program cessation using experimental evidence from a randomized controlled trial in urban Malawi. We primarily study the impacts of the intervention on medium-term fertility, while also revisiting short term positive findings on contraceptive use, children's health, and household labor force outcomes. **Methods** We present evidence from a field experiment conducted in Lilongwe, Malawi between November 2016 and February 2019. 2,143 women, who were either pregnant or postpartum at baseline, were randomly assigned to receive a comprehensive family planning package that included home-based counseling, transport to a high-quality family planning clinic, and free family planning services. This paper presents results from a five-year follow-up survey conducted between November 2021 and May 2022, roughly 2.5-3 years following the end of the program. We present the effects of the intervention among 1,499 women who were re-interviewed during our follow-up survey on fertility, contraceptive use, and employment outcomes. We also present follow-up evidence on growth patterns and cognition for a subset of children who are re-interviewed. **Key Findings** Although short-term results suggested that women were less likely to have a subsequent pregnancy during the trial, our medium-term follow-up provides evidence of substantial catch-up after the end of the program. We also do not find evidence of higher contraceptive use among treatment women, and there is evidence that women substitute away from implants toward injectable contraceptives – this contrasts with short-term findings where women substituted *toward* implants. As may be expected given the growing literature on fadeout in child health effects, we do not find evidence that the short-term effects observed on children's development were sustained in the medium term. Additionally, as one may expect as fertility among treatment women catches up to their counterparts, we also see fade-out of the employment effects observed in the short-term. **Knowledge Contribution** Although a growing literature has shown that family planning services are effective at improving contraceptive and fertility concordance, there is little evidence that tracks fertility and contraceptive dynamics after programs end. Our results suggest that the effects of one program implemented in Urban Malawi faded away after three years. More broadly, these results suggest two things. First, that couples in Malawi exhibit a preference for control over birth spacing rather than birth parity. Second, perhaps the information treatments included in the intervention did not drive the short-term results.

Ind-2082 Barriers to Access and Utilization of Maternal and Neonatal Health Commodities in Zambia: An Analysis of Supply Chain and Demand Challenges

PRESENTER: **Zeddy Chansa**
AUTHORS: Ibrahim Abdallah, Rabson Zimba, Nelia Banda, Maxwell Kasonde, Kalizya Sinyangwe

BACKGROUND: Maternal and neonatal health outcomes in Zambia remain critically poor, with maternal mortality at 252 deaths per 100,000 live births and neonatal mortality at 27 per 1,000 live births—well above global averages [(ZDHS, 2018; World Bank, 2020; UNICEF, 2021)]. Systemic inefficiencies in supply chains and sociocultural barriers exacerbate these challenges. Stock-out rates for life-saving drugs such as

oxytocin and magnesium sulphate range between 30%-50%, driven by procurement delays averaging 4-6 months and logistical inconsistencies [(WHO Zambia Report, 2022)]. These shortages hinder timely interventions for postpartum haemorrhage and preeclampsia, leading to preventable complications. On the demand side, institutional delivery rates are low at 63%, with 45% of women lacking adequate health literacy and 30% avoiding healthcare due to cultural beliefs and misconceptions about institutional care [(Zambia Gender and Health Study, 2019)]. Traditional preferences for home births and limited awareness of medical interventions further compound mortality risks, underscoring the urgent need to address both systemic supply inefficiencies and sociocultural challenges [(ZDHS, 2018; WHO Zambia Report, 2022)]. **RESEARCH AIM** This study seeks to identify and evaluate supply chain inefficiencies and demand-side barriers to accessing maternal and neonatal health commodities in Zambia, providing actionable solutions to improve health outcomes. **METHODS** A mixed-methods approach was employed over nine months, from January to September in 2024. Quantitative data was collected from the electronic Logistics Management Information System (e-LMIS) and Quantification Analytics Tool (QAT), analysing forecasting accuracy, procurement lead times, stock availability, utilization rates, and reporting compliance. Qualitative interviews explored cultural and institutional barriers, focusing on community-level health literacy and traditional practices **RESULTS** Central-level supply chains exhibited forecasting deviations averaging 15%, driven by insufficient historical data and weak demand signals. Procurement lead times, averaging 3.5 months, resulted in stockouts in 18% of cases, affecting oxytocin and antibiotics availability. Maternal health commodities were available in 78% of facilities, but neonatal supplies were unavailable in 34%, increasing mortality risks from postpartum haemorrhage and neonatal infections. Facility-level utilization rates showed better performance for maternal (85%) compared to neonatal supplies (65%), attributed to underuse of equipment like kangaroo care wraps. Cultural resistance and fragmented data systems further compounded these issues. Entrenched beliefs and low health literacy limited the service uptake, with only an 8% increase in nine months, despite interventions. Poor inventory management and misaligned stock levels also hindered equitable access. **CONCLUSIONS AND IMPLICATIONS ON POLICY** Improving maternal and neonatal health in Zambia requires targeted reforms. Central-level actions should enhance forecasting accuracy, streamline procurement processes, and integrate data systems. Facility-level efforts must focus on real-time reporting, demand-responsive supply chains, and equitable stock distribution. Concurrently, community engagement initiatives should address sociocultural barriers and promote health literacy. Together, these strategies can mitigate preventable deaths and provide a replicable model for similar contexts.

Ind-2100 Determinants of Inpatient Care in Hospitals and Adverse Selection in Service Delivery

PRESENTER: **Dedy Revelino Siregar**
AUTHORS: Khaterina Manurung, Wan Aisyiah Baros, Donni Hendrawan, Mahlil Ruby

Backgrounds: Indonesia established the National Health Insurance (NHI) program, operated by Badan Penyelenggara Jaminan Sosial Kesehatan (BPJS-K), in 2014. Since then, the program has significantly developed in terms of enrollees and public health services. A major issue is the growing number of inactive enrollees—those who fail to pay premiums regularly. This percentage increased from 9% in 2019 to 19% in 2022 and has remained above 19% in 2024, indicating a serious problem with payment compliance. One key issue is the behavior of informal participants, who often become active due to illness or childbirth but then default on their contributions once they recover. Therefore, it is important to explore the behavior of informal participants through data analysis to better understand how many are active, giving birth, in arrears on contributions, and to assess the delivery costs and the duration for which participants remain active in paying their contributions. Methods: A cross-sectional method was used with quantitative data on the delivery rates of participants at hospitals over a period of 29 months (2022–2024), covering a total of 6,612,282 participants. The analysis employed descriptive statistics and logistic regression. Independent variables assessed included age group, type of delivery, membership segment, member status, and discharge status. The dependent variable in this study was participant payment compliance, specifically whether it was active or not active in the National Health Insurance program. Results: Logistic regression analysis was employed to assess the odds ratio of participants with a history of delivery, comparing active versus non-active participants in the National Health Insurance program. The statistical results show significant odds ratios for the following variables: discharge status (OR 17; $p = 0.07$), age group (OR 10; $p = 0.00$), member status (OR 11; $p = 0.09$), membership segment (OR 9.4; $p = 0.00$) and type of delivery (OR 8,7; $p=0.00$). The proportion of participants who had deliveries and paid contributions both before and after the service was 79% of the total participants, while those who did not pay contributions regularly before and after the service comprised 21% of the total participants. In summary, 29% of participant deliveries were from contributory assistance participants from the central government, while 24% came from participants in the formal sector. Conclusions: Non-compliance among participants who do not pay contributions regularly, primarily from the informal sector, accounts for 63% of participants with inactive payment status. This issue of non-compliance is common across countries where such delivery services are provided. Therefore, it is essential to establish regulations and policies regarding waiting periods and minimum payment periods following delivery. Keywords: Delivery Services, Adverse Selection, National Health Insurance.

Ind-2826 Decomposing Rural-urban Differences in Prenatal Care Initiation in Taiwan

PRESENTER: **Ching-Ching Claire Lin**
AUTHOR: Tung-Hsien Wu

Objective: Timely prenatal care, identifying risks and reducing potential pregnancy complications, is a critical intervention to address rising maternal death. WHO suggests women to initiate prenatal care at or before 14th week of pregnancy. Achieving this goal, however, could be challenging for rural residents, as they tend to be with higher likelihood of smoking and alcohol use, and with scarce healthcare resources and lower obstetrician-gynecologist supply. Yet the rural-urban differences in initiation of prenatal care as well as causes of such differences are not well understood. This study aims to understand rural-urban differences in delayed initiation of prenatal care, as well as the extent to which these differences are explained by socio-demographics, behavioral risk, and OB-GYN availability. **Methods:** We analyzed Taiwan National Health Insurance Database linked to birth registries to investigate rural-urban differences in late initiation of prenatal care among all women beneficiaries with single delivery hospitalization in 2019. Residing counties were classified as urban or rural based on urbanization index validated by prior studies, a weighted index of the population density, educational levels, population ratio of elder people (65+) and agriculture workers, and the total number of physicians. Delayed prenatal care was defined as “a woman had not had the first prenatal visit” at the following different timepoints (yes/no): (1) during the first trimester (12th, 14th week) of pregnancy; (2) before or during the second trimester (28th, 30th week). We first compared timing of first prenatal care visit between rural and urban women, controlling for socio-demographic

characteristics (age, family income, immigrant status), behavioral risk (smoking or alcohol use during pregnancy), comorbidities, and availability of obstetrician-gynecologist at county-level. We used Blinder-Oaxaca decomposition to assess the extent to which rural-urban differences in late initiation of prenatal care are explained by socio-demographics, behavioral risk, and county-level obstetrician-gynecologist availability. **Results:** For all 130,730 women with single delivery hospitalization in 2019, women in rural areas are associated with lower likelihood of missing their first prenatal visit at 12th week (Rural vs urban 28.39% vs 30.01%, $p<0.001$) and 14th weeks (Rural vs urban 17.82% vs 19.13%, $p<0.001$), but with higher likelihood of still missing prenatal care at 28th week (Rural vs urban 1.90% vs 1.70%, $p<0.023$) and 30th weeks (Rural vs urban 1.44% vs 1.27%, $p<0.033$). Decomposition analysis showed that, only 43% of the rural-urban differences in missing first prenatal visit during the first trimester was explained by the measured variables, but the entire rural-urban differences in 28- and 30-week outcomes were explained by measured variables. For all four outcomes, proportion explained by socio-demographics and behavior characteristics were greater than proportion explained by availability of OB-GYN. **Conclusions:** A greater proportion of rural women had not had their first prenatal visit during the third trimester, compared to those in urban areas. Furthermore, differences in rural-urban socio-demographics explained more differences in late initiation of prenatal care than availability of OB-GYN did. While addressing maternal workforce issues is critical, more policy efforts should target on different socio-economics disadvantageous groups.

Ind-619 Inequity in Child Mental Healthcare Use

PRESENTER: **Trong-Anh Trinh**
AUTHORS: Nicole Black, David Johnston

Background: Worldwide, many children with mental health issues do not receive adequate treatment. A core objective of most health systems with universal coverage is equitable access to needed medical care, regardless of ability to pay. While access to general practitioners has been found to be largely based on need, there is a concerning tendency for pro-rich inequities in access to more specialised services. Such inequities are especially concerning when they affect children and adolescents with mental health disorders. However, we know little about the extent of inequity in children's mental healthcare. **Objectives:** We aim to investigate the importance of household income in determining whether Australian children with poor mental health receive mental healthcare. **Methods**: We use a longitudinal dataset of Australian children aged 10-17 years, that uniquely measures both mental health need (parent and child reports and GP records) and mental health care use (through linked health care records). Conditioning on mental health need, local area fixed effects and child and parental characteristics, we employ between- and within-child analyses to estimate the income inequity in mental health care use. **Results**: We find no evidence of an income gradient in accessing GP mental health services. However, conditional on receiving a GP mental health treatment plan, children from low-income families are significantly less likely to see a psychologist, particularly a clinical psychologist, and less likely to receive prescription medication for emotional disorders within 3 months compared with children from higher income households. The findings are consistent across different measures of low income and treatment time windows. We show that differences in out-of-pocket fees are a likely explanation. **Discussion**: Psychologist services can have high out-of-pocket costs, even when subsidised by public health insurance. Our findings highlight that specific support to low-income families is needed to reduce inequities in accessing a complete range of mental health services.

Ind-822 An Evaluation of Demand for Child Health Care in Four Selected West African Countries: Nigeria, Ghana, Gambia and Liberia

PRESENTER: **Rifkatu Nghargbu**, National Institute for Legislative and Democratic Studies, National Assembly, Abuja
AUTHORS: Hauwa Victoria Ibrahim, Doreen Anyamesem Odame

1. **Background** West Africa is one of the regions with the highest number of births in Africa with about 95 million under-five children, this constitutes 14% of under-five population globally (UNICEF, 2023). However, child survival in these regions is one of the lowest compared to other parts of Africa with mortality ratio of 91.5 deaths per 1,000 live births (UNICEF, 2024). One of the leading causes of deaths are fever from malaria and other childhood illnesses which accounts for under-five mortality recorded every minute in Africa (WHO, 2022). Other life threatening illnesses in children include diarrhea, measles and Acute Respiratory Infections (ARI). Despite this, health seeking behavior of mothers seems to be relatively poor and varies across countries in West Africa. The Demographic and Health Survey (DHS) reports shows that children for whom advice or treatment was sought with fever were 60% in Nigeria, 64% in Gambia, 66% in Ghana and 81% in Liberia, respectively. This implies that there are varying factors that are accounting for the differentials across the four West African countries. The objective of this study is to evaluate demand for child health care and examine factors that are accounting for the differentials in child health care seeking behavior in the four selected West African countries. Although, prior studies have provided some evidences on child health care seeking behavior globally, in low-income countries, middle-income countries and sub-Saharan Africa (Mbagaya et al, 2005; Benova et al 2008; Amin et al 2010; Bennett et al 2015; Adedokun and Yaya, 2020; Yaya et al, 2021 and Tebeje et al 2024), there is a study gap for West Africa particularly factors accounting for differentials in the four selected countries. This study seeks to fill this gap. **Methods** The study is theoretically founded on demand model and Andersen health care services utilization behavior model. Data was derived from DHS for the four selected countries particularly the 2018, 2019, 2022 and 2023 waves of the DHS. The demand model for child health care was estimated using the logit regression. **Results** Results shows that socioeconomic factors of mother such as wealth, employment status, residence, education, region and distance to health facilities are common factors that accounts for differences in child health care seeking behavior patterns across the countries which affects demand for child health care as well. **Conclusion** The demand for child healthcare can be improved through conscious efforts in improving the socioeconomic status of the mother. **Keywords**: Child, Healthcare, Demand, Seeking behavior, Logit Regression, West Africa

Ind-492 Primary Care as Substitute or Complement: Evaluating its Impact on Hospital Hierarchies in China

PRESENTER: **Jia Tang**
AUTHORS: Rize Jing, Song Yueping, Chenxu Ni

This study investigates the substitution and complementary effects between outpatient and inpatient services across China's tiered healthcare

system. Leveraging an extensive dataset comprising over 1.5 million patients covering 2013–2019, we provide a nuanced understanding of how primary care utilization impacts higher-tier healthcare services. Employing fixed-effects regression models to account for regional and temporal variations, our analysis offers novel insights into the dynamics of healthcare service utilization. Our findings reveal significant substitution effects, demonstrating that increased primary care utilization reduces reliance on secondary and tertiary hospital services. Specifically, each additional primary care visit decreases the likelihood of secondary hospital visits by 12.7% and tertiary visits by 13.4%, illustrating the pivotal role of primary care in alleviating pressure on higher-level healthcare facilities. This substitution effect is more pronounced for outpatient services, indicating that enhanced primary care effectively absorbs demand traditionally managed at higher-tier hospitals. Such findings highlight the strategic importance of strengthening primary care to optimize resource allocation and reduce healthcare costs, aligning with global trends in health system reforms. Additionally, we identify a complementary relationship between outpatient and inpatient services within the same care level, driven by induced hospitalization. Our data show that each outpatient visit at secondary hospitals increases the likelihood of inpatient admissions at the same facility by 8.9%, reflecting financial incentives in China's healthcare system that encourage unnecessary hospitalizations. This dynamic underscores systemic inefficiencies and calls for policy interventions to mitigate induced demand. Addressing these challenges is crucial for ensuring that primary care functions as a gatekeeper, preventing unnecessary hospital admissions while maintaining quality care. The study also highlights the homogeneity of outpatient services across different hospital levels, which facilitates substitution between these services. Patients increasingly perceive primary and secondary outpatient services as viable alternatives to tertiary care, supporting the efficacy of tiered healthcare reforms. However, disparities in service quality and capacity remain barriers to fully realizing the potential of primary care as a substitute, particularly in rural and under-resourced areas. Policymakers must prioritize investments in primary care infrastructure and workforce development to address these gaps. This research contributes significantly to the literature by offering the first large-scale empirical analysis of healthcare service substitution and complementarity in a developing country context. It provides actionable insights for policymakers seeking to enhance healthcare efficiency through targeted reforms. Our findings advocate for the recalibration of financial incentives to discourage induced hospitalization and promote equitable access to primary care, ensuring that patients receive the appropriate level of care. As China continues to implement its hierarchical medical system, this study serves as a critical resource for designing policies that optimize healthcare delivery and improve patient outcomes. **Key words:** Substitution effects; Complementarity; Tiered healthcare system; Induced hospitalization; Outpatient care; Inpatient care; Healthcare policy; China's healthcare

Ind-1702 Social Learning and Hospital Choice

PRESENTER: **Wenhui Xu**, Shanghai Jiao Tong University
AUTHORS: Cheng Huang, Li Li

Patient mobility is common in countries with unequal regional distribution of medical resources, and it plays a crucial role in ensuring equitable access to care. However, this phenomenon remains understudied. Using unique administrative data, this paper studies the behavior of patients traveling to Shanghai for medical services and investigates the characteristics of its healthcare market. We focus on how social learning influences patients' hospital choices and shapes market structure. Access to reliable information is vital when selecting healthcare providers, particularly in the absence of hospital review platforms and when providers are far from patients' residences. In such cases, social learning becomes a key factor in decision-making. Through estimates derived from discrete choice models, we find that patients' hospital choices are significantly affected by social learning, where neighbors' decisions influence individuals' perceived payoffs. The strength of this effect varies with the demographic similarities between individuals, and the size of the social network has a negligible impact in our sample. Additionally, we highlight Shanghai as a destination with a concentrated healthcare market and explore the relationship between social learning and this market concentration. Our findings provide novel evidence of social learning in the context of patient mobility, shedding light on its role in perpetuating high market concentration in China's hospital sector.

abs-os54 Health Service Costs and Productivity Losses of Australian Children and Adolescents with Attention-Deficit/Hyperactivity Disorder Clinical Symptoms

PRESENTER: **Ha N.D Le**, Deakin University
AUTHORS: Ms. Lisa Gold, David Coghill, Harriet Hiscock

Background: Attention-deficit/hyperactivity disorder (ADHD) is the most common neurodevelopmental disorder. While much is known about the functional and academic impacts of ADHD, the economic impact of ADHD is less well-documented.

Aims: To explore, in children aged 4-19 years, associations between clinically significant ADHD symptoms and (1) government healthcare costs and (2) productivity losses; and (3) factors influencing these costs.

Methods: Data were drawn from the Longitudinal Study of Australian Children (LSAC). Clinically significant ADHD symptoms (e.g. score > 8) were measured using the hyperactivity scale from the Strengths and Difficulties Questionnaire, collected at each time point from 4-17 years. Medicare data (medical and pharmaceutical services) were used to estimate two-year government healthcare costs from 4-19 years. Child school absenteeism was used to estimate caregiver's productivity losses. Multivariable linear models and linear mixed models were used to analyse the associations between healthcare/productivity losses and ADHD symptoms from 4-19 years, adjusting for child and family factors.

Results: Compared to those with no ADHD symptoms, children with ADHD symptoms incurred higher government healthcare costs (mean difference $162, 95% confidence interval $17 to $308 over two-year period) but not productivity losses. Older children, children of Torres Strait Islander origin, or living in outer regional/remote areas were associated with lower government healthcare costs while having internalising/externalising symptoms, autism or other medical conditions or from both Aboriginal and Torres Strait Islander origins were associated with higher healthcare costs. Child age, socioeconomic position, internalising and externalising problems were associated with higher productivity losses while children from two-parent families or English as a second language or from both Aboriginal and Torres Strait Islander origins were associated with lower productivity losses.

Conclusion: ADHD clinical symptoms are associated with higher government healthcare costs. Children living in rural/remote areas may be missing out on clinical care. Children from both Aboriginal and Torres Strait Islander origins had higher healthcare costs and lower productivity losses. Children with externalising or internalising problems had higher healthcare and productivity costs. Targeting supports to at-risk groups

such as children living in remote areas or those with co-morbid health problems, or those from Aboriginal and Torres Strait Islander could improve their health and may lead to positive long-term social, educational and economic outcomes.

Economic Burden of Chronic Illness

MODERATOR: **Emmanuel Fulgence Drabo**,

Ind-1482 Health-Related Quality of Life and Productivity Losses Across Cancer Stages: A Prospective Cohort Study to Inform Economic Evaluations in Singapore

PRESENTER: **Sara Tasnim**
AUTHORS: Kennedy Ng, Akshar Saxena, Joanne Ngeow

Background: Cancer imposes substantial economic burden through direct medical costs and indirect costs such as productivity losses. While direct medical costs are well documented, data on productivity losses and health-related quality of life (HRQoL) specific to Singapore's context remain limited. Although studies from the United States and Europe have estimated cancer-related productivity losses and HRQoL impacts, these findings may not translate to Singapore due to differences in cultural values, living standards, labor market conditions, work demands, and retirement age. This contextual variation necessitates local investigation of cancer-related productivity losses and HRQoL. The current knowledge gap hinders accurate economic evaluations from a societal perspective, as Singapore-specific utility values and productivity loss estimates are crucial for informing healthcare resource allocation decisions. This study addresses this gap by providing context-specific data essential for comprehensive economic evaluations of cancer care interventions in Singapore.

Aim: To quantify the impact of cancer on HRQoL and productivity losses across different cancer stages among breast and colorectal cancer patients in Singapore.

Methods: We are conducting a prospective longitudinal cohort study at the National Cancer Centre Singapore. Adult patients (≥21 years) with breast or colorectal cancer who understand English are recruited during their clinical appointments. Data collection occurs at baseline, 3, and 6 months using validated instruments: the EQ-5D-5L for HRQoL and the Work Productivity and Activity Impairment questionnaire (WPAI) for productivity losses. Sociodemographic and clinical characteristics are collected via structured questionnaires. The target sample size is 775 participants per cancer type to ensure sufficient representation across all stages (I-IV) and survivors.

Preliminary Results: Current enrollment includes 307 breast and 166 colorectal cancer patients. Among breast cancer patients, mean EQ-5D-5L index scores show a declining trend with advancing stages (Stage I: 0.881; Stage II: 0.790; Stage III: 0.775; Stage IV: 0.739). Patients undergoing treatment report lower HRQoL (0.774) compared to survivors (0.800). Post-diagnosis, 70.92% took time off work, with 32.37% opting for early retirement. Work productivity loss was substantial during treatment, particularly in Stage II (72.1%) and Stage III (77.4%) patients. Employment status changed significantly post-diagnosis, with many patients adapting work arrangements (27.03%) or leaving the workforce entirely.

Conclusions: This ongoing study will provide the first comprehensive assessment of cancer's impact on productivity and HRQoL in Singapore's context. Preliminary findings suggest substantial productivity losses and decreased quality of life, particularly during treatment phases. These results will enable more accurate economic evaluations from a societal perspective and inform evidence-based policies for workplace support programs. The study's longitudinal design will also provide insights into the temporal patterns of these impacts, supporting better resource allocation and intervention timing in cancer care.

Ind-1726 Severity of Visual Impairment and Economic Well-being of Older Adults in India

PRESENTER: **Rajeev Ranjan Singh**

Background: Visual impairment (VI) is a major public health challenge among older adults, often exacerbating economic disparities and reducing quality of life. This study examines the association between the severity of VI and economic well-being among older adults in India, focusing on the role of socio-demographic and health factors in mediating these relationships. Understanding how VI affects household economic status and how socio-economic and health characteristics influence vision outcomes is essential for addressing inequities in ageing populations. **Data and Methods:** The analysis utilises data from the nationally representative survey. Longitudinal Ageing Study in India (LASI): The dataset includes information (biomarkers) on vision health, socio-economic status, and health indicators for adults aged 45 and above. Vision impairment is categorised by severity (distance, near, and overall), and a composite economic well-being index is constructed using monthly per capita expenditure (MPCE), monthly per capita income (MPCI), and the wealth index. Bivariate analyses explore the prevalence of VI by socio-demographic factors, while regression models assess the impact of VI severity on economic well-being, adjusting for key variables such as age, education, gender, living arrangements, and health status. **Results:** Findings reveal that VI is strongly age-dependent, with adults aged 75+ experiencing the highest rates of moderate and severe impairments. Economic well-being emerged as a protective factor, with individuals classified as "living comfortably" or with higher education levels reporting better visual health. Conversely, severe VI is significantly more prevalent among individuals in lower wealth quintiles and those with limited education. Gender disparities were also evident: women reported slightly higher levels of VI across all severity gradients compared to men. Marital status and place of residence played a significant role; married individuals and urban residents generally had better vision health, while widowed individuals and rural residents faced

heightened vulnerability. Visual impairment was found to have a profound negative impact on household income. Severe VI was associated with substantially lower composite economic well-being scores, underscoring the dual burden of health and financial challenges faced by affected individuals. Regression analysis highlighted the protective role of health insurance, positive self-rated health, and urban residence in mitigating the adverse effects of VI. In contrast, factors such as tobacco use, comorbidities, and lower educational attainment exacerbated vulnerability, creating compounded disadvantages for the affected population. **Conclusion:** The study underscores the significant bidirectional relationship between VI severity and economic well-being among older adults in India. Socioeconomic inequalities amplify the impact of VI, disproportionately affecting women, rural residents, and individuals with lower education and economic status. These findings highlight the urgent need for integrated policies addressing vision care, economic support, and social inequities. Promoting education, ensuring equitable access to healthcare, and providing targeted support to vulnerable groups can help alleviate the dual challenges of visual impairment and economic disadvantage. Addressing these disparities is critical to enhancing the well-being and productivity of India's ageing population.

Ind-1985 The Economic Burden of Asthma on Children, Adolescents and Households in sub-Saharan Africa: CHEST-Africa data

PRESENTER: **Nqobile Ndimande**
AUTHORS: Refiloe Masekela, Sandra Kwarteng-Owusu, Tony Kayembe-Kitenge, Kevin Mortimer, Rebecca Nantanda, Josue Mbonigaba, Jibril Mohammed

Background

Asthma remains the most common chronic respiratory disease among children globally, with sub-Saharan Africa having a disproportionately higher prevalence. In addition to the health burden, there is a considerable economic burden. This is evidenced by direct costs for accessing healthcare services for diagnosis and ongoing treatment. There are also indirect costs including school absenteeism consequently missing key foundational lessons, and lost income by caregivers. The UN Sustainable Development Goal (SDG) 3.8 aims for all people to have access to health services without suffering financial hardship. Data in sub-Saharan Africa quantifying the economic burden of asthma is lacking. The aim of this study was therefore to determine the economic burden of asthma in children and adolescents in 4 sub-Saharan African countries.

Methods

Data was collected cross-sectionally using questionnaires adapted from the Global Asthma Network in four sub-Saharan African countries that are part of the Chronic Respiratory Disease Observatory for Africa (CHEST-Africa) study, Democratic Republic of Congo, Ghana, Nigeria, and Uganda. Data was collected from school children in two groups, children (6-7 years) and adolescents (13-14 years). Random sampling was used to select participants and health economic data was collected from the parents/relatives of participants who screened positive for asthma. Data included sources of household income, expenditure on asthma treatment, insurance coverage, and absenteeism. As an indicator of financial hardship, we used catastrophic health expenditure which occurs when household out-of-pocket health spending is more than 10% of household income as defined by the WHO.

Results

4,495 children and adolescents from the 4 countries participated in the main CHEST-Africa study. Of those, 223 (5%) screened positive for asthma and completed the health economic questionnaire. At the WHO 10% threshold, 35% (78/223) of households experienced catastrophic health expenditure. Twenty-five percent of households did not have an employed person in the home and 27% of households relied on support from extended family. A significant proportion (16%) had recently borrowed money to fund asthma treatment costs and 4% did not buy any medication due to unaffordability. Almost a third (30%) had medical insurance but only 17% of those stated that their insurance covered all treatment costs. Over a third (35%) of participants missed at least one day of school within the previous six months due to their asthma.

Conclusion

The costs to access asthma treatment for children and adolescents in sub-Saharan Africa are substantial, and catastrophic for a significant number of households. The indirect cost to people living with asthma are also significant. These findings provide evidence supporting the need for more universal health coverage for non-communicable diseases like asthma which includes all related healthcare costs.

Ind-2585 Provincial Analysis of Years of Life Lost and Economic Impact of Heart Disease Among the Working-Age Population in Indonesia (2018-2023)

PRESENTER: **Mitha Cerinda**
AUTHORS: Yenny Yenny, Susi Ari Kristina, Fentya Yumna Cahyani, Mr. Benjamin Saut Parulian Simanjuntak, Mr. Mahlil Ruby, Rizal Mansur, Mr. Antokalina Sari Verdiana

Background: Heart disease remains the leading cause of premature mortality in Indonesia, significantly impacting the population's health and the country's economy. In 2023, BPJS Kesehatan allocated IDR 17.63 trillion to cover heart disease treatment, making it the most expensive disease among those covered, with 20.04 million cases reported throughout the year. This study aims to quantify the burden of heart disease through the calculation of Years of Life Lost (YLL) and productivity costs. By providing a comprehensive analysis of the health and economic impact, this research highlights the urgent need for effective prevention and management strategies to address the growing burden of heart disease in Indonesia. **Methodology:** This study utilized mortality data from BPJS Kesehatan over the period of 2018 to 2023, involving 218,279 individuals. Heart disease-related deaths were identified using specific diagnostic codes. Years of Life Lost (YLL) were calculated following the Burden of Disease study framework, with WHO life expectancy tables used to estimate the years of life lost for each individual. The analysis was conducted at both national and provincial levels, focusing on the working-age population (15–64 years). Economic losses were assessed by linking YLL data for the working-age population to annual provincial minimum wages. A gender-based analysis was also

performed to identify differences in economic impacts between males and females. **Results:** This study found significant variations in productivity losses due to heart disease across provinces in Indonesia, with Central Java experiencing the highest total productivity loss of IDR 9.39 trillion, followed by East Java with IDR 9.20 trillion. Despite having lower annual provincial minimum wages of IDR 23.5 million and IDR 24.4 million, respectively these two provinces faced the largest economic burdens, highlighting the disproportionate impact of heart disease on regions with lower income levels. In contrast, Jakarta, with the highest annual provincial minimum wages of IDR 58.8 million, reported a smaller total loss of IDR 7.92 trillion, despite a considerable number of YLL. Gender-based analysis revealed that males consistently accounted for a larger proportion of productivity losses across all provinces, contributing 65% of the total loss compared to 35% by females. These findings underscore the significant economic burden of heart disease and its unequal impact across provinces and gender groups, emphasizing the need for targeted prevention and intervention strategies. **Conclusion:** Significant differences in productivity losses due to YLL across provinces and between genders highlight the need for targeted health interventions to reduce YLL from heart disease, particularly within the working-age population. Tailored strategies, including early detection, improved healthcare access, and public health campaigns, are essential to address these disparities and mitigate the economic impacts of premature mortality. These findings provide a foundation for policymakers to design equitable and sustainable public health programs.

Health in the Third Age

MODERATOR: **Cydney M McGuire**,

Ind-177 Social Capital, Cognition, and Mental Health Among Older People in China: A Longitudinal Life Course Study

PRESENTER: **Chengxu Long**, King's College London
AUTHORS: Wei Yang, Karen Glaser

Research suggests that stronger social support systems across life stages facilitate continuous learning and emotional well-being, contributing to better cognition and mental health. However, evidence on the cumulative effect of social support over the life course remains scarce, and even less is known about the impact of broader neighborhood-level social support on individuals' cognition—a crucial dimension in many countries, where neighborhoods serve as key support units for individuals. Using data from 2014, 2015, 2018, and 2020 waves of the China Health and Retirement Longitudinal Study, we employed mediation analysis to explore how individual and neighborhood social support accumulated across life stages are associated with cognition and depression at older ages. Our findings indicate that receiving individual support in youth was associated with a 0.5-point improvement in later-life cognitive scores, although no direct association was observed with depression. In addition, a one-point increase in the neighborhood support score was associated with a 1.2-point improvement in cognitive scores and 0.5 fewer depressive symptoms at older ages. These associations persist among individuals who were socioeconomically disadvantaged in their youth. Furthermore, both individual and neighborhood support in youth exert indirect effects on later-life cognition and depression by helping individuals maintain social support as they age. Our findings contribute theoretical insights into the importance of social support across life stages and highlight the stronger role of neighborhood support in shaping cognition and depression. Strengthening neighborhood social support and fostering lifelong supportive environments may help mitigate disadvantages in earlier life stages and reduce health disparities.

Ind-400 China's Supplementary High-cost Social Health Insurance's Impact on Old Age Poverty: A Nationwide Population-based Study

PRESENTER: **Shiju Dong**, Centre for Health Management and Policy Research, School of Public Health, Cheeloo College of Medicine, Shandong University, Jinan, 250012, China
AUTHORS: Siqian Zhang, Jiajia Li

Summary

Background: In 2012, China initiated supplementary high-cost illness insurance (SHCII) to provide supplementary compensation beyond social health insurance (SHI) coverage for high-cost patients. This study aimed to assess whether the SHCII could mitigate the poverty risk among older adults, a crucial subset of high-cost patients.

Methods: This study developed an old-age-specific poverty measure that combines monetary and non-monetary approaches. Using data from the China Health and Retirement Longitudinal Study (CHARLS: 2011, 2013, 2015, and 2018), we estimated the old age poverty incidence and its dynamic trends. A multinomial logistic regression with a staggered difference-in-difference approach was employed to explore how the SHCII affects older adults, particularly its impact across gender, urban/rural areas, hospitalisation experience, and health status.

Findings: The analysis revealed a gradual decrease in poverty, a slight improvement in the precarious group, and a significant rise in the prosperity group. Compared to the prosperity group, SHCII significantly reduced the likelihood of precariousness (Relative Risk= 0·642, 95% Confidence Interval 0·465-0·887) and poverty (Relative Risk=0·439, 95% Confidence Interval 0·278-0·694), which was more pronounced among women, urban elderly, those who reported good self-rated health, and those who did not undergo hospitalisation.

Interpretation: Despite the great advances towards poverty alleviation among older adults in China, 27·83% faced at least one deprivation in terms of housing, healthcare, pension, and financial security in 2018, but failed to be identified by monetary poverty. Social health insurance reforms must emphasise identifying and managing poverty risk by targeting older adults using a hybrid approach that integrates monetary and non-monetary poverty identification.

Keywords: supplementary high-cost illness insurance, old age poverty, monetary and non-monetary poverty, older adults, China

Ind-939 Intrinsic Capacity in 15 Countries in the Survey of Health, Ageing, and Retirement in Europe: Validation, Variations, and Population Centile Curves

PRESENTER: **Meimei Chen**
AUTHORS: John Beard, Katja Hanewald, Yafei Si, Yuanyuan Gu

Background The world is experiencing a demographic shift with an increasing percentage of older adults in almost every population. In 2015, the World Health Organization released its first world report on ageing and health, which proposed a framework for healthy ageing focused on the development and preservation of older adults' functional ability. An individual's functional ability is defined as the result of the individual's Intrinsic Capacity (IC), their environment, and the interactions between the two. Previous studies have validated the concept of IC and its structure across various settings. However, these are still largely limited to single country scenarios; no study has yet validated the IC construct and predictive validity of this structure using a cross-national dataset.

Objective In this study, we aim to determine and validate the structure of IC using data from the Survey of Health, Ageing, and Retirement in Europe (SHARE), which includes participants from 15 countries. We first examine the structure and validity of the IC construct, and then conduct a cross-national comparison of IC and subdomain scores, stratified by age, gender, country, and socio-economic status. Finally, we derive population centile curves for IC and its subdomains, stratified by gender and country.

Methods We analysed data from 64,872 participants from SHARE Wave 5 (2013) and determined subsequent care dependence in Wave 6 (2015). The methodologies employed included Exploratory Structural Equation Modelling (ESEM), bifactor ESEM, Confirmatory Factor Analysis (CFA), bifactor CFA, and mediation analysis. Construct validity was tested through multiple linear regression, while predictive validity was assessed using mediation analysis. We use Activities of Daily Living (ADL) and Instrumental Activities of Daily Living (IADL) as outcome variables to determine declining performances of older adults in the following wave, since it provides a comprehensive measure of severe disability and loss of independence that is of clinical relevance and different from the items selected to construct IC. Population centile curves were established using the GAMLSS method.

Findings Our analyses revealed IC's structure as one general factor and five subdomains: psychological, sensory, cognitive, locomotor, and vitality. Regression linked IC to age, gender, education, multimorbidity, and socio-economic status. Mediation analysis indicated that IC predicts subsequent declining performance in daily activities. We observed significant variations in IC scores between genders and across countries, allowing us to construct centile curves for IC by gender and country. Generally, men scored higher in IC and all subdomains than females, except for cognitive. Lower socio-economic status was correlated with lower scores in both males and females. Population centile curves show a declining trend of IC and subdomain scores across and within countries for both males and females.

Interpretation IC is a valid, reliable measure that effectively captures individual-level aspects of the functional ability of older adults. The centile curves we have developed show that IC has the potential to serve as a benchmark for health status in older populations.

Ind-2326 Financial Symptoms of Dementia Among Singles and Coupled Households

PRESENTER: **Lauren Hersch Nicholas**, University of Colorado

About 14.7 percent of American adults over the age of 70 have Alzheimer's Disease and Related Dementias (ADRD), neurodegenerative conditions characterized by deteriorating cognitive function that impedes daily life through deficits in memory and other cognitive domains. Common ADRD symptoms, including memory problems and decreased attention and judgment, frequently impair one's ability to manage personal finances. Erratic bill payments, risky financial decisions, and fraud susceptibility are widely recognized as early warning signs of ADRD, though families and physicians often do not detect these behaviors until late in the course of the disease. Despite limited research regarding the full extent of dementia-related losses, the lay press has described numerous anecdotes of loved ones first learning of a patient's decline through catastrophic financial events including foreclosure and asset depletion.

In this paper, we use more than two decades of linked Medicare claims and credit report data for over 2 million older Americans to study dementia-linked adverse financial events, building on our earlier work. We estimate flexible, non-parametric linear probability models that regress credit data events on a series of time from dementia indicators, relative to a never-dementia control group. We separately model single person and coupled households, since a spouse may be able to prevent financial problems by observing deteriorating cognition and/or directly receiving communication about missed payments. We find that dementia-linked financial problems begin to emerge more than a decade prior to clinical recognition. Both single and coupled households are impacted, however singles are twice as likely to experience events such as missed bill payments (i.e. 5 percentage points more likely 2.5 years post-diagnosis vs. 3pp) and subprime credit scores (indicating low probability of repaying a loan if one is extended). Coupleness appears protective against some of the most serious financial catastrophes. While single households develop elevated risk of derogatory mortgages, a pathway to home foreclosure, 4 years before other symptoms of dementia, couples never face elevated risks.

Results highlight the need for assistance with money management for single households with dementia and underscore the need for early detection efforts to protect financial well-being.

Ind-1081 The Impact of Retiring on Suicide: Evidence from South Korea

PRESENTER: **Elcin Tuzel**
AUTHORS: Dain Jung, Kam Ki Tang, Do Won Kwak

Abstract Suicide is a global problem, and older adults are particularly vulnerable. Understanding what contributes to and mitigates suicide risk is critical, especially during major life transitions such as retirement. Evidence on the impact of retirement on mental health is mixed. Against this background, we aim to examine the effect of retirement on suicidal ideation and the role that life satisfaction and social networks may play. In addition, we consider whether retirement also affects inter-partner relationships by considering the effect of retirement on intimate partner violence. We use longitudinal data from the Korea Welfare Panel Study. Our sample consists of 22,474 observations for 2,683 individuals aged 50 or older from 2006-2023. To address the issue that retirement may be endogenous to mental health, life satisfaction, and social networks, we use pension eligibility as an instrumental variable (IV). We also use the event study approach for robustness checks. For the modifiers, we consider individuals' satisfaction with social and family relationships before retirement. Our analysis indicates that retirement has no significant effect on suicidal ideation or attempts. However, we find that when husbands retire, their emotional abuse toward their wives falls by 0.8 SD, and wives' emotional abuse toward their husbands declines by 0.7 SD. Moreover, men who exhibited poorer mental health before retiring reduce all forms of intimate partner violence after retirement. Together, these results suggest that mental health and job satisfaction are important mechanisms shaping how major life transitions—like retirement—affect patterns of intimate partner violence.

Mimimising Harms from Alcohol Consumption

Ind-2300 Economic Evaluation of Later Trading Hour Policies for Bars and Clubs Alongside a Natural Experiment in Aberdeen and Glasgow, Scotland

PRESENTER: **Nurnabi Sheikh**
AUTHORS: Emma McIntosh, Jim Lewsey, Colin Angus, Niamh Fitzgerald

Introduction

On-trade alcohol premises, such as bars, pubs, and restaurants, a significant part of the night-time economy, serving as key places for socialization, entertainment, and cultural events. However, later trading hours for bars and clubs can also be associated with adverse public health outcomes, including higher rates of alcohol consumption, intoxication, assault, and injury. Later trading hours also place increased demands on public services including ambulance, hospital admissions, and police services. The present study aims to conduct an economic evaluation of later trading hours policies for bars and clubs in Scotland.

Methods

An economic evaluation alongside a natural experiment was conducted as part of the ELEPHANT study in Glasgow and Aberdeen. Traditional economic evaluation frameworks were employed, including cost-effectiveness analysis (CEA) and cost-consequence analysis (CCA) for the purposes of transparency of resource and outcome flows. The policy itself was not a typical public health 'intervention' generating expected health improvements as such but rather a policy with unknown impacts. The CEA focused on the primary outcome of alcohol-related ambulance call-outs with 'effectiveness' referring to reductions in alcohol-related ambulance call-outs. The CCA considered both primary and secondary outcomes including all ambulance call-outs and reported crimes. Analysis was conducted from a societal perspective, including impacts to the health sector, criminal justice system, business sector, and third-sector organizations. A range of deterministic sensitivity analyses were performed to test the robustness of the findings. The timeframe for analysis covered the period from 2015 to 2022, with a 1.5% discount rate applied in line with the NICE public health guidelines, and a 3% rate used for sensitivity analyses.

Results

No statistically significant effects of the policy of later trading hours for bars and clubs were observed in Glasgow. For Aberdeen, the base case CEA for the policy of later trading hours was deemed to be less 'effective' due to increased alcohol-related ambulance call-outs and also more costly. The policy change resulted in higher costs than before the policy change. The policy change resulted in an increase of 1,900 alcohol-related ambulance call-outs, alongside an estimated £4.5 million in additional costs during the study period. From a societal perspective, the additional costs attributable to this policy change were estimated to be £6.3 million. The increased costs included £0.94 million to the health sector, £0.78 million to the criminal system, £4.5 million to the business sector, and £94,256 to the third sector. In alternative scenarios, the total societal costs ranged between £7.2 million and £7.6 million.

Conclusions

The later trading hours policy for bars and clubs in Aberdeen was associated with increased alcohol-related ambulance call-outs and overall increased costs to society across multiple sectors, including health, crime justice, and the third sector. These findings were not observed in Glasgow. Although the policy change may offer benefits from a retailer perspective (not estimated in this study due to data limitations), the additional costs being incurred across multiple sectors for some cities should be carefully considered to inform future decisions and legislation on alcohol trading hours locally, nationally, and internationally.

Ind-1629 Economic Evaluation of a Policy to Restrict Density of Licensed Premises

PRESENTER: **Mary Rose Angeles**, Deakin University

AUTHORS: Mishel Shahid, Mr. Lennert Veerman, Amila Suranga Malawige, Leopold Aminde, Mary Wanjau, Moosa Al Subhi, Linda Cobiac, Phuong Nguyen, Ms. Jaithri Ananthapavan

Introduction: Restricting liquor outlet density is an intervention to reduce alcohol availability, potentially influencing alcohol consumption and related harms. The cost-effectiveness has not been examined. This study evaluates the cost-effectiveness of restricting outlet density in two of the most populous metropolitan areas in Australia.

Methods: We conducted an economic evaluation of the implementation of a hypothetical policy to keep the number of liquor licenses approved at 2019 levels, and therefore restricting additional alcohol outlets in Greater Sydney and Metropolitan Melbourne, compared to a status quo (current practice) scenario. This analysis focuses on individuals aged 15 and older in metropolitan areas and adopts a limited societal perspective considering costs and benefits to individuals, governments and the private sector. Productivity impacts were not included. Intervention effectiveness was estimated by comparing the impact of changes in alcohol outlet density on alcohol consumption for the affected population 15-years and older over 20-years. An Australian study reported that each additional liquor license within a 1.6km neighbourhood is associated with an additional 0.15 grams of alcohol consumed per person daily (p=0.002). The current number of liquor licenses together with evidence that 82% of the target population live within 1.6km of any alcohol outlet was used to estimate the potential number of people who would be exposed to a new liquor licenced venue. The projected increase in the number of liquor licences over the 20-year period was informed by regression analysis based on the increase in liquor licences from 2010-2022. The cost of policy development, stakeholder consultation and profit losses to the industry resulting from not issuing additional liquor licenses were calculated based on the best evidence in the literature. All costs and benefits are discounted at 5% and costs are presented in 2020 Australian dollars. The Alcohol Policy (TAP) model, a proportional multistate lifetable Markov model, simulated the policy's impact in health-adjusted life years (HALYs) and healthcare cost savings from reduced alcohol-related diseases and injuries. These outcomes, combined with intervention costs, estimated the policy's cost-effectiveness. Parameter uncertainties were modelled using Monte-Carlo simulation with 2,000 iterations. Scenario analyses were conducted to test the robustness of the results.

Results: Over 20 years, the projected average reduction in population alcohol consumption was 0.21% (95%UI: 0.06, 0.34) for Greater Sydney and 0.13% (95%UI: 0.05, 0.21) for Metropolitan Melbourne. The intervention cost AUD$17.28 million (95%UI: 5.37, 28.72) in Greater Sydney and AUD$9.68 million (95%UI: 3.85, 16.16) in Metropolitan Melbourne. The modelled intervention generated HALYs of 2,040 (95%UI: 665, 3520) in Greater Sydney and 1,010 (95%UI: 364, 1690) in Metropolitan Melbourne. The mean the Incremental Cost-Effectiveness Ratios (ICERs) were below the A$50,000 per HALY threshold: 791 (95%UI: Dominant, 17,300) for Greater Sydney and 1,840 (95%UI: Dominant, 17,800) for Metropolitan Melbourne. In Greater Sydney and Metropolitan Melbourne, 41% of iterations were cost-effective, with 28% being dominant. Across all scenarios tested, there is a 99% probability that the intervention is cost-effective.

Conclusion: Results suggest that a policy restricting liquor outlet density in Australia's two most populous metropolitan areas is a cost-effective strategy. Governments should consider and strengthen policies on licensing approvals.

Ind-2067 Alcohol Use Disorder Treatments for Achieving Abstinence: A Model-Based Cost-Effectiveness Analysis

PRESENTER: **Mr. Anton Avanceña**, The University of Texas at Austin

AUTHORS: Tiffany Kuo, Divya Parameshwar, Madeline Brendle

Alcohol use disorder (AUD) is the most common substance use disorder in the US, affecting 28.9 million (10.2%) individuals aged ≥12 years in 2023. Several pharmacological and non-pharmacological AUD treatments can help individuals with AUD achieve abstinence—one of many goals in recovery—with varying levels of effectiveness and costs. This economic evaluation assessed the costs, health effects, and cost-effectiveness of AUD treatments that promote abstinence. We developed and validated a decision-analytic microsimulation model of individuals with AUD. The model includes six health states: abstinence, four World Health Organization risk drinking levels (low-risk, medium-risk, high-risk, and very high-risk drinking), and death. We parameterized the model using previously published transition probabilities for AUD by sex, age, race, and ethnicity in the US. We compared nine AUD treatments, including four Food and Drug Administration (FDA)-approved pharmacotherapies (oral and injectable naltrexone, disulfiram, and acamprosate), three non-FDA-approved, guideline-recommended pharmacotherapies (gabapentin, baclofen, and topiramate), and two non-pharmacological treatments (psychotherapy and mutual help programs). The effectiveness of each treatment was based on previous meta-analyses or clinical trial data. The model estimated each treatment's costs (2023 US$) from a healthcare payer perspective and health outcomes (in terms of quality-adjusted life years [QALYs]) over a five-year horizon. We assessed cost-effectiveness using incremental cost-effectiveness ratios and net monetary benefits (NMBs) assuming a cost-effectiveness threshold of $150,000 per QALY gained. In the base-case analysis, we assumed that individuals would only be treated once in five years, though we allowed up to five retreatments with the same therapy in scenario analyses. We also conducted deterministic and probabilistic sensitivity analyses to understand the impact of parameter uncertainty on our findings. Our preliminary results found that single treatments of disulfiram, baclofen, and psychotherapy were the cost-effective options when compared to treatments within their respective categories (FDA-approved, non-FDA-approved, and non-pharmacological treatments, respectively). Comparing all treatments, baclofen was associated with the greatest health effects (2.893 QALYs) and the lowest costs ($6,747), thereby dominating all other AUD treatments. Baclofen had the highest NMB even as the number of possible retreatments was increased to five over five years. Probabilistic sensitivity analyses found that disulfiram and baclofen were <50% likely to have the highest NMB at a cost-effectiveness threshold of $150,000 per QALY gained or higher. This economic evaluation suggests that pharmacotherapies, particularly baclofen, are the most cost-effective treatments to promote abstinence among individuals with AUD. Treatment guidelines for AUD can incorporate these findings in their recommendations. Additional research is needed to measure the short- and long-term health-related quality of life associated with different risk drinking levels among people with AUD.

Ind-1723 An Economic Evaluation of Naltrexone and Acamprosate Versus Disulfiram and Psychosocial Therapy Alone in Treating Alcohol use Disorder in Thailand

PRESENTER: **Manit Sittimart**

Background: Alcohol use disorder (AUD) is one of the significant public health concerns in Thailand, contributing to a wide range of social and health issues, including increased rates of liver disease, mental health disorders, accidents, and violence. The National Health Security Office (NHSO) reports that a substantial portion of the population engages in heavy drinking, with a growing need for effective treatment options. Naltrexone and acamprosate, both shown to reduce alcohol craving and prevent relapses, represent promising treatment options that could address the growing burden of AUD and improve patient outcomes. However, there was limited evidence on cost-effectiveness of such treatment in the Thai context. **Objective:** This study aimed to assess the cost-effectiveness of naltrexone and acamprosate, when combined with psychosocial therapy, for the treatment of AUD, in comparison to disulfiram with psychosocial therapy and psychosocial therapy alone. **Method:** A cost-utility analysis was conducted using a Markov model and followed the Thai health technology assessment (HTA) guidelines.* *The target population in the model was patients with moderate to severe alcohol use disorder, as defined by the American Psychiatric Association. The analysis used a societal perspective and a lifetime time horizon with 3% discount rate for both costs and outcomes. Parameters used in the model were derived from published literature and existing databases. Results were presented as an incremental cost-effectiveness ratio (ICER). The Thai willingness-to-pay threshold at 160,000 Thai Baht (THB)/quality-adjusted life year (QALY) was used to determine cost-effectiveness. Sensitivity analyses, including one-way and probabilistic analyses with Monte Carlo simulations (1,000 iterations), were performed to explore influential parameters and uncertainty.* ***Results:*** *The deterministic analysis indicated that acamprosate, with an ICER of 12,348 THB/QALY, was more cost-effective compared to Naltrexone, which had an ICER of 148,203 THB per QALY. Disulfiram was deemed dominated by psychosocial therapy alone. The probabilistic sensitivity analysis indicated that acamprosate had an 87% probability of being cost-effective at Thailand's threshold, while naltrexone had a 5% probability. One-Way sensitivity analysis revealed that the efficacy of acamprosate was among the most influential parameters on the ICER.* ***Conclusion:*** *This study** suggested that acamprosate when combined with psychosocial therapy is the most cost-effective treatment for AUD in Thailand, especially as the willingness-to-pay threshold increases. This study highlighted the potential for acamprosate as a preferred treatment option in the Thai healthcare context.

Ind-1153 Diagnostic Uncertainty and Prescription Practices Among Pharmacists

PRESENTER: **Maximilian Guigas**

AUTHORS: Matthias Rieger, Edward Asiedu, Jan Priebe, Christoph Strupat

Antimicrobial resistance (AMR) is a growing global health concern, causing an estimated 1,27 million deaths in 2019 (Murray et al., 2022). Worldwide Sub-Saharan Africa is the region with the highest number of deaths per 100,000 inhabitants associated with AMR worldwide (Naghavi et al., 2024). To combat this AMR Stewardship programs aimed at health care professionals, especially primary care physicians, received broad attention. However, in Ghana, pharmacists often serve as frontline healthcare providers. In addition, widespread “over-the-counter” sales of antibiotics threaten the sustained efficacy of antimicrobial drugs. This study aims to shed light on how AMR-related knowledge and diagnostic uncertainty influence the antibiotic prescription behaviors of formal and informal pharmacists. Furthermore, the role of economic preferences (e.g. risk aversion, reputational concerns) and personality (altruism, social desirability) in their dispensing behavior shall be evaluated. To the best of our knowledge there are not yet any noteworthy impact studies on antimicrobial dispensing behavior of pharmacists. Hence, we conducted a survey of 480 pharmacies and over-the-counter medical vendors (240 each) in 60 randomly selected neighborhoods in the Greater Accra Region, Ghana. The interview with one sales employee of each facility comprised questions on antibiotic knowledge, dispensing practices and personality measures. It further included four standardized vignettes that aimed to vary patients’ symptoms to signal more/less clear underlying medical conditions to measure individuals’ diagnostic uncertainty. To additionally obtain more objective data on the actual dispensing behavior, an audit (mystery shopper/simulated patient) study was conducted after completion of all surveys. Each facility was visited four times by different actors making up a total of 1920 audit visits. Hereby, the displayed cases varied on five dimensions. Firstly, regarding the presented disease (medication was requested for someone else), secondly the duration of the symptoms, thirdly the intensity with which an antibiotic was demanded, fourthly the subjective wealth of the actor and lastly the location, where they intended to buy the medication. Primary outcomes include the binary decision to prescribe antibiotics and the quality of associated advice. Hypotheses concerning risk aversion, altruism, social desirability, reputational concerns, and AMR knowledge are tested using descriptive statistics and multivariate regression, particularly ordinary least squares (OLS). Initial findings demonstrated a significant relationship between higher AMR knowledge and a reduction in unnecessary antibiotic prescriptions, however this could not be supported by the evidence from the audit study. Pharmacists with greater risk aversion were less likely to dispense antibiotics, particularly when faced with diagnostic uncertainty. Furthermore, social desirability and altruism influenced the likelihood of antibiotic dispensing. The insights from this study suggest important policy implications, advocating for enhanced educational initiatives aimed at improving AMR awareness among pharmacists, thus promoting responsible antibiotic use. Policymakers are encouraged to implement support systems that aid pharmacists in navigating diagnostic uncertainties, thereby strengthening the integrity of pharmaceutical care and combating AMR. Murray, Christopher JL, et al. "Global burden of bacterial antimicrobial resistance in 2019: a systematic analysis." *The lancet* 399.10325 (2022): 629-655. Naghavi, Mohsen, et al. "Global burden of bacterial antimicrobial resistance 1990–2021: a systematic analysis with forecasts to 2050." *The Lancet* 404.10459 (2024): 1199-1226.

Ind-2127 Estimating Physicians' Reimbursement Elasticity for Antibiotic Care Tests Using Discrete Choice Experiments

PRESENTER: **Madison Luick**
AUTHORS: Koen Pouwels, John Buckell

Overuse of antibiotics for respiratory tract infections (RTIs) contributes to antimicrobial resistance (AMR). Point-of-care tests (POCTs) for C-reactive protein (CRP) have been shown to reduce unnecessary prescribing in primary care and are widely used in countries that have comparatively low antibiotic prescribing rates. However, CRP POCTs are rarely used in UK general practices, potentially partly explaining why antibiotic use in UK primary care is higher than in several other European countries. While several EU countries reimburse GP practices for the use of CRP tests, the lack of funding and reimbursement for CRP tests have been identified as barriers to uptake. Introducing a reimbursement scheme in the UK could be a beneficial strategy to incentivise the appropriate use of CRP tests. However, more research needs to be done to better understand what reimbursement strategy would encourage appropriate usage. For example, in Denmark there is evidence that the reimbursement strategy – with reimbursement levels being more than double the amount used in the Netherlands - might have led to overuse of CRP tests among patients in which a CRP test is neither indicated nor validated.

This study evaluated reimbursement levels that could lead to the highest appropriate uptake of CRP tests in UK primary care.

A sample of 511 general practitioners (GPs) in the UK completed an online discrete choice experiment (DCE). The DCE tested the effect(s) of reimbursement levels on administering CRP tests. Five attributes were: patient symptoms, patient pressure for antibiotics, requirements for reimbursement, cost of the test being covered, and any additional reimbursement incentive per test (range: £0-5). Following the DCE, participants were asked questions about their knowledge of AMR and whether they were considering AMR when making their decisions in the choice task. A Bayesian, D-efficient design was used, excluding any combinations considered implausible by clinicians on our study team. The choice between using a CRP test or not was assessed using multinomial logit models with reimbursement level as a categorical predictor.

Current analyses suggest that, when the cost of tests is not covered and there is no reimbursement, GPs prefer not to use a CRP test. Covering the cost of the test and increasing the reimbursement incentive value of the test relative to no reimbursement generally increased the preference for using a CRP test. When modelling reimbursement as a categorical variable, results suggest that a £1 incentive does not meaningfully increase preferences relative to a £0 incentive, and that there may be diminishing returns on increasing the incentive amount after £4. Preferences for using a CRP test also varied by requirements for reimbursement, patient symptoms, and patient expectation for antibiotics.

Preliminary results from this stated choice survey indicate that covering the cost of CRP tests and offering a reimbursement incentive for using them may improve the uptake of CRP tests in UK primary care settings.

Ind-2768 A Comprehensive Study on Healthcare Services and Medication Affordability and Availability Amidst Economic Challenges in Mount Lebanon Governorate

PRESENTER: **Mira Al Aridi**

Background Due to the economic crisis, the COVID-19 pandemic, and the port explosion in Beirut, Lebanon has been plagued by a multidimensional crisis that has affected numerous facets of the country's healthcare system. However, limited studies have examined the effects of the crisis on the accessibility and affordability of healthcare services and medications, specifically in the Mount Lebanon governorate, the most populous governorate in Lebanon comprising both urban and rural regions. Therefore, this study aims to highlight the impact of the economic crisis on healthcare services and medication availability and affordability among different socio-demographic groups in Mount Lebanon. **Methods** The study employed a cross-sectional design and was conducted from January 1 to February 19, 2024. An online survey was conducted to collect data on the sociodemographic characteristics, healthcare-related experiences, and medicine-related experiences of 125 residents of Mount Lebanon. The survey employed a set of suggested questions established by the OECD along with other questions which were developed by the researcher. Descriptive statistics and chi-square tests between socio-demographic subgroups were conducted using SPSS version 29. **Results** Among participants who have experienced medical issues in the past 12 months, 26.5% reported not visiting a healthcare provider due to travel difficulties, 42.2% reported the same problem but due to cost considerations and 45.1% reported that they have skipped a medical test, treatment or follow up due to its cost. In fact, the highest percentages of inaccessibility to healthcare were found among females, elderly, individuals with no or low levels of education, individuals of average to low income groups, and people suffering from chronic diseases or poor health status. Moreover, 58.4% of respondents reported experiencing problems getting their prescribed medicine at the pharmacy, such as it not being available or out of stock. However, no significant differences were found between subgroups concerning medication unavailability. Last but not least, 57.5% of patients have voluntarily requested a cheaper replacement for their prescribed medication at the pharmacy due to cost considerations. **Conclusion** The economic crisis has adversely affected healthcare services and medication availability and affordability in Mount Lebanon, leading to adverse health outcomes. This calls for urgent health policy interventions to mitigate the impact of the economic crisis on public health.

Ind-845 Impacts of Family Doctor System on Medication Adherence of Type 2 Diabetes Patients in China

PRESENTER: **Xichen Tong**
AUTHORS: Haiyan Zou, Luying Zhang, Wen Chen

Background: Nonadherence to medication is a prevalent issue among patients with type 2 diabetes mellitus (T2DM). The family doctor system promotes continuous, integrated, and personalized primary care, which has the potential to improve medication adherence. However, more evidence is needed regarding causal association between family doctor system and medication adherence.

Aim: This study is to assess the impact of the family doctor system on medication adherence among T2DM patients.

Methods: This cohort study analyzed data from 2014 to 2019, drawn from three administrative databases in an eastern city of China, a pioneer in the implementation of the family doctor system. Adult patients with T2DM who continuously registered with family doctors from 2015 to 2019 (n=18,841) were assigned to the intervention group, while those who never registered during this period (n=1,429) were classified as the control group. A difference-in-differences design was employed to compare medication adherence between registered and unregistered T2DM patients after the first stage of family doctor system in 2015 and the second stage in 2018. Propensity score matching was applied to ensure the robustness. The mean proportion of days covered (PDC), and proportion of patients with good adherence (PDC≥80%) were the outcomes of interest. All recommended T2DM medications were included to calculate PDC.

Results: Compared to the unregistered group, PDC across all institutions for registered patients increased by 5.02% ($p<0.001$) after the first stage of family doctor system and by 5.88% ($p<0.001$) after the second stage. The proportion of patients with good adherence increased by 9.49% ($p<0.001$) and by 11.79% ($p<0.001$) after two stages, respectively. The improvement in medication adherence was more pronounced among patients managed in community health centers. In community health centers, the PDC increased by 5.53% ($p=0.003$) during the first stage and by 8.07% ($p<0.001$) during the second stage. Similarly, the proportion of patients with good adherence increased by 11.91% ($p<0.001$) and by 19.27% ($p<0.001$), respectively in each stage. Despite these improvements, the overall rate of good adherence among registered patients in 2019 remained relatively low, reaching only 59.77%.

Conclusions: The family doctor system significantly improved medication adherence among T2DM patients by providing patient-centered, continuous, and integrated primary services, especially in community health centers. Nevertheless, further efforts should be made to enhance medication adherence.

abs-os574 U.S. State Regulations and Co-Location of Opioid Treatment Prescribers

PRESENTER: **Joanne Spetz**, University of California San Francisco
AUTHORS: Laurie Hailer, Bethany Phoenix, Susan Chapman, Matt Tierney

Background and Aims: In 2017, new regulations in the United States allowed nurse practitioners (NPs) and physician assistants (PAs) the ability to become authorized to prescribe buprenorphine for opioid use disorder treatment in office-based settings, which was previously limited to physicians. Prior research has found that state regulations limiting the ability of NPs and PAs to prescribe medications without physician oversight slowed the rate at which they pursued authorization to prescribe buprenorphine. This slowing could affect both the extensive margin – the geographic spread of buprenorphine-authorized clinicians – and the intensive margin – the number of authorized clinicians located in a specific area. This paper posits that regulations that require physician oversight of NPs and PAs inhibited their applications for approval to prescribe buprenorphine but also created a barrier to them establishing new practice sites (i.e., reduced geographic spread). We examine the locations of newly-authorized NPs and PAs to learn the degree to which their ability to obtain authorization affected both the extensive and intensive availability of buprenorphine-authorized clinicians.

Methods: Our primary data source is the roster of clinicians who had authorization to prescribe buprenorphine as reported by the U.S. Drug Enforcement Agency (DEA) from 2019 through 2022. These data were merged with indicators for the regulatory environment faced by NPs and PAs, including whether they must have physician oversight and whether physicians must co-sign prescriptions. We also added control variables to measure health care infrastructure, opioid-related policy investments, demographics, and economic characteristics at the county level. We are estimating regression equations for whether a newly-authorized clinician being in a new location is associated with state regulations and other locational characteristics. We will test whether variables indicating that physician oversight is required for prescribing have a statistically significant effect on the likelihood of co-location. We also will interact indicators for physician oversight requirements with rural location to learn whether these regulations have a greater impact on co-location in rural communities.

Key Results: Preliminary analyses have found that NPs are less likely to have waivers when they are required to have physician oversight, but that PA regulations do not have a significant effect on the (low) share of PAs with waivers. Analyses also have found that these effects are greater in rural communities, suggesting that physician oversight requirements may affect the geographic spread of buprenorphine treatment.

Conclusions and Implications for Policy and Practice: The expansion of the clinician workforce providing buprenorphine treatment is important to addressing ongoing treatment needs of people with opioid use disorder. Restrictions on NPs and PAs could have particularly important effects in rural communities, because prior research finds that not only are NPs and PAs more likely to practice in rural areas of states that allow them to practice independently but they also are often the only health care clinicians in underserved communities.

Ind-2135 Developing a Preliminary Health Economics Model Structure for Household Food Insecurity and Child Health Outcomes within a UK Context

PRESENTER: **Sarah Abraham**
AUTHORS: Laura Gray, Anthea Sutton, Penny Breeze, Hannah Lambie-Mumford

Background

Household food insecurity (HFI) is characterised as disruption to usual dietary intake and/or eating habits due to lack of money or other resources, at the household level. HFI can have detrimental impact on child physical and psychosocial development. Latest figures from the Department of Work and Pensions reported that in 2023, 17% of children were living in low and very low food secure households. School-based feeding interventions in the UK may mitigate the harmful impact of HFI on child health. To evaluate these interventions for their impact on child health as public health interventions, a model structure that characterises the relationships between HFI and child health must first be developed.

Aim

The aim of this study was to develop a conceptual model and preliminary model structure for HFI and child health outcomes in preparation for the development of a public health economics microsimulation model.

Methods

Two rapid reviews were conducted to (i) summarise the quantitative evidence supporting relationships and mechanisms between HFI and child health outcomes in high-income, English-speaking countries and (ii) summarise the current evidence on the effectiveness and cost-effectiveness of UK school-based feeding interventions for their impact on HFI-related child health outcomes. A stakeholder engagement workshop was organised to develop a conceptual model for HFI and child health outcomes, with support from the reviews. Stakeholders identified key pathways and outcomes to be included in the preliminary model structure. To test the hypothesised structure, linear regression models were estimated to evaluate the relationships between HFI and child diet quality, while structural equation modelling (SEM) examined the relationships between HFI, child behaviour and parent mental health. Data analyses were conducted on children aged 7-11 years of the Born in Bradford (BiB) and BiB1000 Growing Up studies.

Results

The first review identified that HFI was associated with child health outcomes via two pathways (i) nutritional and (ii) mental health, including a potential mechanism of action via parent mental health. The second review identified key school-based feeding interventions in the UK and found a significant impact of these interventions on child diet quality, and improvement in child weight status. Stakeholders considered the findings from these reviews and concluded that the HFI and child diet pathway, and HFI and, child mental health pathway, incorporating parent mental health, would be key components of the preliminary model structure. A multivariate linear regression model, stratified by ethnicity, found that HFI was not associated with child diet quality. The SEM found that HFI had an indirect relationship with child internalising, externalising and prosocial behaviour via an impact on parent mental health, but did not directly influence child behaviours.

Conclusion

HFI was not associated with child diet quality, nor directly associated with child behaviour. An indirect pathway between HFI and child behaviour via parent mental health, as a mediator, was identified. A health economics model evaluating interventions that aim to target HFI and its health impacts on children, should consider these complex relationships. Further research is required to understand the relationship between HFI and child dietary intake.

Ind-1294 Intergenerational Educational Effect of In-kind Transfer Program on Child Nutrition: Evidence from India

PRESENTER: **Nisha Mishra**
AUTHOR: Sukumar Vellakkal

Abstract

Background: Though India is fifth largest economy in the world, its nutrition status is alarming as the country ranks 105th out of 127 countries as per Global Hunger Index, 2024. Bihar, one of the poor performing states of India share disproportionately huge burden of child malnutrition with 43% of child being stunted and 23% wasted. One of the strongest predictors of child health is mother's education as an educated mother has better knowledge of health care and nutrition. With the stated goals of increasing girl's school enrolment rate and minimising their school dropout by making it easier for them to access school, the state government of Bihar in 2006 introduced the cycle program namely Mukhyamantri Balika Cycle Yojana. The program provides money to all the girls enrolled in class 9 in a government aided school. The existing literature have studied the program's effect on secondary school enrolment of girls and girl's empowerment in addition to spillover effects on non-targeted females. We add to the literature by studying the intergenerational effect of the program channelised through mother's education on nutrition outcomes of their children in long-term. We also investigate the potential mechanisms driving our results.

Data and Methods: Using data from National Family Health Survey, round-4 conducted in year 2015-16, we employ difference-in-differences technique to estimate the causal effect by exploiting the state and age cohort variations. We consider the girls who have passed their senior secondary examination before 2006 (who were not eligible to get program benefit) as control group whereas the younger girls supposed to enter class 9 in 2006 or later, as the treatment group. Since, the program was implemented in 2006 only in the state of Bihar, we use two states: Jharkhand and Uttar Pradesh as the control states as they geographical and cultural proximity to Bihar.

Results: The main finding of the study indicate that the program has positive effects for children of mothers benefitted through the cycle program. Their health outcomes have improved significantly. A child born to the mother exposed to program are less likely to be stunted and underweight. The potential channel underlying these favourable effects are detected to be increase in mother's years of education, attainment of secondary level of education, and their age at marriage, decline in fertility, and exposure to media like newspaper and radio.

Discussion: The objective of the cycle program was to reduce the gender gap in school by increasing school enrolment for girls, but it has provided several unintended effects to the beneficiaries. By analysing its long-term effect in our study, we suggest the policymakers to focus and supplement such policies with other intervention to have better spillover and intergenerational effects in long run. To combat issues like malnutrition, they need to consider the interdependency of health and education with adequate infrastructure investments in both sectors.

Ind-1607 Association of Food Environment with Diabetes-Related Health Outcomes: Diet, Weight, and Obesity

PRESENTER: **Rocio Garcia-Diaz**
AUTHORS: Marisa Miraldo, Miguel Talamas, Ernesto Del Castillo, Edson Servan--Mori

Background. The prevalence of diabetes in Mexico has surged from 6.7% in 1994 to 15.8% in 2022, a trend linked to dietary changes and increased consumption of processed foods as economic growth and globalization expanded food options. Current research highlights the influence of neighborhood environments and food availability on obesity and diabetes risks, yet is limited by cross-sectional data, inadequate classification of food outlets, and insufficient insight into household food purchasing decisions. The economic burden of diabetes remains substantial, with management costs rising by 26% from 2016 to 2018, imposing significant pressure on Mexico's fragmented health system and impacting equity in healthcare access. Past policy interventions, including taxes on sugary drinks and junk food, school bans, and labeling initiatives, have had limited success due to weak enforcement and public awareness challenges. Addressing diabetes requires robust data, comprehensive prevention strategies, and targeted policy interventions to support informed food choices and mitigate the health and economic impacts of diabetes in Mexico. **Methods**.We used data from the Mexican National Health and Nutritional Survey (ENSANUT), the National Household Income and Expenditures Survey (ENIGH), the National Directory of Economic Units (DENUE), and the Economic Census to analyze food environments and diabetes-related health outcomes across Mexico. Using variation within neighborhoods and across time in the retail landscape, we examine how proximity and density of food outlets impact healthy food intake and health outcomes related to diabetes, controlling for confounding factors at the household, individual, and locality levels. We instrument the entry of convenience chains and supermarkets with an instrument analogous to Talamas Marcos (2024) that leverages regional economies of scale at the firm level and suitability for these establishments measured as the prevalence of wide streets. This approach aims to substantiate a causal relationship between food environments and diabetes-related health outcomes, advancing beyond mere associations. **Conclusion**. Our study provides a comprehensive approach by using GIS data to define food environments at a household level, offering a thorough assessment of not only associations with obesity but also food habits and other dynamics that contribute to diabetes-related health outcomes within households. It fills a gap in the literature by exploring causal mechanisms rather than merely identifying associations between type 2 diabetes (T2DM) and food environments. These insights can inform public health strategies, interventions, and policy directions aimed at addressing diabetes and improving dietary habits. **Keywords:** Food environment, geographical information systems (GIS), Type 2 diabetes (T2DM) related outcomes, household food habits, hierarchical multilevel analysis, instrumental variable

Ind-2506 Does Food Inflation During Pregnancy Affect Stunting?

PRESENTER: **Hisbi Asyihristani Rijal**
AUTHOR: Pipit Pitriyan

The occurrence of food inflation during mother's pregnancy and early life of infants might affect household consumption pattern, i.e., by shifting to low nutrition that further brings a potential risk for mother's and baby's nutrition adequacy. This study aims to estimate the effect of food inflation on stunting by combining data from Indonesia Family Life Survey (IFLS) Wave 4 (2007) & 5 (2014) and food inflation from the CBS (BPS) of Indonesia. We take under-five aged children's as unit of analysis. Knowing the child's month and year of birth from IFLS allows us to track the period of his/her mother's pregnancy. We then collect two kinds of food inflation data, i.e., during maternal 9-month pregnancy and during the early 5-month life of the infants. Since the CBS inflation data covers only 66 cities, we apply the Euclidean distance to employ a spatial nearest neighbor method that enable us to determine the food inflation rate for other cities in the IFLS out of the 66 cities. By performing logit regression analysis, our study finds that a percentage increase of food inflation during 9-month pregnancy increases the probability of stunting by 3 percentage points ($p < 0.01$), while the food inflation during the early 6-month of infants life has statistically insignificant on the prevalence of stunting. Other variables with significant and positive effect on stunting including low birth weight, maternal age, parental heights, paternal years of education, maternal years of education, per capita expenditure quintile, and residential area status. This study results urge food price stability and adequate nutrition during pregnancy.

Ind-2651 Pregnancy, Food Purchases and Nutritional Quality

PRESENTER: **Gabriella Conti**, Department of Economics and Social Research Institute, University College London
AUTHORS: Paula Spinola, Stephanie von Hinke, Melanie Luhrmann, Britta Augsburg

Background:

Pregnancy is a critical period for health investments that significantly impacts child development and lifelong outcomes. While extensive public health guidance promotes healthy eating during pregnancy, little causal evidence exists on how conception impacts households' nutritional

choices and environments.

Methods:

We analyze household scanner data from the UK (2005-2019) covering detailed food purchases and nutritional content. Using an event study design with the Borusyak et al. (2024) imputation estimator, we examine changes in food purchases from 24 months pre-conception through pregnancy and up to one year post-birth. We measure nutritional quality using the UK Food Standards Agency's nutrient profiling model to distinguish between healthy and less healthy foods.

Results:

We find that households increase calorie purchases by approximately 200 calories per day during the third trimester, aligning with NHS guidelines. However, the nutritional quality of purchases deteriorates substantially, with the share of calories from less healthy foods increasing by 2.5 percentage points during pregnancy. This represents about 50% of the difference in healthy calorie share between normal weight and obese individuals, and occurs despite households halving their alcohol purchases during pregnancy. We observe that households reduce purchases of protein-rich foods while substantially increasing sweets and prepared foods. Sugar consumption increases by 5% during the first two trimesters, resulting in approximately 4kg additional sugar consumption over pregnancy. This increase is particularly pronounced among households with higher pre-conception alcohol purchases. These changes in nutritional quality happen regardless of socioeconomic status, pregnancy risk factors such as maternal age and pre-conception BMI, or food price environments. The shift away from alcohol comes with adverse substitution effects, as households with higher pre-conception alcohol purchases show larger increases in sugar consumption during pregnancy.

Conclusions:

We find that pregnancy triggers substantial dietary changes that are largely detrimental to nutritional quality, occurring universally across socioeconomic groups. This suggests that current public health messaging around pregnancy nutrition may be insufficient. Our findings indicate a need for more targeted interventions to support healthy eating during pregnancy, particularly given the importance of prenatal nutrition for child development. The substitution of reduced alcohol consumption with increased sugar intake suggests a need for specific guidance on healthy alternatives when reducing alcohol during pregnancy. These results are highly policy-relevant, suggesting that pregnancy may be a particularly fragile period for nutrition despite its critical importance for both maternal and child health outcomes.

Ind-2214 Time Preference in the Health Domain Among Rural Adults in China

PRESENTER: **Qiqi Liu**
AUTHORS: Cong Li, Jingxian Wu, Danlei Chen

Background: Time preference, a critical component of inter-temporal decision-making, is closely associated with health behaviors and medical choices. In the context of China's urbanization, rural adults—often in socioeconomically disadvantaged positions—face significant health challenges. Despite its importance for public health and sustainable development, time preference among rural adults remains underexplored. Moreover, given the primary focus on time preferences in the financial domain and the domain independence, investigating this population's health time preferences is especially relevant. This study aimed to elicit and describe the time preference in health domain among rural Chinese adults, with comparison to it in the financial domain, and identify its associated factors, thus providing insights to inform targeted health interventions and policies.

Methods: Data were collected through a structured household survey conducted in six counties of Shaanxi Province, China, during July and August 2023. Using a multistage stratified random sampling method, the survey included 1,523 rural individuals aged 18 to 65 from 885 households. In the empirical framework, time preferences in the health domain were elicited using iterative choices between immediate mild health losses and delayed severe health losses, with indicators calculated using exponential, hyperbolic discounting, quasi-hyperbolic discounting models, including variable and fixed present bias cost. Then the best-fitting discount model in the health domain was identified using the Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC). Financial time preferences are elicited using multiple price lists(MPL) for losses. Nonlinear least squares regression were used to examine the determinants of time preference indicators, respectively.

Results: Rural adults exhibited significantly lower discount rates in the health domain compared to the financial domain, indicating greater patience for health-related outcomes. The quasi-hyperbolic specification with a variable present bias cost (r=0.270) was identified as the best-fitting discount model (AIC=16740.45; BIC=16763.63). Moreover, a future-oriented preference (β=7.833) rather than present bias was observed, with respondents showing a greater willingness to shift future health losses to the present. The determinants analysis shows that higher education levels, higher income, being married, larger household sizes, engagement in agricultural work, lack of medical insurance, and

having chronic diseases encourage individuals to consider longer-term health outcomes, while age, healthcare accessibility, and self-rated health have significant but directionally indeterminate effects on time preferences.

Conclusion: This study reveals that rural populations exhibit distinct time preferences in the health domain, characterized by a future-oriented perspective and lower discount rates compared to the financial domain. Key factors influencing time preferences include age, income level, education level, household size, marital status, work type, self-rated health, medical accessibility, coverage of medical insurance and health level. The findings underscored the importance of eliciting health time preferences using health outcomes rather than financial onescand highlighted the need for tailored interventions that consider individual time preference profiles, such as promoting health education and awareness among those with a lower long-term orientation. Particular attention should be given to vulnerable subgroups, including those with lower education levels, poorer health status, unmarried, and from poor households, by providing targeted resources to encourage proactive health behaviors.

Ind-2688 Decomposition of Income-related Health Inequality by Determinants and Dimensions Using EQ-5D-5L: A Cross-sectional Study in China

PRESENTER: **Jingxian Wu**
AUTHORS: Yaping Deng, Cong Li, Yuqi Yang
Background The EQ-5D-5L is a widely recognized instrument for measuring health status globally. Income-related health inequality, a critical public health challenge, has been extensively studied using EQ-5D-5L. However, most studies focus on the contributions of health determinants, overlooking the unique roles of health dimensions. This study bridges this gap by decomposing income-related health inequality among adults in China, considering both the determinants of health and the five dimensions of EQ-5D-5L. **Methods** A nationally representative sample of 29882 Chinese adults aged 18 and above was drawn from the 2023 Psychology and Behavior Investigation of Chinese Residents (PBICR). The concentration index (CI) was used to assess the socioeconomic-related inequality in EQ-5D-5L with household income level taken as the ranking variable. An integrated decomposition method was employed to identify the contributions of determinants and dimensions to the observed overall inequalities. **Results** The estimated CI for the utility value of EQ-5D-5L was 0.0092 ($p < 0.001$), indicating a pro-rich distribution of health outcomes. Pain/discomfort (PD) and mobility (MO) accounted for over 70% of the overall inequality. Chronic disease (20.99%), household income (20.65%), and sex-age (16.22%) were primary contributors, followed by family health (9.41%) and sleep quality (7.76%). Additional contributors included malnutrition risk (6.85%), health literacy (6.10%), and experience of negative events (5.79%). The contributions of leading determinants to the overall predicted inequality exhibited substantial heterogeneity across the five health dimensions. **Conclusion** This study provides insights on the sources of income-related health inequality by integrating the contributions of health determinants and dimensions. PD and MO are key drivers of overall inequality, with chronic disease, household income, sex-age, as well as determinants from psychosocial circumstances and behavioral risk factors, significantly contributing to disparities. The findings highlight the need for targeted public health policies addressing dimension-specific health disparities and socioeconomic inequalities to improve health equity in China. This dimension-based approach to inequality decomposition offers a framework for future research on multidimensional health inequalities.

Ind-2220 Income-Related Inequalities in Chronic Pain Among Middle-Aged and Older Chinese Adults : A Population-Based Cross-Sectional Study

PRESENTER: **Kunlu Tong**
AUTHOR: Jingxian Wu
Background

Chronic pain is one of the leading causes of disability, especially for middle-aged and old adults, and has become an international public health issue. The growing aging population and income disparities worsen the unequal burden of chronic pain, which urged us to understand the role of inequalities on chronic pain to guide actions for pain prevention seeking to reduce its unequal burden. This study aimed to estimate the inequalities of chronic pain among people middle-aged and older in China, to analyze the determinants of pain.

Method

A total of 17,840 respondents over the age of 45 were sourced from the 2020 wave of the China Health and Retirement Longitudinal Study (CHARLS). Chronic pain is graded from mild to severe, based on self-reported pain levels, which include five levels. Income-related inequalities in chronic pain were assessed using the concentration index (CI), with per capita household income as the ranking variable. The recentered influence function (RIF) regression decomposition method was employed to identify the contributions of various determinants to chronic pain inequalities.

Results

The estimated CI for chronic pain is -0.0709 ($p<0.001$) in 2020, indicating pro-poor inequality in chronic pain among middle-aged and older adults. The decomposition analysis revealed that gender (8.0085%, $p<0.001$), education — particularly high school and above (5.3557%, $p<0.001$), and primary school education level (3.4793%, $p<0.001$)— were key factors contributing to increased inequality in chronic pain. In contrast, chronic disease and depressive tendency(-14.1684%, $p<0.001$) significantly reduced pain inequalities. Additionally, individuals with more than one chronic disease (-16.5084%, $p<0.001$) had a greater contribution to pain inequalities than individuals with only one chronic disease (-3.7753%, $p<0.001$). Other factors, such as area of residence (-3.1833%, $p<0.001$) and household per capita income (-1.0276%, $p<0.001$), were more consistently associated with reduced inequalities.

Conclusion This study highlights pronounced pro-poor income inequalities in pain among middle-aged and older adults in China. Socioeconomic factors and physiological factors, such as per capita GDP and chronic diseases, were more consistently associated with reduced inequalities, while education and gender factors were linked to increased inequalities. Public policies must consider low-income populations and gender disparities to reduce chronic pain inequalities. Reducing economic disparities between regions and improving the health literacy of older adults are also important strategies for reducing inequalities. Through this approach, it is expected that the impact of pain on the healthcare system will be reduced, helping to achieve healthy aging and an improved quality of life for all.

This study is funded by the National Natural Science Foundation of China (No. 72104196).

Ind-2652 Redistributing Indonesia National Health Insurance Members: Opportunities to Enhance Public Health Performance and Financial Considerations

PRESENTER: **Ulfathea Mulyadita**

Background: National Health Insurance (JKN) in Indonesia is managed by Social Security Administering Body on Health (BPJS-K). It covers all public and selective contracts with private primary health care (PHC) facilities. At the PHC level, the majority of JKN members are registered to public facilities, known as Puskesmas (78.8%), followed by private clinics (13.7%) and the General Practitioners (4.5%). This means the current doctor-JKN member ratio in Puskesmas is higher than private facilities (1:6,373 vs 1:1,571), despite the ideal mandated ratio by BPJS-K regulation of 1:5,000. To improve equal distribution, the Government of Indonesia (GOI) is exploring alternative for redistributing JKN members from Puskesmas to JKN-contracted private PHC facilities. However, this redistribution policy might adversely affect Puskesmas' health financing since their capitation revenue might be significantly reduced due to shifting of registered JKN members as one of the multiplier factors. Accordingly, this study aims to explore the potential impact of JKN member redistribution on Puskesmas performance and PHC capitation revenue. **Method:** This study utilizes secondary data from 63 Puskesmas in Surabaya in 2021. It consists of the following: Puskesmas profiles, performance-based capitation indicators for personal health performance, and Minimum Service Standard (MSS) data for public health performance. The data analysis was conducted in three steps. First, compared all Puskemas performance scores with target indicators and created a composite score for both personal and public health performance. Second, performed a multiple regression analysis to quantify the impact between public health performance and the doctor-JKN member ratio. Lastly, conducted a simulation to explore JKN member redistribution to private facilities within a 3km radius based on the ratio and public health performance, estimating the potential loss of capitation revenue. **Results:** The results of personal health performance across the 63 Puskesmas indicated that all of them (100%) met the required indicators. However, public health performance results revealed that only one-third (34.9%) of the Puskesmas achieved their targets. Based on multiple regression analyses, a 10.5% reduction in the doctor-JKN member ratio significantly improved public health performance by 1% among all Puskesmas. Further simulation for one Puskesmas in Surabaya demonstrated that redistributing members from a ration 1:9,165 to 1:5,500 to nearby private facilities would be improve public health performance by 0.477%. but also, could potentially lead to a loss of up to 8,330 USD in capitation revenue. **Conclusion:** The study highlights the complex relationship between healthcare performance, doctor ratios, and financial sustainability within Indonesia's JKN system. The findings underlined the potential improvement in public health performance that should be supported by careful consideration of its financial implications, particularly regarding potential revenue loss for Puskesmas. The study suggests that such policies should be accompanied by regulations and incentives to maintain the financial stability of primary healthcare facilities. The role of special allocation funds (DAK) and other incentives to compensate for capitation revenue reductions is considered a potential solution to mitigate financial impacts.

Ind-1357 Sickness Absence as a Side Effect of Delayed Retirement: Evidence from France

PRESENTER: **Mohamed Ali BEN HALIMA**
AUTHOR: Ali Skalli

In 2010, a reform of the French pension system took place. It consisted in postponing the pension eligibility age by 2 extra-years within a rather short transition period as only the 1950-1955 generations were concerned. While the stated objective of the reform was the increase of senior workers' labor supply and the reduction of the pension insurance fund deficit, a number of studies have shown that similar reforms usually induce collateral effects as well, including shifts towards alternative insurance schemes such as unemployment or disability.

In order to assess the effect of the 2010 pension system reform on sickness absence, we use a 2005-2015 panel of administrative data that contains a wealth of information about individuals' working lives, on their individual characteristics, on their health as well as on sick leave. Clearly, the 2010 reform induced a shock that could be seen as a natural experiment and could be used to identify the causal effect of retirement age on sick leave. This, we believe, is an important issue as if such an effect turns out to be significant, then that would imply that while the reform aimed at reducing the pension insurance deficit, it actually also widened that of the public health insurance.

The issue at stake is that of determining the trend in sick leave of the treated generations (1952-1954) had they not been subject to the reform. Thus, the non-treated generations (1946-1951) are used to construct the counterfactual and the effect of interest is identified through

comparison of sickness absence records of the generations that are subject to the reform to those of the generations who are not, age and other characteristics held equal. Heterogeneity of the estimated effects is also examined in a two dimensions; namely gender and health status.

Our main result suggests the pension system reform has induced a significant increase in sickness absence for individuals older than 60, the estimated effects being differentiated according to both gender and health conditions. We consider alternative measures of sickness absence (the probability of being on sick leave and the cumulative annual sick leave duration) and show that the reform has indeed resulted in a significant increase in these. The highlighted effects are gender-sensitive and, most importantly, negatively correlated with senior workers' health status.

These results also imply that while the reform aimed at reducing the pension insurance deficit, it actually also widened that of the public health insurance. In France, sick pay has two main sources: a common and universal part provided by public health insurance and a complementary part provided by employers. This means that any increase in sickness absence is reflected in labor costs as well. The policy implications of these results are also worth discussing. To begin with, reforms based on the age parameters of the pension system should perhaps account for health-related heterogeneities. Perhaps, senior workers with poor health should be allowed to leave, especially when they started their career at early ages and/or when they have strenuous occupations.

Ind-1738 Working Hours and Workers Health: Evidence from a National Experiment in Sweden

PRESENTER: **Daniel Kuehnle**
AUTHORS: Nikolaos Prodromidis, Martin Karlsson

The regulation of working hours has long been a cornerstone of employment legislation, aiming to safeguard workers' physical and mental health while preserving labor productivity. However, credible causal evidence on the health impacts of reducing working hours, particularly over the long term, remains limited. This paper examines the causal effects of reduced working hours on mortality using high-quality population register data from Sweden, leveraging a nationwide policy introduced in 1920. The policy reduced working hours from 56 to 48 per week for about one-quarter of salaried workers, without reducing earnings. This reform represents a rare historical example of a substantial and exogenous reduction in working hours on a national scale.

We address two key research questions: (1) What is the causal impact of reduced working hours on worker mortality and longevity? (2) Through which mechanisms do these health benefits manifest? Employing a difference-in-differences framework, we compare mortality trends among workers eligible and ineligible for the reform. This approach exploits variation across occupations while accounting for time-invariant factors and secular mortality trends. Data sources include the 1910 Swedish Census, linked to the universe of death certificates, and additional administrative data digitized from historical records. We examine both immediate and long-term impacts on mortality and causes of death.

Our findings reveal that the policy led to a substantial reduction in mortality among treated workers, decreasing death rates by approximately 20% (0.2 percentage points annually) over the first six years of implementation. This translates to approximately 12,000 lives saved during this period. The mortality reduction was most pronounced among older workers, with notable declines in deaths due to heart disease and workplace accidents. Further analysis of longevity outcomes shows that the reform increased affected workers' life expectancy by approximately 0.6 years.

Mechanism analyses suggest that reductions in cardiovascular strain and workplace accidents drove these results. Digitized cause-of-death data indicates that heart disease mortality declined by 13% and workplace accident deaths by 20%. We find no significant effects on unrelated causes of death, such as cancer or tuberculosis, underscoring the specificity of the policy's health benefits. Importantly, earnings remained unchanged, isolating the health effects of reduced working hours from potential income effects. Robustness checks, including placebo analyses and various specification checks, confirm the validity of our findings.

These results highlight the potential health benefits of reducing long working hours, particularly in physically demanding occupations. In light of contemporary trends, where one-third of workers globally exceed 48 hours per week, these findings have significant implications for public health and labor policy. Policymakers should consider targeted reductions in working hours for labor-intensive occupations as a strategy to improve health outcomes and longevity, especially given the documented economic feasibility of such reforms.

Our study makes a novel contribution to the literature by providing the first causal evidence on the mortality impacts of reduced working hours in the short- and long-run using population-level data. While our findings are specific to early 20th-century Sweden, the results hold relevance for modern economies debating work-life balance and occupational health regulations.

Ind-2447 The Effect of Long-term Care Insurance on the Labor Market Outcomes of Household Members in South Korea

PRESENTER: **Hye Yoon Chung**
AUTHOR: Anna Kim

This study examines the short-term effects of long-term care (LTC) insurance on household labor market outcomes in South Korea, with a focus on gender differences. Using data from the Korea Welfare Panel Study, we apply a difference-in-differences event study design combined with propensity score matching to estimate the program's spillover effects at both the extensive and intensive margins. We find that LTC insurance increases labor force participation and part-time employment, while having a modest, statistically insignificant negative effect on full-time employment. At the intensive margin, a statistically significant positive effect is observed on part-time workers' earnings, with no significant effects on part-time work hours or full-time workers' earnings and hours. Gender-disaggregated analyses yield statistically insignificant effects, except for part-time employment on men. These findings underscore the importance of flexible employment arrangements in mitigating the labor market impacts of caregiving responsibilities and suggest that LTC insurance can play a valuable role in sustaining labor force participation, particularly through part-time work. While full-time employment is often prioritized in policy discussions, part-time work plays a

critical role in balancing work and care. Though the effects are modest in the short run, LTC insurance appears to help prevent workforce withdrawal, with meaningful implications for labor and social policy.

Ind-1333 Behavioural Responses to Disability Insurance Generosity Under Extensive Earnings-Cumulability

PRESENTER: **Michele Belloni**
AUTHORS: Vincenzo Carrieri, Francesca Zantomio, Irene Simonetti

In developed countries, Disability Insurance (DI) plays a pivotal role in protecting workers from financial instability following health shocks by providing income replacement. However, the design of DI programs significantly influences workers' responses to health shocks. Most existing studies examine DI systems where benefits diminish substantially once labor earnings cross low thresholds. For example, in the US, benefits are lost if reaching a low "substantial gainful activity" threshold, corresponding to about 36% of median labour earnings, creating disincentives to work. In contrast, this study explores DI systems with extensive earnings cumulability, where labor earnings can coexist with DI benefits up to high thresholds, minimizing these disincentives.

The focus is on Italy, where DI allows personal earnings to reach up to 97% of median earnings before any reduction in benefits occurs, and the reduction is modest (25%). This structure provides a unique context for examining labor market participation (LMP) and DI enrollment as separate phenomena. This paper leverages a 1995 Italian social security reform that altered the formula for calculating social insurance benefits, including DI. The reform reduced DI generosity for individuals entering the labor market after 1995 while keeping other design features constant. This change enables us to study behavioral responses to income effects. The analysis uses a unique administrative dataset (WHIP-Health), which links employment histories from a 7% sample of Italian private-sector workers with hospital discharge records, focusing on those who experienced acute cardiovascular (CVD) shocks, such as heart attacks and strokes, between 2003 and 2011.

While experiencing a CDV health shock, these workers faced variation in their prospective replacement rates based on a policy reform enacted at least eight years before the onset of the health shock under consideration. We exploit the combination of these features in a Regression Discontinuity in time Design framework centred around the timing of workers' labour market entry (implying lower current DI generosity for those entered after 1995).

In this way, we offer three main contributions to the existing DI literature. First, we offer novel empirical evidence on the behavioral responses to DI generosity in an extensive earnings-cumulability setting. We present LMP and DI elasticities estimates, representing distinct phenomena in this context. Second, because the normative framework enables us to capture an income effect, we enrich the currently limited evidence on behavioural responses relatable to an income, rather than a substitution, effect (as in Marie and Vall Castello, 2012 and Deuchert and Eugster, 2019). Third, the possibility of focusing on individuals who experienced a CVD shock helps address unobserved heterogeneity and the inherent challenge of observing the actual disability status of potential claimants, offering evidence on a sample of plausibly eligible individuals and thus limiting the role of adjudicators' discretion.

We observe a substantial response in DI participation to reduced benefit generosity. Conversely, the labour supply adjustment is minor, driven by immigrant workers. Overall, our results suggest that DI benefits are broadly perceived as complementary to labor income in an extensive earnings-cumulability context, with important implications for the design of labor-inclusive DI schemes.

Ind-1839 The Impact of Mental Health on Labour Market Outcomes: New Evidence from Genetic Markers

PRESENTER: **Sonja De New**, Monash University
AUTHORS: Danusha Jayawardana, John De New, Clement Wong, Nicolau Martin Bassols

Background

Mental illness is a global health issue where one in five individuals are affected by a mental health condition at any given time. As an important aspect of human capital, mental health can directly impact a number of labor market outcomes. Employing conventional identification strategies such as panel data techniques and instrumental variables (IV) estimators, previous economic studies show that poor mental health adversely affects labor market in terms of lower employment (Frijters et al 2014), earnings (Biasi et al 2021, Levinson et al 2010), and productivity (Bubonya et al 2017, Stewart et al 2003). However, establishing a causal relationship between mental health and labor market outcomes is empirically challenging due to several well-established endogeneity concerns. First, mental health may affect employment outcomes and employment outcomes may affect mental health, resulting in reverse causality or simultaneity bias. Second, the use of self-reported measures of mental health and employment outcomes may lead to measurement error. Third, unobserved confounders such as childhood circumstances, cognitive ability, genetic endowment that affect both mental health and employment can lead to biased estimates. While conventional methods are valuable, they fall short of fully addressing all of the above concerns of endogeneity, as highlighted by Frijters et al (2014) and Bubonya et al (2014).

Contribution and Method

The strong associations between mental health and labor market outcomes are well documented, but are often entangled in concerns over reverse causality. In this paper, we use polygenic risk score (PRS) information from the Health and Retirement Study (HRS) to examine how the genetic risk of depressive symptoms, preceding the individual's labor market participation, are associated with employment outcomes later in life. As we use the medically-assessed polygenic risk scores on the narrow sample of adults of European descent, specific to each individual in our sample, and we provide sensitivity analysis addressing assortative mating and pleiotropic pathways, this study contributes to the literature on the causal effects of the genetic predisposition of depressive symptoms on labor market outcomes. Identifying causal effects, rather than mere correlations, is crucial for informing targeted interventions. Additionally, we contribute to the literature by investigating whether individuals with poor mental health tend to select into lower-quality jobs using a wide range of job characteristics, thus providing insights for creating more supportive work environments.

Results

Whilst both men and women experience significant and substantial earnings reductions with higher PRS scores, we also find gender differences: women with greater genetic risk of depressive symptoms tend to work fewer years than lower risk women; men with greater risk work similar years to lower risk men, but work in jobs with fewer abstract and higher manual tasks. Moreover, we use detailed O*NET information to show that men at greater risk of depressive symptoms work in jobs facing more hazardous conditions, and with fewer interpersonal interactions. Our findings suggest that with a higher genetic risk of depressive symptoms, women participate less in the labor force whereas men select into less desirable jobs, diminishing lifetime earnings trajectories in either case.

Ind-2408 Infant Toddler Quality of Life Questionnaire (ITQOL) Among Cerebral Palsy Children in GAME trial

PRESENTER: **Xin Zhan**

AUTHORS: Catherine Morgan, Iona Novak, Rachael Lisa Morton, Xin Zhan

Background Cerebral palsy (CP) can yield a large and life-long economic burden on families and society. A randomized clinical trial was conducted to assess improvements in motor and cognitive skills. Infant quality of life measured by the Infant Toddler Quality of Life Questionnaire (ITQOL) was an important secondary outcome. **Aim** This study aimed to investigate ITQOL overall and domain scores, for intervention and standard care groups; and examine determinants of change in scores at one and two years following randomization. **Methods** Parent-reported ITQOL scores were collected at year one and two among the intervention group (n=150 infants) and standard care group (n=152 infants). Non-parametric Kruskal Wallis tests were used to analyze the difference in ITQOL overall and domain scores. Generalized linear models with repeated measures and random intercept were constructed to examine the changes in ITQOL scores at two years. **Results** There was no significant impact of the GAME intervention on ITQOL overall scores over time (p=0.09 at year 1 and p=0.25 at year 2). However, there was a significant impact of treatment over standard care over time on some domain scores including, general health perception improvement (Estimate: 5.65, SE:2.30, p=0.01); physical abilities (Estimate: 8.19, SE: 3.01, p=0.01) at year one and (Estimate:12.67, SE: 3.29, p<0.05) at year two; pain and discomfort (Estimate: 10.55, SE: 2.79, p<0.05). Infants with suspected but not diagnosed CP; families with high incomes; families with disability funding; or with few siblings, showed a significant improvement in ITQOL scores over time (Estimate: 2.73 [SE: 0.88], 8.51 [SE: 2.65], 2.35 [SE: 1.00], 1.29 [SE: 0.64], respectively). **Conclusion** Strategies to support families with infants who have a CP diagnosis; are on low incomes; with more than one sibling; or families who do not have disability funding; are needed to improve infant quality of life.

Ind-49 Validity, Reliability, and Framing Effects in Equity-Efficiency Trade-off Studies: A Systematic Review

PRESENTER: **Shehzad Ali**, Western University

AUTHOR: Victoria Chechulina

Objectives Health system resources are limited, and decision makers often need to make trade-offs between equity and efficiency. Such trade-offs are guided by public values that are elicited using choice experiments. There is no standard approach to elicit equity-efficiency trade-offs. Previous studies have found significant variability in public values, raising concerns about the robustness of trade-off experiments. The objective of this systematic review was to determine whether and how equity-efficiency trade-off studies consider validity, reliability and framing effects. ***Methods*** We searched Medline, EMBASE, and Web of Science in January 2024 for health-related equity-efficiency trade-off studies. Two reviewers independently screened titles and abstracts, followed by full-text review, data extraction, and quality assessment. ***Results*** 115 equity-efficiency trade-off studies were identified, of which 29 studies (25.2%) investigated validity, reliability, and/or framing effects. 14 (12.2%) studies assessed validity, 9 (7.8%) studies assessed reliability, and 10 (8.7%) assessed framing or cognitive effects. Validity was most frequently assessed by comparing results to hypothesized expectations, while reliability was commonly assessed by providing a repeated test or questionnaire. Framing and cognitive effects were assessed by varying question order or changing the wording or framing of the scenario. 19 of 23 studies reported high or acceptable validity or reliability, and 5 of 10 studies found no significant framing or cognitive effects. ***Conclusion*** This systematic review highlights the need to consider robustness of elicited values in choice experiments. It will also guide future choice experiments that aim to estimate inequity aversion.

Ind-991 Developing an Australian Value Set for the Recovering Quality of Life (ReQoL) Instrument using Discrete Choice Experiment with Duration

PRESENTER: **Cathy Mihalopoulos**

AUTHORS: Thao Thai, Lidia Engel, Richard Norman, Brendan Mulhern, Jemimah Ride

Objectives

The Recovering Quality of Life (ReQoL) instrument was designed to measure the quality of life outcomes for people over 16 years of age with mental health problems. Our study aims to elicit societal preferences for the ReQoL-Utility Index (ReQoL-UI) health states within the Australian context to facilitate more informed decision-making in Australia.

Methods

A discrete choice experiment (DCE) with duration was embedded in a self-complete online survey and administered to a representative sample (n=1019) of the Australian adult population, stratified for age, sex and geographic location. A partial subset design DCE was used with 3 fixed attributes and 5 varying attributes containing 240 choice tasks that were blocked into 20 blocks, so that each respondent was assigned a block of 12 choice tasks. The value set was modelled using the conditional logit model with utility decrements directly anchored on the 0 to 1 dead-full health scale. Preference heterogeneity was tested using the mixed logit model. A range of models were tested to smooth out the disordering of the utility estimates and to investigate potential interaction effects between dimensions.

Results

The final value set reflects the monotonic nature of the ReQoL-UI descriptive systems while showing stability even considering preference heterogeneity. The best health state defined by the descriptive system has a value of 1 and the worst state has a value of −0.585. Across all attribute levels, physical health level 5 had the largest utility decrement, followed by physical health level 4. The third important level was well-being level 5, followed by hope level 5. In contrast, control level 2 and 3 had the smallest utility decrement (0.01), meaning that these differences in levels of the control item have the least impact on utility.

Conclusion

The value set, which reflects the preferences of the Australian population, facilitates the calculation of an index value for use in the estimation of quality-adjusted life years (QALYs) for cost-utility analyses of mental health interventions in Australia.

Ind-1120 Identifying Suitable Methods to Implement the South African Value Framework in HTA (SAVE-UHC)

PRESENTER: **Celeste Claire Holden**
AUTHORS: Simon Walker, Evelyn Thsehla, Peter Murphy, Yirui Qian, Susan Griffin

Introduction In pursuit of universal health coverage (UHC) countries must use their resources in a fair and efficient manner. Health technology assessment (HTA) uses available evidence to assist in priority setting. HTA traditionally focuses on clinical efficacy, and cost per unit change in health outcomes. More recently, HTA institutions are seeking to incorporate additional value elements in cost-effectiveness analyses such as equity, disease severity and non-health outcomes. South Africa (SA) proposes to create an HTA body through the National Health Insurance (NHI) bill. In anticipation, the South African Values and Ethics for Universal Health Coverage (SAVE-UHC) value assessment framework (VAF) has been created. SAVE-UHC consists of 12 value elements which were determined and tested by a multidisciplinary working group. Despite the framework making explicit the aspects that should be valued in priority setting, the methods and approaches available to operationalize the VAF in an HTA setting have yet to be defined. To address this, we ask how these value elements can be measured in HTA in the South African context? **Methods** We first conducted a mapping exercise from an existing VAF, the International Society for Pharmacoeconomics and Outcomes Research Value Flower (ISPOR VF) to SAVE-UHC. The ISPOR VF describes 12 value elements and proposes potential methods which could be applied for each value element. We categorised results of the mapping exercise into ‘good match’, ‘partial match’ or ‘no match’. In cases of good and partial matches, the methods identified for ISPOR VF could potentially be used for SAVE-UHC. To supplement the methods gleaned from the mapping exercise, we consulted experts in health economics and public health through an online survey and stakeholder workshop. **Results** The mapping exercise showed 5 good matches, 7 partial matches and 2 non-matches. Based on these matches, a list of metrics, approaches to valuation and methods from the ISPOR VF are suggested for the SAVE-UHC elements which had good and partial matches. The online survey provided additional methods for each value element of the SAVE-UHC framework which are presented in the results table. The methods gleaned from the mapping exercise and survey were further discussed in the workshop in terms of their appropriateness, practicality and acceptability. **Conclusions** South Africa, like many other countries, does not yet have a formal explicit approach of considering additional value elements in decision making processes like HTA. This research presents a wide range of methods from different sources which may be used to measure value elements in HTA alongside a context-specific VAF. The approach we used to gather these methods could also be used in other countries seeking to implement their own VAF. Further research is required to determine which of the methods presented in this study are practical and useful to implement given the data and resource constraints in the South African context.

Ind-2389 Psychometric Performance of Preference-Based Instruments in Older Adults: a Systematic Review

PRESENTER: **Valeriia Sokolova**
AUTHORS: Lidia Engel, Jan Faller, Yared Belete Belay, Pei Wang

Background: Population aging is a significant global public health concern. Preference-based instruments are effective tools for assessing the impact of ageing on health-related quality of life (HRQOL) and for evaluating the cost-effectiveness of health and social care interventions. With the coexistence of various preference-based instruments, it is crucial to determine which measure is most suitable for use in older adults.

Aim: The aim of the study was to systematically review and summarize the current evidence on the psychometric properties of preference-based measures in older adults across different settings.

Methods: Four major databases (Medline, Embase, PsycINFO and CINAHL) were searched for original studies, complemented by a forward and backward citation search. Peer-reviewed studies assessing measurement properties including reliability, validity, sensitivity, and

responsiveness of preference-based instruments in older adults (i.e., age ≥ 65 years) were included in the review. Two independent reviewers screened titles, abstracts, and full-text and extracted key information of studies. The methodological quality of included studies was checked using the COSMIN risk of bias checklist.

Results: In total, 90 studies met the inclusion criteria, examining the psychometric performance of the following measures: EQ-5D-3L=47, EQ-5D-5L= 30, ICECAP-O=20, ASCOT=10, SF-6D=6, QOL-ACC=6, HUI3=7, HUI2=5, QWB=4, WOOP=3, AQoL-8D=2, 15D=1. The EQ-5D measures (-3L and -5L) were evaluated across all psychometric properties, with most studies indicating strong performance for both versions. However, some studies highlighted limitations, including ceiling effects, inter-rater reliability issues, and conflicting findings regarding responsiveness to change. Strong supportive evidence was observed for the ASCOT and ICECAP-O even though both measures require further evaluation in terms of their responsiveness to change. Limited evidence was available for the SF-6D, HUI2, HUI3, QWB, AQoL-8D and 15D with existing studies showing mixed results overall. While recently developed, emerging evidence supports the psychometric properties of the two older adult-specific preference-based measures, QOL-ACC and WOOP. However, further research is needed to assess their responsiveness to change and reliability.

Conclusions: Preference-based measures are widely used among older adults but evidence regarding their psychometric performance remains limited. To better inform the selection of measures for future economic evaluation studies, further research is needed, particularly head-to-head comparisons using a consistent methodological approach.

Ind-2686 A Heterogeneity Analysis of HRQoL in Early Adults Born Very Preterm or Very Low Birthweight: Evidence from a Meta-analysis

PRESENTER: **Corneliu Bolbocean**

Aim: Preterm birth and low birthweight negatively affect health-related quality of life (HRQoL) into early adulthood. However, it remains unclear which subgroups of individuals are most affected. We aimed to explore heterogeneity in the effects of very preterm birth or very low birthweight birth (VP/VLBW) on HRQoL in early adulthood with respect to sociodemographic factors. **Data:** Individual participant data were obtained from five longitudinal prospective cohorts of adults born very preterm (VP; <32 weeks' gestation) or with very low birthweight (VLBW; <1500 g) and normal birthweight (≥2500 g) or term-born (≥37 weeks' gestation) controls contributing to the 'Research on European Children and Adults Born Preterm' Consortium. The main exposure was VP/VLBW. Outcome measures included multi-attribute utility scores generated by the Health Utilities Index Mark 3 (HUI3), self-reported at mean ages of 18-26 years. **Methods:** We used novel machine learning methods to identify the risk factors associated with differences in HRQoL. Specifically, we applied Causal Forests (CF) and Shrinkage Bayesian Causal Forests to estimate conditional average treatment effects (CATEs). Heterogeneity in CATEs was explored across the following subgroups of VP/VLBW adults: maternal age, education and ethnicity, and interactions between the three subgroups. **Results:** The effect of VP/VLBW birth varied by maternal age and maternal education. VP/VLBW individuals born to the youngest mothers (≤25 years) had a mean decrement in HUI3 utility score of -0.08 (95% CI −0*.13*,* −0*.02), which was a larger decrement compared with births to mothers aged 26-30 years (-0.02; 95% CI -0.05, 0.01) and ≥31 years (-0.03; 95% CI -0.06, 0.00). We found a mean decrement of -0.05 (95% CI -0.09, -0.01) for VP/VLBW born to mothers with the lowest educational level, a decrement of -0.04 (95% CI −0.08*,* 0*.*00) for those born to mothers with a medium level of education, and an increase of 0.01 (95% CI -0.04, 0.06) for those born to mothers with highest educational level. **Conclusion**: The effects of VP/VLBW birth on HRQoL vary across subgroups defined by maternal characteristics. Further studies that estimate the effects of VP/VLBW status on HRQoL outcomes in mid and late adulthood across socioeconomic strata are needed. Targeted health interventions for VP/VLBW individuals born to younger mothers and mothers with lower educational levels are warranted to alleviate the risk of poorer HRQoL outcomes in early adulthood. **Keywords:** Heterogeneity of treatment effects, machine learning, preterm birth, HRQoL, quality of life.

Ind-2775 Mapping Health Outcome Measures and Health Crisis

PRESENTER: **Mona Aghdaee**, Macquarie University

Background: Nonpreference-based patient-reported outcome measures (PROMs) are popular in health outcomes research. These measures, however, cannot be used to estimate health state utilities, limiting their usefulness for Health Technology Assessment (HTA). Mapping PROMs to a multiattribute utility instrument is one solution. Mapping has become even more relevant with the occurrence of the COVID pandemic. The world of HTA has been affected by: exponential growth of infected adults, countries prioritising HTA related to COVID pandemic, and restrictions on normal operations for economic evaluations (HTA trials were indefinitely postponed/delayed or suspended during the pandemic). Moreover, COVID has also changed priorities and methods of working (remote working and social distancing rules), mode of healthcare delivery, and potentially influence individuals/patients' preferences. These factors will impact the HTA process including preference elicitation (PBM/non-PBMs) in post-COVID world. **Objective:** This study aims to inform post-COVID HTAs and assesses how the COVID pandemic has influenced preference elicitations by Australian and, consequently, the mapping algorithms. **Method:** Cross-sectional data were collected using two online surveys of the Australian general population. The first survey was conducted in February 2018, collecting data on (PROMIS10, EQ-5D-5D, AQoL-8D, Charlson comorbidity index) and the second survey was conducted during the first COVID-19 lockdown in June 2020. The secund survey collected data on the same instruments except PROMIS10. Instead, PROMIS29 was collected. Two physical and mental health summary scores were developed from PROMIS10 and were used to develop a mapping algorithm to predict EQ-5D-5L utilities in 2018 data. In the next step, the algorithm was used to predict EQ-5D-5L utilities in 2020 data. **Results:** In the year 2018, 2,015 Australians participated in the survey and 3,013 participated in 2020. Respondents from 2018 were more likely to have a comorbidity and reported lower EQ-5D-5L utilities. Propensity score matching was used to match respondents with using gender, age, and state. The mapping algorithm developed with data collected from the year 2018 could predict the utilities in year 2020 with relatively high accuracy (Mean Absolute Error (MAE) =0.2055). **Conclusion:** Previous research has shown that individuals' valuation of their health status may have been affected by COVID-19 pandemic. It is not clear whether the pandemic will be influencing mapping algorithms and subsequently economic evaluation in Australia. Our results might not reflect the actual impact of COVID-19, as in June 2020, Australians' health was not impacted by the pandemic and mechanisms such as lockdown and borders closure were in place to protect their health. The next step of our study is

collecting data on year 2022 and investigate the general population preference in the post-COVID era.

abs-os431 An Assessment of the Construct Validity of the ICECAP Capability Wellbeing Measure for Adolescents Aged 11 to 15 in the United Kingdom

PRESENTER: **Isabella Floredin**, University of Bristol
AUTHORS: Samantha Husbands, Philip Kinghorn, Katie Breheny, Louise Proud, Tim J. Peters, Joanna Coast, Paul Anand, Sarah Byford, Mr. Paul Mitchell

Introduction: A range of ICECAP capability wellbeing measures for children and young people (ICECAP-CYP) of different ages are currently in development for use in economic evaluation of health and care interventions. The ICECAP-CYP:11-15 instrument is a measure of capability wellbeing for young people aged 11 to 15. The descriptive system of ICECAP-CYP:11-15 was developed in the United Kingdom (UK) using in-depth and semi-structured interviews with young people and their parents/guardians. The measure comprises eight attributes important to capability wellbeing: *Fun and enjoyment; Learning and experiencing; Attachment; Emotional security and support; Achievement; Identity and choice; Physical safety; Aspiration.* To enable the use of the ICECAP-CYP:11-15 in economic evaluation, a survey was designed and piloted to provide values for these attributes and to examine the validity of the measure's descriptive system. Construct validity is an important element to explore for patient reported outcome measures to assess the extent to which the measure captures what it is intended to measure. This paper explores the construct validity of these attributes. **Methods:** A cross-sectional online panel survey was conducted with children and young people (CYP) aged 11 to 15 located across the UK. A representative CYP population (i.e. age and sex) was sampled through the survey company, embedded within the ICECAP-CYP:11-15 valuation study. Construct validity will be assessed by investigating whether the associations between the responses to the attributes of the ICECAP-CYP: 11-15 measure and other factors (i.e. socio-demographic characteristics; school characteristics; family composition; Child Health Utility (CHU-9D) health status measure; the Good Childhood Index (subjective wellbeing)) are in the anticipated directions and of magnitudes in line with expectations. Associations between variables will be investigated using chi-squared tests (for categorical variables) or one-way analysis of variance (for continuous variables), focusing on the direction and magnitude of associations as well as on p-values. **Results:** The survey was completed between October and November 2022. The sample (n=1,611) has an approximately equal number of children by year of age (25% aged 11, 21% aged 12, 18% aged 13, 19% aged 14, 17% aged 15), an approximate 50/50 split of boys (52%) and girls (48%) and the majority of CYP respondents self-reported being in very good or good health. The majority of responses across the capability levels suggest high levels of capability for all ICECAP-CYP:11-15 attributes. *Physical safety* reported top capability level (69%) more than other attributes. *Learning and experiencing* (52%) and *Emotional security* (54%) reported top level the least compared to other attributes. Preliminary results suggest that ICECAP-CYP:11-15 responses reflect anticipated differences across different socio-economic, health and general wellbeing groups. Validation analysis of associations is ongoing. **Discussion:** Full findings from the survey will be presented at the conference. The new measure is intended to provide information for decisions about resource allocation across health and care interventions. This work provides early evidence for the construct validity of the ICECAP-CYP:11-15 and therefore provides some support for its use in funding decision making. Valuation work will need to be undertaken with this measure to enable its use in economic evaluation.

Ind-1565 Micro-Costing Analysis of Childhood Hodgkin Lymphoma Treatment in the United States (US): Stratification by Risk and Resources Using ARIA Guidelines

PRESENTER: **Sahar Aliabadi**
AUTHORS: Jennifer L. Pauley, Nickhill Bhakta, Yutaka Yasui, Meagan Norton, John T. Lucas, Hannah Sauer, Priyadarshini Kumar, Nancy S. Bolous

Background: Childhood classical Hodgkin Lymphoma (cHL) is a curable cancer accounting for 40-45% of pediatric lymphomas. Multimodal therapy consisting of immunotherapy, cytotoxic chemotherapy and radiation, is critical for optimal survival but remains inaccessible in many global settings. To address these disparities, the Adapted Resource and Implementation Application (ARIA) guidelines were developed to provide resource-adapted, evidence-based recommendations for childhood cancer treatment worldwide. To ensure the successful real-world implementation of these guidelines and support investments towards improving Hodgkin lymphoma therapy, measuring economic costs is crucial to optimize resource allocation, deliver cost-effective care, and reduce barriers to equitable treatment. This study conducts a micro-costing analysis of cHL treatment using the US healthcare payer perspective, stratified by clinical risk groups and ARIA-defined resource-based strata (A-E) to evaluate cost variations based on therapeutic access.

Methods: A micro-costing framework was developed in consultation with a multidisciplinary expert panel. Unit costs in 2024 USD were retrieved from Centers for Medicare and Medicaid Services (outpatient visits, imaging, laboratory, surgery, and radiotherapy); IQVIA (chemotherapy); and St. Jude Children's Research Hospital (pathology). Costs for each phase of cHL treatment (pre-treatment, treatment, and 5-year follow-up) were estimated based on total costs calculated across ARIA-defined risk groups and resource-based strata. Stratum D represented the standard of care; strata C-E assumed access to radiotherapy; stratum B included access to CT imaging but no radiotherapy; and stratum A had no access to CT or radiotherapy. Stratum E mirrored stratum D but substituted vincristine with brentuximab, a novel

immunotherapy. ‘Essential Treatment’ included outpatient services, laboratory tests, imaging, surgery, and chemotherapy, while ‘Essential+Recommended Treatment’ incorporated additional value-additive laboratory tests and imaging.

Results: Total costs of cHL per patient from diagnosis to the end of the 5-year follow-up, varied by 20-fold, from $9,189 for minimum required testing and treatment to $190,009 for the most resource-intensive option. Analyzed by treatment phase: 1)Pre-treatment costs were consistent for ‘Essential Tests’ ($709) but varied for ‘Essential+Recommended Tests’ ($1,266–$1,533); 2)Treatment costs increased with risk level and resource-based stratum, ranging from $4,920–178,894 for ‘Essential Treatment’ and $5,213–179,187 for ‘Essential+Recommended Treatment’. Substituting vincristine with brentuximab in stratum E increased chemotherapy costs dramatically: low-risk, $2,004 (stratum D) to $73,791 (stratum E); intermediate-risk, $4,184–$123,691; and high-risk, $6,281–$173,592. Radiotherapy costs ranged from $3,318–$5,023 for three-dimensional conformal radiation therapy, volumetric-modulated arc therapy, and proton beam therapy; and 3)Follow-up costs totalled $3,691 over five years, regardless of the risk group and stratum.

Conclusion: This micro-costing analysis provides an initial understanding of cost variations across risk groups and therapeutic approaches within a single healthcare system. While prices vary globally, incorporating this heterogeneity is essential for broader applicability. Notably, the overall costs in this study are modest, but incorporating novel FDA-approved immunotherapies, like brentuximab, significantly increased costs. The methodology developed here provides a robust, scalable, and customizable framework for conducting future adaptive health technology assessments across diverse global settings and cancer types. It aims to support universal health coverage and informed health system investment decisions, paving the way for equitable healthcare access and improved policymaking.

Ind-1184 Estimating the Treatment Cost of Colon Cancer in a Tertiary Academic Hospital in the Western Cape, South Africa

PRESENTER: **Kelechi Nnene**
AUTHORS: Bhavesh Nagar, Claire Warden, Jennifer Moodley, Lucy Cunnama, John Ele-Ojo Ataguba, Adam Boutall

Background: Despite the availability of reliable screening methods and effective treatment options, colon cancer continues to impose a significant burden of morbidity, mortality, and economic costs globally. In South Africa, colon cancer has an age-standardized incidence rate of 6.8 per 100,000 and a mortality rate of 6.3 per 100,000, resulting in an estimated mortality-to-incidence ratio exceeding 0.9. This ratio highlights alarmingly poor treatment outcomes relative to colon cancer incidence in the country. To address this, urgent public health measures are needed to improve treatment outcomes. Costing studies can be leveraged to understand the treatment cost burden for colon cancer, providing crucial insights for allocating resources to finance such measures. Despite this, there is a shortage of relevant information on the treatment cost of colon cancer in South Africa.

Aim: This study aimed to assess the treatment options and stage-specific cost of colon cancer treatment from the perspective of healthcare providers at a tertiary academic health facility in South Africa.

Method: The study employed an ingredient-based guideline approach to evaluate colon cancer treatment components and stage-specific costs at the colorectal cancer clinic and combined colorectal oncology unit of Groote Schuur Hospital. The costing process involved two steps: first, treatment options were defined based on the facility’s colon cancer treatment protocol and linked to relevant resource inputs for each cancer stage through expert interviews. Second, a bottom-up costing approach was used to estimate and aggregate total per-patient guideline costs across treatment components for each stage. Resource inputs considered in the cost estimation included the cost of personnel directly involved in patient care, building space used, equipment and procedure specific to each treatment, relevant consumables and pharmaceuticals. All capital items were annuitised using a 3% discount rate. A one-way sensitivity analysis was conducted to address uncertainties, focusing on post-surgical inpatient admissions and staff categories. All costs are presented in 2024 South African Rands (ZAR) and United States Dollars (USD).

Results: Colon cancer treatment components include staging and risk assessment investigations, clinical consultations, surgery and chemotherapy. The estimated guideline-based per-patient costs for treatment are R60,156 ($3,216) for stages I, R67,644($3,617) and II, R75,132 ($4,017) for stage III, and R171,935 ($9,193) for stage IV. Surgical treatment represents a major cost driver, with additional expenses from inpatient admissions following surgery. Sensitivity analysis indicates that reducing postoperative inpatient stay by 50% lowers the treatment cost by approximately 10% across all stages.

Conclusion: Colon cancer treatment costs are significant and increase as the cancer advances. To mitigate these rising costs and reduce the healthcare burden, policymakers and healthcare providers should prioritise early detection through routine screening programs. By identifying and treating colon cancer at its earliest stages, it is possible to reduce the need for more invasive and costly interventions.

Ind-1097 Cost-Effectiveness Analysis of Pembrolizumab for Resected Stage III Melanoma from an Australian Healthcare System Perspective

PRESENTER: **Rashidul Alam Alam Mahumud**, University of Sydney

Aims: This study evaluates the cost-effectiveness of adjuvant pembrolizumab versus standard care after complete resection of high-risk stage III melanoma with lymph node involvement. Building on international evidence, we contextualise this assessment for the Australian healthcare system, aiming to inform decision-makers on the value of pembrolizumab in reducing melanoma recurrence and improving patient outcomes.
Materials and Methods: A Markov cohort model with four health states (recurrence-free, locoregional recurrence, distant metastases, and death) was used to estimate lifetime costs, life-years, and quality-adjusted life-years (QALYs) for patients treated with pembrolizumab compared to standard care. Transition probabilities were informed by the KEYNOTE-054 trial (NCT02362594) and adapted using Australian-specific data to reflect the local population and clinical practice. Health state utilities and adverse event disutilities were sourced from KEYNOTE-054 and a meta-analysis on melanoma patients. Costs were adjusted to the Australian context for drug acquisition, administration,

adverse events, disease management, and terminal care. A lifetime horizon was used, with costs reported in 2024 AUD. Deterministic and probabilistic sensitivity analyses assessed model robustness and the stability of results under varying assumptions and input values. **Results:** Over the lifetime horizon, adjuvant pembrolizumab yielded 8.59 QALYs and 11.28 life-years, compared to 6.37 QALYs and 8.19 life-years for standard care. The incremental cost-effectiveness ratio (ICER) was $36,200/QALY, falling well below Australia's willingness-to-pay (WTP) threshold of $50,000/QALY. Deterministic sensitivity analyses revealed pembrolizumab remained cost-effective across a range of parameter values, with ICERs varying between $12,000 and $46,000/QALY depending on inputs for drug costs, transition probabilities, and utility values. Probabilistic sensitivity analysis confirmed cost-effectiveness in 93% of simulations, providing robust support for pembrolizumab as a valuable intervention in adjuvant melanoma treatment. **Conclusions:** In the Australian healthcare system, pembrolizumab represents a cost-effective adjuvant therapy for high-risk stage III melanoma following complete resection, providing substantial improvements in survival and quality of life over observation alone. With an ICER well within Australia's WTP threshold, this study supports pembrolizumab's inclusion in funded treatment options for melanoma, aligning with national goals of enhancing cancer care access and improving patient outcomes. Future research should explore long-term impacts as real-world data becomes available to further confirm pembrolizumab's value in the Australian setting.
Keywords: Cost-effectiveness, pembrolizumab, melanoma, adjuvant therapy, Australian healthcare, Markov model, quality-adjusted life years

Ind-337 Impact of Immature Efficacy Data on the Economic Evaluation of Innovative Drugs for Rare Cancer: A Case Study of Intrahepatic Cholangiocarcinoma

PRESENTER: **Yi-Wen Tsai**, National Yang Ming Chiao Tung University
AUTHORS: Chen-Han Chueh, Yu-Wen Wen, Nai-Jung Chiang, Ming-Huan Chen, Hao-Min Cheng

Background: Early approvals of innovative treatments for rare cancers can improve patient access to new therapies but also introduce uncertainties in reimbursement decisions due to limited evidence. The U.S. FDA approved pemigatinib (2020) and futibatinib (2023) for advanced intrahepatic cholangiocarcinoma (aICC) with *FGFR2* fusions/rearrangements, based on early results of phase II trials. In 2023, Taiwan's National Health Insurance Administration (NHIA) began reimbursing pemigatinib for this indication.

Objectives: To conduct a head-to-head economic evaluation of futibatinib versus pemigatinib as second-line treatments for aICC with *FGFR2* fusions/rearrangements, comparing early efficacy data with final trial results published in 2024.

Methods: Three-state partitioned survival models were developed for a lifetime simulation, using progression-free and overall survival data from the FOENIX-CCA2 (2023, 2024) and FIGHT-202 (2020, 2024) trials. The hypothesized futibatinib price was derived from the listing pemigatinib price (13.5 mg at NT$12,500), adjusted based on the UK price ratios of the two medicines. Utility, disutility, and aICC-related costs were sourced from the literature. The willingness-to-pay threshold was set at three times the 2023 GDP per capita (NT$3,023,055), with a 3% discount rate applied to quality-adjusted life-years (QALYs) and costs. Scenario analyses examine variations caused by efficacy, treatment duration, costs, and adverse event assumptions. A cost-minimization analysis was conducted, assuming non-inferiority of the two FGFR inhibitors. Deterministic and probabilistic sensitivity analyses explored the uncertainty associated with the parameters.

Results: Economic evaluation results differed between early and final efficacy data from pivotal trials. Early data showed futibatinib incurred an additional cost of NT$116,147 and a gain of 0.17 QALYs, yielding a positive incremental net monetary benefit (INMB) of NT$7,022 and a 54.8% probability of cost-effectiveness. In contrast, the final data indicated an added cost of NT$88,982 with a QALY reduction of -0.45, resulting in a negative INMB of -NT$1,443,189 and a 10.0% probability of cost-effectiveness. According to the final data, cost-effectiveness could only be achieved if the futibatinib price was reduced by over 80%. In a cost-minimization analysis assuming non-inferiority, a 5% price reduction could result in a 59.3% probability of futibatinib being cost-saving.

Conclusions: Contrary to the economic evaluation results based on immature data, updated analysis using mature trial data indicates that futibatinib is not cost-effective as a second-line therapy for aICC with *FGFR2* fusions/rearrangements without a significant price reduction.

Ind-789 Health Economic Evaluation of Drug Therapies Among Individuals With High-risk Clonal Haematopoiesis

PRESENTER: **Nhung Nghiem**
AUTHOR: Mark Polizzotto

Objectives

Clonal haematopoiesis (CH) is among the major causes of age-related diseases, such as blood cancers and cardiovascular diseases (CVD). Fortunately, molecular testing has allowed individuals at high risk of CH to be identified, and epigenetic therapies can be applied to restore normal haematopoietic stem cell function and prevent CH's complications (CVD and all-cause mortality). This study aims to model and compare long-term health outcomes and the cost-effectiveness of various drug therapies targeting CVD and cancers in Australia.

Methods

We employ a Markov cohort model to simulate the Australian population aged 50+ until death or age 110, whichever comes first. We include CVD and all-cause mortality in the model. A health system perspective is used to estimate individual health costs. We use a 3% discount rate in the primary analysis and 0%, 5% and 6% for sensitivity analysis. We evaluate the cost-effectiveness of three classes of interventions, including targeted inhibitors, epigenetic modifiers, and anti-inflammatory agents. In particular, we model five interventions decitabine+tetrahydrouridine (DAC+THU), IDH1 inhibitor (Ivosidenib), colchicine, and canakinumab in the analysis for three diseases: acute myeloid leukemia (AML), myelodysplastic, and CVD. Of note is that the intervention effect sizes for the DAC+THU are hypothetical, as clinical trial results have not been available. Uncertainties on disease and cost parameters are captured in the model. Multiple time horizons are also conducted to inform

policy decision-making, including 2 years (for within-trial analysis), 5 years, 10 years, 20 years, 30 years and 60 years (the end of modelled population cohort).

Results

The most cost-effective CH intervention is expected to be canakinumab, with the highest quality-adjusted life year (QALYs) and lowest incremental cost-effectiveness ratio (ICER). The largest QALYs gain was due to the significant effect size in CVD prevention (30%). We will evaluate cost-effectiveness by sub-group, in particular age, sex, and disease risk. We will present the QALYs gain and costs in the years after the intervention (such as 96 weeks, 10 years and 60 years). We will also present the sensitivity analysis results with and without long-term health outcomes for CVD and all-cause mortality. Whether the sensitivity analyses change the conclusion of this study (for instance, if it is still cost-effective or the same by sub-group) will also be provided.

Discussion and Conclusions

We estimate that all the CH therapies are potentially cost-effective when long-term health outcomes are included in the model. As most of the health gain was due to preventing CVD, this has a huge public health implication in a high-income country setting with a large burden on non-communicable diseases. This is a world-first health economic evaluation for CH with long-term health outcomes – a randomised clinical trial is on the way, coordinated by our team. We will update the modelling with intervention effect sizes informed by clinical trials in CH interventions. Our results will help guide public health policies to prevent CVD and cancers among individuals with high-risk clonal haematopoiesis. 2

Health Insurance and Access to Care

MODERATOR: **Olukorede Abiona**,

Ind-2218 Advancing Universal Health Coverage in Nigeria: Assessing the Effectiveness of the Implementation of Basic Health Care Provision Funds

PRESENTER: **Uchenna Ezenwaka**, University of Nigeria
AUTHORS: Simeon Onyemaechi, Obinna Onwujekwe

Background: Nigeria's progress towards UHC is hindered by inadequate health financing (with out-of-pocket expenditure for health at 70%), exacerbating health disparities, and poor access to healthcare leading to poor health indices. In response to the poor health outcomes, the Nigerian government launched a novel health financing mechanism, 'the Basic Health Care Provisions Funds (BHCPF)' to address health disparities and provide equitable, quality, and sustainable healthcare services to all citizens. Implementation of BHCPF commences in 2021 in all the Nigerian states. However, there is a gap in knowledge on whether BHCPF has improved utilization and access to essential health services (EHS). The study aims to assess the effectiveness of BHCPF implementation in Nigeria and its implications for UHC. **Methods:** A mixed-methods approach combining quantitative (BHCPF utilization data) and qualitative data (key informant interviews, n=30 and FGDs, n=24) was conducted in Anambra State, Nigeria. The interviews were conducted with state and local government health authorities, and stakeholders at the implementation facilities levels were randomly selected across the state. Univariate and linear regression analysis was performed for quantitative data, while qualitative data were analyzed using a thematic content approach. **Results:** The study reveals a significant increase in BHCPF beneficiaries, with a compound annual growth rate (CAGR) of 46% over 2021 to 2023, and a highly significant positive coefficient ($R^2 = 0.998$; $p < .001$) between the time and beneficiary growth. The program increased utilization and access to EHS, reduced out-of-pocket expenses, and enhanced healthcare infrastructure by implementing primary health centres. The utilization of EHS services exceeded 100% annually indicating substantial demand. Access and quality EHS improved tremendously due to the availability of essential medicines and laboratory services, prompt referrals, and extended facility opening hours. The effectiveness of BHCPF implementation was largely driven by the National government's financial commitment, existence and compliance with the operational guidelines and availability of essential medicines. Conversely, several political, institutional and economic challenges limit effective BHCPF implementation. These include exclusion of LGA stakeholders in funds allocation, information asymmetry about BHCFP, inadequate number and skill mix of health workers at the implementing facilities, non-use of injection for treatment policy, lack of incentives and funds community sensitization and monitoring and non-payment of counterpart funds by the Sub-national governments. **Conclusion/Discussion:** BHCPF demonstrates potential in advancing UHC in Nigeria. Effective implementation, addressing identified challenges, and scaling up the program can significantly improve health outcomes and reduce financial hardship. The study contributes to the understanding of innovative health financing mechanisms in low- and middle-income countries, providing valuable lessons for policymakers and stakeholders.

Ind-2512 Ten Years of Indonesia's National Health Insurance and the Urgency of Measuring Effective Coverage: Evidence from NCD Care Cascade Analysis

PRESENTER: **Farizal Rizky Muharram**

Background: Over the past decade, Indonesia's National Health Insurance (NHI) program has aimed to improve healthcare access and utilization. While evidence indicates increased use of healthcare services, the extent to which this has translated into measurable health benefits —referred to as "effective coverage"—remains unclear. This study aims to evaluate the impact of NHI on effective coverage, using non-communicable diseases (NCDs) as a proxy for performance quality. The analysis focuses on the hypertension care cascade—diagnosis, treatment, and control—as a critical indicator of the health system's ability to address the rising NCD burden.

Methods: We analyzed data from three waves of the Indonesian National Health Research (RISKESDAS and SKI) conducted in 2013, 2018, and 2023. Data from 2013 serve as the baseline prior to NHI implementation, while 2018 and 2023 data evaluate its impact. The hypertension care cascade was assessed by measuring the proportion of the hypertensive population who were (1) aware of their condition (diagnosed), (2) receiving treatment (treated), and (3) achieving controlled blood pressure based on standard thresholds (controlled). Both descriptive statistics were used to analyze trends across the three survey years, and multivariate logistic regression was performed to explore associations between care cascade outcomes and sociodemographic factors, including insurance coverage, wealth quintile, and urban-rural residence.

Results and Discussion: Along the care cascade (**Figure 1**), Thanks to the implementation of NHI in 2014, Hypertension treatment rates more than doubled, increasing from **11.1% in 2013** to **21% in 2018** and **22.8% in 2023,** representing an additional 10 million individuals receiving care within a decade. However, control rates showed minimal improvement, only rising from 2.5% in 2013 to 4.4% in 2023, leaving over 95% of hypertensive individuals uncontrolled in 2023. This gap between treatment and control highlights systemic challenges in translating access to care into effective coverage. While NHI reduced wealth-based disparities in treatment **(Figure 2)**, the wealthiest quintile still had 1.75 times higher odds of receiving treatment (AOR: 1.75; 95% CI: 1.68–1.81) and 1.91 times higher odds of achieving control (AOR: 1.91; 95% CI: 1.78–2.05) compared to the poorest quintile in 2023. Urban populations outperformed rural counterparts in all cascade stages, with urban residents having higher odds of being diagnosed (AOR: 1.23; 95% CI: 1.21–1.26), treated (AOR: 1.26; 95% CI: 1.23–1.28), and controlled (AOR: 1.32; 95% CI: 1.26–1.37). Informal workers, and younger age groups had persistently lower odds across all stages.

Conclusion: Despite substantial improvements in treatment rates driven by NHI expansion, control rates that represent quality of care remain critically low. A gap in quality in Wealth is also shown. A focus on quality improvement and pushing quality care to underserved subpopulations is vital to achieving equitable care outcomes.

Ind-549 Survival Benefits of Extending Insurance Coverage for Innovative Medicine: An Instrumental Variable Analysis in Metastatic Colorectal Cancer

PRESENTER: **Wei-Ming Huang**
AUTHORS: Yi-Wen Tsai, Chiao-En Wu, Chen-Han Chueh, Chien-Yu Tseng

Background: To manage the budget impact of innovative cancer treatments, Taiwan's National Health Insurance Administration (NHIA) often implemented a Predetermined Treatment Duration Limit (PTDL) policy, capping reimbursement for high-cost medicines. While international guidelines recommend bevacizumab as targeted therapy for metastatic colorectal cancer (mCRC), the PTDL limited its reimbursed duration to 24 weeks since June 1, 2011, later extending this to 36 weeks on April 1, 2017.

Objectives: This study aims to evaluate whether extending the reimbursed duration of bevacizumab treatment under the NHIA's PTDL policy improves survival outcomes for patients with mCRC.

Methods: This population-based cohort study used the Taiwan Health and Welfare Database to identify two patient cohorts with metastatic colorectal cancer (mCRC) based on initial bevacizumab prescription date: a 24-week cohort (April 1, 2013–March 31, 2016; N = 2,051) and a 36-week cohort (April 1, 2017–March 31, 2020; N = 2,484). Patients were followed for up to two years or until death. We estimated the PTDL policy's effect using a doubly robust approach, first applying inverse probability of treatment weighting (IPTW) based on propensity scores from demographic, disease, and treatment covariates. We then used a weighted Cox proportional hazards model to estimate the hazard ratio (HR) for all-cause mortality. Additionally, a two-stage residual inclusion (2SRI) model, using PTDL as an instrumental variable, assessed the impact of extended treatment cycles on mortality, adjusting for cohort effects by calendar year.

Results: After applying IPTW adjustment, no significant differences were observed in covariates between the cohorts. Overall, the extended PTDL policy was linked to a reduced hazard of all-cause mortality (HR: 0.74, 95% CI: 0.68–0.81), even after adjusting for calendar year effects (HR: 0.83, 95% CI: 0.71–0.96). Additionally, the extended PTDL policy significantly increased the duration of bevacizumab treatment, averaging an additional 4.20 cycles (two weeks per cycle). The estimation from 2SRI indicated that this increased treatment duration was significantly associated with improved survival outcomes, with an HR of 0.91 (95% CI: 0.89–0.93).

Conclusion: Our findings indicate that modifying the PTDL for bevacizumab improved overall survival in patients with mCRC, primarily due to extended treatment duration. This study highlights the need for evidence-based PTDL policy design that meets financial management objectives without compromising patient health outcomes.

Ind-2612 The Effect of Health Insurance on Risk Aversion

PRESENTER: **Anastasia Terskaya**, University of Barcelona

Understanding the determinants of risk preferences is essential as they influence significant economic and social decisions. This study examines the impact of Medicare, the U.S. public health insurance program for those aged 65 and above, on individual risk preferences. Employing a regression discontinuity design around the age 65 eligibility threshold and using data from the Health and Retirement Study (HRS), we find that Medicare enrollment significantly reduces risk aversion. The observed effect is consistent with the concept of risk vulnerability, which posits that reduced background financial risks, such as those associated with healthcare costs, lead to greater risk tolerance.

Our analysis highlights that this change in risk preferences has a minimal influence on health-related behaviors but a substantial effect on financial decision-making, notably an increase in stockholding. The results suggest that Medicare reduces perceived economic uncertainty,

indirectly fostering economic growth through increased financial engagement among older adults. The findings underscore the broader implications of public health insurance policies, suggesting that they not only improve health outcomes but also shape economic behavior by altering risk preferences.

By leveraging detailed income gamble data from the HRS, we measure changes in risk aversion and assess the role of Medicare enrollment. The fuzzy regression discontinuity approach reveals that gaining Medicare coverage decreases risk aversion by approximately 0.4 standard deviation points. However, only a small proportion of the increased stockholding behavior is mediated by changes in risk preferences, indicating that other factors also contribute to this financial behavior.

Robustness checks confirm the validity of our findings. These include balance tests across demographic characteristics, placebo tests using pre-eligibility data, and McCrary density tests to ensure the continuity of the sample around the age cutoff. The results suggest that selection bias or pre-existing differences between eligible and non-eligible individuals are unlikely to drive the observed effects.

In conclusion, this study demonstrates that public health insurance significantly impacts economic behavior by reducing risk aversion. These insights expand the understanding of the economic value of health insurance, emphasizing its role in promoting financial risk-taking and supporting economic growth. Future research should explore the long-term implications of these behavioral shifts and their variation across different demographic groups and policy environments.

Ind-1374 Mental Healthcare and the Labour Market: Quantifying the Impact of Accessing Psychologist and Social Worker Care on Absenteeism

PRESENTER: **Casey Chu**
AUTHOR: Claire de Oliveira

Background: Poor mental health is increasingly recognized as a critical contributor to workplace absenteeism, a major component of lost productivity. This recognition emphasizes the need to address mental health challenges among workers. While workplace programs supporting employee mental health show the potential to mitigate absenteeism, the impact of accessing mental health services beyond workplace programs remains uncertain. Studies have also primarily examined physician-delivered services, overlooking the crucial role of non-physician mental health practitioners such as psychologists and social workers. **Question:** How does access to mental healthcare (especially through psychologists and social workers) impact workplace absenteeism among workers in Ontario, Canada, with mood and/or anxiety disorders? **Methods:** The analysis used several cycles (from 2007 to 2016) of the Canadian Community Health Survey (CCHS), a cross-sectional national survey. We applied a pseudo-panel framework to examine longitudinal trends in cohorts of workers; this was done by constructing cohorts of workers sharing age and sex. The sample included employed, working-aged individuals (25-64 years old) in Ontario with a self-reported mood and/or anxiety disorder. The outcome variable was being absent from work in the past week. The exposure variables include consulting with a mental health provider (including psychologists, social workers, nurses, family physicians and psychiatrists), a specialist (psychologist or psychiatrist), a physician (family physician and/or psychiatrist), or a non-physician (psychologist or social worker) for mental health reasons in the past year, as well as the number of times any mental health provider was consulted. The exposures were also lagged by one year to examine the impact of accessing care two years prior. Pooled and two-way fixed effects linear probability models were used to estimate the relationship between the exposure and outcome, while controlling for relevant sociodemographic and health-related factors. **Results:**Among cohorts of individuals with mood and/or anxiety disorder, seeing both a family doctor and psychiatrist in the past year had a higher probability of absence. In contrast, seeing a psychologist two years ago was associated with a lower probability of absence, and seeing a non-physician mental health provider two years ago was associated with a lower probability of absence. Lastly, each additional mental health visit two years prior was associated with a reduction in the probability of absence. Other exposures did not show significant associations with absence. **Conclusions:** More frequent visits to mental health providers and access to psychologists or other non-physician mental health professionals may yield substantial long-term reductions in work-related absenteeism among workers with self-reported mood and/or anxiety disorders. However, these benefits appear to emerge only after a delay of two years, highlighting the importance of sustained access to mental health care for improving workplace productivity. Future work will explore presenteeism as an outcome and the generalizability of these findings to other provinces in Canada and samples (e.g., individuals reporting high work stress). **Implications:** Employers and policymakers should consider the potential long-term economic benefits of expanding access to non-physician mental health services, especially in health systems like Ontario, which do not cover such services under public health insurance. More comprehensive coverage for these services could reduce workplace absenteeism. However, the delayed nature of these benefits necessitates sustained investment in mental health support.

Ind-135 Impact of COVID-19 Lockdown on Access to Maternal Health and Nutrition Care Services in Rural India: A Single Interrupted Time-series Analysis

PRESENTER: **Rajesh Kumar Rai**, Society for Health and Demographic Surveillance, India
AUTHORS: Anamitra Barik, Nilanjana Gupta, Sabri Bromage, Sandhya S Kumar, Jan-Walter De Neve, Philip Waggoner, Gopal Krishna Dhali, Abhijit Chowdhury, Utz Johann Pape, Pascal Geldsetzer

The global disruptions in essential healthcare service utilization caused by the Coronavirus Disease 2019 (COVID-19) pandemic lockdowns are well-acknowledged. However, the specific impact of these disruptions on maternal health and nutrition care services within rural India requires further empirical investigation. Utilizing data from 57,371 pregnancies recorded between January 2012 and December 2023, this study employed a quasi-experimental single interrupted time series (SITS) analysis to evaluate the impact of the COVID-19 lockdown (March 25-May 31, 2020) on three key maternal health and nutrition care utilizations: receipt of ≥4 antenatal care visits (ANC), consumption of ≥100 iron-and-folic acid (IFA) tablets/ equivalent syrup, and institutional delivery. The robustness of the findings was further examined by addressing potential threats to internal validity and conducting falsification tests. Of 57,371 pregnancies, 34.5% (95% CI: 34.1, 34.9%) accessed ≥4 ANC visits, 38.7% (38.3, 39.1%) consumed ≥100 IFA tablets/ equivalent syrup, and 87.3% (95% CI: 87.0, 87.5%) had institutional delivery. Between January 2012 and December 2023, relative to the pre-lockdown trend, a decreasing trend in the coverage of ≥4 ANC visits (β: -0.22, 95% CI:

-0.31, -0.12, p< 0.001) and in the coverage of institutional delivery (β: -0.17, 95% CI: -0.21, -0.13, p< 0.001) was observed. The downward trend in the prevalence of ≥100 IFA / equivalence syrup intake was observed (β: -0.58, 95% CI: -0.89, -0.27, p= 0.001) for a narrower time frame of January 2019 to December 2021. The evaluation of internal validity, along with falsification tests, bolstered the robustness of the study findings. In light of the study findings, Indian public health systems must prioritize the integration of maternal health safeguards into pandemic preparedness frameworks.

Ind-1939 Determinants of Socioeconomic Inequality in Hepatocellular Carcinoma Screening in Taiwan, 2016 2021

PRESENTER: **Tan-Hao Yang**
AUTHORS: Li-Lin Liang, Chun-Ying Wu

Introduction

The Asian Pacific Association for the Study of the Liver (APASL) Hepatocellular Carcinoma (HCC) Guidelines recommend ultrasound screening for high-risk populations every six months. However, in Taiwan, approximately 36% of HCC patients did not receive ultrasound screening within five years prior to diagnosis. This study investigates the role of socioeconomic status (SES) in inequalities in HCC screening and identifies factors contributing to this disparity.

Methods

We used data from Taiwan's National Health Insurance Research Database (NHIRD). A total of 53,203 newly diagnosed HCC patients from January 1, 2016, to December 31, 2021, were categorized into six cohorts by year of diagnosis. HCC screening was defined as a binary variable indicating whether patients received screening within six months prior to diagnosis, with a three-month washout period applied. SES was determined by insured salary prior to diagnosis. Inequality was assessed using the Erreygers Concentration Index (ECI). Decomposition analysis was conducted to identify contributing factors, including insured salary, demographic characteristics, medical needs, and attributes of patients' residential townships.

Results

Approximately 65% of HCC patients did not undergo screening within six months prior to diagnosis. From 2016 to 2021, significant pro-rich inequality in HCC screening was observed, with ECI values ranging from 0.038 to 0.063, though no consistent temporal trend was identified. Decomposition of the ECI in 2019 (ECI = 0.039, p-value < 0.001) revealed that the insured salary was the largest contributor to inequality (120.7%), followed by medical needs (29.3%) and unhealthy behaviors (18.3%). In 2021, a similar pattern was observed (ECI = 0.047, p-value < 0.001), with insured salary (136.3%), medical needs (38.6%), and unhealthy behaviors (22.3%) remaining the largest contributors.

Conclusion

Pro-rich inequality in HCC screening persists in Taiwan, with insured salary as the dominant contributing factor. Within medical needs, age was the primary driver of inequality, while smoking and drinking were key contributors among unhealthy behaviors. Comparatively, Taiwan's National Health Insurance system demonstrates better performance in reducing inequality compared to studies of other cancer screenings in countries like England, Korea, and Spain, where ECI values range from 0.13 to 0.18. However, the persistent pro-rich pattern and the fact that 65% of HCC patients did not undergo timely screening highlight areas for improvement. Policymakers should implement targeted screening initiatives for elderly populations and enhance health literacy and behavior change programs among low-income groups. These efforts could reduce the socioeconomic disparities in HCC screening and improve early detection rates.

Ind-2282 The Long-Run Impact of Primary Education on Women's Late-Life Cognitive Function in India

PRESENTER: **Nathalie Monnet**
AUTHORS: Mauricio Avendano, Clémence Kieny

The global population is aging rapidly, leading to a sharp increase in the number of older adults affected by cognitive impairment and dementia (Ahmadi-Abhari et al., 2017). As pharmacological interventions for dementia remain limited, preventive measures targeting social determinants of health, and education in particular, have gained prominence.

Natural experiments, particularly those examining compulsory schooling reforms, provide robust evidence of the positive causal impact of education on cognitive health (Banks & Mazzonna, 2012; Glymour et al., 2008). Education may enhance cognitive reserve, delaying the onset of cognitive decline and functional impairment. Additionally, it may influence cognition indirectly by enabling access to better jobs, higher earnings, and healthier lifestyles, all of which contribute to reduced risk of cognitive impairment and dementia. While most of the literature focuses mainly on upper secondary education in high-income countries, the cognitive benefits of primary education remain underexplored, especially in low- and middle-income countries, where the majority of older adults will be living in future decades.

Moreover, in developing countries, gender disparities in education remain pronounced. Despite recent progress, girls continue to lag behind boys in educational outcomes, with UNESCO reporting that 132 million girls worldwide still lack access to education (UNESCO, 2021). In India, the female literacy rate remains significantly lower than that of males (70.3% vs. 84.7%, National Survey of India, 2022), which has been shown to have a negative association with cognitive outcomes (Brucki, 2010).

These disparities have far-reaching implications for cognitive health. Prior research in India has documented a considerable gender gap in cognitive function, driven largely by educational attainment, health status, and social participation (Lee et al., 2014). Understanding how gender

inequality in education impacts cognitive health in older age is crucial, particularly for low-income women, who are disproportionately affected by these disparities.

This study investigates the causal impact of primary education on cognitive function in old age. We focus on women from a poor socioeconomic background because they are more likely to have benefited from compulsory schooling laws than girls from a higher socioeconomic background, or boys. Compulsory schooling laws are believed to have played a crucial role in improving education access for girls, mandating that all children, regardless of gender, attend school up to a certain age. We leverage data from the first wave of the Longitudinal Ageing Study in India (LASI) (2017-2021) and employ an instrumental variable approach to analyze the effects of historical compulsory schooling reforms. Our findings suggest that compulsory school laws increased schooling duration, which in turn significantly enhanced long-term cognitive function among women growing up poor. These results underscore the critical role of primary education in preventing cognitive decline, and the urgent need to address gender disparities in access.

Ind-33 Cost-Effectiveness of a Health Insurance Scheme for Women and Girls in Transactional Sex and HIV Transmission in Cameroon: A Mathematical Model

PRESENTER: **Kasim Allel**, Centre for Global Health Economics, UCL
AUTHORS: Tamoufe Ubald, Serge Billong, Henry Cust, Emilemichel Nitcheu, Iliassou Mfochive-njindam, Julienne Noo, Eric Defo Tamgno, Sandie Szawlowski, Aurelia Lepine

Introduction: HIV prevalence disproportionately affects high-risk populations, particularly sex workers. However, interventions primarily target commercial sex workers, often overlooking women and girls engaging in transactional sex (WGTS) who also face significant risks due to unsafe practices and societal vulnerabilities but lack formal healthcare protection.

Methods: Using existing literature and the POWER randomised controlled trial, we developed a deterministic compartmental model to assess HIV dynamics among WGTS, their sugar daddies, and low-risk female and male populations (age 15-64 years). We evaluated the cost-effectiveness of a national health insurance scheme for WGTS in Cameroon across various coverage levels (0%, 25%, 50%, 75%, and 100%). We calculated the incremental cost-effectiveness ratio (ICER) per disability-adjusted life year (DALY) and HIV-infections averted. We employed univariable (across most relevant parameters) and global sensitivity analyses by varying parameters in the range of +-10% of their original values. Global sensitivity analyses were performed using the Latin hypercube sampling method with 1,000 simulations and we computed the Spearman's partial rank correlation coefficient (PRCC) to indicate parameters' influence. Probabilistic sensitivity analyses (PSA) considered all parameters simultaneously comparing simulated ICERs to willingness-to-pay (WTP) thresholds. Bivariable sensitivity analysis examined variations in health insurance coverage and its efficiency for a target portfolio. Scenario analyses included combinations of PrEP and health insurance coverage for dual application at scale. We used 2023£ and a 3% discount rate.

Results: Implementing insurance coverage levels of 25%, 50%, 75%, and 100% yielded ICERs per DALY averted of £2,795 (£2,483—£2,824), £2,541 (£2,370—£2,592), £2,263 (£2,156—£2,316), and £1,952 (£1,891—£1,998), respectively, versus a 0% coverage baseline. Probabilistic sensitivity analysis indicated an ICER of £2,128 per DALY averted at 100% coverage, with 58% of simulations showing ICERs

Interpretation: A comprehensive health insurance scheme for WGTS in Cameroon could significantly reduce HIV infections and DALYs, especially at higher coverage levels. This highlights the need for targeted healthcare policies for marginalised groups. Broad, inclusive healthcare policies could drastically lower HIV rates and improve public health, supporting progress toward Sustainable Development Goal 3.8 and the WHO's 95-95-95 targets for universal health coverage and HIV control in Cameroon.

Ind-438 Cost-Effectiveness of Tenofovir Disoproxil Fumarate Prophylaxis for Perinatal Hepatitis B Virus Prevention in Ethiopia

PRESENTER: **Abdi Gari**
AUTHORS: Negalign Bayou, Firew Bobo, Temesgen Chala

ABSTRACT

Background: Mother-to-child transmission (MTCT) of Hepatitis B Virus (HBV) is a persistent public health concern. The prevalence of HBV among pregnant women in Ethiopia is notably high, putting thousands of children at risk for MTCT. Tenofovir Disoproxil Fumarate (TDF) prophylaxis is recommended for HBV-infected pregnant women in addition to vaccination. However, the cost-effectiveness of adding TDF

prophylaxis remains unknown in Ethiopia. We aim to identify a cost-effective strategy for adding TDF prophylaxis to prevent perinatal transmission of HBV in Ethiopia.

Methods: A Decision Tree combined with a Markov model was used to determine the cost-effectiveness of different strategies for preventing perinatal transmission of HBV in Hepatitis B surface Antigen (HBsAg) positive pregnant women. We compared the existing Hepatitis B vaccination strategy (*Strategy 1*), with three alternative strategies that added TDF to the existing strategy. *Strategy 2* (TDF prophylaxis for high viral load pregnant women following HBV viral load test), *Strategy 3* (TDF prophylaxis for Hepatitis B envelope Antigen (HBeAg) positive pregnant women following HBeAg test), and *Strategy 4* (TDF prophylaxis for all HBsAg-positive). Costs were measured from provider perspective and adjusted to 2024 USD. Effects were measured as HBV infections and DALYs averted. Model input parameters were from the literature review and local data. Cost-effectiveness was determined by Incremental Cost-Effectiveness Ratio (ICER), using a threshold of multiplies (0.34, 1, and 3) of GDP per capita of Ethiopia. Sensitivity analysis was conducted to test the robustness of the result.

Results: Among the alternatives, *Strategy 4* is the most cost-effective strategy with an ICER of 220.3 USD per DALYs averted. *Strategy 4* would prevent 267 perinatal HBV infections and averts 1048 DALYs per 10,000 HBsAg-positive pregnant mothers. This result were robust to a range of input parameters and has 97% probability of being cost-effective at one times GDP per capita of Ethiopia. The next optimal strategy is *Strategy 2*, with an ICER of 1175.52 USD per DALYs averted. *Strategy 3* was dominated by the available strategies.

Conclusion: Providing TDF prophylaxis for all HBsAg-positive pregnant women starting from 28 weeks of pregnancy has a potential to be a cost-effective strategy in Ethiopia. Introduction of TDF prophylaxis is highly recommended, along with efforts to increase vaccination coverage.

Keywords: Cost-Effectiveness, Mother-to-child transmission, Hepatitis B virus, Tenofovir, Ethiopia

Ind-476 Cost-Effectiveness of Intermittent Preventive Treatment with Dihydroartemisinin-Piperaquine (IPTp-DP) for Malaria in Pregnancy in Papua, Indonesia

PRESENTER: **Firdaus Hafidz**
AUTHORS: Ida Laksanawati, Freis Candrawati, Eve Worrall, Jeanne Rini Poespoprodjo, Reynold Ubra, Temitayo Labor, Jenny Hill, Enny Kenangalem

Background: Malaria in pregnancy is a major risk factor for maternal and neonatal mortality. The prevalence of malaria in pregnancy in Mimika, Papua (17%) represents a substantial health burden. Indonesia's national policy of single screening and treatment with dihydroartemisinin-piperaquine (SST-DP) at the first antenatal care (ANC) visit clears any malaria infections, but leaves women vulnerable to subsequent reinfection. A clinical trial found that IPTp-DP was more cost-effective than SST-DP in Papua however its cost-effectiveness in real-world settings is unknown. Moreover, the Indonesian health system heavily relies on a vertical malaria control programme, and preventive services are not covered by the national health insurance (JKN) benefits package. This study evaluated the societal costs and cost-effectiveness of IPTp-DP in addition to SST-DP in the context of a IPTp-DP pilot through routine ANC by the Ministry of Health in Papua, Indonesia. **Methods**: We employed top-down and bottom-up methods to capture provider and beneficiary costs for IPTp-DP and SST-DP at ten health facilities in Mimika District during the pilot, from February 2022 to November 2023. Provider costs were sourced from facility financial records, covering training, procurement, logistics, and capital investments. Beneficiary costs were gathered through interviews with pregnant women. Health outcome data (malaria incidence, maternal anaemia) were extracted from ANC records and modelled using a decision tree to project pregnancy costs and health outcomes and to calculate incremental cost-effectiveness ratios (ICERs) per DALY averted. The ICERs were compared against three thresholds: WHO-CHOICE (1× GDP per capita, USD 4 731), Pichon-Riviere (USD 1 028) and Ochalek (USD 958). Deterministic and probabilistic sensitivity analyses were conducted to assess model robustness. **Results**: The total annualised-economic cost of IPTp-DP, spanning pre-implementation and two years of implementation, was USD 72,548, comprising 77.1% provider and 22.9% beneficiary costs. The majority of expenses were incurred during the implementation phase year 2, with primarily DP medication, representing a substantial portion of the total cost. Per facility costs ranged from USD 2,871 at Ayuka to USD 11,684 at Timika Jaya, while the cost per course was USD 18.73, and the total cost per woman was USD 35.52 across 5,108 doses. IPTp-DP+SST administered had an ICER of 340.29 per DALY averted, compared to SST alone. **Conclusion**: IPTp-DP+SST currently appears to be cost-effective against all thresholds. However, efforts are still required to identify efficiencies, improve coverage, and optimise the number of courses. National scale-up would necessitate a robust financing plan, prioritising budget allocations and securing sustainable funding.

Ind-561 Incorporating Environmental Considerations Into the Economic Evaluation of FDG-PET/CT for Investigation of Neutropenic Fever in Haematology Patients

PRESENTER: **Michelle Tew**, University of Melbourne
AUTHORS: Carolina Cortes Poblete, Karin Thursky, Monica Slavin, Kim Dalziel, Scott McAlister, Forbes McGain, Abby Douglas

Healthcare accounts for 5.2% of global greenhouse gas emissions, with some countries, like Australia, emitting more than the global average (7%). As nations aim for low-carbon or net-zero carbon healthcare by 2050, it is important to evaluate how healthcare interventions contribute to these goals. Despite the growing emphasis on integrating environmental considerations into health technology assessments and policy decisions to support effective, cost-effective, and environmentally sustainable care, there is a gap in formal guidance on how to evaluate the environmental impacts of new technologies and how such evidence could influence decision-making.

We use a published economic evaluation of a diagnostic technology (18F-fluoro-2-deoxyglucose positron-emission tomography combined with low-dose computer tomography; FDG-PET/CT) as our case study and incorporate environmental impacts (carbon emissions and carbon costs) to understand their implications and how it may impact decision making. The clinical trial and economic evaluation found that FDG-PET/CT is an effective and cost-effective diagnostic tool to support investigations of persistent and recurrent neutropenic fever in high-risk haematology patients compared to standard CT scan, resulting in a reduction in resources used such as biopsies, pathology tests, duration of hospital stay, thus reducing unnecessary care and, potentially, waste production. However, imaging technologies like PET/CT scans are known to have large

carbon footprints.

The carbon emissions of various resources used in the clinical trial (e.g., antimicrobials, blood cultures, diagnostic tests, and hospitalisation duration) were quantified in kilograms CO2 equivalent (kgCO2e) units using data from literature and expert opinion. A process-based life cycle assessment approach was applied to estimate the carbon footprint. The associated cost of emissions was calculated at AUD$56 per tonne of CO2e, based on Australian government carbon valuation guidelines. To compare carbon emissions and costs between two cohorts, nonparametric bootstrap simulations with 1000 replications were used to assess uncertainty levels.

Preliminary results indicated that while the FDG-PET/CT group had a larger carbon footprint from diagnostic imaging resources compared to the standard CT group (28.4 vs. 11.1 kgCO2e), the overall carbon emissions were lower for FDG-PET/CT (933.0 vs. 954.9 kgCO2e), with a small difference of 21.9 kgCO2e (95% CI, -325.2,281.5). The difference in carbon costs between the two groups was also small ($51.2 vs. $52.5), showing a difference of -$2.3 (95% CI, -19.3,14.7). The lower carbon emissions and costs in FDG-PET/CT were primarily driven by shorter hospital stays rather than reductions in other resources. The small impact of carbon costs relative to the high cost of the intervention suggests that integrating environmental considerations into economic evaluations may not significantly affect cost-effectiveness conclusions. However, on a larger scale, especially with high patient volumes, the environmental impact could become substantial and may be an important factor in decision-making.

The study was limited by the lack of standardized data on carbon emissions and addressing these gaps would facilitate the inclusion of environmental considerations in health technology assessments. Further research is needed to understand whether the public values carbon costs the same as the intervention cost and if the current carbon cost valuation reflects the public's opportunity cost of environmental impact.

Ind-576 Comparison of the Performance and Costs of Screening Algorithms Using Rapid Diagnostic Tests for Detection and Treatment of Syphilis

PRESENTER: **Jason J. Ong**, Monash University
AUTHORS: Ying Zhang, Maeve B. Mello, Peters Remco, Eric PF Chow, Cheryl C. Johnson, Christopher K. Fairley

Background: Accurate and affordable screening algorithms are crucial for managing syphilis from a public health perspective. Syphilis rapid diagnostic tests (RDTs) can support scale-up of same-day diagnosis and enable prompt treatment and care, particularly in resource-limited settings.

Methods: We compared the performance and economic costs of three syphilis RDT-based algorithms from a health system perspective: i) treponemal-only rapid diagnostic test (T–RDT), ii) dual treponemal/non-treponemal rapid diagnostic test (T/NT–RDT) and iii) sequential testing using T–RDT followed by T/NT–RDT. A decision-analytic model employing microsimulation of 100,000 individuals was used to estimate the number of missed and overtreated syphilis cases, as well as the costs per person tested and per active syphilis infection treated. All costs are reported in 2024 United States dollars (USD).

Findings: The T/NT–RDT algorithm showed the lowest proportion of missed cases (0%–3%) compared with the T–RDT (8%–14%) and sequential algorithms (8%–15%) across all scenarios. The T–RDT algorithm resulted in the highest overtreatment rates. At a syphilis background prevalence of <1%, the T–RDT algorithm and sequential algorithm had comparable proportions of missed cases, but the sequential algorithm exhibited significantly reduced overtreatment. The T–RDT algorithm was the most affordable and cost-efficient, with costs ranging from USD 6.07 to USD 2148.24 per active case treated across syphilis prevalence (0 to 20%), compared to the T/NT–RDT (USD 20.07–7150.84) and sequential algorithms (USD 23.76–8540.42). The cost per person tested was USD 1.07–1.09, USD 3.58–3.60, and USD 4.27–4.28 for the T–RDT, T/NT–RDT and sequential algorithms across syphilis prevalence (0 to 20%), respectively.

Interpretation: Countries need to consider the structure, aims and available resources within their syphilis response to prioritize their testing and treatment approaches appropriately. The T–RDT algorithm is the most affordable and cost-effective option for managing syphilis at the population-level. In populations with high background prevalence of syphilis (>1%), such as among men who have sex with men (MSM), the choice of diagnostic algorithm depends on the primary objective. If the goal is to minimise missed cases, the T/NT–RDT algorithm may be a better value for money. Conversely, if the focus is on reducing overtreatment, the sequential screening algorithm may be preferable.

Ind-606 Economic Evaluation of Non-Pharmaceutical Interventions (NPIs) on Influenza and COVID-19 Control: A Systematic Review.

PRESENTER: **Dr. Hui Yee Yeo, PhD**
AUTHORS: Hung Trinh, Nhung Nghiem, Peter McIntyre, Steffen Albrecht, Nikki Turner

Background: The COVID-19 pandemic, along with influenza epidemics and pandemics, has a profound impact on global health and economies. To mitigate these effects, extensive public health interventions, including non-pharmaceutical interventions (NPIs), were implemented. Before the COVID-19 pandemic, the effectiveness of NPIs, such as school shutdowns, sanitization, and mask mandates, was often debated, and robust evidence on their cost-effectiveness remains limited. Given the similarities in transmission patterns and symptoms between COVID-19 and influenza, this study aims to assess and compare existing evidence on the economic evaluation of NPIs for both. By doing so, it seeks to provide valuable insights to guide policymakers toward cost-effective and evidence-based pandemic and epidemic response strategies involving NPIs. **Methods**: A systematic literature search was conducted across five medical databases (PubMed, Scopus, EMBASE, CINAHL, EconLit), four health technology assessment databases (NHS HTA, NHS EED, CRD DARE, INAHTA), reference lists, and cited references. The exhaustive search strategy combined four concepts: "influenza," "COVID-19", "WHO-recommended NPIs", and "economic evaluation", covering each database's inception to June 2024. Only full economic evaluations were selected. Two independent reviewers screened and selected studies for inclusion, and quality was assessed with the Consolidated Health Economic Evaluation Reporting Standards

(CHEERS 2022) checklist. A qualitative narrative synthesis was used due to substantial heterogeneity in study characteristics, comparative periods, and outcome measures. **Results:** Out of 6,453 identified studies, 32 were ultimately included in this review (Influenza: 13; COVID-19: 19). A significant portion of these studies originated from the United States (n=12) and high- or upper-middle-income countries (n=17). For influenza, school closure was the most common NPI evaluated (n=11), followed by social distancing (n=4). For COVID-19, school closure and isolation/quarantine were most common (n=6 each), followed by social distancing, travel restrictions, and face masks (n=5 each). Economic evaluations predominantly utilized cost-effectiveness analysis and cost-benefit analysis (n=9 each). Dynamic modeling (n=13) and agent-based models (n=10) were the primary analytical frameworks employed. The majority of studies were rated as "very good" quality (n=20), with CHEERS scores ranging from 63 to 85.7. Two studies achieved an "excellent" rating with a score above 85, while the remaining were categorized as "moderate" quality, scoring between 55 to 70. Overall, most NPIs demonstrated cost-effectiveness from a societal perspective. However, findings on the cost-effectiveness of school closures and lockdowns were mixed. Combining NPIs with antivirals or vaccination interventions was generally more cost-effective than implementing vaccines or antivirals alone. Sensitivity analyses indicated that most interventions were particularly influenced by factors such as pandemic severity, susceptibility rate, transmissibility, cost of illness, discount rate, and time horizon. **Conclusion:** Most NPIs are more cost-effective than no intervention in mitigating influenza epidemics and pandemics, as well as COVID-19 pandemics, with the greatest cost benefits achieved when NPIs are combined with antiviral and vaccination strategies. However, quality assessment revealed several methodological limitations across studies, suggesting that results should be interpreted with caution. Greater emphasis on NPIs in epidemic and pandemic mitigation strategies for influenza and COVID-19 is warranted. This review offers valuable insights for policymakers, supporting more informed decisions regarding NPI adoption.

Ind-804 How Robust is the Current Evidence on Cost-Effectiveness of Automated Insulin Delivery Systems for People with Type 1 Diabetes? A Systematic Review

PRESENTER: **An Tran-Duy**, The University of Melbourne
AUTHORS: Dennis La, Paul Amores, Abdur Razzaque Sarker, David O'Neal, Elif Ekinci, Philip Clarke

Abstract

Background

Automated insulin delivery (AID) systems, a relatively modern approach for managing type 1 diabetes (T1D), automatically adjust insulin delivery in response to blood glucose levels. Assessing the strengths and weaknesses of current evidence on the cost-effectiveness of AID systems is crucial due to their rapid development. This study systematically reviewed and critically assessed the quality of the economic evaluations (EEs) of AID systems for both children and adults with T1D.

Methods

We searched Medline (Ovid), EMBASE (Ovid), Web of Science, CINAHL, EconLit and Cochrane Library from inception to the 2nd of July, 2024 for studies reporting EEs of AID systems in individuals with T1D. We considered AID systems with any levels of automation, from sensor-augmented pumps with low glucose suspend to hybrid closed loop devices. Two reviewers independently screened the studies and extracted data. Study quality was assessed using the Consensus on Health Economic Criteria (CHEC) checklist, the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) checklist and the Good Practice Guidelines for Decision-Analytic Modelling in Health Technology Assessment (Philips') checklist. For each study, the quality score was calculated as the percentage of checklist questions that received a positive answer.

Results

We identified 7632 unique studies, and from these, 21 studies reporting 42 EEs were included for data extraction and quality assessment. Out of the 42 EEs, 35 used the CORE Diabetes Model for the analysis, 37 were industry-funded, and 37 reported the AID systems being cost-effective compared to multiple daily injections (MDIs) or insulin pumps, with or without glucose monitoring. For EEs reporting the AID systems being more costly but more effective (n = 36), the incremental costs (US$ 2023) per QALY gained ranged from 6,977 to 1,172,355.

Among the 37 EEs reporting the AID systems being cost-effective, five focused exclusively on children, 34 were industry-funded, and 21 used cost-effectiveness thresholds recommended by the guidelines, while 16 used thresholds defined by the authors. The incremental costs ($US 2023) per QALY gained ranged from negative values (i.e., the AID systems were dominant) to US$58,215.

Quality scores from the CHEC checklist varied from 84% to 100% and those from the CHEERS checklist ranged from 71% to 100%, both with a median of 89%. For 20 modelling studies (41 EEs) assessed using the Philips' checklist, overall quality scores ranged from 53% to 70%, with a median of 60%. Notably, 13 studies (21 EEs) scored lower than 50% within the data quality category, which includes 33 questions.

Conclusions

Most of the EEs reported that the AID systems were cost-effective. However, many studies have significant limitations, such as the use of insufficient data for parameter estimation and the lack of model adaptation to the jurisdictional settings. Additionally, most of the EEs depended solely on one model without a structural uncertainty analysis. The fact that most studies were funded by companies producing the AID systems also raises concerns about potential bias. Our findings suggest that decision makers should scrutinize the existing EEs and their limitations to ensure accurate interpretation and application of the results.

Ind-883 The Economic Trends of Inpatient Diabetic Foot Care in a Multi-Ethnic Asian Population: Cost Drivers and Impact of High-Cost Users

PRESENTER: **Chloe Chan**
AUTHORS: Pamela Lim, Diarmuid Murphy, Shikha Kumari, Yaser Hasan Muhammed, Ying-Qiu Dong

Background/Aim: Diabetes mellitus (DM) and diabetes-related complications are a growing health problem with significant global disease burden. In the United States, the estimated direct medical costs associated with diabetes were $176 million in 2012 (2.3 times higher than nondiabetic patients), of which 33% were linked to the treatment of foot ulcers, and majority related to inpatient hospital admissions. Despite diabetic foot complications having disproportionally high healthcare expenditure with inpatient costs accounting for the major cost burden, there is limited data within the Asian context. The aim of this study was to evaluate the costs of inpatient treatment of diabetic foot complications with a focus on associated cost drivers and the impact of high cost users to the overall economics in a multi-ethnic Asian population.

Methodology: All patients with diabetic foot ulcer from 1 January 2021 to 31 December 2023 were queried through the hospital's electronic medical records system using International Classification of Diseases, 10th Revision (ICD-10) codes. Patient data obtained included demographic data, clinical data, treatment and outcomes. Financial records were obtained from hospital financial records. The cohort was further subdivided into low (0-25th percentile), intermediate (25-75%), high (75-90%) and extremely high (90-100%) cost groups. Comparative analyses between groups were performed using independent T tests. Multivariable analyses were used to identify associated cost drivers between groups, with statistical significance set at $P < 0.05$.

Results: A total of 1677 patients were identified – mean age was 65.7 years, 63% males, 49.8% with peripheral vascular disease (PVD), 27.3% with end stage renal failure (ESRF) and 10.2% with ischemic heart disease (IHD). The age adjusted Charlson's Comorbidity Index (CCI) was severe in 71.9% of our cohort. Major and minor amputations were performed in 11.6% and 20.1% of patients respectively, with 18.3% 30-day return to surgery and 2.3% in-hospital mortality. The mean length of stay was 13.2±16.6 days, and hospital cost per admission was around $30,000.

Comparison of the extremely high and the non-extremely high cost groups did not reveal any significant differences in age, gender, ethnicity and 30-day readmission rates. However, there was significantly higher rates of patients with high hospital frailty risk score, severe CCI, PVD, osteomyelitis, ESRF, IHD. Notably, the rates of major amputations (40.8% vs 8.4%), minor amputations (42.5% vs 17.6%), total number of surgeries (mean 2.4 vs 0.5) were significantly higher in the extremely high cost group ($p<0.001$).

The median cost incurred for the extremely high cost group (90-100th percentile; n=179) was 20 times higher than the low cost group. The extremely high cost group alone accounted for 40% of the total costs of all DFU patients. Within the extremely high cost group, length of stay ($p<0.001$), number of surgeries ($p<0.001$), ESRF ($p=0.016$), IHD ($p=0.001$), PVD ($p=0.007$) and major amputations ($p=0.039$) were statistically significant independent associations for cost.

Conclusion: Knowledge of the drivers and associations of high cost in inpatient diabetic foot care provides a basis for rethinking the surgical management of this high risk population and the institution of early multidisciplinary care to prevent complications.

Ind-1008 Cost of Active Case Finding for Tuberculosis in Africa: A Multicountry Analysis

PRESENTER: **Mr. Maninder Pal Singh**, London School of Hygiene & Tropical Medicine
AUTHORS: Tahlia Perumal, Jaciara Nissai Sale Mussa, Lawrence Mwenge, Shepherd Shamu, Isabel Massango, Daniel Machavane, Linda Mbuthini, Leticia Chisanga, Bindiya Meggi, Keertan Dheda, Helen Ayles, Junior Mutsvangwa, Anna Vassall, Sedona Sweeney

Introduction

Tuberculosis (TB) remains a significant public health challenge in Africa, compounded by co-morbidities like HIV and diabetes mellitus (DM). Active case finding (ACF) strategies seeks proactive screening of individuals especially in high-risk or underserved populations using different diagnostic tools to identify TB cases early, often before they seek care. It is crucial to improve TB detection rates, particularly in peri-urban areas which have a higher population density and poor living conditions. As part of the XACT III randomised controlled trial, we evaluated the provider-side costs of implementing an integrated ACF strategy using mobile GeneXpert diagnostic units across four African countries. The mobile units simultaneously screened for HIV (via rapid testing), DM (via glucometer), and CD4 count (via PIMA assay).

Methods

XACT III was implemented in Cape Town (South Africa), Maputo (Mozambique), Lusaka (Zambia and Harare (Zimbabwe) in peri-urban areas which have higher incidence of TB. The study collected data on economic costs using a mixed micro-costing (top-down & bottom-up) approach. The cost data was collected from provider's perspective for one calendar year (2021-2022) for capital and recurrent resources each country. The input resources were categorized into human resources, building/infrastructure, transport, equipment, consumables, trainings, and overheads. The list of outputs was prepared based on the activities in which staff was involved namely, community mobilization, screening, diagnostic testing, research and project management. The staff time for each activity was calculated using timesheets, observations and interviews. The capital resources were annualized and a discount rate of 3% was used. The research costs were excluded. All costs were collected in local currency units (LCU) and reported in United States dollars (USD).

Results

Mean annual cost of community mobilization was estimated at $ 811 per 100,000 population ($ 2,000 in South Africa to USD 209 in

Mozambique). The mean cost per person screened was $ 5.74 ($ 17.74 in South Africa to $ 0.53 in Zimbabwe). For GeneXpert test (Point-of-care) Zambia had highest unit cost of $ 41.09 and lowest of $ 27.30 in South Africa with a mean of $ 31.91. The mean cost of $ 3.72 for finger prick test by glucometer test with a range of $ 4.67 in South Africa and $ 2.45 in Mozambique. For HIV rapid testing and PIMA Assay for CD4 the mean cost was $ 4.75 and $ 26.77 respectively.

Across all sites, human resources (HR) constituted the largest share of total costs for activities such as community outreach and screening. Gene Xpert (PoC) and PIMA Assay require specialized equipment and consumables such as cartridges, thus constituting as major cost drivers across all sites. For rapid tests like glucometer and HIV lateral flow, costs were driven by HR and consumables.

Conclusion

Understanding the costs of ACF for TB in resource-constrained settings is essential to assess its budgetary implications and generate evidence on its cost-effectiveness. The identification of cost structures and resource needs will aid in planning for the scale-up of integrated ACF interventions in low- and middle-income countries, contributing to more effective TB screening strategies.

Ind-1101 Evaluating the Impact and Cost-effectiveness of a Reduced-Dose Schedule for Pneumococcal Conjugate Vaccine in Fiji: A Modelling Study

PRESENTER: **Fulgence Niyibitegeka**

AUTHORS: Stephanie Clark, Eleanor Neal, Natalie Carvalho, Petueli Veremalumu, Fiona M Russell, Stefan Flasche, Rachel Devi, Laila Sauduadua, Litiana Volavola

Background Pneumococcal conjugate vaccine (PCV) has reduced the burden of invasive pneumococcal disease (IPD) globally. Yet PCV remains one of the most expensive childhood vaccines. Cost has been a considerable barrier to PCV introduction into national immunisation programs of low- and middle-income countries and as extended valency vaccines are developed, this barrier may worsen. There are also concerns about the long-term financial sustainability of the three-dose PCV schedule with the introduction of more other costly vaccines. Several clinical trials on reduced dose schedules have explored the efficacy associated with two-dose schedules. In 2020**,** the UK switched from a three-dose to two-dose PCV schedule. Fiji introduced PCV in 2012 and is considering switching from a three to two dose schedule. This study was commissioned by Fiji Ministry of Health and Medical Services (MoHMS) following a request for evidence to inform this decision. We aimed to model the effect of switching from 3+0 to 1+1 PCV schedule on IPD and assess the cost-effectiveness and budget impact of this schedule change in Fiji. **Methods** We developed an age-stratified transmission model in R to simulate pneumococcal transmission under different PCV schedules. The model was fitted to carriage prevalence data from cross-sectional pneumococcal carriage surveys, with IPD outcomes estimated by case carrier rates. We modelled the effect of switching from a 3+0 to 1+1 PCV schedule over a ten-years (2024-2034). Epidemiological predictions along with costing parameters were input into an economic model developed in R. The cost of treating pneumococcal diseases (pneumonia and IPD) was estimated from primary data collection in Fijian health facilities. Incremental health systems costs (including provider training, policy change, communication and education) and vaccine dose and delivery costs were sourced from MoHMS and UNICEF data, supplemented with literature estimates. Health outcomes were measured in disability-adjusted life-years (DALYs). Net monetary benefit was calculated as the sum of economic value of health benefits and treatments cost savings less the cost of PCV program. A 3% discount rate was applied to future costs and outcomes. The budget impact was estimated over a five-year time horizon. A probabilistic sensitivity analysis will be conducted. **Results** Preliminary findings are presented. Our model predicts that if Fiji continues with a 3+0 schedule over the next 10 years, vaccine-type (VT) carriage prevalence would be eliminated (0.0% [95% CI 0.0-0.02%]) in children under five years by 2028. Switching to a 1+1 schedule in 2025 is predicted to achieve similarly suppressed VT carriage prevalence in young children by 2030. Despite additional programmatic costs associated with the schedule change, preliminary findings indicate an overall budget saving associated with a 1+1 schedule of US$1,561,472 over ten years. **Conclusion** Switching to a 1+1 PCV schedule in Fiji is predicted to nearly maintain the achieved high impact of the current 3+0 schedule in controlling VT while saving costs. While this evidence can be used to inform a potential schedule change in Fiji, there is a need for continued monitoring and disease surveillance to produce real world evidence that can support model-based predictions.

Ind-1365 Cost-Effectiveness of Combining Community-Based Care with Microfinance to Improve Viral Suppression Among Adults with HIV in Western Kenya

PRESENTER: **Omar Galarraga**, Brown University

AUTHORS: Marta Wilson-Barthes, Catherine Kafu, Juddy Wachira, Ben Mosong, Becky L. Genberg, Dan N. Tran, Diana Chemtai

Background: Findings from the Harambee cluster randomized trial in western Kenya suggest that interventions targeting financial and distance-related barriers to HIV care can help improve viral suppression among adults with HIV in rural, low-resource areas. However, to our knowledge, the cost-effectiveness of these multilevel interventions has not yet been shown.

Objective: We examined the economic costs and cost-effectiveness of combining community-based HIV care with group microfinance to improve viral suppression rates in Kenya.**

Study Design: The cluster randomized trial tested the delivery of care for HIV, hypertension and diabetes within community-based microfinance groups compared to the delivery of standard facility-based HIV care alongside group microfinance and to a matched comparison arm of facility-based HIV care patients alone (standard of care (SOC)). The analytic sample included n=407 members of 29 microfinance groups who received integrated community-based care, n=448 members of 28 microfinance groups receiving facility-based HIV care, and n=300 patients receiving facility care and not engaging in microfinance. All participants were >18 years of age, living with HIV, and an active patient of Kenya's Academic Model Providing Access to Healthcare program. The trial's primary effectiveness outcome was the odds of being virally suppressed (<200 cp/mL or < 400 cp/mL) at 18-months. Economic cost data came from multiple sources and were analyzed from the societal perspective. Generalized estimating equations estimated the incremental cost per patient for the 18-month trial between the intervention and SOC arms. Incremental effectiveness was reported as the number of additional patients achieving viral suppression due to the intervention.

Cost-effectiveness acceptability curves evaluated uncertainty in ICER estimates.

Principal Findings: Compared to patients who receive routine facility-based HIV and do not engage in microfinance activities, delivering HIV care within community-based microfinance groups cost an additional USD$98 per participant (95% CI: $94, $101) and virally suppressed an additional 23 (18, 27) patients over 18-months. This translated to a mean net change of 3.6 percentage points in the proportion of virally suppressed participants between the two arms at 18-months, and an incremental cost-effectiveness ratio of $2,694 ($2,151, $3,273).

Compared to patients who receive routine facility-based HIV and do not engage in microfinance activities, providing routine facility-based HIV care alongside community-based microfinance groups cost an additional USD$8 per participant (95% CI: $3, $12) and virally suppressed an additional 23 (19, 27) patients over 18-months. This translated to a mean net change of 3.4 percentage points in the proportion of virally suppressed participants between the two arms at 18-months, and an incremental cost-effectiveness ratio of $227 ($217, $463).

Implications for policy and practice: The largest cost drivers of community-based care were to the health system, but these costs were partly offset by the health-seeking costs saved by the patient.** If Kenya is willing to pay two times the country's per capita GDP (currently at $2,099) to increase HIV viral suppression, then the societal costs of delivering chronic disease care in the community does not appear to be prohibitive. Further research should evaluate if the multilevel intervention is cost-effective for improving retention in care.

Ind-1916 Assessing the Impact of Utility Models with and without Adjustment for Types of Complications on Outcomes of Economic Evaluations for Type 1 Diabetes

PRESENTER: **An Tran-Duy**, The University of Melbourne

Abstract

Background

Accurately tracking health utility changes over time is crucial for calculating quality-adjusted life years (QALYs), an important outcome measure in economic evaluations (EEs). In diabetes, most of the EEs use models that associate predicted occurrence of diabetes-related complications with health utilities. However, there is currently no consensus on the methods for combining utilities in EEs for diabetes. This study examined how various utility combination methods affect QALYs and incremental cost-effectiveness ratios (ICERs) in type 1 diabetes (T1D).

Methods

A validated T1D patient-level model was used to simulate disease progression and predict complications in a hypothetical cohort with a baseline age of 37 years and with HbA1c of 8.1%. Utility decrements, health state utilities, and complication costs were derived from the literature. Two utility models, additive and multiplicative, were applied to calculate utilities post-complication. In the additive model, utility post-complication equalled utility pre-complication minus the absolute utility decrement associated with that complication. In the multiplicative model, utility post-complication equalled utility pre-complication multiplied with the utility of the health state defined by the complication.

Within each utility model, two methods for combining utilities of complications belonging to one broad condition (coronary heart disease, metabolic disorder or neuropathy) and occurring within the same year were explored: taking the minimum utility or combining them using the same utility model. For acute complications, effects of permanent decline in utilities versus utility recovery one year after the events were also investigated. The EE compared an automatic insulin delivery system reducing HbA1c by 0.87% and annual risk of hypoglycaemia by 95% (the intervention) with an insulin infusion device reducing HbA1c by 0.24% (the control). Life years, QALYs and costs were discounted by 3.5% annually.

Results

An average patient aged 37 years was predicted to live 20.30 years in the control group and 21.04 years in the intervention group. QALYs ranged from 13.538 to 14.934 in the control group, and from 14.602 to 15.901 in the intervention group. In both treatment arms, lowest QALYs resulted from the multiplicative model with no utility adjustment for same-category complications and permanent utility reduction. Highest QALYs resulted from the additive model with minimum utility for same-category complications and utility recovery for acute complications. Differences in QALYs between the additive model and multiplicative model ranged from 0.592 to 1.150 for the control group and from 0.743 to 1.061 for the intervention group. Incremental QALYs associated with the intervention compared to the control ranged from 0.817 to 1.066.

The predicted mean healthcare cost per individual over the remaining lifetime was US$98,849 for the control group and US$186,273 for the intervention group. The incremental costs (US$) per QALY gained ranged from 82,032 to 107,023.

Conclusions

The choice of utility model can considerably affect the estimates of absolute QALYs, incremental QALYs and ICERs in EEs for diabetes. Development of guidelines for combining utilities in diabetes is crucial given that individuals with diabetes experience many complications. EEs for diabetes must transparently describe their specific approaches to integrating health utilities.

abs-os494 Analysis of Policy Options to Reduce the Prevalence of Anaemia in Children Aged 6 to 23 Months in Southern Province of Zambia

PRESENTER: **Clive Banda**

AUTHORS: Chipwaila Chungu, Twambo Nambao, Nonde Sinyangwe, Kutha Banda, Chipo Siafwa, Mambo Nsanzya, Sandra Sakala, Ibrahim Abdallah, Lawrence Mwenge

Background

About 7 out of 10 children aged 6-23 months have anaemia in Southern Province. According to the World Health Organisation (WHO), this is a severe public health concern, and iron supplementation for all children is recommended if the prevalence exceeds 40%. Iron deficiency anaemia can lead to undesirable health and economic outcomes. In Zambia, testing for anaemia and iron supplementation is not routine despite evidence indicating that micronutrient powder (MNP) supplementation produces good results in reducing iron deficiency anaemia-related poor outcomes at a minimal cost.

Methods

Two policy options; supplementing children 6-23 months with Micronutrient Powder (MNP) and mandatory test and treat all children aged 6-23 months for iron deficiency were compared with the status quo. We then conducted a cost-effectiveness analysis using a decision tree. The analysis used the Ministry of Health (MoH) perspective and the intervention timeframe of 3 years. The outcome of the analysis was anaemia cases averted.

Results

Implementing the MNP supplementation policy would avert about 56,908 anaemia cases per year with an Incremental Cost Effectiveness Ratio (ICER) of $9.90. An additional $9.90 is needed to avert one additional case of anaemia. The mandatory test and treat program had an ICER of $240.05, with a need of $240.05 to avert an additional case of anaemia.

Conclusion and next steps

Introducing micronutrient powders to all children aged 6-23 months is an effective option to avert anaemia cases by 50% in the first year of implementation in Southern Province. This strategy was seen to work in Mbala, in Northern Province of Zambia and other countries like Uganda, Kenya, and South Africa. Hence, it can produce similar results in Southern Province if integrated into existing community health programs.

abs-os697 Cost-Effectiveness of PrEP Implementation in Indonesia to Reduce New Cases or DALYs of HIV Infection

PRESENTER: **Mery Nurma Juwita**

AUTHORS: Adiatma Y.M Siregar, Ferry Hadiyanto

Background: The WHO recommends the Pre-Exposure Prophylaxis (PrEP) as an additional prevention of HIV/AIDS. Several countries have implemented PrEP as one of their HIV/AIDS prevention interventions, and Indonesia has started a PrEP pilot project in primary health care and HIV community clinics in several cities in 2022, with PrEP accessed by 2,284 men who have sex with men (MSM) and 340 Female Sex Workers (FSWs), representing 19.14% of MSM and 11.73% of FSW from the target PrEP recipients business-as-usual (BAU scheme). The country has targeted to cover 30% of the HIV-negative population in 2030.

Methods: This study presents a cost effectiveness analysis of PrEP implementation among MSM and FSWs in Indonesia by comparing the BAU PrEP coverage with various scale-up schemes, using the new cases and DALYs averted as the benefits in the Incremental Cost-Effectiveness Ratio (ICER) calculation. The analysis used 25%, 50%, 75%, and 100% scale-up schemes, assuming 25%, 50%, 75%, and 100% coverage of the 2030 target, i.e., 30% of the HIV-negative target populations, respectively. The number of new cases averted was estimated using Spectrum tools, while DALYs averted was estimated using GBD data.

Results: Increased implementation coverage results in increase in costs and aversion of new cases and DALYs, in addition to a better cost-benefit ratio as a result of the averted use of ARVs. The scale-up programs require a total cost ranging from USD32,072,482 to USD128,256,347, while the BAU scheme's total cost for PrEP is USD22,889,674. The cost per new case averted ranges from USD18,478 to USD20,050, and the cost per DALYs averted ranges from USD4,406 to USD4,781. The cost-benefit ratio of PrEP scale up, based on the averted use of ARVs, increases from 1.55 to 1.58.

Conclusion: Using the ICER, all scale-up schemes examined are more cost-effective than the BAU. The 75% scale-up scheme is more cost-effective, indicating that PrEP is more cost effective when provided to specific key population at risk as opposed to the entire eligible population.

MODERATOR: **Laurence Hartmann**,

Ind-488 Construct Validity Test of the Quality of Care Experience- Aged Care Consumers (QCE-ACC) in Residential Aged Care

PRESENTER: **Digisie Jemere**, Flinders University

AUTHORS: Jyoti Khadka, Rachel Milte, Julie Ratcliffe

Abstract

Objective: Providing quality of care for older people remains a consistent global challenge, and the Australian Aged Care system has not been exempted from persistent issues of sub-standard care. The Quality Care Experience – Aged Care Consumer (QCE-ACC) is new instrument designed to measure quality of care from the perspective of older people receiving care themselves. It has two scoring methods – a simple summative score for use in quality monitoring, and a preference-based scoring system amenable for use in economic evaluation. The QCE-ACC has also been adopted as a mandatory quality indicator nationally in Australia in 2023. This study aimed to undertake a detailed evaluation of the construct validity of QCE-ACC among older people living in the residential aged care facilities.

Methods: Older adults over the age of 65 receiving residential aged care services participated in face to face interviewer where they were asked complete a range of questionnaires including the QCE-ACC, QOL-ACC (Quality of Life-Aged Care Consumers), EQ-5D-5L, ASCOT (Adult Social care Outcome Toolkit) and two items measuring self-reported global health and, global quality of life. Feasibility was assessed through examining the missing data and floor/ ceiling effects. Construct validity was explored through two approaches: convergent validity, by testing the correlations between the QCE-ACC and other related instruments against a priori expectations, and known group validity, by evaluating the QCE-ACC's ability to differentiate individuals with levels of self-rated health and quality of life. Internal consistency reliability was measured using Cronbach's alpha (α).

Results: Of the 200 residents (mean age, 85 ±7.7 years), more than half, 113(56.5%) were over the age of 85, 60% were female and majority, 137(68.5%) were Australian born. The QCE-ACC showed adequate feasibility with no missing data and acceptable floor (0.5%) and ceiling effect (24%). The QCE showed moderately statistically significant correlation (ρ = 0.637 &0.619) with the Quality of Life- Aged Care Consumers (QOL-ACC) and Adult Social Care Related Quality of life (ASCOT) measures. The QCE-ACC is capable of differentiating between varying levels of self reported health and quality of life. The QCE-ACC and its dimensions showed good internal reliability consistency (α = 0.77–0.81).

Conclusion: The QCE-ACC demonstrated adequate feasibility, validity and internal consistency to assess the quality of care in residential aged care. This study provides some evidence that supports the use of QCE-ACC in economic evaluation of residential care and supports. It also validated the practicality of its use among older people in long term care settings. Validation of the QCE-ACC on a sample of older people with dementia and cognitive impairment would be useful. The need for developing and testing accessible as well as proxy versions would be a future direction for this work given the significant prevalence of dementia and cognitive impairment in long term care settings.

Keywords: residential care, validity, reliability, older people, quality of care

Ind-1973 The Inter-dependency Between Social and Hospital care: The Effect of Municipality Social Spending on Elderly Hospital-related Outcomes.

PRESENTER: **Irene Torrini**
AUTHORS: Giovanni Fattore, Simone Ghislandi

In recent years, assessments of social systems and interdependencies with the hospital setting have become increasingly relevant. Reduced social services may lead to prolonged hospital stay if patients cannot be discharged due to lack of support in daily living, resulting in increased hospital spending and inefficient allocation of resources. The latter could be freed up while increasing acute sector capacity, accelerating hospital bed turnover, and reducing waiting lists. However, the interdependencies between social and acute services remain unquantified and social care largely underfunded. In this paper, we estimate the effect of municipality social spending (MSS) on elderly hospital-related outcomes by exploiting an administrative panel (2012-2019) of hospital discharge records for the entire Italian over-65 population. To the best of our knowledge, this is the first work addressing the relationship between SS and hospital care in Italy. Available evidence is scarce and provides unclear results. Moreover, many studies use aggregated data and do not account for much of the variability in hospital outcomes, largely determined by patient's and hospital's characteristics. We contribute to the existing literature by estimating standardized measures of municipality length of stay (LOS) and admission costs to examine outcome variability net of the effects of municipality-unrelated factors. We specify a multilevel model in which hospital admissions are nested within municipalityXyear groups and model LOS and costs as a function of patient's demographic and clinical factors, hospital characteristics, and municipalityXyear correlated random effects (CRE), with the latter representing our time-varying standardized (S-) measures. Per-capita hospitalizations and readmissions are also used as outcomes to study not only the substitutability with hospital care, but also the potential of social assistance in preventing the onset of acute cases and managing the post-discharge phase in out-of-hospital settings. The effect of MSS is estimated by specifying a random effects model at the municipality level. We also investigate heterogeneities by municipality population structure, hospital and territorial care supply, and geographic area. Results show that MSS reduces S-LOS, S-costs, and number of admissions and readmissions, indicating substitution between social and inpatient care. The effect is larger for municipalities with a significant percentage of over-65 and high-income individuals, suggesting income-based inequalities and greater effectiveness of social care in improving hospital outcomes for the elderly. Also, while strong effects are found for urban municipalities in the North of the country, the coefficients lose their statistical significance for rural municipalities in the South and Islands. Finally, MSS is found to be more effective in municipalities with a low supply of hospital care and a high supply of out-of-hospital care, with social assistance displacing inpatient care and complementing territorial care. From a policy perspective, this paper emphasizes the importance of investing in social care to improve hospital supply capacity and increase accessibility to inpatient care while reducing costs. In resource allocation decisions, priority should be given to rural and poor municipalities and those located in the south of the country and islands.

Ind-782 Who Benefits Most From Home-visit Nursing Services? Evidence From Long-term Care Beneficiaries in South Korea

PRESENTER: **Sunghun Yun**
AUTHOR: Hongsoo Kim

Background:

As populations age, home-based long-term care (LTC) services, such as home-visit nursing, are increasingly viewed as critical interventions for managing older adults' complex needs to enable ageing in place. While some studies have shown that home-visit nursing interventions can reduce hospitalizations among frail older adults, research exploring whether their effectiveness differs between those with complex needs requiring both nursing care and home visits and those without such needs remains limited. This study addresses this gap by using LTC beneficiaries in South Korea where nationwide public LTC insurance is available, to explore whether visiting nurse interventions for community-dwelling long-term care beneficiaries can delay institutionalization or death and also evaluated their impact on healthcare costs, with a focus on effect heterogeneity due to baseline physical functionality and nursing care needs.

Objective:

To explore the differential impact of home-visit nursing services among LTC beneficiaries in South Korea and identify subpopulations that derive the most benefit, based on nursing and functional needs.

Methods:

We analyzed data from the National Health Insurance Service (NHIS) for whole South Korean individuals newly eligible for LTC services between 2016 and 2018 (n=140,968). Beneficiaries were categorized into four subgroups based on nursing care needs (e.g., wound care, catheter management) and limitations in physical functioning (Activities of Daily Living scores): (1) low nursing/low functional, (2) low nursing/high functional, (3) high nursing/low functional, and (4) high nursing/high functional needs. Baseline characteristics, including comprehensive geriatric assessment variables and pre-treatment healthcare utilization trends, were adjusted using propensity score matching. Health outcomes (e.g., institutionalization, unplanned hospitalizations) and healthcare costs were analyzed using survival models for time-to-event outcomes and regression models for cost outcomes.

Results:

Home-visit nursing significantly reduced healthcare costs among beneficiaries with high nursing and high functional needs (Group 4), with reductions of 39.5% in total healthcare costs, 36.1% in outpatient costs, 74.6% in inpatient costs, and 59.1% in tertiary hospital costs. Beneficiaries with low nursing and high functional limitations (Group 2) also experienced a 53.5% reduction in outpatient costs, although overall cost reductions were smaller and statistically insignificant. In contrast, no significant effects were observed on health outcomes such as institutionalization or unplanned hospitalizations across any subgroup.

Conclusions:

The findings underscore the global relevance of adopting a need-based approach to allocating scarce home-visit nursing resources, particularly as ageing populations and the demand for long-term care services continue to rise worldwide. While these services effectively reduce healthcare costs without compromising health outcomes for high-need populations, their limited impact among low-need populations highlights the necessity of tailoring interventions to individual needs. In Korea, the lack of effective service coordination based on needs suggests a critical area for policy improvement, offering lessons for other countries seeking to optimize the efficiency and equity of their LTC systems. Future research should also examine the broader impact of home-visit nursing on quality of life and caregiver burden, providing insights to inform more holistic and globally applicable LTC policies.

abs-os613 Improving Access to General Medical Care for French Ehpad Residents: Evaluation of a Natural Experiment on the Quality of Drug Prescriptions

PRESENTER: **Laurence Anne Hartmann**, National Conservatory of arts and crafts
AUTHORS: Mathieu Narcy, Elsa Boulet

Since 2017, the Paris Regional Health Agency has implemented an innovative program to address medical care shortages in nursing homes. The initiative provides funding for dedicated prescription time by physicians to care for residents without regular GPs. The program allocates subsidies based on a full-time equivalent (FTE) system, ranging from 0.10 to 0.90 FTE depending on resident numbers. Either general practitioners, specialists, or coordinating physicians can provide this service. Following a series of application calls between 2017-2019, 163 nursing homes (25% of the region's total) joined the program. The funding model uses a capitation system where 0.1 FTE (equivalent to a half-day per week) covers 10-15 patients. The initiative aims to ensure consistent medical monitoring while reducing polypharmacy risks and unnecessary hospitalizations.

The purpose of the research was to determine the extent to which the care consumption of nursing homes residents can be affected by the introduction of a dedicated prescribing time for residents who do not have GP. To assess the causal effect of this time allocation, the methodology used is the "double differences" method. This method can be used because of the quasi-experimental nature of the deployment of the prescription support system, since the financing of this dedicated time did not concern all the nursing homes in the Paris region, but only some of them. The principle of this method is to compare the care consumption of residents in nursing homes benefiting from this dedicated time with that of residents in nursing homes not benefiting from it. In the specific context of our study, this method considers the fact that the introduction of this dedicated time did not take place, for all experimental nursing homes, in the same year, but over three successive years (2018, 2019 or 2020).

The implementation of dedicated medical time significantly impacted prescription patterns and healthcare services delivery. Notable improvements emerged in the detection and treatment of previously underdiagnosed conditions, particularly depressive syndromes. The study observed a reduction in polypharmacy alongside increased screening procedures for biological, radiological, and dental issues.
The analysis revealed distinct approaches between coordinating and non-coordinating physicians:
- Non-coordinating physicians showed preference for single-treatment approaches, including anxiolytics and fluoroquinolone-based antibiotics, with increased reliance on biological testing and hospital referrals.
- Coordinating physicians demonstrated greater focus on long-term treatment management, particularly in adjusting hypnotics and antidepressants prescriptions, while favoring safer antibiotic profiles and preventive care measures.
The findings highlight not only the importance of physician specialization in geriatric care but also the effects of a regular presence in nursing homes for optimal resident care management. Coordinating physicians, with their geriatric expertise and institutional involvement, showed greater tendency toward preventive care and quality-of-life considerations, while non-coordinating physicians adopted more cautious, standard clinical approaches.
These results suggest the value of promoting specialized geriatric training and supporting coordinating physicians in expanding their prescriptive roles within nursing homes. This could inform ongoing legislative discussions regarding the expansion of the French nursing homes coordinating physicians' prescriptive authority.

Ind-1687 Promises Unmet: Changes in Availability and Quality of Antenatal Care in Burkina Faso's Free Maternal Health Program

PRESENTER: **Offosse Marie-Jeanne Ngbesso**
AUTHORS: Aduragbemi Banke-Thomas, Kadari Cisse

Background: Almost 94% of all maternal deaths occur in low and lower-middle income countries including Burkina Faso. To reduce maternal mortality, the government of Burkina Faso have implemented many health financing strategies including free maternal healthcare services in June 2016 under the fee exemption policy, known as the Gratuité scheme. However, recent studies fail to demonstrate a substantial impact of these strategies on service availability. The study objective is to analyze the trend of Comprehensive antenatal care (ANC) provision in health facilities health facilities between 2012 and 2020 with a specific focus on the Gratuité policy implementation period (2016-2020). **Methods:** We conducted a longitudinal trend analysis using repeated cross-sectional surveys. The Service Availability and Readiness Assessment (SARA) conducted in 2012, 2014, 2016 and 2018 and Health Harmonized Facilities Assessment (HHFA) survey conducted in 2020, were used for this analysis. Readiness index was calculated in two ways: simple approach and domain weighted approach. The readiness indicators were defined based on the World Health Organization (WHO) SARA and HHFA guidelines. Gratuité period was coded as a binary variable, with 1 representing the Gratuité period and 0 for the period before Gratuité. Trends were assessed using multivariate linear regression. **Results:** The availability of comprehensive antenatal care (ANC) services in health facilities decreased by 8 points between 2012 and 2020, with a slight recovery in 2020. The decline is more pronounced between 2016 and 2018, coinciding with the introduction of the Gratuité scheme, affecting primary healthcare facilities more than secondary and tertiary facilities. While there was a high decline in urban health facilities (13 points) in the immediate post-Gratuité, Rural facilities saw a decline of only 4 points. The decline is widespread across regions, with some exceptions in Regions with security challenges and humanitarian aid. The study shows a 1.3-point decrease in overall readiness scores for health facilities providing ANC services, with a higher decline following the introduction of Gratuité. Staff and guidelines have a decreased trend, while equipment, diagnosis, medicine, and products have an increased trend. However, the increased trend hides important quality issues such as Hemoglobin and Syphilis testing capacity and IPTP drugs available in less than half of health facilities. **Conclusion:** This study showed decreased ANC services availability and readiness between 2012 and 2020 in Burkina Faso. Universal health care entails both access and quality of care; as such, in addition to removing the financial barrier for all women in Burkina Faso to access ANC services, the government must ensure comprehensive ANC services in all health facilities. There is an urgent need to pay attention to ANC service strengthening, particularly the availability of trained health professionals, guidelines and commodities at all healthcare system levels. Otherwise, women in Burkina Faso might access sub-optimal care due to low service readiness and pay external providers to obtain comprehensive care, exposing households to catastrophic health expenses.

Ind-1599 Can Culturally Tailored Health Strategies Achieve Universal Facility-Based Deliveries and Exclusive Breastfeeding?

PRESENTER: **Nancy Marhadi**
AUTHORS: Zhafirah Yanzli Anisah, Widiantoro Saputro

Indonesia's current maternal mortality rate (MMR) and infant mortality rate (IMR) stand relatively high, at 173 per 100,000 live births and 19.3 per thousand live births, respectively. These indicators are not aligned with the target for the sustainable development goals by 2030. In this respect, it is crucial to improve maternal and newborn health care to improve the MMR and IMR, which are priorities in health concerns in Indonesia and the world. The geographical accessibility to health facilities and the local belief in witch doctor practice remained the significant obstacles in achieving universal facility delivery as well as exclusive breastfeeding in rural Indonesia. To address these issues, the Gunung Timang subdistrict public health centre developed a community-focused, integrated maternal management model designed to empower communities, improve health knowledge, and promote behavioural changes to enhance maternal and newborn health outcomes.

This study adopted a mixed-method approach, using quantitative and qualitative analysis to determine the integrated maternal management model's effectiveness. We analysed maternal and child health service data from 2019 to 2023. We conducted semi-structured interviews with local authorities, public health centre medical staff, local witch doctors, pregnant mothers, teenage mothers, women in delivery, and nursing mothers.

The proposed maternal management model combines eight infant, toddler, and mother health posts (Posyandu), eight youth health classes, six classes for pregnant women, and three nursing mother supportive groups into six major programs. There existed, for example, a partnership

between local witch doctors and public health centre medical staff, as well as a free-of-charge waiting home for maternity to ease resistance in rural communities. Following the integrated model of maternal management, Gunung Timang subdistrict had zero MMR and IMR for five continuous years, starting from 2019 to 2023. Facility-based births increased from 86% to 100%, and the rate of exclusive breastfeeding also rose from 54% to 100%.

Maternal and neonatal mortality can only be prevented if the strategy of providing care for mothers and infants involves management models suitable to the needs and resources available in rural communities. Indonesia should include them in its plan to fulfil the SDG of ensuring the survival of mothers and children.

Keywords: maternal mortality; infant mortality; quality health care; public health; rural population

Ind-2123 Non-Financial Strategies for Modifying Health Worker Effort and Care Delivery in Primary Care Settings: A Systematic Review and Meta-Analysis

PRESENTER: **Vasanthi Subramonia Pillai**, Technical University of Munich
AUTHORS: Caterina Favaretti, Mr. Nikkil Sudharsanan, Julia Gröll

Background: Clinicians often deviate from medical guidelines and significantly under-deliver care in primary care settings. Health worker motivation and effort are critical factors in improving clinical adherence to guidelines and the quality of care delivery. Although financial incentives are an obvious approach to improving care delivery, implementing financial incentives for health workers' behavior change can be challenging because of limited resources and weak regulatory systems in several settings. Moreover, existing evidence shows that the impact of financial incentives is often short-lived. Without long-run effects, temporary financial aid may not provide sufficient impetus to bring about sustained changes in clinician behavior. On the other hand, a growing body of work examining the effect of non-financial incentives has shown promising results in resource-constrained settings. Studies find that strategies such as performance feedback, education and training, and provision of clinical decision support systems are instrumental for clinician behavior change. Some studies also find non-monetary interventions effective in improving care quality among non-medical health workers, who play an important role in healthcare delivery However, currently, there is limited comprehensive evidence on the extent to which each of the strategies works, whether specific strategies outperform others, and under what contexts and circumstances they work the best. Therefore, we conduct a systematic review and meta-analysis to synthesize existing evidence on the causal effects of non-financial strategies on health worker effort and care quality, identifying the most effective approaches to improve primary care delivery.

Methods: The review will include randomized controlled trials and rigorously conducted quasi-random experiments published after 1999, assessing non-financial strategies to improve health worker performance and effort. The primary outcomes are changes in health worker performance (e.g., adherence to care guidelines) and care delivery metrics (e.g., the number of patients screened). Secondary outcomes include health-related metrics such as patient blood pressure levels. Searches will be conducted in EconLit and Web of Science, limited to English-language articles. Data extraction and risk of bias assessment will follow standardized protocols using tools like GRADE and Rayyan.ai. Meta-analyses will estimate pooled effects using standardized mean differences (Cohen's D), and subgroup analyses will explore heterogeneity by intervention type, health worker demographics, and care contexts.

Results: We screened a total of 8502 articles at the abstract stage and included 139 for the full-text screening. Post full-text screening, we identified 73 articles that met the eligibility criteria for the study. Preliminary results will include descriptive summaries of study settings, intervention characteristics, and effect sizes, emphasizing identifying strategies that significantly impact health worker behavior and patient outcomes. We are finalizing the data extraction and plan to begin the meta-analysis shortly. A first draft of the results is expected by February 2025.

Discussion: This review will provide comprehensive evidence on the role of non-financial incentives in modifying health worker effort and care delivery. Findings will have critical implications for policy and practice, guiding the design of cost-effective strategies to enhance primary care services globally. The review will also identify gaps in the existing literature, offering directions for future research.

Ind-1500 Gender Mix and Team Performance: Evidence from Obstetrics

PRESENTER: **Manasvini Singh**
AUTHOR: Ambar La Forgia

Background and Contribution

It is important to understand how the gender mix of teams affects performance in high-stakes professional environments. While existing research on gender dynamics in teams largely focuses on artificial settings like classrooms or online experiments, these findings may not generalize to complex, real-world contexts where teams have to synthesize a range of experiences and expertise to make decisions in collaborative settings. This study addresses this gap by examining the influence of gender mix on expert team performance in a high-pressure environment with life-or-death consequences: childbirth.

Research Question

How does the gender mix of physician teams impact maternal and fetal health outcomes during childbirth, and what are the underlying mechanisms drive differences in outcomes?

Methods

This study uses data spanning the universe of births in Florida over ten years, encompassing over 2 million births. For the main analysis, we focus on a subset of about 580,000 births where patients were quasi-randomly assigned to two-physician teams of varying gender mix (the "team sample"). Controlling for rich patient and physician characteristics, we compare team performance – measured using maternal complication rates and fetal death rates -- across the four team types (Male-Male, Female-Male, Male-Female, and Female-Female). To explore mechanisms, we use births attended by a single physician (the "solo sample") to understand how individual preferences for potentially harmful obstetric practices (e.g., discretionary or discriminatory practices) play out in collaborative team settings.

Key Results

Being in a same-gender team improves performance for female, but not male, physicians. As a result, team performance, ranked from best to worst is: female-only teams, mixed-gender teams, then male-only teams. If female-only teams had performed all deliveries in the dataset, 9.5% of maternal complications and 12.3% of fetal deaths could have been prevented. The findings are not attributable to differences in patient demographics or physician expertise across different team types. Instead, performance differences are driven by two key factors:

1) Gendered preferences for harmful practices: Male-only teams use harmful obstetric practices far more than female-only teams. This occurs because there are gendered differences in individual physician preferences for these practices (i.e., male physicians are more likely to use these practices than female physicians even when practicing individually). 1) Conflict resolution: Mixed-gender teams are more likely to have conflicts in member preferences than same-gender teams, and conflict is particularly harmful for the performance of mixed gender teams led by female physicians. We hypothesize that this may be due to the reversal of traditional gender norms in leadership roles in such teams, which could explain their heightened vulnerability to several frictions to teamwork (such as lack of prior collaboration etc).

Conclusions and Implications

Team gender composition has significant implications for performance in critical healthcare tasks. Policies promoting diverse and collaborative team environments should prioritize addressing gendered preferences for medical practices and improving mechanisms for conflict resolution. These findings have broad relevance for optimizing team performance in other high-stakes contexts.

Ind-417 Generalized Cost-Effectiveness Analysis with Dynamic Prevalence for Improving Health Equity Among Rare Diseases

PRESENTER: **William Padula**, University of Southern California
AUTHOR: Vasco Pontinha

ABSTRACT

Background: According to Lakdawalla & Phelps (2021), there is a documented link related to known relative risk (*r*) preferences in health and willingness-to-pay (*K*) scaled by gross domestic product-per-capita (*M*) using generalized risk-adjusted cost-effectiveness (GRACE) theory for the valuation of health technology. As a result, GRACE addresses limitations of cost-effectiveness analysis pertaining to biases against patients with disabilities, among other health equity concerns. Notwithstanding, the rarity of a disease further exacerbates inequitable patient access to healthcare, as decisionmakers are often persuaded to allocate healthcare resources to larger subgroups, all else being equal under fixed willingness-to-pay, that is, $K = M / [1 – r2]$.

Objective: This paper examines the relationship between relative risk in GRACE theory to relative risk in epidemiologic foundations in order to establish a correlation between WTP and the prevalence of disease*.*

Methods: Using GRACE theory, we mathematically derived the relationship between WTP and relative risk as a function of dynamic prevalence of disease over time, that is, $K(t) = M / [1 – (prevalence t2)2]$. Then by applying foundations of Expected Utility Theory, we establish that willingness-to-pay increases exponentially as diseases become rarer based on the standardized prevalence factor using a Box-Cox transformation of prevalence. We then acquired data from the U.S. Medical Expenditures Panel Survey (MEPS), and linked to disease prevalence data from the U.S. Centers for Disease Control and Prevention (CDC) in order to develop a linear transformation of standardized prevalence factors. We used two data points in our analysis to calibrate willingness-to-pay as a function of disease prevalence: ($0, 100% prevalence); and ($104,000, 33% prevalence), according to Vanness and colleagues (2020) estimation of U.S. willingness-to-pay based on opportunity costs of average care for the Medicare population related to statin use for hypercholesterolemia. Finally, we examined the direct relationship between disease prevalence and willingness-to-pay for two important rare diseases: Sickle Cell Disease and Duchenne Muscular Dystrophy.

Results: WTP thresholds in the U.S. could vary between $104,000/QALY for the most prevalent *observed* conditions and $990,049/QALY for

the rarest observed medical conditions. In particular, we found that for Sickle Cell Disease, with a prevalence of 0.03% and a standardized prevalence factor of 0.825, K = $326,233/QALY. For Duchenne Muscular Dystrophy, with a prevalence of 0.015% and a standardized prevalence factor of 0.912, K = $621,247/QALY.

Conclusion: As a result, this novel approach referred to as "Generalized Dynamic Prevalence" offers a solution to empirical incorporation of the rarity of disease with dynamic prevalence over time in cost-effectiveness analysis in addition to other novel value elements established in GRACE theory, namely health equity, disease severity, insurance value, and value of hope. This approach to generalized cost-effectiveness analysis suggests a method by which dynamic prevalence may help inform priorities for resource allocation across rare disease cohorts.

Ind-1105 Cost-Effectiveness of Myopia Prevention Interventions Among Children and Adolescents in China

PRESENTER: **Bonan Fan**
AUTHOR: Yan Li

ABSTRACT

Introduction: Myopia poses a significant public health challenge in China. While several interventions have been shown to be effective in preventing and controlling myopia among children and adolescents in China, their cost-effectiveness remains unknown.

Methods: We developed a decision-analytic microsimulation model to simulate the progression of myopia in children and adolescents in China. The model assessed the cost-effectiveness of multiple interventions—including 0.01% atropine eye drops, increasing outdoor activities, orthokeratology (ortho-k) and their combinations—in preventing and controlling myopia. We estimated model parameters using data published by the National Health Commission of China and from the literature. The model calculated the quality-adjusted life years (QALYs), healthcare costs, and incremental cost-effectiveness ratios (ICERs) for the interventions versus the status quo. Deterministic and probabilistic sensitivity analyses were conducted to assess the robustness of our findings.

Results: Increasing outdoor activities was cost-saving in preventing myopia in children and adolescents in China. Among the interventions, ortho-k yielded the highest incremental QALYs, at 0.583 years. Single 0.01% atropine eye drops showed the highest ICER at $67,524/QALY. Whether used alone or in combination with increasing outdoor activities, atropine eye drops lack cost-effectiveness. Increasing outdoor activities, whether implemented alone or in combination with ortho-k, has potential to prevent myopia and related diseases in the largest number of children and adolescents, with an estimated impact on over 16.2 million individuals in China. The combined intervention of ortho-k, increasing outdoor activities and atropine eye drops could prevent the greatest number of severe myopia-related conditions, including myopic maculopathy and blindness, affecting over 1 million individuals.

Discussions: This study demonstrates that increasing outdoor activities, ortho-k and the combination of any intervention with ortho-k are effective and cost-effective strategies for preventing and controlling myopia in children and adolescents in China. In particular, increasing outdoor activities is cost-saving. However, 0.01% atropine eye drops, whether used alone or in combination with increasing outdoor activities, are not cost-effective. These findings provide evidence for the integration of these interventions into national school health programs, potentially leading to significant public health and economic benefits.

abs-os227 Econometric Analysis of Synergistic Demand-Side Health Financing Programs: Harnessing the Power of Integration

PRESENTER: **Taufik Hidayat**, Universitas Indonesia
AUTHORS: Judite Gonçalves, Thomas Hone, Nur Cahyadi, Christopher Millett, Budi Hidayat

Background: Subsidized health insurance (PBI) and conditional cash transfers (PKH) are key components of demand-side health financing (DSF) programs in Indonesia. Evaluating their combined impacts is challenging due to variations in interventions, which may violate the Stable Unit Treatment Value Assumption (SUTVA). We address this by using a multivalued treatment approach, which accounts for treatment variations and enables robust analysis.

Research Gap and Contribution: This study addresses a gap in the literature by evaluating methods for assessing the impact of individual and combined DSF programs on maternal health and financial protection. Using advanced econometric models, we analyze the synergistic effects of subsidized health insurance and PKH, and propose strategies to enhance the reliability and validity of impact estimates.

Research Questions: (1) What are the most effective econometric methods for quantifying the impacts of individual and combined DSF programs?

Methods: Using data from a three-wave PKH panel survey (baseline, midline, and end-line), we compare four groups: households receiving subsidized health insurance (PBI), PKH, both PBI and PKH, and a control group. Covariates are balanced using generalized propensity scores (GPS) with a multivalued treatment approach, and balance is assessed via standardized mean differences (SMDs), variance ratios (VR), and percentage bias. Treatment effects are estimated using inverse probability treatment weighting (IPTW) and matching (GPSM), with models including generalized estimating equations (GEE), generalized linear models (GLM), and Difference-in-Differences (DiD). Nine models are compared, and the best model is selected based on predefined model selection criteria.

Findings: Diagnostic tests confirmed that GPS IPTW and GPSM effectively balanced the groups. The combined PBI-PKH group showed the most significant improvements in maternal health-seeking behaviors and financial protection. Average treatment effect on the treated (ATT) estimates were consistently higher than average treatment effects (ATE), and DiD models generally provided the lowest impact estimates.

Conclusion: The choice of evaluation method should consider the research context, especially the need to balance covariates and address unobserved factors. Combining DSF programs improves maternal health outcomes and financial protection.

abs-os229 Economic Evaluation of Multiple Demand-side Health Financing Subsidies in Indonesia

PRESENTER: **Susan Griffin**, Centre for Health Economics, University of York
AUTHORS: Simon Walker, Budi Hidayat, Pujiyanto Pujiyanto, Peter Murphy

Background and Motivation: Impact evaluations of policies such as subsidized health insurance (PBI) and conditional cash transfers (PKH) provide information on whether they improve health access and outcomes. However, they are infrequently extended to provide the kind of cost-effectiveness information required to determine whether these schemes should be prioritised over other uses of public money. This study demonstrates how impact evaluation can be extended to assess the value for money of these programs through cost-effectiveness analysis (CEA), multi-sectoral analysis, and equity analysis.

Research Gap: While previous studies have explored the impact of the PBI and PKH programs, both individually and combined, on healthcare utilization, there has been limited evaluation of their cost-effectiveness, especially in terms of equity and broader social outcomes. This study fills this gap by showing how the results of impact evaluation can be used to inform a comprehensive economic evaluation, assessing both health outcomes and their effects on inequality.

Research Questions: The key questions are: 1) Who are the relevant decision makers to inform with economic evaluation of PBI and PKH? 2) What are the equity concerns and associated priority population groups relevant to inform the value assessment? 3) How does a traditional cost-effectiveness analysis of PBI and PKH differ to one that incorporates impact on health inequalities and outcomes beyond health?

Methods: This study uses an extended impact inventory approach to economic evaluation, considering multiple Government sectors, health and education outcomes, and impacts on consumption and productivity. We show how the health outcomes considered in impact evaluations such as prenatal visits and child immunizations can be extended to understand their impact on key outcomes such as Disability-Adjusted Life Years (DALYs) averted, school enrollment, and healthcare utilization. Finally, we review the way in which the policy cost can be estimated and incorporated to determine value for money.

Conclusions and Policy Implications: This study offers valuable evidence on how impact evaluations can be extended to consider the cost-effectiveness and equity of PBI and PKH. Findings will guide policymakers in resource allocation, ensuring equitable healthcare access for vulnerable populations, and supporting Indonesia's progress toward Universal Health Coverage (UHC).

abs-os222 The Synergistic Effects of Multiple Demand-Side Health Financing Programs on Maternal Health and Financial Protection in Indonesia

PRESENTER: **Budi Hidayat**, Universitas Indonesia
AUTHORS: Judite Gonçalves, Taufik Hidayat, Royasia Viki Ramadani, Thomas Hone, Nur Cahyadi

Background: Demand-side health financing (DSF) includes mechanisms that improve access to healthcare by providing incentives directly to consumers rather than to providers. Indonesia has shifted funds from fossil fuel subsidies to DSF initiatives benefiting the poor, addressing previous inequities in which supply-side health financing favored the wealthy, and introduced subsidized health insurance for the poor (PBI) and conditional cash transfers (PKH). This study assesses the impact of Indonesia's DSF programs on maternal health-seeking behaviors and financial protection, examining both the individual and combined effects of the PBI and PKH programs—a novel aspect of this research.

Research Gap: While the individual effects of PBI and PKH on healthcare utilization have been studied, their combined impact on maternal and financial protection remains unexplored. This study addresses this gap by assessing the independent and joint effects of PBI and PKH on maternal health-seeking behavior and financial protection.

Research Question: How do the individual and combined effects of the PBI and PKH programs impact maternal health outcomes and financial protection?

Methods: We used a three-wave PKH panel survey to assess the effects of PBI alone, PKH alone, and the combined PBI-PKH intervention compared to a control group. We calculated generalized propensity scores to estimate the conditional probability of DSF participation based on

demographic characteristics, applying a multivalued treatment framework. We then estimated average treatment effects on the treated (ATT) and average treatment effects (ATE) using the population-averaged Generalized Estimating Equations regression models, with inverse probability weights derived from the initial analysis. Outcomes included maternal health-seeking behaviors and financial protection measures).

Key Results: Individual DSF programs had modest impacts, with PKH alone showing often insignificant effects. However, their synergistic combination significantly improved maternal health seeking behaviors ($p<0.01$). The integrated programs led to a 47% (ATT) and 44% (ATE) increase in outpatient visits, a 49% (ATT) and 48% (ATE) rise in skilled deliveries, and a 41% (ATT) and 43% (ATE) increase in facility-based births. Folic acid supplementation and tetanus toxoid immunization rates also improved by 41-44%. Additionally, integrated programs reduced delivery costs by 34% (ATT) and 37% (ATE), lowered out-of-pocket health expenses as a share of household income by 12% (ATT and ATE), and cut total out-of-pocket health expenses by 2%.

Conclusions: Combined subsidised health insurance and conditional cash transfers significantly improves maternal health and financial protection, demonstrating the value of synergistic interventions.

Implications for Policy and Practice: Indonesia's shift from fossil fuel subsidies to funding DSF programs presents a valuable model for other nations seeking to improve health outcomes and financial protection for vulnerable populations. Policymakers should expand combined DSF programs, to improve access and reduce financial barriers for vulnerable populations.

Understanding Mental Health Prevalence, Service Use and Economic Consequences: Evidence from a Multidisciplinary Project in Indonesia

MODERATOR: **Laura Anselmi**, University of Manchester

CONVENER: **Jon Gibson**, University of Manchester

DISCUSSANT: **Risky RKH**,

abs-os663 Evidence on Mental Health Prevalence and Service Use: Indonesia's 2015 2020 National Health Insurance Data

PRESENTER: **Ms. Laura Anselmi**, The University of Manchester

AUTHORS: Alfariany Fatimah, Hasbullah Thabrany, Herni Susanti, Sri Idaiani, Matt Sutton, Dwidjo Susilo, Jon Gibson, Irmansyah Irmansyah, Asri Maharani

Background: Individuals with mental illnesses in Indonesia face significant barriers to accessing care, including stigma, social isolation, limited availability of healthcare providers, and low mental health awareness. Current evidence on mental health prevalence and healthcare utilisation primarily relies on survey and surveillance data, with limited use of register-based data. This study analyses data from the National Health Insurance (BPJS) sample, representing 1% of insured individuals, to assess mental illness prevalence, patient characteristics, and healthcare utilisation. The findings are compared with data from the Basic Health Research Survey (RISKESDAS) to identify gaps from self-reported and diagnosed mental health conditions. **Methods:** Using BPJS sample data (2015–2020), mental illness prevalence was examined by age, gender, and province, with descriptive statistics on healthcare utilisation. Logistic regression was used to assess associations between mental illness diagnoses and individual characteristics such as sex, age, marital status, insurance segmentation, and province. Prevalence and service use findings were compared with RISKESDAS data to evaluate disparities between self-reported and diagnosed mental illnesses. **Preliminary Results:** From 2015–2020, 44 per 10,000 individuals covered by BPJS were diagnosed with mental illnesses. Males (45 per 10,000) had slightly higher prevalence rates than females (42 per 10,000). Prevalence peaked in the 50–54 age group and was highest among non-salaried workers (76 per 10,000). Regionally, Central Kalimantan had the highest prevalence (79 per 10,000), while West Sumatra reported the lowest (9 per 10,000). Logistic regression analysis confirmed these trends. Males were more likely to be diagnosed than females (OR=0.693), while individuals aged 51–60 had higher odds of diagnosis (OR=1.516) compared to the reference group (0–10 years). Non-salaried workers had increased odds of diagnosis (OR=1.729) compared to non-workers, and being married reduced the likelihood of diagnosis compared to being single (OR=0.731). Regional analysis showed that individuals in 12 provinces were less likely to be diagnosed, those in 3 provinces were more likely, and the remaining 18 provinces showed no significant difference compared to Aceh. A difference was observed when comparing BPJS and RISKESDAS data. Self-reported depression prevalence in RISKESDAS (6.1%) was much higher than the diagnosed rate in BPJS data (0.04%). However, differences narrowed for treated depression cases (0.55% vs 0.05%). **Policy Implications:** These findings highlight the need to address regional and demographic disparities in mental health diagnosis and care in Indonesia. The stark contrast between self-reported and diagnosed depression underscores the importance of expanding access to mental health services and improving diagnostic capacity. Policymakers should prioritise regions and groups with high unmet needs, including non-salaried workers and specific provinces, to ensure equitable mental health care.

abs-os669 Mental Health and Labour Market Outcomes: Absenteeism and Presenteeism by Job Type in Indonesia

PRESENTER: **Jon Gibson**

AUTHORS: Ms. Laura Anselmi, Asri Maharani, Matt Sutton, Alfariany Fatimah

Purpose: This study investigates how mental health and job characteristics influence productivity in Indonesia by examining absenteeism (taking time off work) and presenteeism (attending work while unwell). It explores the interplay between mental health status, job type, and workers' attendance decisions. We investigate how different job types and mental health status influence workers' decisions to either attend work while unwell or take time off. **Methods:** We analysed primary survey data from 19,234 Indonesian workers across diverse employment categories. Mental health status was measured using depression (CESD-10) and anxiety (GAD-7) scores, while job types were classified as government, private sector, self-employed, casual workers, unemployed, and retirees. A bivariate probit model was used to jointly estimate absenteeism and presenteeism behaviours, focusing on the interaction between job type and mental health status to identify patterns and moderating effects. **Results:** Absenteeism rates varied across employment categories, with government and private sector employees showing the highest rates (10.9%), followed by self-employed (8.1%) and casual workers (7.9%). Presenteeism was most prevalent among unemployed individuals (19.0%) and retirees (14.7%) but less common in the formal sector (3.6%). Mental health significantly influenced these behaviours, with depression and anxiety increasing the likelihood of absenteeism and presenteeism, though the effects varied by job type. Formal sector employment moderated the impact of poor mental health, reducing its effect on work attendance decisions compared to other employment categories. **Conclusions:** The relationship between mental health and work attendance in Indonesia is mediated by job characteristics. Workers in formal sectors are better protected from the productivity impacts of poor mental health, potentially due to structured workplace policies and support systems. These findings emphasise the importance of targeted workplace mental health interventions, particularly for informal sector workers and unemployed individuals, to address productivity losses associated with absenteeism and presenteeism.

abs-os589 Mental Healthcare-Seeking, Use and Out-of-Pocket Expenditures in Indonesia: Evidence From a Large Community-Based Survey

PRESENTER: **Asri Maharani**, University of Manchester
AUTHORS: Herni Susanti, Hasbullah Thabrany, Dwidjo Susilo, Jack Wilkinson, Jon Gibson, Ms. Laura Anselmi, Sri Idaiani, Ida Ayu Mas Amelia Kusumaningtyas, Mashita Fajri Maysuro

Background: Mental disorders are a growing health burden in Indonesia, with approximately 12 million people experiencing depression. Despite this, data on mental healthcare utilisation remain limited, hindering effective healthcare planning. This study investigates mental healthcare-seeking, utilisation, and out-of-pocket (OOP) expenditures among adults in Indonesia, with a focus on the impact of probable mental health disorders (MHDs) on service use. **Methods:** We conducted a survey of 19,236 adults aged 18+ between July and October 2023. Participants completed the 10-item Center for Epidemiologic Studies Short Depression Scale (CES-D-10) and the 7-item Generalised Anxiety Disorder (GAD-7) tool to screen for depression and anxiety, respectively. Data on help-seeking for mental health issues, treatments received, healthcare costs, and health insurance status were collected. Healthcare insurance was categorized into social, local government, and other types. Respondents with probable MHDs were identified using CESD-10 scores ≥10 and/or GAD-7 scores ≥4. Outpatient and inpatient service utilisation and OOP expenditures were compared between adults with and without probable MHDs. Logistic regression models assessed associations between demographic, socioeconomic factors, insurance ownership, and mental healthcare utilisation among individuals with probable MHDs. **Results:** Approximately 2,119 (11%) respondents sought mental healthcare, with 615 receiving outpatient care and 39 receiving inpatient care. The average OOP cost was IDR140,359 (SD=288,637) for outpatient services and IDR1,372,000 (SD=2,447,296) for inpatient services. Only 36% of outpatient users and 56% of inpatient users utilized health insurance, with social health insurance being the most common. Probable MHDs were identified in 849 (4.42%) respondents with depression, 2,339 (12.17%) with anxiety, and 602 (3.13%) with both. Help-seeking was more frequent among those with probable MHDs (19%) compared to those without (10%), and OOP costs for outpatient care were significantly higher for respondents with probable MHDs. Logistic regression showed that social health insurance (OR=1.63; 95% CI=1.30–2.06), local government insurance (OR=1.72; 95% CI=1.10–2.69), and other insurance types (OR=2.95; 95% CI=1.86–4.67) increased the odds of help-seeking among individuals with probable MHDs. Older age, female gender, and being in the wealthiest quintile were also associated with higher odds of help-seeking. **Conclusions:** The presence of mental health disorders increases healthcare utilisation and OOP costs, highlighting the financial burden on affected individuals. Inequalities persist, with wealthier individuals and those with insurance more likely to access mental healthcare. Policies to expand health insurance coverage, improve access to affordable care, and address disparities are critical to meeting the growing demand for mental health services. Enhanced investment in prevention, promotion, and treatment interventions is recommended to reduce the burden of mental disorders on the Indonesian healthcare system.

abs-os651 Treatment Pathways for Mental Health Disorders in Indonesia: A National Analysis of Care Settings Using Health Insurance Data, 2019 2020

PRESENTER: **Sri Idaiani**
AUTHORS: Ida Ayu Mas Amelia Kusumaningtyas, Herni Susanti, Penny Bee, Alfariany Fatimah, Irmansyah Irmansyah, Jack Wilkinson, Helen Brooks, Asri Maharani, Dwidjo Susilo

Background: Effective management and recovery for individuals with mental health disorders depend on appropriate mental healthcare. In Indonesia, mental health services are provided through both psychiatric and non-psychiatric care settings. However, limited data exist on how mental health conditions are managed across these pathways. Although the Indonesian Mental Disorder Diagnosis Classification Guidelines III (based on ICD-10) provide standardised diagnostic criteria, the extent to which non-psychiatric settings adhere to these standards and deliver care remains unclear. This study explores the distribution of mental health diagnoses across clinical settings and identifies factors influencing treatment pathways in Indonesia. **Methods:** We analysed 4,335 outpatient visits with ICD-10 F code diagnoses recorded in the National Health Insurance Agency (BPJS-K) database from 2019–2020. These data were linked with information from the 2019 Health Facility Research (Rifaskes) on the availability of psychiatrists, clinical psychologists, and mental hospitals. Using multilevel logistic regression, we examined the association between disorder types, provider availability, and the likelihood of receiving treatment in psychiatric versus non-psychiatric settings. Adjustments were made for demographic factors, marital status, BPJS insurance segmentation, and healthcare provider availability. **Results:** Of the patients studied, 75.5% (n=3,275) received treatment in psychiatric clinics. However, patients with psychological development

disorders were significantly more likely to receive care in non-psychiatric settings (adjusted odds ratio [AOR] 217.0; 95% CI 120.5–390.9). Similar trends were observed for childhood-onset behavioural and emotional disorders (AOR 43.0; 95% CI 24.3–77.7) and organic mental disorders (AOR 7.49; 95% CI 4.63–12.12). The likelihood of receiving treatment in non-psychiatric settings was higher in type A hospitals (AOR 31.97; 95% CI 9.46–106.83), type C hospitals (AOR 1.78; 95% CI 1.01–3.13), and other hospital types (AOR 4.16; 95% CI 1.68–10.28) compared to mental health specialist hospitals, with no significant differences observed for type B or D hospitals. **Conclusion:** Most patients with mental health disorders in Indonesia are treated in psychiatric clinics. However, specific diagnoses, such as psychological development disorders, childhood-onset behavioural disorders, and organic mental disorders, are more frequently managed in non-psychiatric settings. These findings reveal gaps in Indonesia's mental healthcare system, particularly for complex cases requiring specialised care. Strengthening referral systems and improving access to mental health specialists are essential to minimise these gaps.

abs-os543 Integration of HIV services with Primary Healthcare: Economic Perspectives and Lessons for Planners and Practitioners

PRESENTER: **Elise Smith**, Genesis Analytics
AUTHORS: Aisha Abdulkadir Muazu, Ibrah Seninde, Kiprotich Cheruiyot, Carl Shutte

Background: Global evidence indicates that integrating HIV services with other health programs enhances health outcomes, improves health system efficiency, and is generally cost-effective. As countries move closer to epidemic control, and in the face of declining international funding for HIV programs, it is increasingly recognized as an important strategy for building a more sustainable HIV response and supporting progress toward universal health coverage. However, the majority of evidence is based on integration pilot projects and there is little evidence on how these integration processes are implemented, especially for integrating health systems more broadly, and what the financial implications of full integration might be.

Methods: We conducted country case studies on HIV integration efforts that have been piloted or implemented in Kenya, Malawi, South Africa, Uganda and Tanzania, and Zimbabwe. Data was collected through key informant interviews and from published literature to understand how the integration of HIV services with PHC impacted on the cost of service delivery, and how the process of HIV integration unfolded, focusing on the entire health system and enabling environments. Qualitative and quantitative data was analysed to distil key insights and lessons learned from country experiences with integrating HIV services to inform and improve future health service integration initiatives.

Results: Our research shows that the cost implications of HIV integration are highly variable and context-specific, even within a single country. While integration generally results in efficiencies, such as improved utilisation of human and capital resources that lead to unit cost savings, these do not necessarily translate into total cost or budget reductions. In some cases, higher direct costs, particularly for diagnostics, supplies, and drugs, were observed, often reflecting the delivery of higher-quality services, especially in research-driven pilot projects. However, the broader cost implications at the above-facility level and across health systems remain unclear due to limited research, as most available studies are small-scale pilots. Additionally, there is a significant gap in understanding the upfront investments required for integration at both service delivery and systems levels, despite indications that these investments may be substantial. A key outcome of this research is a comprehensive pathway to integration, which highlights critical considerations for country decision-makers and planners throughout the entire integration process. These considerations address alignment with broader health system goals, health system readiness, affordability, and sustainability.

Conclusion: HIV integration presents both opportunities and challenges, with implications for resource use and sustainability. While integration can enhance service quality and efficiency, its cost and budgetary impacts are highly context-specific and often necessitate substantial upfront investments. Addressing key gaps in research, particularly regarding above-facility costs and systems-level resource requirements, is essential to inform scalable integration strategies. Practical insights from this research can guide countries in aligning integration plans with broader health system strengthening goals, offering actionable steps to support the UNAIDS sustainability roadmap and the transition from vertical programs to integrated models.

abs-os573 Macro-Fiscal Trends and HIV Financing: Evidence on Fiscal Space and Domestic Ability to Pay in Four African Countries

PRESENTER: **Steve Cohen**, Genesis Analytics
AUTHORS: Carl Shutte, Elise Smith, Kiprotich Cheruiyot, Sergio Torres Rueda

Background

Low- and middle-income countries (LMICs) in Sub-Sahara Africa face substantial challenges in increasing domestic funding for HIV programs as donor investments in health decline. Contributing factors include sluggish economic growth, high debt burden, competing development priorities and inefficient revenue collection mechanisms. Between 2024 and 2030, debt service costs are projected to consume, on average, over 54% of tax revenues in the sub-Saharan African (SSA) region.

The decline in donor investments has placed additional strain on domestic systems, which often lack the institutional and financial capacity to fill funding gaps. We present evidence to enable countries and their development partners to plan and execute a managed HIV financing transition, based on a realistic assessment of domestic ability to pay for essential services and functions, and a better understanding of realistic opportunities to increase fiscal space for health and HIV.

Methods

We applied a mixed methods approach that included a qualitative synthesis of evidence, thematic analysis from key informant interviews and quantitative analysis of financial and non-financial data including key health financing indicators in 3 countries, namely Malawi, South Africa and Zimbabwe. We modelled future funding values by external and domestic sources for HIV based on assumptions and scenarios developed.

Results

We found that the study countries were all challenged by high debt servicing costs, constrained budgets and reduced fiscal space for health initiatives. Additionally, we found that low GDP growth projected in the majority of the study countries is limiting resource mobilisation; exacerbated by population growth expanding at a higher rate than GDP growth in some of the study countries. We determined that inefficient revenue collection systems, inflation and currency volatility increased the cost of imported medical supplies, reducing purchasing power, and making donor-funded programs more expensive. Our HIV funding projections demonstrated that in Malawi and Zimbabwe, donor investments in HIV will be required in the long term even if the countries increase domestic financing and find efficiency savings under an optimistic scenario.

Conclusions: Donor policy on HIV financing transitions should consider not only epidemiological and programmatic factors, but also a data-driven assessment of a country's ability to pay for essential HIV services and functions over a long-term timeframe. Governments and their development partners must collaborate to align investments to sustain HIV gains whilst setting data-driven commitments for increased domestic responsibility for HIV financing as domestic ability to pay changes over time.

abs-os570 More Health for Money: Finding Efficiencies in National and Sub-National HIV and TB Programmes in Times of Constrained Domestic Funding

PRESENTER: **Ibrah Seninde**
AUTHORS: Sajid Sherif, Nthabiseng Khoza, Steve Cohen

Background

Despite the South African Government historically contributing over 70% of total funding for the HIV response annually, the increase in treatment coverage has strained the public health budget, with a notable increase in the HIV/AIDS budget, from R8,8 billion in 2010/11 to R23,5 billion in 2022/23. Anticipating an additional 2 million people to enrol on life-long ART by 2027, financial demands will increase, whilst resources for health are expected to remain severely constricted due to macro-economic and fiscal realities. This underscores a pressing need for the government to enhance the efficiency of its HIV programme to sustain its gains towards achieving and maintaining the 95-95-95 targets. We present a case study which demonstrates how more health for money can be achieved through optimising HIV programme allocations and protecting baseline HIV budgets during periods of fiscal austerity, using economic evidence and related advocacy approaches.

Method

We developed a structured process to identify and mitigate weaknesses and inefficiencies in provincial HIV budgeting and spending activities. This process included the following steps: needs assessment for grant managers, diagnostic assessment of provincial budgets and spending activities, development of tools and analytical solutions, capacity strengthening of key officials, monitoring of provincial budgeting and spending for HIV and annual adaptive management.

Results

The intervention produced tools and solutions that included an integrated financial and non-financial budget planning tool, performance management dashboards, root-cause analysis method for spending variances and budget execution rates, and capacity building self-assessments.

Conclusion

This case study demonstrates how leveraging integrated financial and non-financial HIV data analytics for adaptive grant management and sub-national performance management combined with targeted PFM improvement strategies can optimise health spending, ensuring "more health for money" in the context of constrained sub-national HIV budget allocations.

abs-os616 Gender Biases on Digital Health Platforms: Evidence from India

PRESENTER: **Dweepobotee Brahma**, National Institute of Public Finance and Policy
AUTHOR: Nikita Sangwan

Background: The fast adoption of digital health platforms accelerated by the recent Covid-19 pandemic has transformed the way healthcare services are provided particularly in low-and-middle income countries with limited access to healthcare. While online health platforms have immense potential in increasing access to healthcare, they can also perpetuate and exacerbate gender-based inequalities. Digital platforms make it easier for customers to discriminate against women when the gender can be easily identified from names or profile photographs. The algorithms powering these platforms can reinforce bias if the input data itself contains a gender bias. This paper aims to investigate the gender gaps on digital health platforms in India, which already has a strongly prevalent bias against female professionals. We examine the availability of medical practitioners on a digital health platform, the demand for these practitioners and the engagement of the users with medical professionals in terms of their rates of booking appointments with them. **Methods:**This study uses a novel dataset scraped from *Practo* – a popular online platform for booking doctor consultations in India. *Practo* allows patients to book appointments with doctors across various specializations with filters for the locality. It provides detailed information about doctors, including their specialization, years of experience, consultation fees, patient ratings, and availability. Our scraping tool was programmed to extract the details of the doctors (Unique ID, Gender, Specialization, Years of Experience, Consultation Fees, Patient Ratings (average rating, number of reviews), Location (city, clinic) and Availability (days and hours of consultation) by the locality. We follow the physicians on this platform over a month to track their booked consultations. The final dataset comprises information on 25,466 doctors from six major cities in India. We employ fixed effects linear regressions to tease out the differences across male and female physicians over several dimensions including consultation fees, ranking on the platform, booking rates and reviews on the platform while controlling for a host of several other characteristics. **Results:** Overall, preliminary results indicate strong gendered effects across multiple outcomes indicating the presence of systematic bias against female physicians. Female physicians are ranked lower on the platform compared to their male counterparts even after controlling for specializations, qualifications, consultation fees. Female physicians are also rated lower (measured through recommendations and reviews) by patients and have systematically lower appointment booking rates compared to male physicians after controlling for other characteristics. However, we find no significant difference in consultation fees especially within specializations. Future analysis will delve deeper into these results through statistical decomposition methods. **Conclusion:** The contributions of this paper are two-fold. First, it studies the large private practice market in healthcare across major Indian cities for which there is paucity of evidence. Second, it adds to the growing body of literature documenting gender gaps in the highly skilled market for physicians and contribute to our understanding of how market forces and algorithmic forces behind digital platforms interact to perpetuate to gender biases.

abs-os615 Economic Evaluation of AI in the Diagnosis of Breast Cancer: Evidence from a Multi-Centre Study in the UK

PRESENTER: **Divya Srivastava**, London School of Economics & Political Science

Background: Breast cancer is the most common cancer in women globally. Cancer diagnosis is performed through manual, labor-intensive, and subjective histological review of biopsies. In the UK, breast biopsies should be reported within 5 working days; however, this proved to be increasingly challenging, due to a persistent widening gap between demand for testing and pathologist workforce.

The most recent UK survey on the histopathologist workforce reported that only 3% of departments had enough staff to meet clinical demand, with 45% outsourcing services and 50% using locums with additional costs of £27million a year. Artificial Intelligence (AI) could transform the diagnostic landscape by making pathways more efficient, shortening waiting list, reducing subjectivity, and improving health outcomes. However, this technology and its requirements such as set-up costs, maintenance and effectiveness have not been evaluated in England.

Research objectives: This study investigates whether the AI technology to support breast cancer diagnosis is cost effective and its budget impact on the English NHS.

Methods: The AI technology is piloted in five hospitals in England between (July 2024 and August 2025). We use pseudonymised data originating from 7,000 consecutive patients undergoing breast biopsies for the empirical analysis.

We develop a cost-consequence model to evaluate the potential value of the technology. The model processes all the incoming biopsies providing computed-enhanced features, such as heatmaps, region of interest (ROIs), and cancer likelihood scores (i.e. for invasive cancer and ductal carcinoma in situ), to support diagnosis and triage patients. We assume that cancer survivability is linked to the stage of the cancer when detected. General population survivability was based on the Office for National Statistics and life expectancy for each woman is estimated. This is adjusted in the event of the women developing a carcinoma at any stage (i.e. early stage: NPI I, II or III, or advanced). We use the empirical estimates to conduct a budget impact analysis. Published estimates from the literature are used to support the model development including cost estimates, and utility values.

Results: Our preliminary findings reveal a high level of accuracy of the AI technology in ruling in/out cancer, with sensitivity of 100%, specificity of 99.8%, positive predictive value (PPV) of 99.7%, and negative predictive value (NPV) of 100%. The preliminary findings show an increase in volume (50% more patients diagnosed within 5 days) and a 45% reduction in additional immunohistochemistry tests, with consequent reduction of second reviews (pathologist time), lab staff time, and improved patient turnaround time.

Conclusions: With AI a current government priority in health care in England, these findings have important implications for decision-makers and healthcare providers in the NHS. Our findings show that the deployment of AI technology could potentially lead to improvements in health care delivery and improve clinical workflow practices in England in high pressure working environments.

abs-os612 Surfing in Australia: Internet Access and Productivity in Healthcare

PRESENTER: **Ms. Susan Méndez**, University of Melbourne

AUTHORS: Diana Contreras Suárez, Arezou Zaresani

Background: Broadband infrastructure, which provides high-speed internet, facilitates faster data access and processing, enables real-time communication and collaboration, and fosters the adoption of cutting-edge technologies, all of which should improve overall productivity, in particular in information-intensive industries, like healthcare. **Research Question:** This study investigates the impact of high-speed internet access on the productivity of general practitioners (GPs) in Australia, as measured by their volume of consultations and practice styles. **Methods:** We use the time discontinuities in access to high-speed internet created by the slow rollout of the National Broadband Network (NBN) across Australia. We use detailed GP-level data from the Medicine in Australia: Balancing Employment and Life (MABEL) national longitudinal survey of doctors linked to their practice location and administrative records of their service provision from the Medicare Benefit Schedule (MBS) and Pharmaceutical Benefit Scheme (PBS). We estimate a dynamic event study model that addresses the challenges of staggered treatment timing and potential contamination of estimated coefficients in conventional Two-Way Fixed Effects models, providing unbiased estimates of the causal effects of NBN availability on GP productivity. **Results:** This presentation studies the impact of access to high-speed internet on GPs' volume of consultations, prices and practice styles, proxied by prescription rates and discusses the consequences that investments in high-speed internet infrastructure and the promotion of digital technologies in primary care settings could potentially have in healthcare delivery and efficiency.

Advances in Risk Adjustment and Consumer Choice: Balancing Fairness, Efficiency, and Policy Design in Health Insurance Markets

MODERATOR: **Francesco Paolucci**, University of Bologna

CONVENER: **Lukas Kauer**, University of Lucerne

abs-os382 A Dynamic Model for Private Health Insurance in Australia: Optimal Settings for Costs to Government and Consumer Welfare

PRESENTER: **Michael McLean**, Finity Consulting Pty Australia

Government policy currently seeks to incentivize participation in private health insurance (PHI) in order to alleviate financial pressure on public hospitals. This objective is pursued through three primary policy instruments: the Private Health Insurance Rebate (rebate), the Medicare Levy Surcharge (MLS), and the Lifetime Health Cover (LHC) loading. The rebate provides a percentage subsidy on insurance premiums, with the rate varying according to an individual's income, age, and family type. The MLS imposes a tax surcharge on individuals whose income exceeds a specified threshold and who choose not to maintain hospital cover. The LHC imposes a 2% surcharge on premiums for each year an individual over the age of 30 does not hold hospital cover. The rebate constitutes a significant cost to the federal budget, amounting to approximately $7 billion annually, while the MLS also represents a loss of tax revenue for the government due to individuals with health insurance being exempt from the surcharge. Numerous studies have criticized these incentives, arguing that the benefits of the small increase in PHI participation resulting from these policies is outweighed by the cost. However, a recent report commissioned by the Department of Health and Aged Care, utilizing extensive industry claims data, calculated the net fiscal impact of the rebate and MLS. The report concluded that these incentives generate net savings for the government. Specifically, the healthcare costs the government would incur in the public hospital system for individuals without PHI are outweighed by the costs associated with the rebate and the tax forgone through the MLS. Additionally, the report examined the broader social costs of PHI enrolment, noting that while the policies may reduce government healthcare expenditures, they could impose costs on society. The methodology underlying this analysis relied on several assumptions, including the absence of moral hazard, adverse selection, a static PHI market, and constant participation rates, with the aim of estimating net impacts rather than identifying opportunities for policy improvement. The present study seeks to build upon this recent analysis by incorporating demand elasticity estimates derived from an economic choice experiment to develop a dynamic model of the PHI system. The dynamic model will incorporate realistic assumptions, including adverse selection, moral hazard and elasticities of premiums and regulatory tools. The model will use a set of input policy parameters, such as the rebate and MLS rates, and integrate them with predictive models for healthcare costs. These models will be applied to the Australian population to generate updated estimates of PHI enrolment patterns and net government and social costs. This model will enable a comprehensive assessment of the net costs to government and the broader social costs under a wide range of policy scenarios. Ultimately, this study aims to identify policy scenarios that improve upon the current system, particularly in terms of reducing the net costs to government and minimizing the social costs of PHI enrolment.

abs-os18 Can Risk-rating of Incremental Premiums Improve Consumer Sorting Across Coverage Options in Mandatory Health Insurance Markets?

PRESENTER: **Josefa Henriquez**

AUTHORS: Francesco Paolucci, Richard C van Kleef, Marcello Antonini

Community rating in mandatory health insurance schemes is common for fairness reasons, but its known that it causes inefficient consumer sorting across coverage options, affecting welfare. This study explores if risk rating of incremental premiums can enhance sorting efficiency. Specifically, it evaluates the effects of risk rating on consumer choices between basic and more comprehensive coverage options, using data from Chile's private health insurance market. The research addresses the central question: Can risk rating for more comprehensive coverage improve consumer sorting in mandatory insurance markets?

This study employs the "EFC" graphical framework (Einav, Finkelstein & Cullen, 2010) and simulation-based modeling using Chilean health insurance data. Three scenarios are simulated: (1) a baseline without moral hazard and perfect risk adjustment, (2) includes moral hazard, and (3) adds both moral hazard and imperfect risk adjustment. The sample includes ~2m individuals with data on demographics, health expenditures, and plan types. Particularly, the paper models the curves that characterise market equilibrium in mandatory health insurance: incremental marginal costs, willingness to pay (WTP), and average costs (AC) curves across different premium settings.

Results show that under perfect risk adjustment, risk rating of incremental premiums can improve consumer sorting. With imperfect risk adjustment the welfare effects of risk rating are less clear as incremental premiums will not just reflect the direct effect of more comprehensive coverage on healthcare spending but also the under/overcompensations from the (imperfect) risk adjustment system.

This has important policy implications since state-of-the-art risk adjustment models do not perfectly compensate for unpriced risk heterogeneity regarding basic coverage. While a hybrid approach—community rating for basic coverage and risk rating for incremental premiums—may balance fairness and efficiency, our key finding reveals that the effectiveness of this approach depends on the quality of risk adjustment in basic coverage and the degree of correlation between consumers' preferences for additional coverage and their basic coverage costs.

abs-os45 Improving Risk Adjustment with Limited Availability of Morbidity Data the Case of Switzerland

PRESENTER: **Lukas Kauer**

AUTHORS: Christina Vetsch-Tzogiou, Reto Bürgin, Michael Stucki

Objectives

Risk adjustment (RA) schemes in health plan payment are designed to curb the incentive for risk selection among insurers. The Swiss RA has been refined several times since its introduction in 1996. The latest reform in 2020 introduced a new risk adjustor, pharmaceutical cost groups (PCG), which captures the use of prescribed drugs for chronic diseases. The aim of this study was to assess the performance of the different RA models, their potential impact on the incentives for risk selection, and to discuss the potential policy implications.

Methods

We used two data sets, covering the entire adult population (6.99 m in 2022), and containing information on health insurance, healthcare spending, medication use, and demographic factors. We compared the model performance of five different RA models in use since 2014, examining individual-level spending predictions and over- or undercompensation. We also explored whether the current RA scheme offers possibilities for risk selection by investigating spending variation within similarly compensated individuals.

Results

Performance of the Swiss RA has improved substantially over time. In particular, including information about the use of medication since 2017 increased goodness of fit. Recent refinements, particularly the inclusion of PCG, led to a considerable reduction in under- and overcompensation in many subgroups. However, several of the currently used PCG exhibited significant spending variation which may offer new potentials for risk selection.

Discussion

Reforms of the Swiss RA scheme have continuously reduced the incentives for risk selection and improved the prediction of spending. As new potential for risk selection might arise, the regulators should closely monitor the behaviour of insurers. The next steps in reforming the RA involve finding new indicators that capture morbidity not yet considered in the current RA scheme.

abs-os2 How Good is Good Enough?: A Simulation Study of Adaptive HTA

PRESENTER: **Jamaica Roanne Briones**
AUTHORS: Peter Baker, Ms. Wanrudee Isaranuwatchai, Alexander Morton

Adaptive Health Technology Assessment (aHTA) offers a context-sensitive and efficient alternative to full HTAs, particularly valuable for small countries and resource-limited settings. This study evaluates the impact of uncertainty on aHTA decision-making and identifies factors contributing to high levels of uncertainty. We conducted simulations to derive an aHTA Incremental Cost-Effectiveness Ratio (ICER) by sampling ICERs from systematic reviews of selected technologies and performing pragmatic ICER adjustments. The uncertainty in aHTA ICERs was assessed using a threshold-based decision rule to evaluate the accuracy of reimbursement decisions. This involved comparing aHTA ICERs with a distribution modelled on SRs against a baseline ICER from studies conducted in Thailand, our reference country. Additionally, we quantified the financial impact of implementing an aHTA strategy.

Results indicate that aHTA performance is situationally dependent. The aHTA ICER is most reliable when it is significantly different from the WTP threshold—either significantly below or above it. Lower variability between studies increases confidence in the aHTA ICER, especially when the studies included in the simulation have a similar evaluation framework. In terms of net monetary impact, it may be prudent to balance the need for evidence when there is a low or moderate risk of uncertainty with the decisions based on uncertain evidence, particularly when technologies have a low budget impact, thereby reducing the risk of decision errors. Furthermore, aHTA ICER adjustment methods, such as price correction, show promise in scenarios where they can reduce variability between studies hence lower the risk of incorrect decisions.

Our findings support previous research suggesting that aHTA methods are appropriate when certain conditions are met, such as certainty in economic evidence and a lower budget impact. This study provides quantitative evidence reinforcing the potential value of aHTA as a complement to a country's toolkit for prioritising technologies for full HTA. Nonetheless, it is essential for countries to build the capacity to conduct comprehensive HTAs, especially for strategically significant technologies.

abs-os12 Adaptive HTA in India: A Pertuzumab Case Study

PRESENTER: **Akshita Vikani**, TBA
AUTHORS: Anuja V R, Sajith Kumar S, Tom Drake, Abha Mehndiratta, Anamika Dhiman, Tabassum Wadasadawala, Seema Gulia, Manju Sengar, C S Pramesh

Background

The National Cancer Grid (NCG) of India has established a team of health economists to conduct and institutionalize adaptive Health Technology Assessments (HTAs). These adaptive HTAs aim to support evidence-informed decision-making in resource-stratified guideline development and national health benefit package (HBP) decisions. This abstract presents a case study assessing the cost-effectiveness of pertuzumab, used as neoadjuvant therapy in combination with trastuzumab and chemotherapy for Human Epidermal Growth factor Receptor- 2 (HER2) positive operable, inflammatory, or locally advanced breast cancer. Although pertuzumab has received regulatory approval from the Central Drugs Standard Control Organisation (CDSCO), European Medicines Agency, and Canada's Drug Agency, cost-effectiveness evidence for its use in India remains lacking. An economic evaluation was deemed essential to inform the potential inclusion of the intervention within the NCG's resource-stratified clinical guidelines and the Health Benefit Packages (HBPs) under the Ayushman Bharat–Pradhan Mantri Jan Arogya Yojana (AB-PMJAY).

Aim

This study aimed to apply an adaptive HTA methodology to assess the cost-effectiveness of pertuzumab as neoadjuvant treatment for HER2 positive operable, inflammatory or locally advanced breast cancer

Methods

Using the methodology outlined in the National Health Authority's adaptive HTA manual, we searched for relevant evidence across HTA agencies, PubMed, and the Tufts cost-effectiveness registry. Cost and clinical effectiveness data were adjusted for inflation, purchasing power parity, and life expectancy differences, and standardized to 2023 Indian Rupees. Adjusted incremental cost-effectiveness ratios (ICERs) were calculated using data from three HTA reports (UK, Canada, Malaysia) and four economic evaluations (Canada, USA, Singapore, Italy).

Results

Pertuzumab's incremental costs outweigh its health benefits in all but two studies (Singapore and Italy). The adjusted ICERs exceeded India's cost-effectiveness threshold of one GDP per capita, suggesting that pertuzumab is not cost-effective for the Indian healthcare system.

Conclusion

Through this study, we have taken initial steps toward institutionalizing adaptive Health Technology Assessments (HTAs) within the National Cancer Grid (NCG). By applying the adaptive HTA approach to evaluate the cost-effectiveness of pertuzumab for HER2-positive breast cancer, we have demonstrated its practical utility in addressing local evidence gaps. This approach not only informs clinical guideline development and health benefit package (HBP) decisions but also lays the groundwork for broader adoption of adaptive HTAs at the national level. Our findings highlight the potential of adaptive HTAs to support evidence-informed policymaking and enhance the efficiency and equity of health care delivery in India.

abs-os14 iDSI Guide to Rapid Review of International HTA Reports: An Adaptive HTA Method

PRESENTER: **Peter Baker**, Center for Global Development
AUTHORS: Andrés Pichon-Riviere, Javier Guzman, Daniel A Ollendorf, Lieke Fleur Heupink, Shankar Prinja, Srobana Ghosh

Background In the past two decades, health technology assessment (HTA) has become integral in determining the services provided by publicly funded health systems, especially in low- and middle-income countries (LMICs). However, LMICs face significant challenges in formalizing the entire HTA process and conducting full HTA appraisals due to the urgency of funding decisions, limited technical capacity, and constrained data. These hurdles necessitate an alternative approach to ensure timely, evidence-based decision-making. This field is known as adaptive HTA (aHTA), but no current global guidance on best practices for aHTA exists. *Aim* This paper aimed to develop guidance for a novel adaptive HTA method to simplify the HTA process in resource-limited settings. *Methods* We reviewed the aHTA literature including case studies from the iDSI network in Romania, India, Indonesia, and Ghana. Workshops were held with experts in the field to further develop and refine the method. *Findings* We developed a method called the *"Rapid review of international HTA reports"*, that focused on international HTA reports and cost-effectiveness analyses (CEAs) from other countries. The key steps in this process include, 1) scoping: aligning the decision problem with relevant international evidence; 2) evidence acquisition: identifying and extracting data from HTA reports and CEA studies; 3) supporting analyses: price benchmarking, treatment cost calculations, and budget impact assessments; and 4) synthesising results and recommendations: translating the findings into locally relevant recommendations. We provide optional modules for contexts where additional evidence or analyses are required, such as systematic reviews or evaluations of the transferability of international economic data to the local setting. *Conclusion* The rapid review aHTA framework offers a structured yet flexible approach that enables LMICs to adapt international HTA evidence to local conditions. By utilising HTAs from other countries, LMICs can benefit from the technical capacity and high-quality evidence already available internationally. This approach significantly reduces the time and resources needed for full HTA while still delivering robust data for decision-making. The *Rapid review of international HTA reports* methodology represents a practical and efficient alternative to traditional HTA in LMICs. While it has limitations, such as the potential for incomplete adaptation to local contexts, it offers a rapid and feasible solution for evidence generation. This approach can play a crucial role in informing national policies on universal health coverage and prioritisation of essential health services. The guide provides a standardised method to empower LMICs to make better-informed decisions in public health resource allocation.

abs-os46 Enhancing Timeliness of HTA for Decision Makers: Experience in Adopting Adaptive Approaches in Indonesia

PRESENTER: **Auliya A. Suwantika**
AUTHORS: Ahmad Irsan A. Moeis, Lusiana Siti Masytoh, Ery Setiawan, Miftah Miftahussaadah, Panji Fortuna Hadisumarto, Putri Listiani, Mardiati Nadjib

Background

Health technology assessment (HTA) is critical in selecting healthcare service benefit packages for Indonesia's national health insurance program (*Jaminan Kesehatan Nasional*/JKN). Established in 2014, the Indonesian Health Technology Assessment Committee (InaHTAC) uses HTA to evaluate health technologies in the potential inclusion of benefit packages.

Aim

This study assessed the development and implementation of adaptive HTA (aHTA) methodologies (i.e., rapid review and CEA) in Indonesia by investigating how these approaches could improve the efficiency, timeliness, and decision-making process for including cost-effective and affordable health technologies under the JKN program.

Methods

A case study was employed to track the aHTA process and application in real-time decision-making, evaluating its role in facilitating the inclusion of high-value technologies in the JKN program. Challenges were identified and analyzed, with lessons learned contributing to refining aHTA methodologies. A comparative analysis was also performed to evaluate the efficiency of aHTA relative to traditional HTA processes.

Results

A pilot for aHTA using rapid review was conducted in 2023 to evaluate pembrolizumab for non-small cell lung cancer, examining the feasibility of using aHTA for inclusion decisions. A method featured a streamlined review process, leveraging secondary data and expert opinions, and resulted in an accelerated timeline. Evidence from international HTA agency databases, chosen considering that these results have undergone rigorous processes, were applied. However, the transferability of these HTA reports became an issue because they came from high-income countries with different contexts from Indonesia. While data on clinical effectiveness might be transferable, differences in health systems and service delivery limited the transferability of available economic evaluation models. In addition, the biggest identified challenge was the methods did not always inspire confidence among stakeholders, which might be caused by limited and uncomprehensive information about this novel method. Nevertheless, several advantages were also identified, such as the relatively uncomplicated aHTA method and the ability to produce results relatively quickly for government decision-making with some transferability consideration, including the optimal cost-effectiveness value using a value-based pricing approach.

Conclusions

Despite the challenge of aHTA implementation in Indonesia, several advantages were identified during the pilot study. Hence, collaborative efforts to strengthen this new method in further discussions with key stakeholders regarding the transferability and generalizability of these

systematic and multidisciplinary evaluations are essential, including for assessing new medical technologies.

The Contribution of Health Economics in a Changing Climate: Understanding Impacts and Adaptation

MODERATOR: **Paula Lorgelly**, University of Auckland

CONVENER: **Mark Harrison**, University of British Columbia

abs-os247 Climate-Vulnerable Communities in Fiji: Priorities to Adapt and Thrive Amidst Climate Change

PRESENTER: **Duncan Mortimer**, Monash University
AUTHORS: Rohan Sweeney, Amelia Turagabeci

Background: Each year, over 50,000 people in the Pacific are displaced due to climate impacts and natural disasters. Communities face difficult choices: stay and adapt, relocate, or defer relocation - each with significant implications for health and well-being.

Pacific Island communities are highly vulnerable to extreme weather events and gradual climate changes that damage homes, degrade land, and disrupt livelihoods like fishing and farming. These impacts heighten the risk of injury and illness and further threaten physical and mental health by disrupting traditional ways of life. Relocation may reduce exposure to immediate physical risks but introduces challenges such as displacement, financial insecurity, and loss of cultural identity, which can harm psychosocial health.

In Fiji, 50 villages have been identified for potential relocation within the next 5 to 10 years. Many more communities must adapt as climate change disrupts their living conditions. However, little quantitative research exists on community preferences for where and how to live in the face of such challenges. Understanding these priorities is important for designing adaptation and relocation policies that address community needs and minimize psychosocial impacts.

Methods: We conducted a discrete choice experiment with 630 adults from 25 climate-vulnerable Fijian communities to evaluate preferences for living with climate change. Attributes were informed by literature and 9 focus groups, separated by age and gender, conducted across 4 communities (October 2023).** Respondents completed 9 hypothetical choices between two future living-situations. Living-situations were unlabelled and characterized by the following attributes: (i) location (stay-put, stay-put with significant adaptation, or relocate to a location chosen by the government or the community), (ii) access to fresh and healthy food, (ii) work opportunities, (iii) proximity to services, (iv) affordability and stress, (v) exposure to storm and tide disruptions, (vi) housing type, and (vii) connection to culture, community, and land.

Results: Approximately 60% of respondents reported recent climate-related damage to property or income, with 50% anticipating a possible or likely need to move within the next 10 years. Preliminary analyses revealed that location was the main driver of preferences. Respondents strongly opposed government-selected relocation sites, preferring to stay in their current community with significant adaptation, followed by relocation to a community-chosen site. Housing type also mattered, with respondents even preferring detached, storm-vulnerable dwellings over modern apartments. Reducing exposure to storm and tide disruptions ranked highly, while job type and commuting distance were less important. Of note, health-related attributes, such as proximity to health services and access to healthy food, were lower-order priorities.

Preference heterogeneity emerged: younger adults (under 40 years) were more willing to relocate to community-selected sites and prioritized reducing exposure to storm and tide disruptions, while older adults (over 40 years) valued maintaining community connections more highly.

Conclusion: This research provides insights into the priorities of climate-vulnerable communities in Fiji, emphasizing the importance of community-driven relocation and local adaptation to mitigate climate change impacts. These findings can inform policies aimed at enhancing the resilience and well-being of Pacific Island communities.

abs-os39 Estimating The Economic Impacts of Extreme Weather Events on Healthcare Systems A Scoping Review

PRESENTER: **Nazafarin Esfandiari**
AUTHORS: Glory Apantaku, Sarah Batke, Mr. Mark Harrison

Background: Climate change-induced extreme weather events – such as floods, heatwaves, and wildfires – have been escalating in frequency and intensity globally, posing challenges to various sectors, including healthcare. The healthcare sector is uniquely vulnerable to these events, experiencing direct consequences in the form of increased healthcare demand due to injuries, illnesses, and mental health issues, as well as indirect effects such as disruptions to healthcare infrastructure. While the health implications of extreme weather events are well documented, there is perceived to be a gap in comprehensive methodologies for estimating their economic impacts on healthcare systems. Therefore, there is currently uncertainty about how and whether to incorporate environmental costs and benefits into the evidence presented to decision-makers, and where evidence is presented, there is a wide variation in the factors included in these assessments and the quality of evidence presented.

Objective: This scoping review aims to understand current approaches to conducting economic assessments of the impacts of extreme weather

events on healthcare systems.

Methods: The electronic databases (including MEDLINE, Web of Science, and SCOPUS) were searched for articles published from database inception to May 2024 using search terms developed in consultation with expert librarians. Targeted searches of the grey literature supplemented searches of the published literature. The search strategy comprised a combination of terms capturing extreme weather events (e.g., various types of events) and their economic impacts on healthcare systems (e.g., healthcare utilization costs).

Results: The review of the literature is ongoing, but to date, the titles and abstracts of 9,438 unique studies have been screened, and data has been extracted from 30 studies. All studies have been published since 2011, with 76% published in the last five years, and most studies (60%) focused on regions of Australia and the US. The studies covered extreme heat/heatwave (n=13), flood (n=4), wildfire (n=3), extremes of heat and cold (n=6), extreme cold (n=1), typhoon (n=1), and multiple events (n=2), and they mostly applied a healthcare system perspective. However, there is little consistency in their operationalization. While some studies considered effects as narrow as emergency department visits for specific illnesses, the majority only considered hospital and emergency department visits and only for specific illnesses like respiratory diseases or urinary tract infections, and few considered the cost of impacts beyond healthcare utilization such as lost income, mortality, or wellbeing. The data sources varied markedly between studies, ranging from self-reported survey data to local and national administrative datasets. Critically, none of these studies referenced any framework for reporting the economic costs of climate events to the health system.

Conclusions: As a body of evidence, there is a methodological gap that points to a lack of consistency and comprehensiveness in the impacts assessed and data quality. Developing a comprehensive approach that enables the understanding of the immediate and long-term economic consequences of extreme weather events can enhance the resilience of health systems by informing targeted interventions and policies that mitigate vulnerabilities.

abs-os249 Public Preferences for Environmentally Responsible Healthcare

PRESENTER: **Sandy Tubeuf**, Université Catholique de Louvain
AUTHOR: Charlotte Desterbecq

The relationship between health and the environment is complex and mutually influential. Environmental factors are significant contributors to health challenges, mental health issues, and premature mortality. Paradoxically, the healthcare sector itself is a major source of pollution, generating greenhouse gases, particulate matter, plastic, and pharmaceutical waste that degrade air, water, and soil quality. Addressing these dual challenges requires not only developing sustainable healthcare models but also understanding public willingness to engage with environmentally responsible healthcare practices.

This presentation reports on an original and pioneering on-going study that explores public attitudes toward sustainable healthcare. While research on consumer preferences for sustainability in sectors such as sustainable fish, eco-tourism, organic food, or reduced meat consumption is well-established, the healthcare sector remains underexplored. This research is the first of its kind to systematically investigate public preferences in the healthcare context, setting the stage for further inquiry into this critical area.

This presentation covers three key components of this research project. First, a scoping review was conducted to map empirical studies on population preferences for environmentally responsible choices in healthcare. This review revealed broad public support for integrating environmental considerations into healthcare decision-making. However, clinical effectiveness and disease severity consistently outweighed sustainability concerns, highlighting the complexities of aligning environmental and health priorities.

Second, group interviews with healthcare users provided qualitative insights into their perceptions of climate change, healthcare-related pollution, and their potential roles in reducing such pollution. Participants widely recognized climate change as an urgent environmental and human health threat and reported engaging in pro-environmental behaviors in their personal lives. However, awareness of the healthcare sector's environmental impact was limited. Participants emphasized the need for targeted information campaigns to raise awareness among both healthcare users and providers. Key barriers identified included low public willingness to accept environmental trade-offs in health-related decisions and ethical concerns about shifting the burden of environmental responsibility onto individuals.

Finally, the presentation outlines the design of a discrete choice experiment (DCE) that builds on the findings of the scoping review and group interviews. The DCE is structured to explore the trade-offs individuals are willing to make when choosing between hypothetical healthcare treatments with varying attributes, such as clinical effectiveness, cost, and environmental sustainability. The DCE protocol and structure, including the design of choice sets and data collection strategies, are currently under development. It targets a nationally representative sample of the Belgian population aged 18 to 70, collecting sociodemographic data, health information, and environmental attitudes to provide a rich dataset for analysis. The structure and preliminary results will be presented and discussed during the session.

By integrating findings from the scoping review, group interviews, and DCE design, this original research provides a comprehensive assessment of public attitudes toward sustainable healthcare. It represents a critical first step in addressing a previously neglected area of research. While this study is likely to inspire further investigations, its findings can already inform policies that align clinical excellence with sustainability goals, ensuring a socially acceptable and ethically responsible transition to greener healthcare systems.

Ind-1934 Evaluating Cost-Effectiveness of Early Screening and Integrated COPD Interventions in China: An Agent-Based Model

PRESENTER: **Yumei Zhu**
AUTHOR: Yuwei Bai

Background: Chronic obstructive pulmonary disease (COPD) poses a significant burden in China, with current prevention strategies often neglecting individual variability and environmental factors, limiting their cost-effectiveness. Traditional evaluations focus on single interventions, oversimplifying complex dynamics. This study uses an agent-based model to assess the cost-effectiveness of early screening and integrated interventions in China, aiming to develop more targeted and efficient COPD strategies for diverse populations from a healthcare system perspective. Methods: An agent-based model was developed to simulate COPD progression in individuals aged 40–80 years, accounting for individual differences and environmental factors. Early screening strategies, including the COPD Screening Questionnaire and portable spirometry, were evaluated alongside interventions such as influenza and pneumococcal vaccinations, smoking cessation, increased physical activity, and environmental improvements. Four strategies were compared: (1) no screening or intervention, (2) screening only, (3) interventions only, and (4) combined screening and interventions. Key outcomes included quality-adjusted life years (QALYs), costs, COPD-related mortality, and exacerbation rates. Population data were drawn from the national COPD monitoring project, and disease parameters were derived from published studies. Scenario and sensitivity analyses assessed the robustness of key assumptions, while model results were validated against national survey data. Results: The baseline analysis identified annual screening using a combination of the COPD Screening Questionnaire and portable spirometry as the most cost-effective screening strategy. Among single interventions, vaccination demonstrated the greatest effectiveness in reducing COPD prevalence and related complications. At a willingness-to-pay (WTP) threshold of 1–3 times the national per capita GDP, population-wide screening and integrated interventions showed moderate cost-effectiveness compared to no screening or intervention, outperforming screening or interventions alone. Among integrated strategies, combining screening, vaccination, and increased physical activity proved most cost-effective. For high-risk groups, including individuals with comorbidities, smoking habits, or prior disease history, the optimal strategy was annual spirometry screening combined with smoking cessation and vaccination. Conclusions: This agent-based model effectively integrates individual variability and environmental factors, enabling realistic simulations of COPD outcomes. The findings underscore the urgent need to optimize COPD prevention and control strategies in China. Early screening and integrated interventions are pivotal for improving health outcomes. Future efforts should focus on personalized strategies tailored to high-risk subgroups to enhance the precision and cost-effectiveness of prevention measures.

Ind-2027 Economic Evaluation 0f Workplace-Based Hypertension Screening Programme for Public Sectors Employees in Sri Lanka

PRESENTER: **Anuji Gamage**, KDU
AUTHOR: Rohini Seneviratne

Increasing prevalence of non-communicable diseases such as hypertension among employees is a burden to the individual, the family and the country. This reports the cost-effectiveness of implementing annual workplace-based hypertension screening programme among public sector employees **Methods** A linked decision tree model was developed and populated using epidemiological, cost, and health outcome data gathered from various secondary sources which were relevant to the Sri Lankan context to represent pathways, of employees screened and no screening Input model parameters considered an annual hypertension incidence of 2.5%, a screening test sensitivity of 70%, and a current treatment compliance rate of 10%. Costs were estimated for screening (Rs. 1,000 per employee), diagnosis and follow-up for newly diagnosed cases (Rs. 3,500), annual treatment (Rs. 24,000), and CVD-related hospitalizations (Rs. 15,000 per event) alongside productivity losses (Rs. 200,000 per hospitalization for 95 employees). Health outcomes were evaluated using Years of Life Lost (YLL), with CVD-related proportional mortality at 18% and a YLL rate of 17.2% per 100,000 population. The analysis considered a comparator scenario of no screening, where hypertension prevalence would rise to 32%, leading to increased CVD-related complications. **Results** For a workforce of 10,000 employees aged 30–60 years, the annual screening cost was Rs. 32.4 million, inclusive of screening, diagnosis, follow-up, and treatment costs. The no-screening scenario, with an assumed prevalence of 32%, resulted in Rs. 67 million in costs due to untreated hypertension, including hospitalizations and productivity losses. The cost difference of screening compared to treatment and loss of work was Rs. 34.6 million.The incremental cost-effectiveness ratio (ICER) was -Rs. 66,117 per YLL averted. Compared to Sri Lanka's cost-effectiveness threshold of Rs. 3,749,550 per YLL averted (three times GDP per capita), the program is highly cost-effective. **Conclusion** The negative ICER indicates that screening not only improves health outcomes but also generates cost savings by reducing hypertension-related hospitalizations and productivity losses. Additionally, early diagnosis and treatment facilitated by screening improves productivity and would reduce morbidity and mortality among

employees. Timely, cost-effective interventions and periodic screening are important to prevent the upsurge of hypertension among employees. These results strongly support the integration of workplace screening into Sri Lanka's national non-communicable disease (NCD) prevention and control strategies. More evidence on the value of expanded capacity to include other screening in combination may inform new f models to support such investments leading to a more efficient and sustainable publicly funded healthcare system.

Ind-1119 Long-term Cost-effectiveness of Health Behaviour Intervention to Manage Type 2 Diabetes in Nepal: A Markov Modelling

PRESENTER: **Padam Kanta Dahal**, CQUniversity Sydney Campus
AUTHORS: Biraj Karmacharya, Melanie Lloyd, Lal Rawal, Rashidul Alam Alam Mahumud, Zanfina Ademi, Yeji Baek, Corneel Vandelanotte, Grish Paudel, Tomohiko Sugishita

Background: Long-term cost-effectiveness analyses of health behaviour interventions to effectively manage type 2 diabetes mellitus (T2DM) in low-income countries are crucial for minimising economic burden and optimising resource allocation. Therefore, this study aimed to estimate the long-term cost-effectiveness of implementing a health behaviour intervention to manage T2DM in Nepal. **Methods:** A Markov model in combination with a decision tree was developed to compare the costs and outcomes of the health behaviour intervention against usual care among 481 (238-intervention and 243-control) participants from healthcare and societal perspectives. The model integrates empirical trial data, with published data to inform parameters not collected during the trial. The model estimated costs, quality-adjusted life years (QALYs) and cost-effectiveness over 5 years, 10 years, 20 years, 30 years and a lifetime horizon with 3% annual discounting. Sub-group, scenario, both one-way and two-way analyses and probabilistic sensitivity analyses (PSA) were performed to assess the impact of uncertainty in the model under the threshold of 3 times gross domestic product (GDP) per capita (i.e., US $4140) for Nepal. **Results:** Base-case analysis with lifetime horizon showed that the health behaviour intervention compared to usual care improved QALYs by 3.88 and increased costs by US $4293 per patient, with an incremental cost-effectiveness ratio (ICER) of US $1106 per QALY gained from a healthcare perspective. From a societal perspective, QALYs also improved by 3.88 and costs increased by US $4550, with an ICERs of US $1173 per QALY gained. In the PSA, the probability of the health behaviour intervention being cost-effective was over 95%. **Conclusions:** The health behaviour intervention for managing T2DM was cost-effective over a lifetime horizon compared to usual care. To maximise its impact, this intervention should be scaled up nationwide, and future research is warranted to assess the long-term cost-effectiveness across diverse settings in low-income countries. **Keywords:** Type 2 diabetes, long-term cost-effectiveness, Markov modelling, health behaviour intervention

Ind-1600 Revisiting Cost-Effectiveness of Folic Acid Supplementation in Primary Stroke Prevention in China: Considering Vitamin B12 Deficiency Masking Issue

PRESENTER: **Xiyin Chen**
AUTHOR: David Bishai

Backgrounds Vitamin B12 (B12) or folate deficiency can lead to macrocytic anemia. However, treating B12 deficiency with folate alone can resolve anemia while allowing nerve degeneration to progress—a phenomenon known as the "masking" effect of folic acid. This masking delays the diagnosis of B12 deficiency, preventing timely treatment and increasing the risk of irreversible nerve damage. Although studies in China have shown that folic acid supplementation cost-effectively reduces stroke risk in hypertensive adults, the cost-effectiveness of folate supplementation in primary stroke prevention after adjusting for the potential risk of B12 deficiency masking has not been addressed. **Objectives** To evaluate the cost-effectiveness of four policy options for folic acid supplementation in primary stroke prevention for hypertensive patients in China, accounting for the masking effect of vitamin B12 deficiency. Policy A: No action to address folate status. Policy B: Folate supplementation without pre-screening for B12 deficiency. Policy C: Folate supplementation with pre-screening for B12 deficiency and adding B12 supplements for deficient patients. Policy D: Folate supplementation only for folate-deficient patients, with pre-screening for both B12 and folate deficiencies and adding B12 supplements for B12-deficient patients. **Methods** A decision tree with a five-year period of intervention based on the China Stroke Primary Prevention Trial (CSPPT) from the Chinese healthcare system perspective estimated incremental cost-effectiveness ratio (ICER) for Policy B, Policy C, and Policy D versus Policy A. Deterministic and probabilistic sensitivity analyses were performed for Policies C and D versus Policy A. Subgroup analyses for Policy C versus Policy A were conducted across gender, age, genotypes, and homocysteine levels. **Results** At a willingness-to-pay (WTP) threshold of three times the national GDP per capita ($38,198), Policy B was not cost-effective compared to Policy A, with an ICER of $47,968 per QALY, driven by QALYs lost due to delayed B12 deficiency diagnosis, and underestimated neuropathy treatment costs. In contrast, Policy C and Policy D were cost-effective compared to Policy A, with ICERs of $32,615 and $20,287 per QALY, respectively. Deterministic sensitivity analysis showed that Policy C and Policy D would cease to be cost-effective if the hazard ratio (HR) for the first stroke exceeded 0.83 and 0.85, respectively. Probabilistic sensitivity analysis showed a 72.7% and 83.5% likelihood that the additional costs of Policy C and Policy D, respectively, would remain within the WTP threshold. Subgroup analyses indicated that Policy C was more cost-effective for males, individuals aged 55–64, those with the MTHFR CC genotype, and homocysteine levels above 10.5 μmol/L. **Conclusions** Folate supplementation with integrated screening for B12 and folate deficiencies is considered the most cost-effective strategy for primary stroke prevention in hypertensive elderly patients in China. Future research should focus on advancing precision medicine to assess the feasibility and cost-effectiveness of nationwide implementation across diverse sub-populations within the context of integrated screening, ensuring efficient and tailored public nutrition strategy delivery.

Ind-2065 Cost-Effectiveness of Hypertension Management to Reduce the Burden of Dementia

PRESENTER: **Marie Lan**
AUTHORS: Ava John-Baptiste, Shehzad Ali

Background: The number of people living with dementia, and subsequent economic burden, is expected to increase drastically worldwide over the next 20 years. Due to lack of accessible and effective treatment options, primary prevention of dementia is a high priority for policymakers. Approximately 40% of dementia cases worldwide are attributable to 12 modifiable risk factors including hypertension. The World Health Organization guideline for dementia risk reduction recommended the management of hypertension to reduce the risk of cognitive decline and dementia. A recent systematic review found only 4 full economic evaluations assessing the impact of modifying hypertension to

prevent dementia, with no Canadian studies identified. Over 20% of Canadians with hypertension are undiagnosed, and of those, almost 40% have uncontrolled hypertension, making it a feasible target for dementia prevention in Canada. Economic analyses are essential to identifying cost-effective mechanisms to reduce the future burden of dementia. **Objective:** The objective was to evaluate the cost-effectiveness of improving hypertension detection and management to reduce the burden of dementia in Canada. **Methods:** We created a Markov model consisting of 8 states: a starting hypertension state, 3 dynamic hypertension states (Undiagnosed, Diagnosed and Uncontrolled, and Diagnosed and Controlled), three dementia states (Mild, Moderate, Severe), and death. We modelled a cohort of 1000 Canadians beginning at age 45 for a lifetime time horizon, from health payer and societal perspectives. We evaluated the impact of several hypothetical screening scenarios: one-time and annual hypertension screening programs, with varying levels of expected improvement in detection and management. **Results:** Hypertension modification led to an increase in life expectancy (+0.03 to +1.85 years), and delay in the average age of dementia onset (+0.03 to +1.29 years) for all scenarios. Incremental cost effectiveness ratios ranged between $16,190/QALY to $49,613/QALY. Interventions that improved blood pressure control rates, in addition to improved awareness, were consistently more cost-effective than scenarios that improved awareness only, regardless of intervention effectiveness. **Conclusions:** Dementia prevention through improved management of hypertension has the potential to be cost-effective in Canada. This is of particular interest to policymakers seeking to invest in dementia prevention. The study contributes to the small but growing economic evidence for targeting hypertension to prevent dementia. Future research should be directed towards creating and evaluating scalable hypertension interventions that improve both screening and control rates in Canada. The model can also be adjusted to apply to other jurisdictions.

Ind-2842 The Economic and Healthcare Resource Impact of Early Insulin Initiation in Type 2 Diabetes Mellitus Patients

PRESENTER: **Dhia Ticha**
AUTHORS: Gemala Chairunnisa P, Royasia Viki Ramadani, Budi Hidayat, Zahrina Laborahima

Introduction: A significant number of individuals with Type 2 Diabetes Mellitus (T2DM) remain undiagnosed. Indonesia ranks among the countries with the highest prevalence of diabetes, with an estimated 19.5 million cases reported in 2021. The burden of non-communicable diseases (NCDs), including T2DM, is also evident in the Indonesia healthcare expenditure patterns, where a substantial portion of public funds —amounting to 3.16 billion USD—is allocated to NCD management. NCD-related costs are the largest contributors to National Health Insurance (JKN) spending, with T2DM and its comorbidities alone accounting for 10% of total JKN expenditure. Additionally, NCDs consistently rank among the top 10 secondary diagnoses in outpatient and inpatient settings based on the number of visits and claim expenditures. This study is part of a broader initiative to assess the budget impact of insulin initiation at primary care in Indonesia, specifically focusing on its effects on cost outcomes and healthcare resource utilization of early insulin initiation among T2DM patients.** **Methods:** A systematic review was conducted using databases such as Medline (PubMed), EMBASE, Scopus, and Google Scholar. Articles published between 2007 and 2022 were screened using PICO criteria and inclusion/exclusion standards to identify relevant studies. **Results:** Out of 5,087 studies identified, 62 met the inclusion criteria. Basal insulin was the most examined intervention, appearing in 52% of cases. While insulin initiation generally increased costs within the first 6–12 months, long-term analyses demonstrated cost savings. Studies comparing early versus delayed insulin initiation revealed reductions in overall costs, including decreases in outpatient visits, pharmacy expenses for oral antidiabetic drugs (OADs), specialist consultations (from 25 to 16 per patient), and hospitalization rates. When comparing insulin adherence patterns (continuers versus interrupters or discontinuers), outpatient and pharmacy costs were higher for those discontinuing insulin. However, diabetes-related medical care, emergency department visits, and total medical expenses were significantly lower for adherent patients. Hospitalization rates and inpatient costs were also reduced among continuers. These findings highlight the importance of follow-up and consistent insulin management to maximize cost-effectiveness. Primary healthcare centers (PHCs), being community-based facilities, hold significant potential to support sustained insulin adherence. **Conclusion:** While initial insulin initiation may temporarily increase costs, total long-term expenses decrease. This review specifically examines early versus late insulin initiation, revealing that although pharmaceutical and medical device costs may rise, overall diabetes-related expenses are reduced. Early insulin therapy also decreases healthcare visits, although outcomes can vary depending on factors like complications and analysis duration. **Keywords**: Type 2 Diabetes Mellitus, insulin initiation, systematic review.

Ind-1804 The Effectiveness of a Co-Management Intervention for Chronic Conditions: A Pilot Study in Qingdao, China

PRESENTER: **Qian Fu**
AUTHORS: Da Feng, Zhanchun Feng, Jiaxin Lv, Xiao Li, Zhe Jin, Yangfan Sun

Importance The management of patients with multiple chronic conditions presents significant challenges to healthcare systems. **Objective** This study aimed to assess the effectiveness of a co-management model in enhancing health outcomes for patients with diabetes, hypertension, and hyperlipidemia. **Design, Setting, and Participants** This quasi-experimental study used data from "Co-management of Three Highs and Prevention of the Six Diseases" database in Qingdao, China from January 2019 to June 2023. **Interventions** A quasi-experimental design was chosen because it was not feasible or ethical to randomly assign participants to the intervention and control groups. Existing patient groups were used, with the intervention group consisting of patients with three chronic conditions in Chengyang District, and the control group consisting of patients from Licang and Shibei Districts. **Main Outcomes and Measures** The primary outcomes were diastolic blood pressure, systolic blood pressure, fasting blood glucose levels, and lipid profiles by the multilevel logistic regression models. Secondary outcomes were follow-up visits Health service utilization and healthcare costs by a two-period difference-in-differences model multilevel logistic regression, zero-inflated Poisson regression generalized linear mixed model. **Results**: A total of 89,000 patients were enrolled in the intervention group across the three chronic conditions. The analysis revealed a significant reduction in diastolic blood pressure in the intervention group, with an average decrease of 2.989 mmHg compared to the control group which was observed notably among elderly patients and those with comorbidities. The average fasting blood glucose level decreased by 0.134 mmol/L, with significant improvements observed in elderly and diabetic patients. Health service utilization decreased significantly, with outpatient visits reduced by 97.57%, inpatient visits by 25.38%, and total medical costs by 19.60%. **Conclusions and relevance** The co-management model demonstrated significant improvements in diastolic blood pressure and fasting glucose levels, alongside increased follow-up visits. The intervention also resulted in substantial reduction in health service utilization and overall medical costs. These findings suggest that integrated co-management strategies

can effectively improve patient outcomes and reduce healthcare burden in populations with multiple chronic conditions.

Ind-2470 Modelling the Potential Impact of Tobacco Tax in Kenya: Implications for Primary Prevention of Non-Communicable Diseases and Health Financing

PRESENTER: **Robinson Oyando**

Background: In Kenya, two out of ten people smoke tobacco. Tobacco taxation reduces smoking-related premature deaths and increases government revenues but has been criticised for disproportionately affecting poorer people. We assess the distributional consequences (across different wealth quintiles) of a specific excise tax on cigarettes in Kenya in terms of both financial and health outcomes. **Methods:** We use extended cost-effectiveness analysis methods to estimate, across income quintiles, the health benefits (years of life gained), the additional tax revenues raised, the net financial consequences for households, and the financial risk protection provided to households, that would be caused by a 40% increase in tobacco price through excise tax fully passed onto tobacco consumers. For our modelling analysis, we used plausible values for key parameters drawn from data on price elasticities, healthcare cost, income, tobacco consumption that were sourced from the literature and representative national surveys*.* **Results:** Our modelling analysis showed that a 40% increase in tobacco price through excise tax would lead to 115 million years of life gained (95% uncertainty range 94–168 million) over 20 years (a third of which would be gained in the lowest income quintile), a gain of US$352 billion ($308–391 billion) of additional tax revenues from the excise tax (14% of which would come from the lowest income quintile, compared with 24% from the highest income quintile). The excise tax would increase overall household expenditures on tobacco by $188 billion ($116–253 billion) but decrease these expenditures by $11 billion (–$41 to $2.5 billion) in the lowest income quintile and would reduce expenditures on tobacco-related disease by $12·0 billion ($8·7–13·1 billion, 28% of which would benefit the lowest income quintile). Finally, it would provide financial risk protection worth $0·9 billion ($0·6–1·2 billion), mainly concentrated (74%) in the lowest income quintile **Conclusion:** Increased tobacco taxation can be a pro-poor policy instrument that brings substantial health and financial benefits to households in Kenya.

abs-os433 Economic Evaluation of the Ghana Heart Initiative: A Health System Strengthening Intervention for Cardiovascular Disease Management

PRESENTER: **Kavita Singh**, Heidelberg University

AUTHORS: Eugene Kallson, Ms. Manuela De Allegri, Elom Otchi, Alfred Yawson

Background: Cardiovascular diseases (CVDs) pose serious threats to economic development and healthcare systems due to the rapidly rising burden in low- and middle-income countries (LMICs). Health system interventions addressing existing CVD coverage gaps are on the rise in these contexts but effective knowledge translation is lacking. Further, limited economic evidence exists on health system interventions to manage CVD in Sub-Saharan Africa, a region with one of the highest age-standardized CVD burdens. We address this knowledge gap by estimating the economic costs and budget impact of implementing the Ghana Heart Initiative (GHI), a health system intervention piloted in the Greater Accra region since 2019 and later scaled up nationally. The GHI consisted of development and dissemination of evidence-based guidelines for CVD, health worker training, essential equipment supply, 24x7 CVD call center support, and data management support. **Methods**: The GHI economic evaluation adopted a health system perspective, considering program-level costs incurred by the GIZ, the Ghana Health Services (GHS) and Ministry of Health (MoH) using an established activity-based costing approach. We tracked all resources utilized, identifying seven activity clusters for cost categorization, during the pilot phase of GHI from 2018 to 2022, with design (12 months) and implementation phases (36 months). We constructed three scenarios around service delivery, design or expansion elements to forecast the budget impact of nationwide scale-up. **Results:** Economic evaluation revealed total costs of 1,740,853 Euros, with design costs comprising 8.5% (€148,558) and implementation costs of 91.5% (€1,592,295). Human resources constituted the highest expense, followed by consumables, transportation, and room rental. The total financial cost per intervention facility per year was €10,337.0 and the economic cost per facility was €10,615.0. The annual cost per health worker targeted was €861.0. and annual cost per person screened/managed was €34.5. Scaling GHI to 100% coverage would require 2.4% of Ghana's total health budget (€26.7 million, or per capita cost €0.81), whereas focusing on essential service delivery components could reduce the costs to €10.7 million or per capita cost €0.32 (~1% of the national health budget), assuming coordination and monitoring costs are covered by parallel NCD programs. **Discussion/Conclusion**: The low cost of scale-up of GHI suggests that this intervention presents a viable strategy to respond to the growing CVD epidemic in low- and middle- income countries, and should qualify as a priority intervention across other Sub-Saharan African countries with similar demographics and health systems.

abs-os447 Cost-Effectiveness Analyses of Cascade Screening for Familial Hypercholesterolemia: a Comparative Analysis Between Singapore and Thailand

PRESENTER: **Jing Lou**

AUTHOR: Hwee Lin Wee

Background: Familial Hypercholesterolemia (FH) is an autosomal dominant disease with strong genetic linkage. With FH, elevated levels of LDL-C begin at childhood, causing cardiovascular disease (CVD) at a relatively young age. Cascade screening on FH has been found cost-effective in many countries. However, cost-effectiveness analyses (CEA) on cascade screening for FH has not been done in Asia. And existing studies have not analysed how country-specific characteristics affect cost-effectiveness of the screening. It will be interesting to see if differences in localised model parameters such as cost, treatment options and uptake of genetic testing by family members between countries have any impact on the conclusions (i.e. incremental cost-effectiveness ratios (ICER)). Comparison between studies of different countries may not reveal the true impact of country-specific characteristics, due to confounding effects from methodological, structural and parameter uncertainties between studies.

Aim: This study aims to compare between Singapore and Thailand (i) cost-effectiveness of the cascade screening for FH with genetic testing and (ii) drivers for ICER, and to analyse what country-specific characteristics lead to the differences.

Methods: We compared population health characteristics, screening protocols, screening uptake rates and treatment protocols between the two countries. To control for structural uncertainty, country-specific characteristics were put into a same hybrid tree-Markov model structure. To alleviate methodological uncertainty, country-specific parameters were estimated based on the same clinical assumptions using data from the same source, whenever available. Drivers of cost-effectiveness were analysed using one-way sensitivity analysis. To reduce impact from unbalanced parameter uncertainty between the two countries, each variable deviates from its base-case value by 10%, except that probability parameters and health-related quality of life deviate from their base-case value by +/- 0.05 (=0.5x10%), as X is equivalent to 1-X. Costs where quantified from healthcare system perspective for Singapore while from societal perspective for Thailand, as required by local guidelines respectively.

Preliminary results: Although the two countries tied in FH prevalence, Thailand has higher CVD incidence rate and higher relative mortality risk with CVD. Genetic tests are used more intensively during the screening in Thailand, while FH patients are treated more intensively in Singapore. Proband screening uptake rate is higher in Thailand, while family member participation rate is higher in Singapore. As a result, the screening is more cost-effective in TH than SG in terms of absolute ICER value. However, ICER is well below the cost-effectiveness threshold (CET) in SG, while closer to the CET in TH. From the probabilistic model, the probability for the screening to be cost-effective is ~80% in SG, while ~60% in TH. The close proximity of ICER to CET in TH is mainly due to the high treatment cost in FH compared to that for non-FH. Common drivers for ICER between the two countries include cost and effectiveness of lipid-lowering treatment for FH, prevalence of FH mutation among probands, age of proband and family members, health loss and medical cost associated with CVD, CVD risk associated with FH and number of family members and their participation rate. Cost of genetic testing is a driver for Thailand only, due to high cost and intensive use of genetic testing in Thailand.

Conclusion: Cascade screening for FH is likely to be cost-effective in Singapore. In Thailand, cost-effectiveness of the screening could be significantly improved by reducing the treatment cost of managing FH.

Ind-803 Who Wants to Pay More Taxes for Better Long-Term Care Services? Evidence From OECD Countries

PRESENTER: **Sylvain Botteron**
AUTHORS: Christophe Courbage, Joël Wagner

Introduction: Increasing long-term care (LTC) needs and expenses pressure the financing of LTC which mainly relies on public funding in most countries (OECD, 2017). This calls for a better understanding of the resources allocated in financing LTC and individuals' willingness to pay (WTP) to fund these LTC services through taxation or social contributions.

However, research on the topic is relatively scarce and country-specific. It shows the important role of age, income, political factors and perception of LTC risk in driving the WTP for social insurance (see e.g. Brau and Lippi Bruni (2008) and Amilon et al. (2020)).

Our study expands the literature on stated preferences for LTC by using recent OECD surveys to investigate how various individual and country characteristics influence the WTP to increase taxation and social contribution to improve LTC services and access.

Methods: We use data from the 2020 and 2022 waves of the OECD's "Risks that Matter" surveys, which is a cross-national survey covering 25 OECD countries and examining people's perceptions of the social and economic risks they face. In particular, we use answers to the following question to carry out our analysis: "Would you be willing to pay an additional 2% of your income in taxes/social contributions to benefit from better provision of and access to LTC services for elderly people (including e.g. home, community-based, institutional care)?".

We first employ generalized linear mixed-effects models configured as logistic regression models. These models include country-fixed and random effects, allowing us to estimate the impact of country-level variables alongside individual-level effects. Finally, we also conduct standard logit regressions for individual countries to analyze local nuances further.

Results: The analysis shows that individuals with higher education, income, older age, female gender, LTC responsibilities, or left-wing political views are more willing to support increased taxation or contributions for better LTC access. At the country level, higher LTC spending as a proportion of GDP decreases WTP for increased taxation and social contributions. In contrast, greater government trust and cash benefits policy for carers increase it.

Conclusion: This study highlights a generational, social, and political divide in attitudes toward public LTC funding across OECD countries. It shows that increasing taxes and social contributions to improve LTC services is supported by specific population categories. Such results can be useful to policymakers when organizing and prioritizing LTC services.

Ind-421 Tax on Oil Production and Health Financing in Brazil

PRESENTER: **Fernando Antonio Slaibe Postali**
AUTHORS: Adriano Dutra Teixeira, Maria Dolores Montoya Diaz, Natália Nunes Ferreira Batista, Rodrigo Moreno-Serra, Luciano Mancuso Salomão, Judite Gonçalves

Context: Brazil has one of the largest public health systems in the world (SUS), covering approximately 160 million people nationwide. The SUS governance structure is based on shared responsibility among the federal government, states, and municipalities to provide healthcare for the entire population. A significant subset of Brazilian municipalities is also entitled to a share of oil tax revenues (oil royalties), proportional to the volume of oil production within their territories. To address ongoing challenges in achieving Universal Health Coverage (UHC) and securing sustainable financing, Brazil enacted legislation in 2013 (Act 12,858/2013), mandating that 25% of oil royalty revenues allocated to municipalities be invested in healthcare. This law, applicable only to oil wells that began operations after December 2012, introduced a new stream of earmarked funds to municipal budgets, specifically aimed at strengthening local health systems. The phased implementation of this policy offers a unique opportunity to assess its impact on municipal health spending and outcomes. **Objectives**: This study aims to evaluate the impact of this legislation on healthcare expenditures and outcomes of municipalities benefiting from receiving oil royalties. It focuses on primary healthcare spending and outputs since they are the main responsibility of municipalities according to the Brazilian Federative Pact. By examining how oil royalties influence specific areas of health spending, this study sheds light on the policy's effectiveness in expanding fiscal space for health in Brazilian municipalities. **Methods**: We employ a difference-in-differences (diff-in-diff) approach with multiple treatment periods, following the methodology proposed by Callaway and Sant'Anna (2021)[^1]. This approach leverages the gradual adoption of the policy, allowing us to measure its impact over time and account for variations across municipalities with differing fiscal capacities and sizes. Data were sourced from the Brazilian National Health System Database (SIASUS/Datasus) and the National Treasury (Finbra), covering the period from 2008 to 2022. Heterogeneity analyses further explore the effects among municipalities with above-average royalty revenues. **Results**: Findings indicate that the law's overall impact on increasing health and education spending was limited. However, in municipalities receiving higher-than-average royalty revenues, prolonged exposure to the policy was associated with increased healthcare spending, particularly in hospital care. Improvements in health promotion procedures were also observed in highly benefiting municipalities, suggesting targeted improvements in healthcare expenditures where royalty allocations were more substantial. On the other hand, no significant impact was found in public hospital beds and primary health care teams (Family Health Strategy). **Discussion**: The results highlight the complexities of using earmarked revenues to influence health outcomes, as the policy showed limited success in universally improving health indicators across municipalities. Nonetheless, the observed increase in healthcare spending among wealthier municipalities underscores the potential of oil royalties to expand fiscal space for health, albeit unevenly. These findings have implications for policymakers in refining oil revenue allocation rules to better support health financing, particularly in resource-rich but economically diverse regions. [^1]: Callaway, B. and Sant'Anna, P. H. (2021). Difference-in-differences with multiple time periods. Journal of Econometrics, 225(2):200–230.

Ind-2153 Convergence in Healthcare Expenditure among Indian States: Does Fiscal Space Matter?

PRESENTER: **Jalandhar Pradhan**
AUTHOR: Ajit Nag

Background: The top priority in the United Nations' Sustainable Development Goals-2030, is to achieve Universal Health Coverage (UHC), which ensures equal access, quality, and financial security for healthcare services to all in need. Government financing for healthcare is less prevalent in low- and middle-income countries (LMICs) than private sources of financing, which may cause problems in achieving UHC. Despite encouraging economic growth, many LMICs, including India, still require sufficient public funding to meet the UHC. Healthcare is crucial for creating human capital, preserving global well-being, and contributing to development. The most significant obstacles to establishing UHC in India are the unequal distribution of fiscal resources and the lower prioritization of budgets for healthcare across Indian states. **Aim:** The key questions addressed in this study are: i) Is there any convergence in health expenditures across Indian states?; ii) Does club convergence occur in healthcare expenditures among the Indian states?; iii) How does fiscal space impact each club's and overall government healthcare expenditure?; iv) Would domestic revenue mobilization through tax and non-tax revenue enhance healthcare financing? **Methods:** In this paper, data from the state finance budget report of the Reserve Bank of India has been used to analyze the relationship between government health expenditure with other variables such as Tax Revenue, Non-Tax Revenue, Fiscal Transfer, Borrowings and per capita net states domestic product for a panel of 22 Indian states from 1990-91 to 2020-21. The variables have been adjusted for inflation and population size. The study employs the club convergence approach proposed by Phillips and Sul (2007) to investigate whether states converge toward a single steady-state equilibrium or multiple groups. **Results:** The results reveal that Indian states haven't achieved a single steady-state equilibrium. Instead of overall convergence, the findings show two final club convergence and two divergence states (Arunachal Pradesh and Bihar) for health expenditure. Our panel regression analysis indicates that tax revenue, non-tax revenue, fiscal transfers, and per capita income positively influence per capita government health expenditure. However, borrowings negatively impact the long-term allocation of government expenditure on healthcare within each convergence club. The analysis suggests that heavy reliance on borrowed funds may lower the priority of health spending. The result emphasizes increasing revenue through tax base expansion, earmarked taxes, and sin taxes to boost fiscal space across Indian states. **Conclusions:** These findings highlight the need for policymakers to revise health spending strategies to enhance coordination and support growth and state integration. Additionally, the government should efficiently allocate central transfers and establish an expenditure management framework to prioritize healthcare, ensuring balanced healthcare spending among states. **Keywords:** Club Convergence, Fiscal Space, Tax Revenue, Non-Tax Revenue, Fiscal Transfer, Borrowings, Per capita income

Ind-380 Worldwide Resource Need for Normative Health Service Packages: Ingredient-Based Microcosting Using the UHC Compendium

PRESENTER: **Charlie Nederpelt**
AUTHORS: Rob Baltussen, Hassan Haghparast-Bidgoli, Gerard Joseph Abou Jaoude, Gavin Surgey

Introduction The World Health Organization (WHO) and Disease Control Priorities (DCP) network created health service packages (HSPs) to support countries in achieving universal health coverage (UHC). The WHO Universal Health Coverage Compendium (UHCC) is a novel database containing input-defined definitions for a comprehensive list of essential health services. To mobilize and allocate resources, policymakers require understandable, accurate estimates of financial, workforce and material needs. We present the first methodology and proof-of-concept results for a health system-wide, ingredient-based costing producing these outputs efficiently, using the UHCC. **Methods** Facility-level service delivery costs were estimated for four HSPs: Core UHCC, complete UHCC, DCP-3 Highest Priority Package (HPP) and DCP-3 Essential Universal Health Coverage (EUHC). We constructed a linear, ingredient-based microcosting model, multiplying frequency of each UHCC input type [labor, drugs, in vitro diagnostics, consumables] with unit cost estimates sourced from scientific literature and tools like WHO-CHOICE and pharmaceutical cost databases. Costs were converted to 2016 USD to align with previous DCP-3 costing estimates. National delivery costs were modeled by multiplying country-specific unit costs with Populations-in-Need estimates sourced per intervention from scientific publications, United Nations Population Division, WHO and Global Burden of Disease data. National delivery costs were differentiated across normative delivery platforms, and corrected for noncommunicable disease multimorbidity. To validate externally, average delivery costs were compared to 2016 DCP Cost Model results. Unit cost for selected noncommunicable disease interventions were compared to international professional bodies' cost estimates. The proportional contribution of different input categories in total cost was compared to published literature across different countries. **Results** Unit cost and national program cost were estimated for 132 low, lower-middle and upper-middle income countries. Delivery cost of DCP-3 HPP was 2016$427 billion, varying between 4.2-11.4% of national GDP. Cost estimates for Core UHCC and Complete UHCC were significantly higher at $663 billion and $1.431 billion, corresponding to 6.6-27.8% of GDP in studied countries. Unit costs for DCP-3 HPP and EUHC HSPs deviated from previous estimates by -33 to +42% for HPP, and -5 to +74% for EUHC interventions. Presented unit costs for EUHC and HPP services were within 20% margin of previous estimates for 106/215 (49%) of services. Presented unit cost estimates matched those published by international professional bodies well for e.g. diagnosis and treatment of diabetes mellitus (+7%), ischemic heart disease (+13%), and ischemic stroke (+5%). Primary cost-drivers were labor [22%], medicine [14%] and overhead [38%], which is broadly reflective of published results from several lower and lower middle-income countries. **Conclusion** This study presents initial ingredient-based cost estimation of authoritative HSPs. Large discrepancies compared to previous cost estimates highlight the necessity of data contextualization and warrant further exploration. Results require cautious interpretation and, at worst, represent potential underestimation of normative UHC resource needs. Methods and estimates presented are intended as a starting point for improvement with localized data, and are accompanied by clear workflows for such contextualization.

Ind-1563 Modeling Potential Distributional Health and Financial Risk Protection Impacts of National Health Insurance in Uganda

PRESENTER: **Dorit Talia Stein**

AUTHORS: Stéphane Verguet, Freddie Ssengooba, Aliyi Walimbwa, Goodarz Danaei

Background: There is no National Health Insurance Scheme (NHIS) in Uganda, with only 1% of the population having health insurance. There is also a rising burden of cardiovascular diseases (CVDs), with poor health system performance for managing risk factors such as hypertension. In this analysis, we simulated the potential impact of NHIS that generates demand for hypertension care on health and financial risk protection (FRP) outcomes.

Methods: We developed a microsimulation model using nationally representative surveys, administrative data, and stakeholder input. We evaluated the impact of insurance enrollment—with and without improving supply-side capacity—on hypertension treatment coverage, CVD cases and deaths, and catastrophic health expenditures (CHE) over ten years among adults with hypertension. In business-as-usual, individuals progressed through outpatient care-seeking, diagnosis, and hypertension treatment cascade steps, with anti-hypertensive (HTN) treatment initiation reducing CVD risk. CHE occurred when out-of-pocket (OOP) inpatient medical costs exceeded thresholds of household consumption. We modeled two insurance scenarios: universal enrollment and staggered enrollment over time for the informal and unemployed sectors. Care-seeking and HTN treatment probabilities changed with insurance enrollment. Diagnosis and treatment probabilities additionally improved with supply-side improvement. We summarized care cascade outcomes, CVD cases, and CHE cases averted (vs. business-as-usual), overall and by employment status.

Results: Universal insurance enrollment improved HTN treatment coverage at ten years to 55% (from 41%), or to 81% with supply-side improvements. Staggered enrollment increased HTN treatment coverage to 50% without, or 75% with, supply side improvements. Overall, universal enrollment into insurance would avert 240 (95% uncertainty interval [UI]: 103, 403) CVD cases per 100,000 people with hypertension vs. business-as-usual, increasing to 790 (640, 950) with supply-side improvements. Staggered enrollment would avert 110 (-150, 360) CVD cases per 100,000 people with hypertension over ten years, increasing to 600 (360, 850) with supply-side improvements. In total, universal enrollment averted 6,590 CVD cases (increasing to 21,600 with supply-side improvements) compared to 3,000 with staggered enrollment (and 16,540 with supply-side improvements). Among the informally employed, 4,580 CVD cases were averted with universal enrollment and 1,830 with staggered enrollment, with similar reductions among the unemployed sector. In terms of FRP, universal enrollment would avert 70 (-40, 180) CHE (25% threshold) cases per 100,000 people with hypertension vs. business-as-usual, reducing to 30 (-110, 150) with staggered enrollment. In total, 1,810 CHE cases would be averted with universal enrollment (increasing to 5,980 with supply-side

improvements) compared to 780 with staggered enrollment (4,350 with supply-side improvements). CHE cases averted among the informally employed would reduce from 1,160 cases averted with universal enrollment to 450 cases averted with staggered enrollment.

Conclusion: The potential health and FRP impacts of NHIS in Uganda would be dampened by staggered insurance enrollment and constrained by supply-side capacity to diagnose and treat hypertension. Foregone benefits would be greatest among the informally employed and unemployed. Uganda should pursue universal insurance enrollment, with focused efforts to enroll the informal sector and unemployed population, and invest in improving quality-of-care and service delivery infrastructure to maximize the potential benefits of a national health insurance program.

Ind-1983 Equity in Insurance Contributions Under Non-Employment-Based Health Insurance Plans in the Japanese Mandatory Health Insurance System

PRESENTER: **Ayako Honda**, Hitotsubashi University
AUTHORS: Ruru Ping, Takashi Oshio

Title: Equity in Insurance Contributions in the Japanese Mandatory Health Insurance System

Background

In 1961, Japan achieved full health insurance coverage using a combination of employment-based and non-employment-based insurance plans. The Japanese mandatory health insurance system offers a range of plans that can be broadly categorized as employment-based and non-employment-based plans. Non-employment-based plans are further subdivided as plans for people aged 75 and over and plans for people not covered by other plans (residence-based plans). The multiple plan structure has more than 1500 insurers covering different population groups, and each insurer determines their own member contribution rates. As recent economic and demographic changes are challenging the Japanese health system, the Government is undertaking reforms that aim to improve efficiency and equity in the system. However, limited studies have addressed equity in the member contributions paid for health insurance plans in the Japanese system, impacting on the ability to formulate appropriate reforms.

Aim and Objectives

This study explores vertical equity in the member contributions paid in the Japanese mandatory health insurance system, that is, alignment between member contributions and people's ability to pay. This study aims to assess vertical equity in: (1) general insurance contributions in the Japanese mandatory health insurance system, and (2) member contributions paid in different insurance plan types.

Methods

The study uses cross-sectional data from a national survey (Comprehensive Survey of Living Conditions, 2010-2022) and estimates the Kakwani index, which is the difference between the concentration index of insurance contributions and the Gini coefficient for household ability to pay (ATP). ATP is measured using market income, pre-tax income, and after-tax income. Household income is adjusted using an equivalence scale.

Key findings and discussion

Based on after-tax income, overall insurance contributions under Japan's mandatory health insurance system are progressive, even though payment rates are not adjusted for ATP. Insurance contributions in plans for those aged 75 and over and residence-based plans are regressive when using market income but are progressive when using pre-tax income and after-tax income. Social security benefits appear to mitigate disadvantage by redistributing income to improve ATP. In addition, government subsidies assist low-income groups to make insurance contributions. Insurance contributions made in employment-based plans are slightly regressive, indicating the need to review contribution rates, with consideration given to ATP and removing upper limits on contribution rates. As insurers in Japan's mandatory health insurance can determine member contribution arrangements, and contribution rates vary between insurance types and insurers, further study on the horizontal equity of insurance contributions is necessary to determine whether households with the same ability to pay make the same contributions.

Ind-2383 The Long Road to Equality for People with Disabilities: Evaluating the Adequacy of National Health Insurance s Benefit Packages

PRESENTER: **Dwi Oktiana**
AUTHOR: Muhammad Vinka Lutfian

Introduction

Access to health services remains a significant challenge for people with disabilities in Indonesia, despite more than 200 million (70%) of the people have registered into the national health insurance (JKN). The National Survey of 2023 found 48.8% of people with disabilities had health symptoms in the past month compared to 24.6% non-disabled individuals. Alarmingly, 28% of people with disabilities have not enrolled into the JKN, leaving 75% of them unable to seek medical treatment when they are suffering from ill-health. This disparity is further exacerbated by higher poverty rates among people with disabilities, driven by living expenses that are 30% higher than those of non-disabled individuals. Health care equality for people with disabilities remains elusive, with JKN covering only 7 out of the 50 assistive devices recommended by the World Health Organization (WHO). This study aims to evaluate the adequacy of the JKN benefit package for people with disabilities, explore potential improvements, and identify barriers to accessing health services.

Methods

Using a mixed-methods approach, the study integrates quantitative data from surveys of 120 people with disabilities, primary utilization data of the JKN, and secondary data of the national surveys of socio-economic and employement. Qualitative data were gathered through in-depth interviews with people with disabilities and their families, consultations with policymakers at the national and regional levels, and focus group discussions with disability organizations. Data collection was conducted in four selected districts/cities and at the national level. Quantitative data were analyzed to provide descriptive statistics, while qualitative data were examined using Jean-Frederic Levesque's (2013) Access to Health Services framework.

Results

The findings reveal significant inadequacies of the JKN benefit for people with disabilities as follow: (1) the reimbursement rates are far below the cost of standard assistive devices needed, (2) long replacement periods for assistive devices reduce the effectiveness of the co-payment—for example, locomotor prostheses can only be replaced every five years, with a reimbursement cap of USD 150. (3) no data on disability on the membership database complicates utilization reviews, and (4) the JKN only covers medical care but does not cover disabilities.

Conclusiion & Recommendation

Disable people have the following barriers to healthcare: (1) insufficient availability of specialized health professionals, (2) lack of eligibility to be covered by health insurance due to people registration issues, (3) lack of disable friendly of public transports, (4) inadequate infrastructure of health facilities for disable (e.g., steep ramps, broken guiding blocks, absence of Braille or sound systems), and (5) limited awareness and training among health and non-health workers about disability-specific needs.

We recommend (1) disability organizations to undertake Health Technology Assessment to demonstrate the economic benefits to add assistive devices, (2) Adopting standard universal design health facilities, and (3) Adding the JKN data on all disabilities to enhance policy planning and monitoring.

Ind-1712 Estimating Costs for Hereditary Diseases through Premarital Screening

PRESENTER: **Hasbullah Thabrany**, Thinkwell/USAID Health Financing Activity
AUTHORS: Dini Kurniawati, Iko Safika, Ratu Martiningsih, Wira Hartati, Nurul Rahmayanti, Mutia Astrini Pratiwi

Background:

Indonesia has a Maternal Mortality Rate of 189 per 100,000 live births and an Infant Mortality Rate of 17 per 1,000 live births. The prevalence of stunting remains high at 21.5% in 2023. A significant number of women continue to suffer from both communicable and non-communicable diseases. Specifically, 2% have diabetes mellitus, 10.5% have hypertension, 0.22% have tuberculosis, and 0.13% have hepatitis (Indonesia Health Survey [SKI], 2023). Among pregnant women, 28% experience anemia, and 16% are diagnosed with HIV (SIHA, 2023). Without proper screening, potential annual claims could amount to IDR 9.8 trillion (approximately US$ 625.6 million). To mitigate higher claim costs, the Ministry of Health prioritizes screening for 14 major diseases, focusing on at-risk populations. Premarital screening aims to prevent disease transmission between partners, support healthy pregnancies, avoid hereditary diseases, and contribute to a healthier future generation. Therefore, there is a need for a model that estimates the potential cost savings from JKN claims through premarital screening. This study evaluates the economic benefits of premarital screening and the potential cost savings resulting from disease reduction.

Methods:

The methods employed in this study include a literature review and secondary data analysis. The secondary data was sourced from Statistics Indonesia, covering 2018 to 2023, which we used to predict future marriage rates 2025-2030 through linear regression. We utilized SKI 2023 to evaluate disease prevalence and accessed the government's E-Catalog to procure goods and services to obtain standard pricing. We adjusted the figures based on the average annual inflation rate to estimate costs. Ultimately, we projected costs for three different screening package scenarios (basic, moderate, and comprehensive) and applied two assumptions regarding JKN membership in the screening benefit package including Anthropometric, Physical and Mental Test, Hemoglobin, HIV and Syphilis, Hepatitis B, Diabetes Mellitus, Tuberculosis, Hypertension, and Thalassemia

Results:

The estimated number of prospective brides and grooms nationally in 2025 is 3.5 million, which will decrease to 2.9 in 2030. Therefore, the screening costs the government should provide for 2025 are IDR 26.7 billion (US$1.7 million) and IDR 256.0 billion (US$ 16.3 million), screening costs 2025-2030 are IDR 161.9 (US$10.3 million) billion to IDR 1.8 trillion (US$115 million) depending on the selected scenario and assumption. Furthermore, the prevalence of both hereditary and communicable diseases among individuals aged 20-30 is 26%. Through screening, it can be monitored to prevent the progression of more advanced diseases. If 26% undergo treatment, the annual claim burden could be reduced by IDR 2.5 trillion (US$160 million). Further, we will do some economic impact based on modeling to calculate future savings from the screenings.

Conclusions:

The Indonesian government could set an example for developing countries by implementing premarital screening programs. This initiative could help prevent hereditary severe diseases and manage communicable diseases, ultimately reducing future healthcare costs. We recommend that the government monitor and evaluate the quality of life for individuals participating in these premarital screenings.

Ind-1735 Cost-Effectiveness Analysis of Screening Three-Year-Old Children for Social-Emotional Problems Combined with Parenting Program in Swedish Settings

PRESENTER: **Inna Feldman**
AUTHORS: Anni-Maria Pulkki-Brännström, Anneli Ivarsson, Filipa Sampaio, Emanuela Pires, Masoud Vaezghasemi

Background. Problem behavior in childhood and adolescence is a predictable consequence of problematic adjustment in early childhood. As such, poor social-emotional functioning is a risk factor that has been linked with mental health problems later in childhood, adolescence and adulthood. Therefore, early detection and addressing social emotional problems among small children are crucial.

Aim. The aim of this study was to assess the long-term cost-effectiveness of a population-based screening to detect social-emotional problems with ASQ:SE® in 3-year-old children combined with an evidence-based parenting intervention Incredible Years® (IY), provided to parents of children with high levels of social-emotional problems

Methods. A decision-analytic Markov model was developed, to compare two alternatives: 1) all 3-years-olds get screened for social-emotional problems, and parents for children at a high risk receive IY parenting program; 2) no screening and no intervention ("do nothing"). The prevalence data on social-emotional problems in 3-year-olds was provided by Västerbotten Region (Sweden). The cohort of 3-year-olds with social-emotional problems was modelled until they reached 19 years old. The model considered development of emotion problems (anxiety) and attention deficit hyperactivity (ADH) problems, over 16 years. Effectiveness of IY was sourced from published literature. The analyses were conducted from a limited societal perspective, including healthcare and educational costs. Health outcomes were assessed with DALYs averted and results were expressed as Incremental Cost-Effectiveness Ratios (ICER).

Results. Screening with ASQ:SE combined with the evidence-based parenting intervention IY demonstrated larger costs (incremental cost €148,639) and more DALYs averted (incremental DALYs 14.72) than no screening and no intervention, with an ICER of €10,100/DALY averted. The preventive approach evaluated in this study was cost-effective compared to a "do-nothing" alternative in the Swedish setting, at a local willingness to pay threshold of €53,122.

Conclusion. The findings align with previous research; prevention aimed at children's mental health problems will likely provide good value for money. Successful implementation of population-based screening for social-emotional problems combined with an effective evidence-based parenting intervention might be an important way to contribute to sustainable and efficient healthcare system in Sweden.

Ind-1047 Impact of Child Maltreatment on the Costs of Health Service Use and Productivity Loss: Findings From the Australian Child Maltreatment Study

PRESENTER: **Dai Quy Le**
AUTHORS: Marie Yap, David Lawrence, Daryl Higgins, Cathy Mihalopoulos, James Scott, Divna Haslam, Long Le, Ben Mathews, Eva Malacova

Background: A recent nationally representative survey in Australia found approximately 62% of adults experienced some form of child maltreatment (Mathews et al., 2023). Child maltreatment has been linked to more than 184,000 Disability-Adjusted Life-Years due to mental ill health (Grummitt et al., 2024) and increased healthcare service utilization in Australia (Pacella et al., 2023). However, the impact of child maltreatment on the costs of healthcare and productivity loss remains unknown in Australia. **Objectives:** This study aimed to examine the costs of health service use and productivity loss due to unemployment associated with child maltreatment in Australia. **Methods:** Cross-sectional data from the Australian Child Maltreatment Study (ACMS), which included 8503 participants (49.2% female, age M = 38.1, SD = 18.7), were analyzed in this study. The ACMS utilized the 16-item Juvenile Victimization Questionnaire-R2 to assess five types of child maltreatment, including physical abuse, sexual abuse, emotional abuse, neglect, and exposure to domestic violence. Health service use was self-reported using items adapted from the 2007 National Survey of Mental Health and Well-being (Australian Bureau of Statistics, 2008). Additional demographic, economic, and health-related information such as age, sex, employment status, residential postcode, current financial stress, height, and weight were also collected. A bottom-up costing approach using individual-level data to estimate the cost of health consultation, overnight hospitalization, and overall health service utilization. Costs of health consultation were calculated by multiplying the frequency of visits to each type of health professional by unit costs from the Medicare Benefits Schedule. Overnight hospitalization costs were derived using a formula and unit costs from the Independent Health and Aged Care Pricing Authority. Costs of productivity loss due to unemployment were estimated using the human capital approach. Two-part models, comprising logistic regression and generalized linear models, were used to estimate and compare health service use and costs between those with and without child maltreatment experiences. Sensitivity analyses were conducted by varying assumptions about out-of-pocket and hospitalization costs. **Results:** Annual healthcare cost for each individual with CM was A$1,670 higher than those without CM. Productivity losses due to unemployment averaged A$2,750 extra annually for those in the labor force with CM. These costs increased with the number of CM types experienced and remained highest among those with any neglect, followed by sexual and emotional abuse. A notable portion of health service use costs was likely attributed to mental health services. Subgroup analyses also revealed higher health service use costs for females and individuals with diverse gender identities.

Findings mostly remained robust across sensitivity analyses. Overall, CM was associated with annual health service use costs of A$21.6 billion and productivity loss of A$24.1 billion **Conclusion:** Child maltreatment imposes substantial healthcare and productivity costs on the Australian healthcare system and economy. This highlights the need for greater investment in child maltreatment preventive interventions in Australia.

Ind-1124 Economic Evaluation of a Parenting Intervention for Children Development Embedded in a Social Safety Net Programme in Urban Bangladesh

PRESENTER: **Sheikh Jamal Hossain**
AUTHORS: Jena Derakhshani Hamadani, Jane Fisher, Hassan Haghparast-Bidgoli, Anisur Rahman, Fahmida Tofail, Syed Moshfiqur Rahman

Introduction: Evidence from low- and middle-income countries has shown that parenting intervention alone or in combination with other interventions, can improve children's development. Many parenting interventions also have shown a positive impact on maternal health and well-being. However, there is limited evidence on the cost and cost-effectiveness of these interventions. We aimed to conduct an economic evaluation of a parenting intervention to improve children's development embedded in a social safety net programme in urban Bangladesh **Methods:** We conducted an economic evaluation study of a cluster-randomized trial where 599 mother and child dyads participated in a 12-month intervention. Mothers in the intervention group (n=299) attended fortnightly parenting sessions and received 800 Bangladeshi Taka US$ 6.20) unconditional cash transfer (UCT) from the Government of Bangladesh as a social safety net each month whereas the comparison group (n=300) received only UCT. The primary outcome was children's development and secondary outcomes were maternal well-being and children's quality home stimulation environment. We estimated the incremental cost-effectiveness ratios (ICERs) using the primary outcomes. We also presented our results as a cost-consequence analysis. Deterministic sensitivity analysis was conducted to assess the impact of the uncertain parameters on the findings. Costs were adjusted for inflation, discounted, and converted to 2023 US$. **Results:** The total intervention cost was US$30,183, comprising a start-up cost of US$ 4,080 and implementation cost of US$26,103. The cost per mother and child dyad was US$ 101. Compared to UCT arm, the intervention significantly improved children's cognitive, language and motor development. Additionally, mothers experienced benefits such as reduced depressive symptoms, decreased exposure to violence, improved quality of life, enhanced child care knowledge, and improved child stimulation environment. Cost-effectiveness analysis showed that an additional US$ 100 spending is estimated to lead to a 0.42SD improvement in cognition, 0.38SD in language and 0.17 SD in motor development. Sensitivity analyses supported these findings. **Conclusion:** The findings showed that the intervention is cost-efficient and potentially cost-effective when compared with the limited comparable studies in LMICs. The intervention had benefits beyond children's development including reductions in maternal depressive symptoms, violence against mothers, improvement in quality of life and children's quality stimulation environment. These findings support potential scale up of the intervention in Bangladesh and similar settings.

Ind-1686 Economic Evaluation of a Group-based Peer Support Intervention for Fathers of Young Children

PRESENTER: **Cindy Liang**
AUTHORS: Jemimah Ride, Casey Hosking, Rebecca Giallo

Background:

Early parenthood can be a particularly stressful time. Most interventions targeting parental mental health during this period focus on mothers, with fathers' risks of poor mental health relatively neglected, despite evidence that fathers' mental health is also important for children's outcomes. This economic evaluation aimed to assess the cost-effectiveness of a novel psychosocial intervention targeting this population.

Methods:

This economic evaluation was conducted alongside a pragmatic randomised controlled trial comparing a 6-week group-based peer support intervention (Working Out Dads) with usual care. The population consisted of fathers of young children (aged between 0-4), living in Victoria Australia, who were experiencing mental health difficulties or at risk of poor mental health and suicide. Intervention costs were determined from trial records. Healthcare utilisation was obtained from administrative public sector healthcare data, augmented by a resource use questionnaire to capture self-reported public and private sector healthcare utilisation, plus productivity and travel costs. The base case took a public sector perspective with costs measured in 2021 Australian dollars. Outcomes were measured in quality adjusted life years using the Assessment of Quality of life (AQoL-8D) instrument. Mean costs and quality of life years (QALYs) were compared between the groups at 6 months follow up to estimate the incremental cost-effectiveness ratio (ICER). Uncertainty surrounding the ICER was estimated using probabilistic sensitivity analysis. Scenario analyses were conducted from different perspectives.

Results:

The trial was conducted between January 2021 and January 2024. The sample consisted of 293 fathers (147 in the WOD intervention group, 146 in the usual care group), with a sample mean age of 36.6 years. Analyses are currently underway by the research team. Intervention cost was higher for the WOD group, and preliminary results based on resource use questionnaire data suggests that total public sector healthcare costs were lower for the intervention group compared to the usual care group. Quality adjusted life years were similar between two groups. Further findings will be available once linked data are analysed.

Conclusion

Despite the long-ranging impact of parental mental health problems during the early childhood period, both for parents and children, interventions targeting fathers' mental health have been relatively under-studied. This group-based peer support intervention offers potential to address risk factors for paternal depression and suicidality and could be a valuable tool. The results of this economic evaluation will be vital to inform policymakers considering implementation of this approach. It will identify the value of the intervention to the public sector and to

families, and identify key drivers of cost-effectiveness and sources of uncertainty regarding the results.

Ind-1221 The Long-Run Effects of Childhood Primary Health Care Expansion: Evidence from China s Barefoot Doctors

PRESENTER: **Feng Huang**
AUTHOR: Chunjie Wu

China’s barefoot doctor program was a model and inspiration for the famous 1978 Alma-Ata Declaration on primary health care, a low-cost strategy that achieved high health outcomes. Started in 1965, about 1.5 million peasants who received intensive three- to six-month training in anatomy, bacteriology, birth control, maternal and infant care, and other topics—were dispatched to provide basic health care for their rural communities. What are the long-run impacts of early childhood exposure to primary health care expansion? We collect a unique county-level dataset on the Barefoot Doctor program from historical gazetteers from 1965 to 1977. We then divided the number of barefoot doctors by the county population in that year to generate the density of barefoot doctors. We use data from the China Health and Nutrition Survey (CHNS 2000 to 2011) for long-term outcomes. Exploiting the variations in the density of barefoot doctors across counties and over time, we employ a cohort difference-in-differences model to identify the program's influence. First, counties had different numbers of barefoot doctors. We use a continuous measure of the intensity of treatment (i.e., density of barefoot doctors), and thereby capture more variation in the data. Second, there is substantial variation in early-life exposure within and between cohorts within the same county. The cohorts born between 1946 and 1954 were at least 11 years old when the PHCE was initiated in 1965; their early childhoods were not exposed to the program. Those born between 1962 and 1965 were partially exposed to the program, and those born between 1966 and 1970 were fully exposed. A primary threat to our identifying assumption is that barefoot doctors were not randomly distributed, so counties with more barefoot doctors could have systematically differed from those with fewer barefoot doctors before 1965. We assess the plausibility of this parallel-trend assumption in the following ways. First, we allow the trend to vary with the pre-determined county characteristics that were key observable determinants. In our main specification, we add the interactions of linear cohort trend and county-level variables in 1965, which include the number of hospital beds per 10,000 persons. We find that greater exposure to Barefoot Doctors significantly improved educational attainment and labor market outcomes in the long run. Additional exposure to Barefoot Doctors in utero has more significant effects. The effects are larger for females in educational attainment and labor force participation. We find that one underlying mechanism may be better primary health care and better health in childhood. This paper provides the first evidence that Barefoot Doctors have lasting impacts on health and economic outcomes and sheds light on primary healthcare expansion in other developing countries.

Ind-2655 Cost-Effectiveness of Vaccination Strategies to Control Future Mpox Outbreaks in England

PRESENTER: **Josephine Walker**
AUTHORS: Peter Vickerman, Gayatri Amirthalingam, Siwaporn Niyomsri, Miranda Mindlin, Bennet Dugbazah, Xu-Sheng Zhang, Jessica Edney, Hamish Mohammed, Sema Mandal

Background: In 2022, a global outbreak of mpox occurred among gay and bisexual men who have sex with men (GBMSM). In England, the outbreak was controlled through reductions in sexual risk behaviour and vaccination of high-risk GBMSM. However, mpox continues to circulate, including an expanding outbreak in Africa, and so there is a risk of future outbreaks in the UK and other non-endemic countries.

Aim: We evaluated the most cost-effective vaccination strategy to minimise the risk of future mpox outbreaks among GBMSM in England.

Methods: A mathematical model of mpox transmission among GBMSM was developed to estimate the costs per quality-adjusted-life-year (QALY) gained for different vaccination strategies starting in 2024 (20-year time-horizon; 3.5% discount rate; willingness-to-pay threshold £20,000/QALY). The model was calibrated using English surveillance data from the 2022 outbreak and two community surveys. Reactive vaccination (only during outbreaks) and pre-emptive vaccination (continuous routine) strategies targeting GBMSM at high-risk for mpox were compared to no vaccination. Baseline projections incorporated importation of new mpox cases, and a vaccine effectiveness of 78%/89% for 5/10 years with 1/2 doses at £160/dose. Based on the 2022 outbreak, costs were estimated for case management, vaccination and public health responses during futures outbreaks.

Results: All vaccination strategies reduced future outbreaks, gained QALYs and reduced costs compared to no vaccination. Continuous pre-emptive vaccination (daily rate 41 doses) was most cost-effective, saving £38.4 million and gaining 546.3 QALYs over 20-years. Threshold analyses suggested vaccination of GBMSM at high-risk for mpox is cost-effective if the vaccine costs less than £636 per dose. Pre-emptive vaccination remains the optimal strategy across numerous sensitivity analyses, including for importation of more severe and transmissible clades, but the optimal vaccination rate can vary. Reactive vaccination only becomes more cost-effective when public health response costs are not included.

Conclusions: Pre-emptive vaccination of high-risk GBMSM is a crucial cost-saving strategy to prevent future mpox outbreaks. Similar

vaccination strategies should be considered for GBMSM in other countries to minimise the risk of future outbreaks.

Ind-1564 Evaluating the Cost-effectiveness of Typhoid Conjugate Vaccine's Introduction in Indonesia

PRESENTER: **Jonathan Hasian Haposan**

AUTHORS: Emma Watts, Hardini Tri Indarti, Alindina Anjani, Julie Bines, Virginia Pitzer, Ida Safitri Laksanawati, Asal Wahyuni Erlin Mulyadi, Jarir At Thobari

Background: Typhoid fever is a life-threatening infection caused by the bacterium Salmonella typhi and Salmonella paratyphi. The WHO estimates the global typhoid fever disease burden at 11-21 million cases annually, resulting in about 128 000–161 000 deaths per year. Despite the demonstrated high efficacy, safety, and long-term immunogenicity of Typhoid Conjugate Vaccines (TCVs), they have only been introduced in eight countries worldwide to date, not including Indonesia. Therefore, this study aims to estimate the cost-effectiveness of introducing TCV into the Indonesia's National Immunization Program (NIP).

Methods: We used a dynamic typhoid transmission model to project cases, hospitalizations, deaths, and disability-adjusted life-years (DALY) under different strategies. We then evaluated the cost-effectiveness of routine vaccination among children 9 months of age with and without a catch-up campaign (to 15 years of age) using the costing data from Surveillance of Typhoid Fever in Indonesia (SETIA) Study and other published data. We used incremental cost-effectiveness ratios to summarize the cost-effectiveness of the introduction of typhoid conjugate vaccine into the National Immunization Program in Indonesia, from both the healthcare sector perspective and societal perspective

Results: Over a 10-year time horizon, routine TCV program would cost USD 106.1 million, rising to USD 282.4 million with an additional catch-up campaign. Routine program could avert 1.4 million cases, 828 thousand outpatients, 14,800 hospitalizations, and 9,000 deaths caused by typhoid fever. Compared to no vaccination, the ICERs of routine program were USD 240.7 and 239.1 per DALY averted (5% GDP per capita), respectively from healthcare sector and societal perspectives. Compared to routine only, the ICERS of combined program were USD 521.5 and 519.8 per DALY averted (11% GDP per capita), respectively from healthcare sector and societal perspectives. Both strategies are highly cost-effective at a willingness-to-pay threshold of 25% GDP per capita, with combined strategy offering the greatest overall benefits.

Conclusion: Introducing TCV into Indonesia's NIP, particularly with a catch-up campaign, could substantially reduce typhoid-related morbidity and mortality, and is highly cost-effective. We therefore recommend that policymakers adopt TCV into the national schedule, prioritizing the catch-up campaign to maximize benefits.

Ind-1909 Health and Economic Impact of Locally Developed Bivalent HPV Vaccination in China

PRESENTER: **Peixuan Zhang**

AUTHORS: Xinyu Wang, Ying Xu, Zhong Liu, Andrew Clark, Ye Yao, Weibing Wang, Kim Mulholland, Kaja Abbas

Abstract

Background: China has two recently domestically manufactured bivalent HPV vaccines (Cecolin and Walrinvax), but they are excluded from China's National Immunisation Programme. We aim to estimate the health and economic impact of vaccinating adolescent girls to protect against cervical cancer using these vaccines in China.

Methods: In collaboration with stakeholders in China, we used a static cohort model to estimate the lifetime health and economic impact of vaccinating a single-aged girl cohort during 2025-2034 with Walrinvax or Cecolin. The primary outcome measure was the cost (2023 US$) per disability adjusted life year (DALY) averted from a government perspective. We parameterised the model with country-specific data from the literature, government websites, and global databases.

Findings: Compared to no vaccination, a single-dose schedule of Cecolin for 14-year-old girls would be the most cost-effective option (100% probability of being cost-effective at a threshold of 1xGDP per capita). The one-dose schedule would achieve a 37%-45% health gain over the lifetime of the 2025-2034 vaccinated cohort. The two-dose schedule would increase costs by 49% and avert 20% more cases, assuming 80% protection from the first dose. Targeting high-burden regions in the first 5 years would be more cost-effective, but result in 53% fewer health gains in comparison to national-level vaccination. The estimated annual budget (310-808 million US$) would account for 0.013-0.034% of government health expenditure.

Interpretation: A domestic bivalent HPV vaccination programme would be cost-effective in China. Under short-term supply or budget constraints, adopting a one-dose schedule or prioritising high-burden regions would be optimal.

Ind-2238 The Quality of Health Economic Data Supporting Economic Evaluations of Vaccine Programmes in the United Kingdom (QUEST)

PRESENTER: **Phuong Bich Tran**

AUTHORS: Hei Hang Edmund Yiu, Sophie Staniszewska, Mr. Stavros Petrou, Edward M Hill, Nia Roberts, Matt J Keeling, Corinna Clark, Omar El Deeb, Joseph Kazibwe

Background: Public health policies in the UK rely on economic evaluations, but debates around the frameworks used by the National Institute for Health and Care Excellence (NICE) and the Joint Committee on Vaccination and Immunisation (JCVI) often overlook the quality of input data. Challenges persist in obtaining sufficient and reliable data on costs and health outcomes for economic evaluation models. This study aims to assess the quality of health economics (HE) data, including cost and health utility values, used in vaccine evaluations informing JCVI decisions and explore challenges in sourcing and applying them. Our research includes a systematic review and a qualitative study.

Objectives and methods: The primary objective of the review is to compile and analyse evidence on the quality of HE data used in economic evaluations of vaccines in the UK, aiming to provide strategic recommendations for improving the reliability, consistency, transparency, and comparability of future health economic research on vaccines. A protocol will be registered with PROSPERO and conducted following PRISMA 2020 guidelines. We will assess studies from a list of vaccine-related economic evaluations provided by JCVI that have influenced JCVI decisions since 2000. Over 36 studies across 15 vaccine programmes will be included. Data extraction and analysis will involve general quality assessment using the CHEERS 2022 checklist and the Proposed Framework for Quality Assessment of Decision-Analytic Models, as well as identifying sources for the HE data. Specific attention will be given to evaluating the application of cost data and the quality and relevance of health utility values for vaccination models using specific checklists relevant to each data type. A narrative synthesis will summarise findings, with subgroup summaries examining variations by vaccine types, age groups, data sources, etc.

To enhance these findings, the qualitative component will gather insights from researchers and modelers, focusing on their perceptions of HE data quality and exploring challenges in data identification, access, analysis, and reporting, especially concerning UK vaccine evaluations informing JCVI decisions. Fifteen participants, including policymakers and evaluators recruited through JCVI and the Department of Health and Social Care, will be interviewed or, if time-limited, engaged in focus groups. Data will be anonymised, stored securely, and analysed via NVivo15 using thematic analysis. Findings from both the review and interviews will be synthesised for the final manuscript, highlighting key insights and recommendations. Members of the public will be involved across all stages of the project. Ethics approval will be obtained from the University of Oxford Central University Research Ethics Committee.

Discussion and implications: The quality of HE data inputs into economic evaluations impacts the validity of assumptions, generalisability of findings, and robustness of sensitivity analyses. Improved data quality holds promise for producing reliable, credible, and policy-relevant economic evaluations of vaccines, informing decision-making and maximising the public health impact of vaccination programmes. We have conducted a pilot data extraction for the review and anticipate having preliminary results by the time the IHEA Congress takes place next summer.

Ind-1645 Leveraging AI for Policy Documents Review: Case study using Public Summary Documents of the Pharmaceutical Benefits Advisory Committee

PRESENTER: **Yingying Wang**
AUTHORS: Ms. Marie-Anne Boujaoude, Yi-shin Yang, Cate Bailey, Kim Dalziel, Nancy Devlin, Natalie Carvalho

Background and Objectives:

Traditional methods for systematic review of policy documents are slow and unsustainable in the face of rapidly changing public health policies. Artificial Intelligence (AI), including natural language processing (NLP) techniques and large language models (LLMs) powered by NLP, has the potential to revolutionize the review of policy documents. This study aims to determine whether NLP tools and LLMs were able to reliably extract key information from policy documents. We use the Pharmaceutical Benefits Advisory Committee (PBAC) Public Summary Documents (PSDs) in Australia as a case study. The PBAC makes public funding decision recommendations about medicines. This study is embedded within a broader project looking at factors influencing PBAC outcomes.

Methods:

We gathered 263 PBAC PSDs from 2019 to 2024 from the PBAC website. We compared three approaches for reviewing PBAC PSDs: manual review, NLP tools available in Python (e.g., spaCy, NLTK), and ChatGPT-4o. The extracted information included both textual and numerical data: PBAC outcome, incremental cost effectiveness ratio (ICER) ranges for the base case and sensitivity analysis, population characteristics, disease area, intervention, comparator, efficacy and safety claims, budget impact, uncertainties in clinical and economic evidence, equity considerations, price negotiations, and consumer comments. NLP tools were programmed to perform rule-based and targeted extractions, focusing on structured outputs from all documents. For ChatGPT-4o, a sample of 30 documents were randomly selected and queried the model using pre-defined extraction rules. Manual review served as the benchmark, involving human reviewers extracting the same information.

Results:

Compared to manual review, NLP tools were effective at locating sections containing key details, adhering strictly to predefined coding rules. However, NLP tools may miss content that should be captured due to not being defined in coding. NLP tools did not generate new information; instead, they only summarised and structured outputs based on the coding logic provided. ChatGPT-4o, on the other hand, is user-friendly and excels at general summarization tasks. It performs well with straightforward textual information, such as identifying disease areas. However, it struggles with extracting precise numerical data, such as ICERs or budget impacts, even when provided with increasingly specific instructions. Additionally, we observed fabrication of data in ChatGPT-4o's outputs: some of the information (both numerical and textual data) did not exist in the original documents. Both NLP tools and ChatGPT faced challenges when dealing with complex documents. For instance, documents with addendum where multiple base case ICERs were reported were less likely to yield precise results.

Conclusions:

Both NLP tools and LLMs may facilitate the review of policy documents. NLP tools are good at extracting original text when built on robust coding frameworks and ChatGPT-4o performs well in general summarization tasks. However, NLP tools' reliance on extensive coding and the risks associated with ChatGPT-4o's fabrication of outputs, combined with the complexity of policy documents, highlight the ongoing need for manual review to ensure accuracy of decision-making at the current time.

Ind-46 Excise Taxes Targeting Unhealthy Foods in Tonga: Have They Worked?

PRESENTER: **Andrea Teng**, University of Otago
AUTHORS: Viliami Puloka, Nick Wilson, Alice Kim

Background: Fiscal policies are recommended by the World Health Organization for promoting a healthy diet, but while taxes are common for sugar-sweetened beverages, they less commonly target unhealthy foods. The Pacific Island nation of Tonga has some of the highest obesity and diabetes rates in the world and has introduced excise taxes on unhealthy foods. The aim of this study was to examine the impact of excise tax increases in Tonga between 2013 to 2018 on food prices and food import volumes, including taxed and untaxed items.

Methods: Interrupted time series analysis was applied to measure the first-year impacts of each excise increase on indicator food prices (retail outlet surveys by the Tonga Department of Statistics) and import volumes (from the Tonga Ministry of Revenue & Customs). Nine tax increases were investigated, varying from T$0.40/kg to T$2.50/kg ($US0.17/kg to US$1.08/kg). These corresponded to increases of at least 10% in import price (with a 28% mean increase). Generalised least squares regression (GLS) was used to do segmented regression analysis fitting a linear model on monthly data. Observed post-tax trends were compared with a no tax scenario, based on the projected pre-tax trend, with adjustment for autocorrelation when it was present, and for potential time-varying confounding by GDP per capita, international visitor numbers, month, T$/US$ exchange rate, oil prices (proxy for transport costs), and international food prices (where relevant). For percentage change outcomes, we used bootstrapping to produce 95% confidence intervals, and average effects across foods were calculated from random effects meta-analysis. Controlled and sensitivity analyses were also carried out. All analyses were done in R 4.3.1.

Results: In the first-year post-tax, retail prices increased for eight of the nine indicator foods, with an average increase of 13% (95%CI: 5% to 21%). Five price increases were statistically significant: mutton flaps (20% increase), corned beef (20%), ice cream (11%), salted beef (6%) and mayonnaise (3%). Correspondingly, import volumes decreased for eight of nine taxed foods with an overall mean decrease of 41% (95%CI: 17% to 58%). Two import volume decreases were statistically significant: sausages (68% reduction) and ice cream (72%). Of the locally produced products, only sausages (taxed at half the level of imports), appeared to have an increasing production trend. Locally produced sausages only reached 13% of the total sausage market in volume by 2019. Findings were shared with stakeholders in Tonga mid-2024.

Conclusions: Unhealthy food excise taxes in Tonga were associated with increased prices and decreased imports of the taxed foods. Changes could not be explained by increased local production. These findings add to the existing international evidence that food excise taxes can be effective in raising prices and decreasing supply of unhealthy foods. Policy improvements such as tax level adjustments for inflation and equivalising tax levels across imported and locally produced foods could be used to support greater nutritional benefits.

Ind-221 Nudging Nutrition: Lessons From the Danish ""Fat Tax""

PRESENTER: **Giovanni Mellace**
AUTHORS: Nadja van t Hoff, Christian Møller Dahl, Sinne Smed

Taxes are increasingly recognized as an effective policy tool for influencing health behaviors. While growing evidence supports the effectiveness of several taxes, such as the sugar tax, much less is known about the impact of taxes on saturated fats. Existing research often relies on simulation models or uses observational data without geographic control groups, limiting the ability to draw causal inferences about how such taxes shape consumer behavior. Our study addresses this gap by providing the first causal analysis of a tax on saturated fat and its effects on consumer behavior.

In October 2011, Denmark introduced the world's first and, to date, only tax specifically targeting saturated fats. However, this tax was repealed in January 2013. Leveraging exogenous variation from untaxed consumers in Northern Germany, we employ a difference-in-differences approach to estimate the causal effects of both the introduction and repeal of the tax on consumption and expenditure across eight targeted product categories. Using state-of-the-art difference-in-differences method, we control for observed household characteristics, employ a doubly robust estimation technique, and provide conservative confidence intervals, enhancing the reliability of our findings.

Our results reveal significant heterogeneity in the tax's impact across different products. During the taxed period, consumption of bacon, liver sausage, and cheese notably declined, particularly among low-income households. In contrast, expenditure on butter, cream, and margarine rose, driven by higher prices. Interestingly, we did not observe differences in price sensitivity between high- and low-income households, suggesting that the tax disproportionately affected low-income groups.

Following the repeal of the tax, consumption did not return to pre-tax levels. Instead, we observed an overall increase in consumption of certain products, raising concerns about potential unintended consequences from the brief implementation of the tax. Additionally, we found evidence of increased cross-border purchases of butter by households living within 50 km of the German border, though we did not find strong evidence of spatial heterogeneity in the tax's broader effects.

These findings suggest that while the Danish saturated fat tax was effective in reducing consumption of some targeted products, its regressive impact on low-income households and the rise in cross-border shopping highlight important challenges for policymakers. When designing and implementing food-related taxes, it is essential to consider these unintended effects to ensure both equitable outcomes and sustained behavioral changes. Future policies should explore complementary measures to maintain long-term effects after the repeal of such taxes.

Ind-231 Demystifying Anti Health Tax Advocates Arguments: Impact of Taxation on Production, Sales, Revenue and Consumption of Unhealthy Products in Uganda

PRESENTER: **Richard Ssempala**, Makerere University School of Economics
AUTHORS: Eric Ssegujja, Henry Zakumumpa, Freddie Ssengooba

Background: Globally, it is increasingly being recognised that consumption of selected products perceived to be unhealthy contribute to the burden of Non-Communicable Diseases (NCDs) such as heart disease, stroke, cancer, diabetes and chronic lung disease. However, adoption of measures including fiscal policies to address the challenge remains contested and with limited literature about these measures especially in Low and Middle-income countries. To address this gap, we focused our study on excise duty and Value Added Tax (VAT) -tax regimes on selected unhealthy commodities in Uganda such as alcohol, tobacco and sugar sweeten beverages to assess their impact on production, sales, revenue and consumption for the period of 10 financial years from FY 2014/15- FY 2023/24. **Methodology:** We used quantitative approaches to analyse data given its strengthen in generating knowledge to measure the impact and identifying relationships. The data was extracted from Government of Uganda Revenue collection body (Uganda Revenue Authority); supplemented by qualitative findings from documentary analysis of parliamentary records related to the respective tax bills and Acts. Content analysis was adopted as an analytical technique for the qualitative data using Atlas.ti data management software. **Results:** Overall, results revealed four mainly findings; Firstly, the production of unhealthy commodities during the studied period was on an increase with greater quantities observed in Non-alcoholic drinks (soft drinks), followed by alcohol/ Beers and cigarettes. Secondly; despite of an increase in excise duty, sales of unhealthy commodities reflected a general increase year on year. Non-alcoholic commodities and alcohol/ beers registered the higher sales following increase in excise duty on the same with highest sales observed in the Fy 2022/23. Thirdly; Revenues collected from unhealthy commodities has generally been increasing irrespective of the tax rates. Specifically, revenues from sale of beers and non-alcoholic drink has been increasing; reduced revenue are only seen during covid-19 period. For cigarettes, revenues negatively respond to the tax rates. Lastly; Consumption of the commodities continued to increase across the studied period. From the studied period it can be deduced that the current tax rates have not had a statistically significant negative impact on the production, sales, consumption and revenues collected by Uganda Revenue Authority from the sale of these commodities. **Conclusion:** Taxation of unhealthy commodities had minimal/insignificant impact on production, sales, revenues and consumption reflecting the feasibility of introduction of health taxes as recommended by WHO if NCDS are to be reduced. Results have further demonstrated that minimum damage can be inflicted on the economy a key framing opponents of such taxes often front to scare away government from prioritising health taxes.

Ind-1958 Leveraging Parental Preferences to Inform Policy on Sugar-Sweetened Beverages: A Discrete Choice Experiment

PRESENTER: **Nyamdavaa Byambadorj**
AUTHORS: Undram Mandakh, Rohan Best, Kompal Sinha

This study addresses growing concerns regarding childhood obesity and cardiovascular diseases by exploring the effects of possible policy measures on the intention to choose sugar-sweetened beverages (SSBs) in Mongolia, a low-income country. Focusing on parents' preferences for purchasing SSBs, we employed a stated preference choice experiment to analyse how various product attributes, including price, labelling, sugar content and store placement, affect parents' purchase decisions. Price increases were the most effective intervention, with larger increases leading to a substantial reduction in purchase probability. Labelling also played a crucial role, particularly graphic warnings, which strongly deterred selection. Reducing sugar content positively influenced preferences. Also, less prominent store placement lowered SSB selection probabilities. Additionally, estimates of willingness to pay suggest consumers are less willing to purchase SSBs with graphic warning labels and placement in the back row and bottom level. These findings highlight the importance of integrating multiple regulatory measures to effectively curb SSB consumption and mitigate associated health risks in Mongolia. **Keywords** Sugar-sweetened beverage, Discrete choice experiment, Price elasticity, Marginal effects, Willingness to Pay

abs-os750 Exploring Consumer Preferences for Sugar-Sweetened Beverages in East Africa: Evidence from a Discrete Choice Experiment

PRESENTER: **Mr. Senzo Mthembu**
AUTHORS: Hassan Haghparast-Bidgoli, Gershim Asiki

Sugar-sweetened beverages (SSBs) are a significant contributor to the growing burden of non-communicable diseases (NCDs) in East Africa. While public health policies increasingly target SSBs through pricing and taxation strategies, there is limited evidence on consumer preferences and their potential behavioural responses to such interventions. This study employs a Discrete Choice Experiment (DCE) to examine consumer trade-offs and preferences for SSB attributes, including price, packaging, and sugar content, in the context of potential taxation and reformulation policies.

The study surveyed 1,200 respondents across three regions in Kenya: Nairobi, Nyanza, and Coastal Kenya. Participants completed a structured questionnaire capturing demographics, SSB consumption patterns, and choice tasks involving hypothetical purchasing scenarios. Each choice set presented five SSB brands with varying attributes—price (tax included), sugar reduction levels, and package size—alongside a "none of these" option. Data were analysed using multinomial logit (MNL) and latent class models (LCM) to estimate consumer preferences, attribute importance, and market segment heterogeneity. Price and cross-price elasticities were calculated to assess potential brand-switching behaviours under tax scenarios.

Preliminary findings indicate that price is the most influential factor in consumer decision-making, with participants displaying significant sensitivity to price changes. While sugar reduction was moderately preferred, further reductions reduced product appeal. Packaging size also influenced preferences, with smaller sizes favored over bulk options. Latent class analysis identified three consumer segments: price-sensitive (50%), health-conscious (30%), and brand-loyal (20%). Simulated tax scenarios revealed potential shifts towards lower-priced brands or reduced consumption.

This study provides critical insights into consumer preferences for SSBs in Kenya and highlights the potential for price-based interventions to reduce SSB consumption. These findings can inform evidence-based public health policies targeting the rising burden of NCDs in East Africa.

10:30 AM –12:00 PM TUESDAY [Evaluation Of Policy, Programs And Health System Performance]

Evaluation of Mental Health Programs/Outcomes

MODERATOR: **Suja S Rajan**,

Ind-18 Saving Lives, Saving Money? The Effect of a Multisectoral Suicide Prevention Program on a Healthcare System

PRESENTER: **Olukorede Abiona**, University of Technology, Sydney (UTS)
AUTHORS: Henry Cutler, Mona Aghdaee, Dandan Yu, Yuanyuan Gu

The World Health Organization (WHO) made preventing suicide a global imperative in 2014, suggesting to governments they reduce their suicide rates by implementing a comprehensive multisectoral suicide prevention strategy. Some European governments have since implemented this strategy type, although evaluations of their effectiveness are hampered by small sample sizes, confounding factors and low data quality. This study estimates the impact of a large, community based multisectoral suicide prevention intervention on healthcare resource use and costs in Australia. We exploit a stepped trial conducted between 2017 and 2020 and use a large linked state government administrative dataset with millions of observations from emergency department presentations, inpatient hospital care, primary care, allied health and medicine supply. Patients from a population of one million people in four local health networks exposed to the suicide prevention intervention were matched to patients from local health networks that were not exposed, using entropy balancing. A multigroup, staggered difference-in-differences approach was employed to account for different intervention start dates and for potential heterogeneous effects across local health networks and time. We present the Intention to Treat (ITT) causal effects of the intervention on healthcare resource use and costs. The effect is disaggregated across time and each treated local health network. Heterogeneity within each local health network is explored by separately estimating ITT on emergency department presentations, inpatient hospital care, health care delivered outside the hospital and pharmaceutical supply. Sensitivity analysis tested whether results are robust to an alternative estimator and whether results are sensitive to a placebo treatment period or placebo treatment group. Our study provides valuable insights into the potential impact of large community based, multisectoral suicide prevention interventions on healthcare systems, to better understand the mechanisms of impact associated with these types of strategies. This could help other countries better design, implement and scale-up a comprehensive multisectoral suicide prevention strategy.

Ind-405 Area-level Mental Health and Health Care Utilization Impacts of Welfare Reform: The Case of Universal Credit Natural Migration in England

PRESENTER: **Silas Amo-Agyei**
AUTHORS: Luke Munford, Matt Sutton, Konstantinos Daras

Background: The introduction of Universal Credit (UC) in 2013 marked a substantial overhaul of the UK welfare system, consolidating six means-tested benefits into a single payment for working-age individuals. While the policy aimed to streamline benefits and incentivize employment, evidence suggests that it may have unintended consequences for the mental health of claimants. Limited existing research points to negative mental health impacts, likely stemming from the complex claims process, heightened conditionality, financial insecurity, and reduced benefit payments. Given UC's focus on low-income households, these short-term mental health effects could exacerbate health and broader social inequalities. **Research question:** What is the impact of UC's natural migration on small-area mental health and healthcare utilization across England? What is the broader societal cost of mental health issues arising from this welfare reform, and what are the associated costs of mental health care utilization due to the UC rollout? **Methods:** This study employs staggered difference-in-differences techniques to evaluate mental health trends at the small-area level, specifically within Lower Super Output Areas (LSOAs), which were exposed to UC at varying times. We treat the phased rollout as a natural experiment. Our primary data source is the Small Area Mental Health Index (SAMHI) created by Daras and Barr (2021), offering annual measures of mental health across LSOAs in England from 2011-2019. Mental health indicators, such as average daily antidepressant usage, depression prevalence, and mental health-related hospital attendance, are derived from NHS Digital and the Quality and Outcomes Framework. Additional population-level data is sourced from the Office for National

Statistics (ONS) and the UK Department of Work and Pensions (DWP). **Results:** We find that LSOAs exposed earlier to UC exhibit worse mental health outcomes compared to areas with later exposure. Baseline estimates suggest UC migration has increased overall mental health needs by 0.038 standard deviations (SD), depression rates by 0.03%, mental health-related hospital attendance by 0.036 SD, and average daily antidepressant usage by 0.45 units per person. These effects hold robustly across multiple model specifications and sensitivity checks. The findings also indicate substantial societal costs due to the mental health impacts of UC migration and a significant rise in mental healthcare utilization costs attributable to the reform. **Conclusions and implications for policy and practice**: Our results underscore the adverse mental health consequences of UC migration at the small-area level, along with the corresponding rise in healthcare utilization and societal costs, stressing the impact on local healthcare systems. Policymakers should consider these findings as evidence of the potential health-related repercussions of welfare reforms like UC. Future welfare reforms could benefit from strategies to mitigate such unintended mental health effects, reducing the strain on healthcare services and supporting overall population well-being.

Ind-1572 The Impact of Mental Health Parity on Self-Assessed Mental Health Among U.S. Military Beneficiaries

PRESENTER: **Jangho Yoon**, Uniformed Service University

Aim: In the U.S., mental health insurance benefits have traditionally included fewer covered services and higher deductibles, copayments, and coinsurance compared to medical care benefits. In October 2016, TRICARE, a health care program providing comprehensive healthcare services to 9.6 million military beneficiaries (active-duty and civilians), implemented a behavioral health parity rule intended to reduce disparities between behavioral health and medical care benefits. This research examined changes in self-assessed mental health levels among civilian TRICARE beneficiaries attributable to the parity implementation.

Methods: We analyzed observational data from the 2010-2020 Medical Expenditure Panel Survey, the national healthcare survey, which collects comprehensive information on verified health conditions and sociodemographic characteristics in a nationally representative sample of the non-institutionalized U.S. civilian population, including TRICARE beneficiaries. The sample included non-elderly adults aged 18-64, comprising 1,166 TRICARE beneficiaries and 72,996 privately insured or uninsured individuals. Outcomes included perceived and validated mental health measures: a binary measure of self-assessed poor mental health; Mental Composite Summary (MCS) scores derived from the Short-Form 12, ranging from 0 (worst) to 100 (best); binary measures of serious mental illness (SMI) and moderate mental illness (MMI) based on the Kessler Psychological Distress Scale and its validated cut-points; and an indicator for potential depression based on the 2-item Patient Health Questionnaire (PHQ-2) and its validated cut-point. We used the difference-in-difference model to compare pre-post changes in the outcomes for the policy intervention group of TRICARE beneficiaries with counterfactual trends from the civilian counterparts. We then employed the difference-in-differences-in-differences model, further differencing the pre-post and intervention-control changes in the outcomes for individuals with SMI and other individuals without SMI. All estimates were adjusted for comprehensive demographic and socio-economic characteristics as well as various time trends. To support the validity of our study design, we confirmed that our sample satisfied the parallel trend assumption. All estimates were survey-weighted and adjusted for a multistage complex survey design.

Results: Behavioral health parity implementation was associated with a 7.3 point increase in MCS scores ($p=.003$), a 25.5 percentage-point decrease in the probability of having SMI ($p<.001$), a 20.5 percentage-point decrease in the probability of potential depression ($p=.013$), and a 9.7 percentage-point decrease in the probability of reporting poor mental health ($p<.001$) among civilian TRICARE beneficiaries. The beneficial effects of behavioral health parity increased in magnitude as family income levels decreased. Specifically, behavioral health parity was associated with a 55.1 percentage-point decrease in the probability of SMI among individuals living below the poverty level ($p = .001$), a 35.1 percentage-point decrease among those with low family income ($p < .001$), a 28.7 percentage-point decrease among those with moderate family income ($p < .001$), and a 10.4 percentage-point decrease among individuals with high family income ($p < .001$). Similar patterns were observed for MCS scores, potential depression, and self-assessed poor mental health.

Conclusion: The implementation of behavioral health parity led to significant overall improvements in self-assessed mental health among civilian TRICARE beneficiaries, with particularly pronounced benefits for those with greater financial need.

Ind-1628 Violations of the Male Breadwinner Norm and Mental Health

PRESENTER: **Rachel Knott**, Monash University
AUTHORS: David Johnston, Nidhiya Menon

Evidence highlights that mixed-gender marriages are governed by several traditional norms. These include that married women are shorter, younger, and lower-earning than their spouses. We focus on the last of these traditions, the ‘male breadwinner’ norm. Although studies have evaluated the costs of violating the male breadwinner norm, little is known about the mental health consequences. We explore this issue using national administrative tax data, healthcare records and locations data linked with Census data on more than 970,000 couples in Australia who were residing together and working at the time of 2011 Census. We supplement the administrative data with subjective data on wellbeing, satisfaction and family life from couples surveyed in the Household, Income and Labour Dynamics in Australia (HILDA) study.

We show that violations of the male breadwinner norm are associated with meaningful outcomes. Specifically, after controlling for male and female earnings, education, occupation, industry, location, and other characteristics, our administrative data reveals that when women out-earn their husbands, the likelihood of separation in the next three years increases by a considerable 17.4% (relative to the mean). Survey data supports the hypothesis that the separations are caused by martial strain. In marriages violating the male breadwinner norm, women are more satisfied with their pay, while men are less satisfied. Relatedly, financial decision-making power shifts towards women. Consequently, men report lower mental wellbeing, and women report lower relationship satisfaction.

Our main results suggest that the reported differences in marital outcomes lead to mental health issues for men. Men who earn less than their wives are significantly more likely to use prescribed antidepressants, anxiolytics and sedatives in future years, with estimates largest among men without a history of such medication use. For example, it is estimated that the use of sedative medications is 10.3% higher among men

without a history of sedative use. In contrast, estimated associations are small for women, indicating similar health outcomes for women who earn more and less than their spouses. We also find small, statistically insignificant associations from regressions using different (placebo) relative income cut-offs and health outcome variables (e.g. prescribed medication for physical health conditions). These results support the interpretation of our results: that violation of the male breadwinner norm causes increased stress within the household, particularly among men, leading to worse mental health outcomes.

Ind-1942 Association of Legalizing Youth-Friendly Cannabis Edibles and Extracts with Adolescent Cannabis Use: Quasi-Experimental Evidence from Canada

PRESENTER: **Shweta Mital**
AUTHOR: Hai Nguyen

Background: In October 2018, Canada legalized sale of dried or fresh cannabis and cannabis oil to individuals above the minimum legal age. Subsequently, in October 2019, cannabis edibles and extracts was legalized in most provinces, including products that appeal to adolescents such as cannabis chocolates, candies, desserts and cannabis vaping products. An exception was the province of Quebec, which banned sales of cannabis edibles and cannabis vaping products that could entice children and youths. Quebec's government stated that these bans would protect children and youth from accidental cannabis poisoning and reduce normalization of cannabis use among youths. There is not yet evidence on the impacts of legalizing youth-friendly cannabis edibles and extracts on adolescents. **Research Aims:** Our study has three objectives. We first examine the effects of legalizing youth-friendly cannabis edibles and extracts on overall prevalence of adolescent cannabis use. Next, we study the impacts on modes of cannabis consumption (i.e., cannabis edibles, cannabis smoking and cannabis vaping) and the co-use of alcohol and cannabis. Finally, we assess the relationship between the legalization and adolescents' perception of harm associated with cannabis use. **Methods:** We use nationally-representative, individual-level survey data for a large sample of over 106,000 youths in grades 7 to 11 and difference-in-differences design to compare changes in outcomes in provinces that legalized cannabis edibles and extracts in October 2019 with changes in Quebec where youth-friendly cannabis edibles and cannabis vaping products were banned. Outcomes of interest were cannabis use in past 12 months; past 12-month use of edible cannabis use, cannabis smoking, cannabis vaping and co-use of alcohol and cannabis; and perception of harm from occasional and regular cannabis use. **Results:** The legalization was associated with 3.8 percentage points (p=0.01) or 26% increase in past 12-month cannabis use and 3.4 percentage points (p<0.01) or 43% increase in use of cannabis edibles among adolescents. While there was no statistically significant change in cannabis vaping associated with the legalization, cannabis smoking increased by 4.4 percentage points (p<0.01) or 34% and co-use of alcohol and cannabis increased by 2.4 percentage points (p=0.02) or 28%. The legalization was also associated with a lower perception of harm from occasional cannabis use. **Conclusion and Policy Implications:** The legalization of cannabis edibles and extracts increased not only edible cannabis use and cannabis smoking among adolescents in grades 7-11 but also the overall prevalence of cannabis use and co-use of alcohol and cannabis. Policy measures to curb adolescents' access to cannabis edibles and extracts and raise awareness about harms from cannabis use are needed.

abs-os35 Return on Investment for Typhoid Vaccination in Low-Middle Income Countries

PRESENTER: **Haijun Zhang**
AUTHORS: Bryan Patenaude, Salin Sriudomporn

Background: Typhoid still has substantial burden among low-and middle-income countries (LMICs). The World Health Organization has recommended the programmatic use of typhoid conjugate vaccines (TCV) in endemic countries. The demand for TCV is projected to increase with rising country adoption and continuation of the vaccine. We conducted a return-on-investment (ROI) analysis of TCV vaccine for both routine immunization, and supplemental immunization activity (SIA) campaigns among 26 Gavi-supported LMICs from 2021-2030.

Methods: We estimated the economic benefits through the cost-of-illness (COI) approach using the cases and deaths averted generated by the International Vaccine Institute (IVI) and the Yale School of Public Health (YSPH). COI includes both direct (treatment and transportation) and indirect costs (productivity loss) averted. Costs of the immunization program include vaccine costs (doses, syringes, injection supplies) and immunization delivery costs (personnel, cold chain equipment and maintenance, transportation, distribution services, and other recurrent costs). We estimated the ROI by dividing the net benefits (benefits minus costs) by costs of TCV. For TCV SIA, a base case of $2.48 delivery cost per dose was used and a measle SIA delivery cost at $1.13 per dose was used as a lower bound to determine the ROI at different delivery cost.

Results: The total COI between 2021-2030 under Gavi supported countries was estimated at $7.0 billion for TCV routine immunization, and $8.9 billion for TCV SIA. The total cost of TCV routine immunization is estimated at $0.97 billion, and $2.7 billion for TCV SIA under the base case scenario. For the lower bound of $1.13 delivery cost per dose, the total TCV SIA immunization cost is reduced to $1.4 billion. The ROI for TCV routine immunization was estimated at 6.25. For TCV SIA, the ROI estimated using the base case delivery cost of $2.48 was estimated to be 2.33.

Conclusions: Our findings suggest that both TCV routine and SIA yield substantial positive ROIs for Gavi supported countries. The evidence generated will allow policymakers to determine and advocate for the most efficient strategies for resource mobilization and investment to ensure sufficient coverage and sustainable immunization programs, globally.

Ind-336 Cost-Effectiveness of Long-Acting Injectable Cabotegravir for HIV Prevention Among Men Who Have Sex with Men in China: A Mathematical Model

PRESENTER: **Bo Zhang**, Sun Yat-Sen University

AUTHORS: Pengyue Guo, Hao Lin, Yijing Wang, Jing Gu, Chun Hao, Wangnan Cao, Jinghua Li

Background: Long-acting injectable cabotegravir (CAB-LA) is recommended by the World Health Organization for HIV prevention due to its safety and high efficacy. Compared to daily oral pre-exposure prophylaxis (PrEP), CAB-LA does not rely on strict adherence, which may alleviate challenges in many Asian countries where HIV and same-sex behaviors are highly stigmatized. Recently approved in China and priced at 7,918 CNY per injection, the cost-effectiveness of CAB-LA at this price has not been well studied. **Objectives:** We aimed to evaluate the cost-effectiveness of CAB-LA alone and in combination with daily oral PrEP among men who have sex with men (MSM) in China over a 20-year period (from 2024 to 2043). **Methods:** We used a compartment model of the HIV epidemic developed by our team to assess the cost-effectiveness of different interventions, compared to no PrEP use. These interventions included daily oral PrEP only, CAB-LA only, and a combination of both. Each strategy was evaluated under four coverage scenarios, ranging from 25% to 100% in 25% increments among high-risk MSM. Incremental cost (international dollars, Int.$) per quality-adjusted life year (QALY) gained was assessed as the primary outcome, along with incremental QALYs, incremental costs, and healthcare savings. The model incorporated the recent price of 7,918 CNY per CAB-LA injection and different discount rates to explore the health economic effects. **Results:** At the price of 7,918 CNY per injection, the cost-effectiveness of different PrEP types compared to the status quo varied significantly. Oral PrEP demonstrated the highest cost-effectiveness, with an average cost-effectiveness ratio (CER) of 8,090-8,470 Int.$/QALY, while CAB-LA had a lower cost-effectiveness, with an average CER of 60,520-68,320 Int.$/QALY compared to the status quo. The optimal strategy involved a gradual transition from exclusive oral PrEP use to a combination of oral PrEP and CAB-LA, ultimately leading to full CAB-LA use. However, CAB-LA is not cost-effective compared to oral PrEP under these conditions. The incremental cost-effectiveness ratio (ICER) for switching from oral PrEP to a combination strategy was 218,750 Int.$/QALY, for transitioning to exclusive use of CAB-LA use, the ICER was 274,500 Int.$/QALY. The cost-effectiveness of CAB-LA improves as its price decreases, becoming more advantageous than oral PrEP only after a 90% price reduction. **Conclusions:** Transitioning from oral PrEP to CAB-LA among eligible MSM is not cost-effective in China. While CAB-LA may not be affordable as a standalone strategy due to its high cost, it could serve as a complementary option to oral PrEP. CAB-LA's resilience to adherence and risk compensation issues makes it a critical tool in comprehensive HIV prevention strategies. Our study offers valuable insights into the market pricing of CAB-LA in China and provides relevant health economic data for policymakers. **Keywords:** HIV, Long-acting injectable cabotegravir, Cost-effectiveness analysis, China, Mathematical model.

Ind-820 Cost-effectiveness and Budget Impact of Clinic-based HIV Diagnosis and Viral Load Testing to Prevent Mother to Child Transmission in Papua New Guinea

PRESENTER: **Sophy Ting-Fang Shih**, University of New South Wales

AUTHORS: Quang Nguyen, Gillian Scott, Angela Kelly-Hanku, Janet Gare, Simon Pekon, Adam Bartlett, Roselyn Siki, Melissa Schulz, Richard T Gray

Background:

To address low coverage of HIV viral load (VL) testing and delays in infant diagnosis in Papua New Guinea (PNG), ACTUP-PNG was established to accelerate the uptake of point-of-care (POC) HIV VL testing and infant diagnosis. The aim of this study was to estimate the healthcare resources required to implement clinic-based POC testing and cost-effectiveness of potential interventions to reduce HIV transmission from mothers to children in PNG.

Methods:

A micro-costing was conducted using procurement and financial information from the project to estimate costs of clinic-based testing implementation. Time and motion data were also collected by purpose-designed tools to estimate staff time costs of testing. A decision analysis combined with Markov simulations, for infants who were exposed to HIV infection up to 5 years old, was undertaken to evaluate the cost-effectiveness of potential interventions compared to the status quo scenario in PNG. Incremental cost-effectiveness ratios (ICER) were reported by costs per disability-adjusted life-years (DALYs) averted. A budget impact analysis was undertaken from the funders' perspective to assess affordability of scaling up clinic based POC HIV testing in pregnant women and infants. Costs were estimated in 2022 US dollar (US$) and PNG kina (K).

Results:

Costs included fixed costs for training, transportation, quality control, overheads, and variable costs of consumables and cartridges. The costs per test were estimated as: US$45 (PGK166) for VL testing using GeneXpert; US$46 (PGK169) for VL testing in children (age <10) using m-PIMA; US$37 (PGK135) for infant diagnosis using GeneXpert. On average, one patient visit took 2.2 hours and an average labour cost of US$15 (PGK42) were estimated from 299 people with HIV.

Most interventions aimed at increasing coverage of HIV-related services were either cost-saving or cost-effective compared to status quo, judged by the threshold of US$ 4,119 per DALY averted (one GDP per capita in PNG). Expansion of infant prophylaxis coverage would be a dominant intervention, saving both lives and costs. Implementation of early infant diagnosis by POC testing and switching to new effective prophylaxis drugs would result in ICERs $348/DALY and $413/DALY averted, respectively. However, increasing access to antenatal care along or in combination with other single intervention was not cost effective (ICER ranges: US$5,793- US$14,524 per DALY averted).

In status quo with 36.7% maternal HIV testing, 67.5% prophylaxis coverage and no infant diagnosis within 6 weeks prior to the ACTUP-PNG

project, total annual cost of testing and treatment during pregnancy, prophylaxis at birth for at-risk infants, and infant diagnosis incurred US$2.3 million (K8.1 million). Increasing prophylaxis coverage to an achievable target (91.3%) would save US$4,629 (K16,295), while switching to new active prophylaxis would need additional annual budgets US$6,284 (K22,120). Increasing infant diagnostic POC testing by 50% would incur additional US$22,761 (K80,118).

Conclusion:

Given current high level of vertical HIV transmission in PNG, priorities should be given to increased coverage of infant prophylaxis and early infant diagnosis by POC testing. Adequate financial support is needed to reinforce PNG's laboratory capacity and workforce to ensure an ongoing strengthen HIV care in PNG.

Ind-1406 Comprehensive Analysis of Dengue Management and Costs in Emergency and Hospitalisation in One of a Tertiary Care Centres in Malaysia

PRESENTER: **Amirah Azzeri**
AUTHOR: Mohd Hafiz Jaafar

Dengue fever continues to be a significant public health concern in Malaysia, placing substantial clinical and financial demands on healthcare systems. This study provides a holistic examination of dengue presentations, case-mix indicators, and the associated costs at the emergency department (ED) and hospitalisations, with insights derived from the University Malaya Medical Centre (UMMC) in 2022. By integrating retrospective data, this research aims to inform healthcare policies, enhance clinical management, and optimize resource allocation in dengue-endemic regions. All the calculation was based on case-mix tariffs, which were derived through a comprehensive top-down costing exercise. In the ED setting, data from 1265 dengue patients were analysed based on ICD-10 codes (A97.0, A97.1, A97.2, A97.9 and Z11.5), revealing that these cases constituted 4% of total ED visits during the study period. The median patient age was 35 years, ranging from 0 to 95, with a nearly equal gender distribution (49.3% male and 50.7% female). A significant proportion of patients (55.4%) were discharged after initial treatment, while 36.7% required hospital admission. Despite the majority recovering, 2.2% succumbed to the disease. The economic analysis showed that the mean cost per dengue case was RM 212.37, contributing to a total ED expenditure of approximately RM 268,648.05. The case-mix indicators of 638 hospitalized dengue cases highlighted further complexities in resource utilization. Male patients slightly outnumbered females (52.5% vs. 47.5%), and most patients were admitted to the medical ward (87.6%), with others in the pediatric ward (7.2%). The median age of hospitalized patients was 41 years, with a median hospital stay of four days. Almost all patients were categorized as severity level 1 (99.4%), reflecting a high proportion of mild cases. The MyDRG code A-4-13-I was predominant among these admissions. The average cost of hospitalization was RM 1936.41 per patient, leading to an annual expenditure of RM 1,165,720.89 for dengue management in UMMC. In total, it was estimated that the hospital incurred RM 1, 434, 368.94 million (USD 320,674.31) for the management of dengue alone. These findings underscore the dual challenge of managing diverse clinical presentations and significant healthcare costs associated with dengue fever. At the ED level, early and accurate diagnosis is critical for efficient triaging and cost containment. In contrast, tertiary hospitals must optimize inpatient care strategies to address the substantial financial burden posed by prolonged hospital stays. The study highlights the importance of accurate case-mix coding and data integration across healthcare levels to capture the true burden of dengue comprehensively. By leveraging these insights, healthcare providers and policymakers can design targeted interventions to reduce morbidity, mortality, and economic strain associated with dengue. Emphasizing prevention, enhancing diagnostic accuracy, and implementing cost-effective clinical practices will be key in strengthening Malaysia's response to this persistent health challenge.

Ind-1621 Cost-Effectiveness of Seasonal Influenza Vaccination in Mongolia 2022/23: A Modeling Study

PRESENTER: **Tsogt Mend**
AUTHORS: Munkh-Erdene Luvsan, Urtnasan Chuluunbat, Gantsooj Baatar, Malembe Ebama, Burmaa Alexander, Oyungerel Darmaa, Baigalmaa Jantsansengee, Lindsey Hehman, Stacie Gobin

Background: Influenza is a major global health threat, causing substantial morbidity, mortality, and economic loss, particularly impacting high-risk groups such as healthcare workers, children, the elderly, and those with chronic conditions. Mongolia's population is especially vulnerable due to its harsh climate and nomadic lifestyle. With influenza's clear seasonal pattern and the country's recent transition to a fully sustained national vaccination program, the need for strong evidence on the cost-effectiveness of influenza vaccination is critical to guide policy and resource allocation. This study addresses the economic and health impact of seasonal influenza vaccination in Mongolia.

Methods:

The study employed a budget impact and cost-effectiveness analysis to evaluate the incremental cost-effectiveness of seasonal influenza vaccination compared to no vaccination. It focused on children aged 2-5 years, pregnant women, and adults aged 65 and above. Costs and benefits were discounted at a 3% annual rate, and outcomes were measured using Quality-Adjusted Life Years (QALY). The WHO CETSIV tool was used to model costs and effectiveness, following WHO guidelines. Data included disease burden, program costs, and health outcomes, with expert validation of inputs and assumptions.

Results:

The Study Year 3 (2022/23) analysis found high influenza-associated incidence rates in Mongolia, particularly affecting children under 5. The incidence rate for children under 1 year old was measured at 57.70% and 32.20% for children aged 1-5 years old. This estimated attack rate is more than three times the predicated attack rate for this age group based on a systematic review of vaccine randomized controlled trials (RCTs) that reported on laboratory-confirmed seasonal influenza. Out-of-pocket costs for inpatient and outpatient care increased, especially for children. Vaccination efforts showed 84.8% coverage in children, but were logistically expensive. The elderly saw a high coverage rate

(96.8%), while only 9.2% of pregnant women were vaccinated. Overall, influenza vaccination was cost-effective, with the ICER showing substantial cost savings and health benefits for high-risk groups.

The strategy of sending vaccination teams to schools results in high costs, averaging approximately 96,234.94 MTN per child. However, by shifting 85% of these vaccinations from schools to healthcare facilities, the cost per child could be significantly reduced. This approach would bring the cost down to 18,455.21 MNT per child, leading to a more cost-effective and efficient vaccination program, while still ensuring that children receive necessary immunizations.

Conclusion:

This study examines the challenges of vaccine reluctance and the economic burden of influenza in Mongolia, focusing on the period post-COVID-19. The economic analysis reveals that children under five incurred the highest healthcare costs, highlighting a substantial economic burden on families. A comparison across three survey years indicates rising out-of-pocket costs, particularly in rural areas, where the economic burden of influenza is most pronounced.

Recommendations include targeted educational campaigns to improve vaccine uptake, particularly among pregnant women and children under 2 years, and exploring more cost-effective strategies for vaccinating children.

Keywords Influenza vaccine, cost-effectiveness, Mongolia, health economics, vaccination policy

Ind-1834 Cost-Effectiveness and Budget Impact Analysis of TAK-003 for National Immunization Program in Indonesia

PRESENTER: **Jarir At Thobari**
AUTHORS: Hardini Tri Indarti, Welly Welly, Philip Towle, Sarah Maria Saragih

Background

Dengue presents a substantial public health burden in Indonesia. In 2017, an estimated 7.535 million dengue cases incurred approximately $681 million in costs. The TAK-003 dengue vaccine has shown sustained efficacy against symptomatic and severe dengue, yet its cost-effectiveness as a public health intervention in Indonesia remains unassessed. This study evaluates the cost-effectiveness over a 20-year time frame and budget impact over 5 and 10 years of a dengue vaccination strategy in Indonesia

Methods

We conducted a cost-effectiveness analysis using a static model with a dynamic component to assess the health and economic impact of TAK-003 vaccination from a payer and societal perspective. Indonesia-specific data, including demographics and costs, were used wherever possible to inform the model. Vaccine-related parameters, such as efficacy, were based on the DEN301 trial. The model evaluated a routine vaccination strategy for a 9-year-old cohort, with catch-up vaccinations for children aged 10- to 12-years, against a no-vaccination scenario over a 20-year timeframe. The primary outcome was the cost-effectiveness of the vaccination program, with benefits expressed as cost per disability-adjusted life year (DALY) averted. Sensitivity analyses, with 1,000 iterations, assessed result robustness. Additionally, budget impact analysis examined financial implications at 5-year and 10-year, evaluating costs for an initial catch-up vaccination followed by routine vaccinations for the 9-year-old cohort.

Results

TAK-003 vaccination substantially reduced dengue infections and hospitalizations. The cost per DALY averted is dominant over no vaccination. Over a 20-year horizon, it is expected to prevent approximately 47.9 million infections and 3.3 million hospitalization cases. At an illustrative price of $25/dose, the vaccination strategy shows very cost effective. Sensitivity analyses show that the ICER/DALY avoided is highly influenced by discount rate, probability of symptoms (given infection, and cost of vaccine acquisition per dose.

The budget impact analysis shows that the vaccination strategy generates significant cost savings over time. From the payer perspective, savings in medical costs exceed vaccination costs by $96 million in year 10. Meanwhile, from the societal perspective, savings in medical costs, productivity losses, and school absenteeism outweigh vaccination costs by $356 million in year 5 and $2 billion in year 10.

Conclusion

Vaccination with TAK-003 offers considerable reductions in dengue infections and hospitalizations, delivering significant public health benefits and cost savings. These findings support the implementation of TAK-003 within Indonesia's national immunization program, underscoring its economic viability from both societal and payer perspectives. The adoption of TAK-003 represents an impactful strategy for dengue control in Indonesia, with the potential to reduce incidence, hospitalization, and outbreak impacts.

Ind-1949 A Customisable Tool for Efficient Priority-Setting: Optimising Seasonal Malaria Chemoprevention Across Heterogeneous Contexts

PRESENTER: **David Bath**, London School of Hygiene & Tropical Medicine
AUTHORS: Halimatou Diawara, Bienvenu Camara, Eric Adehosi, Seydou Traore, Ibrahim Diarra, Lamine Mahaman Moustapha, Ibrahim Alkassoum, Issaka Sagara, Alassane Dicko, Jonas Loua, Alioune Camara, Abou Yahaya, Hadiza Jackou, Moriba Haba, Chrestien Yemeni, Suzanne Van Hulle, Joel Sodjinou, Agamaraki Adamou, Kano Assane, Paul Snell, Germaine Ekoyol, Jean Louis Ndiaye, Andre-Marie Tchouatieu, Catherine Pitt, Paul Milligan

Background: Seasonal malaria chemoprevention (SMC) involves the prophylactic administration of antimalarials to children at monthly intervals during the peak of each malaria season. In areas of seasonal transmission, 4 SMC cycles to children under 5 years has been shown to be effective and cost-effective, and is now delivered at scale in 17 African countries, reaching 49 million children in 2022. In many SMC areas, the peak malaria season is longer than 4 months, and there is evidence that a fifth SMC cycle may be cost-effective. Similarly, 3 cycles may be cost-effective in areas with a shorter season. However, national malaria control programmes (NMCPs) lack practical guidance on the optimal number and timing of cycles across areas of heterogenous transmission and seasonality. Our priority-setting tool, customisable to the country context, aims to identify the expansion pathway for SMC strategies in individual areas, rank all possible strategies, and select the combination of strategies that maximises total health impact for a given budget. In this presentation we describe our overall framework, and modelled findings for an example country, Guinea.

Methods: We estimated the cost, effectiveness, and cost-effectiveness of different SMC strategies (3-6 cycle lengths) in individual sub-national areas for Guinea. Areas were defined at the district level and grouped into operational units in consultation with the NMCP. The effectiveness of each strategy was estimated based on district-level data on SMC coverage, malaria incidence, seasonality, and other data on SMC efficacy and malaria mortality. The optimal timing of each strategy was calculated to maximise effectiveness. Financial and economic costs were estimated for each strategy in each area, from a provider perspective, based on prospective data on SMC delivery collected in 2022 in 3 countries (including one district in Guinea) and other secondary cost data, applying assumptions relating to economies of scale. We evaluated each strategy's cost-effectiveness against all other strategies and the cost-effectiveness frontier for each area; all possible strategies were then ranked nationally from most to least cost-effective and progressively selected until the cumulative cost reached Guinea's SMC budget constraint. The impact of individual and combined parameter uncertainty was explored through deterministic and probabilistic sensitivity analyses.

Results: Model development is ongoing and will be completed in early 2025. We will present the cost per child of different SMC strategies (3-6 cycles) and how costs scale by population and SMC coverage. The effectiveness of strategies in reducing peak season malaria cases will be illustrated for areas of varying transmission and seasonality. We will also present the cost-effectiveness frontier for sample areas, and illustrate on a map of Guinea the most efficient combination of strategies for a given budget.

Conclusion: Updated WHO malaria guidelines recognise that SMC strategies must be adapted to local epidemiology, without specific guidance on which SMC strategies to deliver, where, and when. Our priority-setting tool provides evidence to assist NMCPs in choosing SMC strategies that maximise the health impact of scarce resources across heterogenous contexts. The tool can be customised to individual country settings and regularly updated using routinely-collected data.

Ind-2460 Cost-Effectiveness of Novel Latent Tuberculosis Infection Screening and Treatment Modalities in Zambia

PRESENTER: **Lawrence Mwenge**, ZAMBART
AUTHORS: Richard Mwape, Buumba Tapisha, Kwame Shanaube, Ab Schaap, Helen Ayles

Introduction: Tuberculosis (TB) remains a significant public health challenge in Zambia. Despite the effectiveness of current TB infection control approaches, limitations persist in accessibility, timeliness, and resource allocation. There has been immerging TB infection testing technologies, such the skin test (Cy-TB) and the TB-Feron FIA, to enhance early detection, effective treatment. The two novel latent TB infection (LTBI) screening modalities, the skin test (Cy-TB) and point-of-care Interferon-Gamma Release Assay (IGRA), specifically TB-Feron FIA, show promise. However, these benefits must be weighed against their costs and the overall effectiveness in reducing TB infection screening. This study evaluates the cost and cost-effectiveness of Cy-TB and TB-Feron FIA compared to existing strategies in Zambia. **Methods:** We are undertaking a prospective economic evaluation, following standard economic evaluation guidelines. Primary cost data has been collected from the provider's perspective, covering standard care, Cy-TB, TB-Feron FIA, and TB treatment costs. Effectiveness will be estimated using trial outcomes and literature, measured in disability-adjusted life years (DALYs). A cohort-based model will compare interventions to standard care, featuring a cost-utility analysis (CUA) to calculate the incremental cost-effectiveness ratio (ICER) and probabilistic analysis (PA) to assess cost-effectiveness likelihood. The CUA will estimate incremental cost per DALY averted. **Results:** Costing data collection has been completed and data analysis is underway. Cost-utility will be completed during a decision modelling workshop in May 2025. The study will generate costs and incremental cost-effectiveness ratios of the interventions in terms of incremental cost per disability adjusted life-year averted. The results will contribute to informing policy decision in implementing TB-control in Zambia and similar settings. Results will be compared to other studies in similar settings for validation. **Conclusion:** This study demonstrates the importance of understanding the cost-effectiveness of TB infection control in resource-constrained settings. Our findings will provide valuable insights for policymakers, healthcare providers, and stakeholders. The results will inform resource allocation decisions, ensuring efficient implementation of National TB-control programs. Cost-effectiveness analysis informs policymakers and funders, enabling prudent investment in healthcare to maximize health benefits with available resources.

Ind-2693 Cost Effectiveness of Prevention Strategies for Human Anthrax in Uganda: a Health Sector Perspective

PRESENTER: **Yasiini Nuwamanya**
AUTHORS: Paul Okello, Susan Waako

Background: Anthrax, an acute zoonotic illness caused by Bacillus anthracis affects up to 100,000 humans annually. The major forms include cutaneous, gastrointestinal and inhalational anthrax; 95% being cutaneous. The case-fatality rate varies by form, up to 90%. Human transmission occurs through ingestion or contact with meat or products from infected animals or inhaling spores. From 2017─October 2024, Uganda reported 26 laboratory-confirmed human anthrax outbreaks in 18 districts; all associated with eating or contact with meat from cattle that died unexpectedly. Key drivers of anthrax infections include lack of anthrax surveillance and vaccination program for livestock, and illicit meat trade. These outbreaks increase morbidity, mortality and health expenditure in addition to causing loss of income for government and individuals. Preventing anthrax in animals is crucial for human protection but no routine measures are currently in place. **Aim:** We aimed to

compare the cost-effectiveness of different prevention strategies for human anthrax infections in Uganda, and inform policy. **Strategy options and perspective:** We modelled four strategies. Status quo involves reactive livestock anthrax surveillance during outbreaks and no livestock vaccination program. The alternative strategies include establishing a routine livestock anthrax surveillance system, routine anthrax vaccination for cattle and a combination of both. **Methods:** We conducted a full economic evaluation using the health sector perspective. We used Markov modelling in Amua software with a cohort size of 5 million people in 18 affected districts. The health states included "Healthy", "Sick/ Recovered", "Death from Anthrax" and "Other causes", using a cycle length of 1 month over a time horizon of 5 years. We merged the sick and recovered states due to the short prognosis of human anthrax. We modelled the event pathways for outcomes for each state. The parameters included probabilities of exposure to *Bacillus anthracis*, developing anthrax, hospitalization, and death from anthrax or other causes. The outcomes included costs of treatment, outbreak investigation and response, vaccination and anthrax surveillance, and QALYs. We computed incremental cost-effectiveness ratios for cost-effectiveness. We awarded a utility of 1 for a Healthy state, 0.5 for "Sick/Recovered" and 0 for death. We discounted the outcomes at 3% using the net present value method. Our data sources included the Uganda database of anthrax outbreaks, Uganda Bureau of Statistics, WHO life-tables and expert opinions. **Results:** Both routine anthrax surveillance (ICER=237 USD/ QALY) and vaccination (ICER=637 USD/QALY) were cost-effective: ICERs were below Uganda's per-capita GDP of 1,142 USD. However, the vaccination strategy was more effective, gaining 2,300 more QALYs compared to surveillance. A combination of both strategies was the most effective but not cost-effective (ICER=8,035 USD/QALY); larger than 7 times the Uganda's per-capita GDP. Sensitivity analysis revealed that our alternative strategies were sensitive to the incidence of anthrax, effectiveness of the surveillance system and prevalence of consumption of meat from cattle that died unexpectedly. **Next steps:** We intend to collect more data on the incidence of anthrax, consumption of meat from cattle that die unexpectedly and the anthrax surveillance system. Upon completion of the decision modelling, we will write a policy brief for dissemination to stakeholders.

Ind-87 Attributable Societal Cost of Antimicrobial Resistance in Ghana. A Microsimulation Study

PRESENTER: **Evans Otieku**
AUTHORS: Ama Fenny, Appiah-Koran Labi, Monica Jejeti, George Kwesi Hedidor, Robert Ofori Amoah, Ulrika Enemark

Background: There is a global consensus that the mounting public health threat attributable to antimicrobial resistance (AMR) requires investment case studies to persuasively galvanise national governments and other stakeholder interests and resources to implement National Action Plans (NAP) to mitigate AMR. Therefore, we performed a microsimulation analysis predicting the potential societal cost savings for AMR mitigation in Ghana. **Methods:** We combined AMR epidemiology data from the World Health Organisation's (WHO) Global Antimicrobial Surveillance System surveys in Ghana with micro-cost data attributable to AMR to perform a microsimulation analysis focusing on equity groups, predicting the potential societal cost savings should AMR be mitigated in Ghana. Costs were calculated under a business-as-usual scenario considering a seven-year time horizon from 2024 to 2030 and reported in purchasing power parity equivalent in international United States dollars, adjusting for dominant AMR causative pathogens, mortality, age groups, gender, and wealth quintile. **Results:** We predicted almost 78,000 annual AMR infections and 6,300 attributable deaths. MRSA and third-generation cephalosporin-resistant bacteria accounted for 20.2% and 79.2% of the predicted yearly infections, corresponding to an estimated mean societal cost of about USD 435 million. In decreasing order of magnitude, the estimated cost of productivity loss due to AMR-attributable mortality amounts to 40.6% of the annual cost, followed by the cost to healthcare providers 24.1%, direct medical cost to patients and caregivers 22.4%, productivity loss for surviving patients and caregivers 10.4%, and direct non-medical costs to patients and caregivers 10.4%. Resistant infections in children under five years and persons above 60 years contribute to 48.2% and 26.9% of the estimated annual societal cost, respectively. There was no statistically significant gender difference in the predicted number of resistant infections and costs. Except for the predicted number of resistant infections, the estimated mean annual costs between wealth quintile groups were significantly different (p=0.03) due to differences in productivity costs between wealth quintile groups. **Conclusion.** The study shows that everyone is at risk of AMR infection, and the attributable societal cost implications are enormous and avoidable. Given Ghana's NAP budget of about USD 21.3 million, the returns on investment in AMR mitigation will outweigh the cost should the government and other stakeholders invest in AMR interventions.

10:30 AM –12:00 PM TUESDAY [Demand & Utilization Of Health Services]

Ind-980 Housing Price as a Determining Factor of Aged Care Accommodation Payment Choices

PRESENTER: **Henry Cutler**, Macquarie University
AUTHORS: Dandan Yu, Mona Aghdaee, Anam Bilgrami, Yuanyuan Gu

Background: As the ageing population continues to grow, the demand for residential care services has surged in many countries. Governments have responded by implementing targeted policies to support the most disadvantaged populations, while increasingly placing the burden of financing residential aged care on individual consumers. In Australia, residential aged care consumers who are ineligible for government subsidies choose from three accommodation payment options: up-front lump sum payments that are refundable to the resident on leaving the facility (known as refundable accommodation deposits), rental-style daily accommodation payments, or a combination of the two. Since home equity constitutes a substantial portion of net wealth for most elderly people, affording a lump-sum payment for residential aged care accommodation often necessitates downsizing their homes through financial instruments or property sales. **Aims**: Given that local real estate market conditions affect consumers' ability and willingness to withdraw home equity, our study examines how housing price fluctuations shape their accommodation payment choices and contributes to the limited body of research on the factors influencing these decisions. **Methods**: We

utilise an administrative dataset collected by the Aged Care Financing Authority of Australia, which contains information on the characteristics of residential aged care facilities and consumers, as well as their accommodation payment choices from 2016-17 to 2018-19. This dataset is merged with housing price indices, calculated from CoreLogic RP data for each postcode area, based on the consumers' place of residence. Multinomial and fractional logistic regressions are employed to model the payment choice. **Results**: In areas with larger housing price increases, residential aged care consumers are more likely to choose the up-front lump sum payment and less likely to opt for daily payments or the combination. An increase in housing price changes also raises the proportion of the lump sum payment in the total accommodation price. These results are robust to alternative housing price indices, adjustments for potential measurement errors, and various modelling strategies. A placebo test on consumers who are unlikely to own property reveals no significant effect of housing price changes, indicating that the observed relationship is not driven by other confounding factors. We also find that married consumers' payment choices are less influenced by housing price fluctuations. When housing prices rise rapidly, the impact of these increases on the likelihood of choosing lump sum payments diminishes. This may be because some consumers view their property as an investment and prefer to pay daily accommodation fees using returns from property appreciation. **Conclusions**: Payment choices for residential aged care profoundly impact the financial well-being of elderly individuals. This study highlights the role of housing equity as a buffer against adverse shocks in later life and reveals that residential aged care providers are vulnerable to the risks associated with real estate market fluctuations, particularly those relying on lump sum payments as interest-free loans to fund capital investments. These insights offer invaluable support for residential aged care providers in refining their financial planning strategies.

Ind-1017 Residents Preferences for Osteoporosis Community Intervention: an Empirical Analysis from Shanghai, China

PRESENTER: **Yijia Feng**
AUTHOR: Luying Zhang

Background： Osteoporosis is a chronic disease that requires long-term treatment and management. Results of the *First National Epidemiological Survey on Osteoporosis* in 2018 showed that the prevalence of osteoporosis among people over 50 years of old in China was as high as 19.2%, resulting in a great economic burden of disease. Early community intervention has been proved to be an effective means of control in osteoporosis. However, residents' preferences of osteoporosis community intervention remain underexplored in China. This study aims to investigate the preferences of osteoporosis community intervention in China. **Methods:** A discrete choice experiment was conducted in 6 communities in Shanghai to elicit population's preferences for osteoporosis community intervention. We constructed a mixed logit model including a total of 14 levels of 6 attributes including access to screening information, screening duration, service supplier, mode of administration, management approach and out-of-pocket (OOP) costs. Willingness-to-pay (WTP) and scenario prediction were also calculated to further complete the preferences results. Subgroup analyses were performed mainly according to respondents' age, income, geographic location and whether already have osteoporosis. **Results:** A total of 170 valid questionnaires were collected through face-to-face interviews from 6 communities in Shanghai. We found that OOP costs was the most concerned factor, followed by screening duration, service supplier and access to screening information. Subgroup analyses revealed that screening duration and service supplier showed a greater impact on respondents' utility in the suburban samples compared to those resided in urban communities. This may be due to the lower accessibility of screening services and community GPs in suburbs. Scenario prediction results provided further evidence that when optimizing community intervention programs for osteoporosis, the combination of short screening duration, service supplied by specialists from tertiary hospitals and management supplied by GPs made more significantly positive contributions to improving residents' total utilities. **Conclusions:** This study provided valuable insights into population's preferences for osteoporosis community intervention in China. Acknowledging the impact of attributes in community intervention strategies on residents' utilities and their WTP means a lot to optimize community interventions.

Ind-1234 Effects of Cost-Sharing on Utilization, Expenditure, and Health Outcomes Among the Elderly in City A, China: A Regression Discontinuity Analysis

PRESENTER: **Zixuan Fu**
AUTHOR: Yanming Lin

Background: Rising healthcare costs, driven by an aging population and increasing insurance generosity, pose significant challenges to the financial sustainability of health insurance systems. While increasing patient cost-sharing is a potential strategy to control expenditures, it involves trade-offs, such as reducing healthcare overuse while risking reduced access to necessary care and undermining financial protection. Further research is needed to understand the impact of cost-sharing change on utilization, health outcomes, and risk protection, particularly for the elderly. **Method:** Using discharge data from two tertiary hospitals in City A, northern China (2013–2018), which accounted for 35.6% of all inpatient admissions in the city's tertiary hospitals during this period, we analyzed 108,127 discharged cases of patients aged 65–75 enrolled in the Urban Employee Basic Medical Insurance (UEBMI). In City A, the deductible for hospitalization under UEBMI decreases sharply at age 70, reducing out-of-pocket expenses by approximately 10%. Exploiting this discontinuity, we employed a regression discontinuity design to estimate the effects of reduced cost-sharing on healthcare utilization, expenditures, and mortality. **Results:** The deductible reduction at age 70 led to a 10.0% increase in inpatient admissions, with higher increases in surgical (10.7%) than non-surgical (8.4%) admissions. Elective surgeries, such as cataract surgeries (15.9%) and joint replacement (24.0%), experienced larger growth, suggesting patients may delay elective procedures to benefit from lower cost-sharing. The reduction in deductible had no significant effect on hospital length of stay. Total healthcare expenditures per admission decreased by 1.6%, primarily due to a 1.5% reduction among non-surgical patients, while no statistically significant changes were observed for surgical patients. Out-of-pocket expenditures per admission declined by 12.3%, with reductions of 13.2% for non-surgical patients and 5.8% for surgical patients. The proportion of out-of-pocket expenses in total medical expenditures decreased by 1.8%, including declines of 1.9% for non-surgical and 1.4% for surgical patients. Changes in reimbursement were statistically insignificant across all patient groups, including both surgical and non-surgical patients. Mortality estimates showed no statistically significant changes across all patient groups, indicating that reduced cost-sharing had no measurable effect on health outcomes, at least in the short run. **Conclusion:** Lowering the deductible at age 70 significantly increases healthcare utilization, particularly for elective surgeries, while improving financial

risk protection through reduced out-of-pocket expenses. Notably, the reduction does not negatively impact health outcomes or contribute to excessive growth in healthcare expenditures. These findings indicate that moderate reductions in cost-sharing for elderly individuals with substantial healthcare needs and higher medical expenses can effectively balance increased utilization and enhanced financial protection without undermining the sustainability of the health insurance system. 21

Ind-1854 National Insurance Claims Data to Assess Adult Vaccine Access in Herpes Zoster in Indonesia

PRESENTER: **Labbaika Nurmadani**
AUTHORS: Hasbullah Thabrany, Yufan Puteri Astrini, Mutia Anggun Sayekti, Rifqi Abdul Fattah

Approaching the era of an aging society, Indonesia will face increasing health risks including the weaken immunity that is likely lead to rising healthcare costs. Prevention plays an essential in ensure the aging population lives healthily while preventing excessive healthcare costs due to unaddressed illness. Immunization as the pivotal preventive approach is regulated under Health Ministerial Decree 12/2017, highlighting the focus on childhood immunization, with limited coverage on adults and the elderly immunization. This inequity neglects the risk of vaccine-preventable diseases on adult and elderly population that may significantly hamper the health system, such as Herpes zoster. Herpes Zoster is caused by the reactivation of the Varicella Zoster Virus (VZV), the same virus responsible for chickenpox. This disease can lead to severe pain that disrupts daily activities and may also result in Postherpetic Neuralgia (PHN), causing prolonged pain lasting months or even years. According to the Centers for Disease Control and Prevention (CDC), the incidence of Herpes Zoster in the United States ranges from 2 to 9 cases per 1,000 people, with an estimated 96 deaths annually and a mortality rate of 0.28–0.69 per 1 million population. The risk of morbidity and mortality from Herpes Zoster increases with age and decreased immune system. In addition to adults, immunocompromised also have a high risk of developing this disease. Understanding the importance in expanding the access to adult vaccines, particularly for Herpes Zoster, local data is essential to demonstrate the burden of Herpes Zoster in Indonesia. This study aims to determine the disease rate and associated demographic characteristics of Herpes Zoster cases as a foundation for informed policymaking.

Applying quantitative methods to analyse one percent of JKN claims data from 2015 – 2022 in obtaining the results, we further used ICD codes in primary and secondary diagnoses related to Herpes Zoster (code group B02). The analysis revealed that 7 per 10,000 National Health Insurance participants were affected by Herpes Zoster between 2015 and 2021. The disease was more prevalent among females (54%) compared to males (46%) and was most common in the 61–70 age group. Additionally, Herpes Zoster was more frequent in immunocompromised groups, such as those with HIV/AIDS, autoimmune disorders, and cancer, compared to individuals with other risk factors like diabetes, heart disease, and chronic respiratory diseases. The total cost of treatment amounted to IDR15.3 billion (USD975,259) for inpatient care and IDR7.3 billion (USD465,319) for outpatient care.

Expanding the access to the Herpes Zoster vaccine will require collaborative and continuous efforts, specifically in increasing awareness and education within at-risk populations about the vaccine's significance as well as improving the knowledge and skills of healthcare professionals. Collaborative efforts between the public and private sectors are essential for ensuring the availability of the vaccine to vulnerable groups, alongside the development of a sustainable public funding plan to support Herpes Zoster vaccination programs. Vaccination against this disease can significantly reduce both the economic burden on individuals and healthcare systems, while promoting the health and productivity of the adult and elderly populations.

Ind-1972 Pensions as a Pathway to Protection: Enhancing Vaccine Uptake in Aging Populations

PRESENTER: **Reshmi Sengupta**
AUTHOR: Debasis Rooj

India’s rapidly growing aging population presents significant challenges for public health, particularly in preventing illnesses among older adults through timely immunization. Despite the increasing burden of vaccine-preventable diseases, adult vaccination rates in India are worryingly low. This paper examines whether access to work-related pensions, a key source of income security in later life, can encourage older adults in India to seek preventive healthcare, particularly immunization. Using nationally representative data from LASI Wave 1 and focusing on individuals aged 60 and older, we apply a copula-based bivariate regression model to estimate the joint receipt of pensions and outpatient visits for immunization. This method addresses significant econometric issues, including endogeneity, nonlinear covariate effects, and rare-event bias resulting from low vaccination rates. We find that receiving or expecting a contributory pension greatly increases the likelihood of recent outpatient visits for immunization. Pensions also appear to increase awareness of senior benefits, reduce food insecurity, and enhance media exposure, suggesting both financial and informational avenues that encourage preventive health actions. The findings are consistent across various model specifications and instrumental variable analyses. By demonstrating the positive impact of pensions on health behavior, this study provides new evidence on how formal social support can help promote healthy aging. Our results underscore the need to expand contributory pension coverage, particularly for underserved groups, as a cost-effective means to enhance public health and mitigate future healthcare demands in aging societies. This has broader implications for policy development in other low- and middle-income countries experiencing similar demographic shifts.

Ind-2794 How Do Socioeconomic Inequalities Affect Health Outcomes in Healthcare Utilization Among Middle-Aged and Older Migrants in India?

PRESENTER: **Suraj Maiti**
AUTHORS: Reshmi R. S., Amar Bharti

Background

Migration and population aging are significant demographic forces impacting global health outcomes and economic stability. As of 2017, the global aging population was 962 million, with projections suggesting this number will double by 2050. In India, the internal migrant population increased from 309 million in 2001 to approximately 600 million by 2021. Migrants in India often face economic vulnerabilities, including

inadequate wages and poor working conditions, which exacerbate their health issues and limit access to healthcare services. The National Health Policy (NHP) 2002 aimed to improve equitable access to healthcare across India. Despite these efforts, disparities in healthcare utilization persist, particularly among middle-aged and older migrants. We aimed to explore whether inequalities in socio-economic factors influence healthcare utilization and outcomes among this demographic, focusing on the inequities in accessing inpatient and outpatient services.

Methods

We utilize data from the Longitudinal Ageing Study of India (LASI) (2017-18). The complete case analytical sample included 36,595 migrants identified based on their place of birth and continuous residence. The Anderson conceptual framework guided the choice of healthcare utilization determinants, categorizing explanatory variables into predisposing factors (age, sex, marital status, education, social group, residence), enabling factors (monthly per-capita household consumption expenditure [MPCE], working status, health insurance), and need factors (limitations in activities of daily living [ADL], self-rated health [SRH], morbidities). Descriptive statistics, bivariate analysis, and hierarchical nested logistic regression were used. Concentration curves and the Erreygers concentration index assessed socio-economic inequalities in healthcare utilization.

Findings

We found that 58.7% (95% CI: 56.3%, 61.1%) of migrants utilized outpatient care, while only 7.3% (95% CI: 6.6%, 8.2%) accessed inpatient care. Significant associations were observed between healthcare utilization and factors such as age, region, MPCE quintiles, working status, limitations in ADL/IADL, morbidity presence, and SRH. Migrants with poor SRH were 2.17 times more likely to use inpatient care compared to those with good SRH. Additionally, those with both non-communicable diseases (NCDs) and communicable diseases (CDs) were 3.45 times more likely to seek inpatient care than individuals without morbidity. The concentration indices for outpatient (0.049; 95% CI: 0.026, 0.073) and inpatient care (0.192; 95% CI: 0.131, 0.210) indicated a pro-rich inequality in healthcare utilization.

Conclusion

Significant socio-economic inequalities exist in healthcare utilization among middle-aged and older migrants in India. Predisposing, enabling, and need factors influence healthcare access for this vulnerable group. Implementing health insurance schemes for outpatient services will be crucial to improving healthcare utilization among elderly migrants. Developing micro-level policies that enhance access to healthcare at migrants' destinations is essential for addressing these disparities effectively.

Ind-2665 Living Alone? The Effect of Living Alone on Patient Length of Stay in Public and Private Hospitals

PRESENTER: **Jinglin Wen**
AUTHOR: Luigi Siciliani

Following the COVID-19 pandemic, hospitals are under pressure to absorb elective backlogs that have accumulated due to the suspension of health services. Reductions in length of stay can generate additional capacity to treat patients and increase efficiency. One non-clinical determinant of length of stay is whether the patient lives alone. Patients who live alone may lack support at home once discharged and the hospital may need to keep the patient longer despite being clinically fit for discharge. On the other hand, patients living alone could have other sources of support (e.g. family and friends) that mitigate such effects. The size of the effect of living alone on length of stay is in principle indeterminate. This study tests whether living alone affects length of stay of patients treated by public and private hospitals treating NHS patients requiring an elective hip replacement. Economic theory suggests that private providers have stronger incentives to contain costs, and this could translate into shorter length of stay and the extent to which non-clinical determinants, such as living alone are taken into account. We use administrative data from the Hospital Episode Statistics matched with Patient-Reported Outcome Measures Survey (PROMs) for four financial years before (2016/17-2019/20) and three years after COVID-19 (2020/21-2022/23). We conduct patient level linear regression models and control for a range of patient characteristics, such pre-operative health, age, ethnicity, comorbidities and past emergency admissions), hospital characteristics (through hospital fixed effects), and availability of local supply of care homes, rehabilitation and community care (through small area fixed effects). We further use (coarsened exact) matching to compare private and public hospitals.** We find that patients who live alone stay 0.23 days longer in private hospitals and 0.42 days in public hospitals in the pre-pandemic period, and 0.17 days in private hospitals and 0.39 days following the pandemic. After matching, the effect of living alone reduces in public hospitals to 0.36 days in the pre-pandemic period and 0.32 days following the pandemic. We also show that the effect of living alone is concentrated in the post-operative rather than the pre-operative length of stay. And that the effect is larger for male and older patients, and those living in rural areas.

abs-os254 Long-Term Care in Indonesia: Need, Use and Inequality in Use

PRESENTER: **Lotte Beeldman**
AUTHORS: Judith Bom, Ms. Igna Bonfrer, PhD, Job van Exel

Background: Many low- and middle-income countries now face rapid population aging, accompanied by an increasing number of older people requiring care due to age-related disabilities or chronic health conditions. However, few have sufficiently developed formal long-term care (LTC) systems to support their growing older populations. In many countries, including Indonesia, informal family care remains the predominant form of LTC available to older people. Due to urbanization, changes in family structures, and an increase in women's participation in the workforce, this form of care has recently come under rising pressure. Despite these shifts and the growing population of older people requiring care, research on the needs, utilization, and inequalities in LTC in Indonesia is limited. Currently, Indonesia has no public long-term care insurance, and LTC services are not included in the national "JKN" health insurance program.

This research aims to address critical gaps in understanding these dynamics, highlighting the necessity of a comprehensive and equitable

approach to LTC policy in Indonesia.

Methods: Data from the RAND Indonesian Family Life Survey (IFLS) 2014/2015 (wave 5) was used to estimate the need for, use of, and inequalities in the use of LTC in the Indonesian population aged 45 years and older. Indicators on activities of daily living (ADL) and instrumental activities of daily living (IADL) were used to assess the level of need for care services. Additionally, a distinction was made between the receipt of informal (unpaid) care and formal (paid) care. Using data on need, receipt of care, and socioeconomic indicators, income inequality in the use of and intensity (hours per month) of informal LTC was estimated using a concentration index.

Results: Approximately 22% of the population aged 45 years and older has at least one limitation in either ADL or IADL, indicating some need for LTC. Almost 72% of people with such needs receive some form of care, with most of this care being informal. Only 4% of people with needs receive paid or formal care. There is a clear pro-poor distribution of need for care within the population (CI = -0.067). While there is no income inequality in the distribution of receiving any care when in need, the intensity of care is distributed pro-rich (CI = 0.073).

Conclusion: Older people in Indonesia rely predominantly on informal care services, with minimal use of formal LTC. This reliance may be due to the unavailability of formal services, unaffordability due to the lack of insurance, or personal preferences for family care. Additionally, there is a clear pro-rich distribution of the intensity of care received, leading to socioeconomic inequalities. Considering current societal changes in Indonesia, such as urbanization and shifting family structures, the heavy reliance on informal LTC is likely to become unsustainable in the near future. To prevent unmet needs and inequalities within its aging population, the Indonesian government should reconsider its LTC policies and explore the implementation of a long-term care insurance system to facilitate the expansion of an affordable formal LTC infrastructure.

Healthcare Affordability Challenges

MODERATOR: **Lan Yao**,

Ind-1396 Catastrophic Health Expenditures and Medical Impoverishment in Bangladesh

PRESENTER: **Abdur Razzaque Sarker**

Introduction: In the South-East Asia Region (SEAR), Out-of-Pocket (OOP) healthcare expenditure, hereafter referred to as OOP expenditure for short, is the main source of healthcare funding. It was observed that more than half of the SEAR countries including Bangladesh spent more than one-third of their current health spending on household OOP expenses. Bangladesh uses a combination of general revenue taxation, out-of-pocket payments, donations from development partners' contributions for healthcare financing strategies. Indeed, (OOP expenditure is one of the most noteworthy payment strategies for healthcare in Bangladesh and the share of OOP expenditure has been increasing alarmingly from 55.9% in 1997 to 68.5% in 2020 according to the Bangladesh National Health Account which was about 73% in 2021 according to the Global Health Expenditure dataset. This study aimed to investigate the impact of OOP expenditure on CHE and impoverishment in Bangladesh and identify their determinants. Findings from this study may have implications for setting future healthcare policy priorities for achieving UHC in Bangladesh, and may provide lessons for other countries in the South- Asian region. **Methods:** We used data from the latest Household Income and Expenditure Survey 2022 (HIES-2022) carried out by the Bangladesh Bureau of Statistics, with a sample of 14,395 households. The well-known methodology developed by Wagstaff and Doorslaer was used in this study to estimate the incidence of catastrophic health expenditure (CHE) and impoverishment effect of catastrophic health spending. We used the generalized linear model (GLM) with a log link and gamma distribution to assess the associations between the explanatory variables and annual OOP cost. Multilevel logistic models were employed to identify the determinants of CHE and impoverishment. **Results:** The incidence of CHE was estimated at 17.72% and 7.07% using 10% and 25% of the total consumption expenditure as thresholds, respectively. Given the 40% of non-food expenditure threshold level, about 9.46% of households faced CHE due to OOP costs in Bangladesh. About 3.7% of the population (6.13 million) fell into poverty during 2022 in Bangladesh. The incidence of CHE was higher among male-headed households, larger households, households with older people, those with chronic illnesses, those utilizing hospital care, and people in the poorest wealth quintiles. These were the main determinants of both CHE and impoverishment. **Conclusions:** The financial hardship due to OOP expenditure was high in Bangladesh. Therefore, people with such characteristics should be brought under pre-payment schemes such as social health insurance. These results will also enable policymakers to adopt various healthcare financing strategies and improve the efficiency of public investments in health.

Ind-865 Which Diseases Drive Catastrophic Payments of Households? Results from a National Expenditure Survey

PRESENTER: **Aleli Kraft**

AUTHORS: Owen O'donnell, Joseph Capuno, Kayleen Calicdan

Background Indicators for SDG 3.8 (Achieve Universal Health Coverage) include an index of service coverage and catastrophic spending – the proportion of medical expenditures that exceed 10% or 25% of total household expenditure. Reducing out-of-pocket spending (OOP) for health is vital to reducing catastrophic health spending. Most past studies of OOP, including those in the Philippines, have utilized national household expenditure surveys that do not have details on conditions that contribute to OOP. Sources of OOP have been described in terms of main sources; i.e., outpatient or inpatient care, and medicines. Thus, our study seeks to answer the following questions; (a) which diseases contribute to the OOP of households, and (b) which diseases are likely to cause household catastrophic payments. Methods We use data from the

Philippine National Health Expenditure Survey, a nationally representative health survey collected between November 2018-May 2019 that seeks to complement the National Health Accounts and collect data not covered by DHS surveys and other household expenditure surveys. We use information from 11,014 households and associated 15,055 healthcare visits. We estimate OOP as the sum of the charges paid for using (1) own household resources, savings and income, (2) sale of property, and (3) personal loans. We exclude transfers from charities, local government units (LGUs) and reimbursements from health insurance. We include charges from outpatient (OP) visits, medications and medical equipment and supplies in the last 6 months, and inpatient visits (IP) in the last 12 months. Disease categories are represented by ICD-10 codes for OP and IP visits which are the bases for the construction of a binary variable that is equal to one if any member of the family had an OP or IP visit due to the specific disease. We estimate Poisson models for OOP for all households and those with positive OOP. We estimate probit models on the likelihood of catastrophic spending at the 10% and 25% thresholds. We control for household size and composition, household head characteristics, per capita monthly non-medical expenditure quintiles, and location. Results Respiratory conditions and cardiovascular diseases account for the highest causes of household visits to health facilities. Households that have members who had neoplasms, diseases of the genito-urinary system and endocrine and metabolic disorders have the highest contributions to OOP. These also increase the likelihood that households will incur catastrophic spending. On the other hand, cardiovascular diseases, respiratory diseases and endocrine and metabolic disorders contribute to higher predicted overall prevalence of catastrophic health spending. Discussion There are differences between diseases that contribute most to household OOP and those that contribute to the overall prevalence of catastrophic spending. If the objective is to improve financial risk protection at the household level, then benefits could target diseases which contribute most to household OPP. If the objective is to reduce the prevalence of catastrophic spending at the aggregate level, then benefits can target diseases which not only contribute to OOP but have high population prevalence as well.

Ind-1678 Trends in the Incidence and Intensity of Catastrophic Health Expenditure in Urban and Rural China: 2010-2022

PRESENTER: **Yaping Deng**
AUTHORS: Jingxian Wu, Cong Li

Background Catastrophic health expenditures (CHE) occur when out-of-pocket (OOP) healthcare payments exceed a predetermined threshold, imposing financial hardship and increasing poverty risk. This study aims to examine the trends in the incidence and intensity of CHE among urban and rural households in China from 2010 to 2022and explore the associated factors influencing CHE occurrence. **Methods** Data were obtained from the China Family Panel Studies (CFPS), a national representative household survey conducted biennially from 2010 to 2022. CHE was defined as OOP healthcare payments exceeding 10% of total household expenditures or 40% of non-food expenditures. Incidence was measured by the headcount ratio (percentage of households experiencing CHE), while intensity was assess using overshoot (extent to which OOP payments exceed the threshold among all households) and mean positive overshoot (MPO, extent to which OOP expenditures exceed the threshold among affected households). A random-effects logit model was applied to identify factors associated with CHE occurrence. **Results** From 2010 to 2022, the incidence and intensity of CHE declined significantly in both urban and rural households, with sharper reductions observed in rural areas. Using the 40% threshold, the incidence of CHE dropped from 33.8% to 11.2% in rural households (annual decline rate: 1.89%) and from 17.1% to 8.9% in urban households (annual decline rate: 0.68%). Intensity, as measured by overshoot, decreased from 13.4% to 2.5% in rural households and from 4.8% to 2.0% in urban households. MPO declined from 24.4% to 9.2% in rural areas and from 12.3% to 8.9% in urban areas. Similar trends were observed using the 10% threshold. The random-effects logit model revealed consistent patterns across thresholds. Factors associated with a lower likelihood of CHE occurrence included higher education (particularly university or above) and stable employment of household heads, and enrollment of family members in commercial health insurance, while social health insurance coverage had limited impact. Conversely, inpatient care utilization was the most significant driver of CHE, followed by older household heads and poorer self-rated health among family members. Rural households were more vulnerable to CHE when chronic illness or children under five years were present, whereas the presence of older adults was more strongly associated with an increased likelihood of CHE in urban households. **Conclusion** This study demonstrates significant reductions in the incidence and intensity of CHE in China over the past decade, particularly in rural areas. However, persistent disparities remain for households burdened by inpatient care costs, chronic illnesses, or specific demographic vulnerabilities. Policy reforms should prioritize reducing inpatient OOP expenses, especially for high-cost services, while expanding insurance coverage and targeted subsidies for rural households with chronic illnesses or young children. Simultaneously, enhanced support for urban households with older adults is essential to further mitigate CHE risk and promote greater equity in health financing under Universal Health Coverage.

This study is funded by the National Natural Science Foundation of China (No. 72104196).

Ind-721 Hard Life, Hard choices: How Out-of-Pocket Payments Affect Households' Consumptions and Savings Trade-offs

PRESENTER: **Antoine Marsaudon**
AUTHORS: Paul Dourgnon, Renaud Legal, Damien Bricard

Context

Out of Pocket payments (OOP) are the medical care expenses that are not reimbursed by insurance. These include deductibles, coinsurance, copayments for covered services, and costs for services which remain not covered. Households facing costly treatments, poor healthcare coverage are likely to bare high OOP. While former research addressed the prevalence, distribution and economic consequences of “catastrophic OOP” or “surprise payments”, little is known on the impact of heath shocks and related increase in OOP on non-medical consumptions and savings.

OOP may affect households through an income effect and a preferences effect. When facing an increase in OOP following a health shock,

households may reduce their non-medical consumption, reduce their savings or their financial assets, receive financial transfers from relatives or borrow money. Beside the above income effects, households demand for non-medical goods may also change if the marginal utility of non-medical consumption was dependent of health status. Individuals may less value non-medical consumptions complemental to good health (such as travels or sports), and more those that are substitutable to good health (such as home delivery or home assistance).

Objectives

A large literature has studied the impact of high OOP payments on households' financial situation (budget deficit, financial debts, personal bankruptcy) and on total consumption. Our study adds up to the literature by exploring whether households facing OOP payments are also undergoing changes in non-medical consumptions patterns and on savings.

Methods

We base our study on micro data from the pooled 2011 and 2017 French Household Budget cross-sectional Surveys, which collected medical and non-medical consumptions enriched with fiscal data. This survey enables to identify health shocks, defined as unexpected high health expenditure, and unmet health needs. Non-medical consumptions include housing, food, leisure, transport, clothing, communications, and education. We use linear models to estimate correlations between OOP and non-medical consumptions expenditures, controlling for households' characteristics, and potential unmet needs, i.e. the fact that households may cope with an OOP shock by reducing their health consumption.

Results

We show significant correlations between OOP and most non-medical consumptions, also with savings. We estimated the same models across expenditure quintiles, measured as percentage of household income, to account for nonlinear interactions. Models were also estimated across income quintiles in order to explore social variations in coping behaviors.

Conclusions

Out of pocket Payments represent a significant challenge for health systems equity, especially in systems where payments are based on fee for services and relying on cost sharing as a cost containment tool. Not only does it induce inequalities in access to healthcare services, but it also impacts financially poor and unhealthy individuals and households, and the consumption of other goods which may be considered important or essential.

Ind-1051 The Unaffordability of Affordable Care Act Health Insurance Plans

PRESENTER: **Cheryl Damberg**
AUTHOR: Risha Gidwani

Insurance is the gatekeeper through which most Americans access medical care. The 2010 passage of the Affordable Care Act (ACA) was heralded as a way to expand health insurance in an affordable manner to millions of Americans previously unable to afford such protection. The ACA offered Americans ineligible for public or employer-sponsored insurance an opportunity to directly purchase insurance, many of whom have received federal subsidies to enable them to afford coverage. ACA marketplace participants select from a wide array of private health plans. Complexity of choice is a significant contributor to poor health insurance selection, with literature showing that an increase in choice set can make decision-making more difficult. In the context of the ACA marketplace, this complexity can arise from the excessive number of health insurance plans combined with numerous cost, coverage, and provider network features that need to be jointly considered for each plan.

Given the critical importance of selecting appropriate health insurance for millions of Americans choosing ACA marketplace coverage, this study aimed to characterize the current landscape of health insurance plan choices on the ACA marketplace and the extent to which plans and plan selection remain in reach of the average consumer. We investigate the choice set facing millions of Americans and the affordability of available plans, with a particular focus on identifying the proportion of plans that are considered unaffordable.

Methods: We evaluated the affordability and selection of health plans on the ACA marketplace using 2023 HIX Compare data, which contains detailed benefit design information on 100% of ACA plans offered in the U.S and using the U.S. Census Bureau's Small Area Health Insurance Estimates to estimate the proportion of Americans eligible to purchase ACA insurance. Using modified Commonwealth Fund definitions, an ACA plan was considered unaffordable if the premium exceeded 10% of the median annual household income in the county. Median county-level annual household income was obtained from the American Community Survey Years 2018-2022, the most recent years available. We analyzed plan availability, premiums, and affordability across U.S. counties, evaluating disparities by race, ethnicity, and rurality.

Results: 97% of counties offer at least 25 plans, with 54% of the ACA-eligible population facing more than 150 options. Despite this variety, affordability remains a significant issue: 68% of Bronze plans are unaffordable for a 27-year-old individual, and 96.9% of all plans are unaffordable for a family with two adults. High premiums, coupled with poor health insurance literacy, particularly among racial minorities, exacerbate financial burdens and hinder access to care.

Conclusions/Policy Implications: The amount of choice ACA customers face is so large as to be overwhelming, underscoring the need for streamlined plan options to reduce complexity of choice. Further, the unaffordability of ACA-based insurance needs to be addressed to ensure equitable access to healthcare. Future policies to reduce the cost of ACA plan coverage and/or continued subsidies to purchase insurance may be needed to ensure access to care. Before accessing a single health care service, many ACA enrollees experience financial burden simply due high premium costs.

Ind-2239 Socio-Economic Inequalities in the Financial Burden of Diabetes: Evidence From Punjab

PRESENTER: **Sujata Sujata**
AUTHORS: Ramna Thakur, Martin Siegel

Background Diabetes is a rapidly growing global health crisis, with India holding the second-highest number of cases, and the burden is unevenly distributed across the country's different regions and socioeconomic groups. With a low insurance coverage rate, households face significant out-of-pocket healthcare expenditures (OOPHE), which account for 58.7% of the overall health expenditure. Hence, the primary objective of this study is to examine inequalities in the physical and financial burden of diabetes with respect to household and area-level factors in the Indian context. **Methods** We collected quantitative data on self-reported diabetes, OOPHE, and socio-economic variables from 4,418 households in different districts of the Indian state of Punjab. Socioeconomic inequalities in diabetes and OOPHE are measured using the concentration index, and the progressivity of OOPHE is analyzed using Kakwani index. The incidence of CHE is estimated using the budget share approach. We used an adapted two-part model to analyze variations in the probability of having diabetes and incurring OOPHE across various socio-economic groups. **Results** We found that diabetes and OOPHE are concentrated among the richest households. OOPHE was proportional to household consumption; however, in the subgroup of diabetics, the share of OOPHE in households' monthly per capita consumption expenditure (HMPCE) is highest for the poorest, followed by middle quintile. Across different deprivation groups, we don't find any significant variation. The overall incidence of CHE was 1.24% at the 10% threshold, and it was highest in the middle quintile. In the subgroup of diabetics, the overall incidence was 10.91% at the 10% threshold, peaking at 32.5% in poorest quintile. Across different deprivation groups, the incidence shows an increasing trend. The Kakwani index, though negative, is not statistically significant. The results of the first part of two-part model showed significant variations in the likelihood of diabetes with socioeconomic status. However, in the second part, significant variations in OOPHE were observed only by age, education, consumption and place of residence. **Discussion and Conclusion** We conclude that consumption expenditure and area-level deprivation are significant determinants of diabetes. However, OOPHE is driven by individual socioeconomic factors, with the poorest and middle-class households bearing the most burden. It points towards a lack of insurance coverage and healthcare accessibility among them. Most health insurance schemes in India exclude outpatient services. Diabetes is best treated in outpatient care settings; we thus argue that there is a need for universal health coverage, which includes outpatient treatments irrespective of socio-economic status.

Ind-1568 Financial Risk of Scaling Up Viral Load Testing to Achieve Triple 95 Target in Indonesia

PRESENTER: **Mutia Astrini Pratiwi**, ThinkWell, LLC/USAID Health Financing Activity
AUTHORS: Hasbullah Thabrany, Amalia Zulfah Wijaya, Ratu Martiningsih, Anastasia Susanto, Romauli Romauli, Diah Eva Sari Husnul Khotimah, Iko Safika, Endang Lukitosari

Introduction. In July 2024, the Ministry of Health (MOH) reported that 50% of people living with HIV (PLHIV) were receiving antiretroviral therapy (ART). Still, only 42% of those on ART achieved viral suppression, falling short of the global 95-95-95 target. Indonesia faces challenges in reaching viral suppression, the ultimate goal of its HIV program. As the country transitions to upper-middle-income status, donor funding currently covers 20% of program costs and is expected to decrease. Currently, reimbursements for viral load (VL) tests are set at IDR 45,000 (approximately US$2.90) for Point of Care (POC) machines and IDR 200,000 (approximately US$12.90) for High Capacity (HC) machines. Many healthcare providers have expressed concerns about the inadequacy of these reimbursements.

Methods. We surveyed 41 health facilities across 14 provinces to calculate the average unit costs of POC and HC machines. We estimated the required number of VL tests using data from the 2024 HIV/AIDS Information System. Our projections cover five years, from 2025 to 2030, based on four different scenarios:

1. 50% of PLHIV on ART use POC machines, and 50% use HC machines at the current reimbursement rate.
2. 31% of PLHIV on ART use POC machines, and 69% use HC machines at the current reimbursement rate.
3. Based on average unit cost estimations, 50% of PLHIV on ART use HC machines, and 50% use POC machines.
4. Based on average unit cost estimations, 69% of PLHIV on ART use HC machines, and 31% use POC machines.

Results. The average unit costs of using POC and HC machines in 2023 were IDR 913,000 (approximately US$58.87) and IDR 1.7 million (approximately US$111.37), respectively. Based on current reimbursement rates, the government should allocate between IDR 258 billion and IDR 320 billion (approximately US$17 million to US$21 million) for VL tests from 2025 to 2030. If the government pays based on market average costs, the estimated expenditure would rise to approximately IDR 2.98-3.32 trillion (US$192-214 million).

Conclusion and Policy Implications. Each funding choice has advantages and disadvantages, and the cost difference could put PLHIV at risk of not receiving appropriate VL tests, potentially leading to issues with achieving VL suppression. To minimize financial risk and ensure access to VL tests, reimbursements should be set at or above average market costs for both public and private providers. This study found that significant cost disparities could put future governments at greater financial risk when providing ART for existing and new cases.

Ind-761 Costs of Antenatal care Service Utilisation and its Effects on Low Birth Weight in Eastern Ethiopia: Implications for Improving Free Maternity Policy

PRESENTER: **Tadesse Tolossa Daba**
AUTHORS: Eric HY Lau, Merga Dheresa, Julie Abimanyi-Ochom, Ms. Lisa Gold

Background- Most SSA countries are implementing free maternity services starting from the first antenatal care (ANC) to postnatal care. However, out-of-pocket health expenditures (OOP) and opportunity cost, such as travelling time, significantly affects the utilization of maternal services in low- and middle-income countries (LMICs). Limited evidence exists on the cost incurred for maternal health service utilization and the effect of these costs on low birth weight (LBW).

Objectives- To assess the association between OOP expenditures and LBW in Eastern Ethiopia.

Method- A prospective cohort study followed 395 pregnant women for ten months to see the incidence of LBW. Cost of ANC and other follow up variables was collected during pregnancy. Direct medical and non-medical cost were summed up to give OOP expenditures. Face to face interview was used to collect data. Poisson regression with robust variance estimate was used to assess the independent predictors of LBW. Adjusted risk ratios (RR) with 95% confidence intervals were computed, and statistical significance was declared at p-value <0.05 in the final model. The direct and indirect effects of OOP and mediators on LBW was explored using a Generalized Structural Equation Modeling (GSEM). High-risk ethics application was granted from Deakin University (No 2023-342).

Result- 385 women were followed for 10 months, yielding a response rate of 97.4%. Pregnant women spent direct medical costs of 9.3 USD, direct non-medical costs of 13.7 USD, and incurred an average opportunity cost of 3.1 USD. Overall, 71.5% (95% CI: 66.4, 75.4) of women experienced OOP payment due to ANC utilization. OOP expenditure was 23.4 USD for women who gave birth to LBW baby, compared to 20.3 USD for those without LBW baby. The study found that 10.9% of women had LBW neonates. After controlling for confounding factors, OOP expenditure (aRR = 3.23, 95% CI: 1.19, 8.73), prenatal depression (aRR=2.93, 95%CI: 1.67, 5.15), and lack of birth preparedness and complication readiness (BPCR) (aRR=4.26, 95%CI: 1.59, 11.41) increased the risk of LBW. In GSEM, prenatal depression (β=1.22, CI:0.18, 2.38) and lack of BPCR (β=1.16, CI: 0.01, 2.16) mediated the association between LBW and OOP expenditures. Prenatal depression mediated the association by 25.7% and lack of BPCR mediated by 18.5%.

Conclusion- In this study, despite the ANC service being supposed to be given free of charge, the majority of the women experienced high OOP expenditures. There was a significant positive association between OOP payment and LBW which was partly mediated by prenatal depression and lack of BPCR. Therefore, policies aimed at reducing LBW should prioritize reducing financial stress during pregnancy and integrating mental health counselling, early screening and treatment programs within prenatal care services, particularly among financially disadvantageous women.

Ind-617 Out-of-Pocket Expenditures and Financial Risks Associated With the Treatment of Chronic Kidney Disease in Ethiopia

PRESENTER: **Solomon Tessema Memirie**, Addis Ababa University
AUTHORS: Sisay Tesfaye, Lina Mohammed Ahmedtaha, Mizan Habtemichael, Maekel Belay Woldemariam, Workagegnehu Hailu, Ole F Norheim, Hamelmal Hailegiorgis

Background: The burden of chronic kidney disease (CKD) is rapidly rising and becoming a major public health concern in low-and middle-income countries such as Ethiopia with an associated staggering economic burden. We aim to quantify the extent of out-of-pocket (OOP) health expenditures and the magnitude of associated catastrophic and impoverishing health expenditures for CKD care in Ethiopia. **Methods**: We conducted a prospective costing analysis for CKD care, from the household (patient) perspective. We collected data on OOP direct medical and nonmedical expenditures (2023 USD) and household consumption expenditures from a cohort of 433 patients that were followed prospectively for 6 months. Patients were recruited from 6 health facilities (3 government and 3 private) from 4 constituencies (Oromia, Amhara, Sidama and Addis Ababa) in Ethiopia. Data were collected from January 1 to August 31, 2023. We used descriptive statistics to measure the magnitude of OOP expenditures and the extent of catastrophic and impoverishing health expenditures. We used logistic regression model to assess the drivers of catastrophic health expenditures (CHE). **Results**: The mean annual OOP expenditures was $2,337 that varied by type of visit: $668 for outpatient visits, $2,759 for inpatient care and $5,312 for dialysis. Direct medical expenditures (particularly dialysis followed by drug and supply expenses) were the major drivers of cost accounting for 76% to 85% of the total OOP expenditures. Transportation expenditures were the major contributor among the direct nonmedical expenditures. Among those who sought outpatient, inpatient and dialysis care, 36%, 67% and 90% incurred CHE, respectively at a 10% threshold of annual consumption expenditures. The type of visit, and the type of facility visited were significantly associated with the odds of incurring CHE (p-value < 0.05) while adjusting for wealth quintile, disease stage, area of residence (urban/rural), family size, age of the patient and insurance membership status. **Conclusions**: The household economic burden for CKD care is substantial in Ethiopia. This is likely to impede access to CKD care and exacerbate the impoverishment which is prevalent in Ethiopia. This would be an obstacle in achieving universal health coverage and sustainable development goals in Ethiopia.

Ind-2682 Unequal Burden: Exploring Out-of-Pocket Healthcare Costs and Catastrophic Expenditure for Children Under Five in Northern Sri Lanka

PRESENTER: **Mathurahan Selvarasa**
AUTHOR: Anuji Gamage

Background SDG indicator 3.8.2 focuses on financial risk protection during healthcare out-of-pocket expenditure. Out-of-pocket expenses have become a growing concern in many countries, and Sri Lanka's recent economic crisis has exacerbated household out-of-pocket expenditure (OOPE) on healthcare, adversely impacting vulnerable groups, including children under five. Increasing trends of healthcare costs, with limited social security systems, have led to disparities in healthcare access and increased financial vulnerability. This study examines the patterns of OOPE and determinants of catastrophic healthcare expenditure (CHE) in Vavuniya District of Northern Sri Lanka to identify gaps and propose solutions for financial protection and equitable service delivery. **Aim** To describe the patterns of household OOPE, assess the prevalence of CHE, and identify the socio-economic and demographic factors associated with CHE among households with children under five in Vavuniya District. **Methods** This community-based descriptive cross-sectional study surveyed 359 randomly selected households with children under five from four Medical Officer of Health (MOH) areas in Vavuniya District. Data were collected using an interviewer-administered questionnaire that captured socio-demographic characteristics, health-seeking behaviors, and OOPE for healthcare services. CHE

was defined as healthcare expenditure exceeding 10% of total household income. Descriptive statistics and multivariate analyses were performed using SPSS software to identify key patterns and associated factors. **Results** The majority of the households were rural (67.41%, n=243) and comprised nuclear families (69.36%, n=249). Primary carers were predominantly female (97.78%, n=351) with majority studied upto O/L or above (90.81%, n=326) engaged in unpaid family work (80.78%, n=290). Median preventive healthcare cost was Rs. 800.00 with an IQR of Rs. 1050.00 but entirely composed of direct non-medical costs. However, private outpatient care incurred significant direct costs (mean Rs. 1684.07 per visit), while government outpatient care involved high indirect costs (mean Rs. 745.21). Fever and respiratory tract infections were the most common illnesses prompting healthcare visits. CHE was identified in 6.9% of households, with significant associations with ethnicity, household income, the number of children, and the severity of illness. Families relying on self-medication or home remedies (15.88%) exhibited higher vulnerability. **Conclusion** The study emphasises the need for policy interventions to alleviate the financial burden on vulnerable families and enhance healthcare equity. Solutions should focus on strengthening financial risk protection, promoting awareness of appropriate healthcare-seeking behaviours, and improving access to affordable, quality healthcare services for children under five. **Keywords** Out-of-pocket expenditure, catastrophic health expenditure, children under five, healthcare equity, financial protection, Vavuniya District

Ind-12 What Contributes to Out-of-pocket Health Expenditure in Cambodia's Uncovered Population? A Distributional and Decomposition Analysis Using Survey Data

PRESENTER: **Sovathiro Mao**, General Secretariat for the National Social Protection Council
AUTHORS: Andrea Hannah Kaiser, Pichenda Koeut, Marlaina Ross, Jesper Sundewall, Sokunthea Koy, Searivoth Vorn, Bjoern Ekman

Introduction: Out-of-pocket health expenditures (OOPE) are an inefficient and inequitable means of health financing. Identifying the factors driving these expenditures is crucial to design effective prepayment schemes. This study uses Cambodia—a country with high OOPE and prevalent informal employment—as a case study to analyse the relative contributions of healthcare, health, and social factors to OOPE and the OOPE budget share (OOPE as a proportion of total annual household expenditure) across different points in their distribution.

Methods: We used data from a 2023 cross-sectional survey among 3254 households engaged in informal employment with no access to prepayment schemes (uncovered households). We employed unconditional quantile regression to investigate the distributional effects of healthcare, health, and social factors on OOPE and the OOPE budget share. To examine the heterogeneity in the contributions of these factors to the explained variance in OOPE and the OOPE budget share at different quantiles, we combined unconditional quantile regression with Shapley decomposition.

Results: Uncovered households incurred high OOPE, leading to elevated incidences of financial hardship. Healthcare factors, including levels of care, private providers, medications, and visits were the largest contrib utors to the explained variance in OOPE and the OOPE budget share. Health factors, including severity, days lost to illness/injury, noncommunicable diseases, and injuries, also contributed substantially. Social factors contributed less overall, with wealth being the primary driver. Contributions of these factors varied across different points in the outcome distributions.

Conclusion: These findings underscore the need to improve financial protection for uncovered households. The Cambodian government should consider expanding prepayment schemes that directly address the main healthcare drivers identified in this study. Schemes should provide effective access to comprehensive outpatient care and essential medications, and necessary services at higher care levels, including in the private sector. Addressing the rising burden of noncommunicable diseases alongside multisectoral efforts to reduce injuries may also be important.

Improving Health Insurance Uptake and Targetting

MODERATOR: **Dominic Albert Nkhoma**,

Ind-1453 Effect of Free Healthcare Policies on Health Insurance Enrolment and Determinants of Enrolment Among Informal Sector Workers in Kenya

PRESENTER: **Phidelis Wamalwa**
AUTHORS: Christoph Strupat, Ms. Manuela De Allegri

Background: Many Sub-Saharan African countries are transitioning from free healthcare to national health insurance (NHI) policies to ensure sustained financing for universal health coverage policies. Informal sector workers (ISWs) are usually excluded from government subsidies and expected to contribute directly to the scheme. This leads to them being described as “missing middle” since their low incomes often result in inadequate coverage, perpetuating healthcare access inequalities. This paper describes current coverage rates among ISWs in Kenya, their

determinants and equity implications, and examines the extent to which the implementation of free healthcare policies can serve as catalyst for ISWs' decision to enrol in and contribute to insurance.

Methods: We used nationally representative repeated cross-sectional household data collected among ISWs in Kenya in 2018 (1118 households) and 2020 (2608 households) before and after the rollout of the free healthcare pilot, respectively. Our analysis included a total of 6900 (2354 in 2018 and 4546 in 2020) individuals, from the age of 18 years and above. We employed a two-level mixed effects logistic regression model to assess the determinants of NHI enrolment, and examined the socio-economic inequalities in NHI enrolment using concentration curves and the Wagstaff index. We constructed a pre-and-post, quasi-experimental design applying difference-in-differences estimation modelling to assess the effect of exposure to the free healthcare policy pilot on individuals' decisions to enrol later in the NHI Scheme.

Results: The overall NHI enrolment rate was 21.75% (95% CI 20.63-22.89). Determinants such as age, employment, microfinance institution membership, advanced education level, wealthiest households, and satisfaction with quality of care were significantly (p value <0.05) positively associated with NHI enrolment. The study further found pro-rich inequalities in NHI scheme enrolment with a concentration index of 0.35 (95% CI 0.30-0.41; p-value <0.001). As regards the effect of the free healthcare policy, enrolment in the NHI Scheme increased by 7%, from 15.2% to 22.2% (p = 0.04), in the intervention counties. Individuals in the intervention counties had a 65% greater probability of enrolling in the National Health Insurance Scheme than did those in the control counties (odds ratio-1.65; p=0.071).

Conclusion: The free healthcare policy favoured the decision to enrol in the NHI Scheme. However, enrolment rates among ISWs remain low, and significant pro-rich inequalities exist, primarily driven by age, economic factors, education, and perceived quality of care. Policymakers should consider exploring non-traditional communication channels to educate ISWs about NHI enrolment procedures and benefits. Utilizing microfinance institutions as onboarding structures, assigning premiums based on affordability, and expanding subsidies for low-income ISWs can help increase awareness, improve affordability, and reduce disparities, ultimately boosting enrolment. These findings are relevant to low- and middle-income countries implementing or considering to implement contributory NHI schemes. The findings are particularly important to Kenya, informing the process of ISWs inclusion as the country transitions to mandatory NHI enrolment policy.

Ind-973 Heterogeneous Preference for Supplementary Health Insurance: A Behavioral Economics Perspective

PRESENTER: **Lizheng Xu**
AUTHORS: Chaofan Li, Lei Si, Stephen Jan, Shunping Li, Jiaqi Yuan

Aims: Despite the universal health insurance coverage achieved in 2011, patients in China with serious health conditions, such as cancer and rare diseases, continue to face high risks of having catastrophic health expenses. Supplementary health insurance has the potential to reduce such risks. This study aims to assess residents' preferences for supplementary health insurance and analyze the heterogeneity from behavioral economics perspective. **Methods**: We conducted a discrete choice experiment (DCE) with five key attributes: premium (4 levels), benefit package (4 levels), deductible (3 levels), reimbursement rate (3 levels), and coverage for pre-existing conditions (3 levels). The attributes and levels were developed through literature review, policy comparison, Delphi method, and qualitative interviews with residents. Using a D-efficient design, we constructed 14 unlabeled choice sets, randomly assigned into two blocks. Respondents chose between two alternatives and an opt-out option in each choice task. A pilot survey assessed questionnaire feasibility, leading to refinements in attributes and levels. For the formal survey, 1,359 respondents were selected from 12 counties across three Chinese provinces using quota sampling according to residential location and age. Data were collected through face-to-face, computer-assisted interviews conducted by trained interviewers. After excluding invalid questionnaires, 1,254 responses were analyzed using conditional and mixed logit models to estimate attribute coefficients, relative importance scores, and willingness to pay. We further explored preference heterogeneity across disease risk awareness, numeracy, and risk attitudes using mixed logit models with interaction terms and subgroup analysis. **Results**: Among the 1,254 respondents, over 70% were female, and half resided in rural areas. Roughly 37% were aware of the risk of medical expenses, 16% had high numeracy, and 53% held risk-averse attitudes. A significantly negative coefficient of the "opt-out" option (β = -9.742, p<0.001) indicated a preference for enrolling in supplementary health insurance over the status quo. All attribute coefficients were statistically significant (p<0.01), with relative importance scores as follows: reimbursement rate (31.62%) > premium (30.83%) > benefit package (16.24%) > deductible (16.15%) > coverage for pre-existing conditions (5.15%). Respondents were willing to pay RMB 327.08 for a 90% reimbursement rate, RMB 182.32–287.66 for an expanded benefit package, and RMB 146.70–180.13 for including pre-existing conditions. The mixed logit model with interaction terms revealed that preferences for supplementary health insurance varied significantly (p<0.05). The respondents with high numeracy, disease risk awareness and risk aversion attitude were more likely to prefer enrolling in supplementary health insurance than opt out (p<0.05), and they also had higher preference for deductible 5,000 RMB than for deductible 20,000 RMB. **Conclusion**: Most respondents expressed willingness to enroll in supplementary health insurance, showing the highest preference for attributes of reimbursement rate and premium, moderate preference for benefit package and deductible, and lowest preference for reimbursement of pre-existing conditions. Heterogeneity analysis suggest that interventions aimed at improving risk communication and numeracy may enhance uptake rates for supplementary health insurance.

Ind-1853 The Double-Edged Sword Effects of Medical Insurance Integration on Health Equalities: Evidence From a Quasi-Natural Experiment in China

PRESENTER: **Jianhui Wang**
AUTHOR: Miao Yu

Background: Health inequality among different demographic groups have attracted wide attention in both developed and developing countries, as it stems from the unequal distribution of resources such as income, household registration, medical care, and pension. Governments worldwide have been working hard to carry out institutional reforms to address health inequality and maintain social stability, but the impact of these reforms on promoting equitable health outcomes remains unclear.

Objectives: This study focuses on China's urban and rural social medical insurance integration reform. China has been working hard to integrate the medical insurance schemes for urban and rural residents into a unified program, with the goal of mitigating disparities in medical insurance coverage and enhancing welfare benefits for rural residents. The objective of this study is threefold: i) Develop a comprehensive indicator to reflect the health status of urban and rural residents before and after the reform. ii) Assess the impact of reforms on health equalities between and within urban and rural residents. iii) Explain the mechanisms that contribute to the narrowing or widening of health inequality.

Design: The study utilizes *a quasi-natural experiment design*. Three *primary datasets* are used: i) Medical Insurance Integration Policy Dataset, which records the timing of integration reform in each city. ii) Individual's Health Outcomes Dataset, derived from the China Family Panel Studies, a national longitudinal study conducted from 2012 to 2020, providing data on self-rated health, physical health, mental health, and personal characteristics. iii) Income and Expenditure Data of China's City Government Medical Insurance Fund, collected from China's city statistical yearbook. The study employs three *methods*. The entropy method to measure comprehensive health indicators; staggered Difference-in-Differences (DID) to evaluate the impact of the integration reform on health outcomes; and the concentration index and decomposition method to estimate health inequality among rural residents at different income levels pre and post reform.

Results: The urban-rural medical insurance integration reform has a "double-edged sword" effect. It significantly improves the health outcomes of rural residents while not having a positive effect on urban residents, indicating a successful narrowing of health disparities between urban and rural areas. Mechanism tests reveal that the reform leads to higher health awareness, medical service utilization, and preventive consumption among rural residents, reducing inequality between urban and rural areas. However, the reform also widens health inequality within rural groups. Higher-income groups in rural areas utilize more medical services and receive greater government compensation, resulting in a reverse subsidy phenomenon where the poor subsidize the rich. Regional disparities in medical insurance fund compensation levels further contribute to heterogeneous health inequality.

Conclusions: Accelerating the integration of urban and rural medical insurance systems is an effective approach to reduce unfair treatment between urban and rural areas. However, when policy resources are not effectively allocated, new inequalities may arise. Therefore, the implementation of medical insurance policies should be more refined. For instance, providing financial compensation to areas with limited medical resources and establishing a multi-level social medical security system for residents at different income levels can address these issues.

Ind-284 Toward Risk-Adjusted Capitation for Primary Care in Nigeria: Evidence from Kaduna State's Social Health Insurance Scheme

PRESENTER: **Abubakar Yerima Mohammed**
AUTHORS: Catherine Goodman, Olufunke Fasawe, Abubakar Muhammad Hassan, Bala Sai'du

Background:

Effective provider payment mechanisms that align provider incentives with payer objectives are essential for achieving Universal Health Coverage (UHC) goals. However, this remains a significant challenge in Nigeria. State Health Insurance Agencies (SHIAs) primarily use crude capitation as the payment mechanism for primary care, with a capitation value of just N500 ($0.31) per life. This low and unadjusted rate leads to challenges such as risk selection, quality skimping, and under-provision of care. While risk-adjusted capitation has the potential to mitigate these issues, research on its implementation in Nigeria, particularly within state social health insurance schemes, is limited. This study addresses this gap by analyzing the factors influencing primary care service utilization under the Kaduna State Social Health Insurance Scheme, providing evidence to guide the development of equitable and effective capitation adjustments.

Methodology:

The study employed robust administrative datasets sourced from the Kaduna State Contributory Health Management Authority (KADCHMA). Data on primary care utilization from public primary health facilities and the comprehensive database of enrollees were merged to create an analytical master dataset. After applying the Multivariate Imputation using Chained Equations (MICE) technique to address missing data, multivariate logistic regression was employed to ascertain the relationship between primary care utilization and four predictive factors—age, gender, socioeconomic status, and geographical location.

Results:

The findings indicate that the middle-aged group (30-59 years) exhibited a heightened likelihood of primary care utilization, contrasting with lower utilization likelihood among those below 20 years and above 60 years. Females were 8.5% more likely to utilize primary care compared to males. Enrollees who paid insurance premiums demonstrated a 33% increased likelihood of primary care utilization relative to the poor enrollees who cannot afford insurance premiums that are covered by government subsidy insurance programs. Additionally, rural, and semi-urban residents exhibited a higher likelihood of using primary care services compared to urban residents.

Conclusion and Policy Implication:

This study has unveiled the existing inequities in access to primary care services under the Kaduna SSHIS, further accentuating the imperative for risk adjustment of capitation for primary care services. Moreover, the research highlights the distinct and significant predictive roles of demographic factors (age and gender), socioeconomic status (as reflected in insurance premium payment capacity), and geographical location (urban, rural, or semi-urban) in primary care utilization. Consequently, the findings support the appropriateness of these variables as essential needs factors for adjusting capitation payments for primary care services within the Kaduna State Social Health Insurance Scheme.

As Nigeria's new administration embarks on designing version 2.0 of the Basic Health Care Provision Fund under the Health Sector Renewal

Investment Program, this study offers valuable insights into how health care needs can inform equitable capitation adjustments and facility budget allocations. However, for evidence-based resource allocation to be effective, significant investments in robust data systems are imperative. The study also identified systemic weaknesses, including manual reporting and low service utilization data reliability, which must be addressed to ensure sustainable improvements in health care delivery

Ind-1348 Leveraging Machine Learning to Predict Hospital Activity in Kazakhstan Using Health Insurance Data

PRESENTER: **Daliya Kaskirbayeva**
AUTHOR: Tim Ensor

Kazakhstan introduced compulsory social health insurance (CSHI) schemes in 2020 as part of its efforts toward achieving universal health coverage. The current financial planning tool for hospital services in Kazakhstan, integrated into the CSHI, relies on a linear regression-based approach to predict hospital activity. Adequate prediction of hospital activity is crucial for insurance systems to ensure the sustainability and adequacy of premiums to cover healthcare costs. This study aims to evaluate the performance of machine learning (ML) models in comparison to the linear regression model currently used by the government. **Methods** We analyzed Kazakhstan's national hospital episode statistics from 2021 to 2023 using machine learning models, including Extreme Gradient Boosting (XGBoost) and artificial neural networks, to predict hospitalization rates and lengths of stay. A systematic literature review was conducted to identify parameters commonly used in regression and machine learning models for such predictions. Based on the findings, we included sociodemographic variables (age, gender, occupation, and region of residence), health-related variables (diagnosis, admission and discharge dates and times, ward type, procedures, hospital outcomes, and emergency vs. elective admission status), and hospital-level variables (e.g., rural vs. urban location, referring primary care facility location, hospital ownership, payment schemes such as the guaranteed package or health insurance, geographic location, bed capacity, and availability of medical and non-medical staff). **Results** The dataset included all hospital episodes reimbursed by the centralized health services purchaser (Health Insurance Fund): 3013041 observations in 2021, 3 313 144 in 2022, and 3 684 455 in 2023. Machine learning models demonstrated higher accuracy, measured by the area under the ROC curve (AUC), than traditional regression models when applied to the same dataset used for training. **Conclusion** Extreme gradient boosting showed superior predictive performance compared to the linear regression model traditionally used by Kazakhstan's Ministry of Health. Model performance improved further when a more restricted set of variables was used. To enhance prediction accuracy, more detailed patient-level data (e.g., education level) and hospital-level data (e.g., human resource training for medical equipment use) are needed. Improved prediction models can support better decision-making at both government and clinical levels.

Modelling Frameworks for Valuing Health Economic Outcomes

MODERATOR: **Nhung Nghiem**, "John Curtin School of Medical Research, Australian National University"

Ind-640 How Ageing People Respond to Severe Health Shock: the Effect on Consumption, Income and Wealth

PRESENTER: **YI SUN**

This study examines the economic impact of spousal loss on older adults in the UK, leveraging harmonized longitudinal data from the English Longitudinal Study of Ageing (ELSA). Unlike existing literature centered on US datasets with high out-of-pocket healthcare costs, this analysis situates spousal loss within the UK's universal and low-cost healthcare system. The findings reveal a significant and sustained increase in surviving spouses' consumption, particularly in leisure and food expenditures, accompanied by a marked decline in household income. While these trends challenge conventional models predicting resource-constrained consumption following health shocks, the evidence highlights the role of resource redistribution within households. Wealth effects are modest. These insights suggest that, in a context of minimal medical expenditure risks, lifestyle changes and reallocation of financial resources drive observed patterns in post-widowhood economic behavior. Methodologically, the study employs the staggered Difference-in-Differences approach to account for heterogeneous treatment timing and ensure causal inference. Event study analyses confirm the exogeneity of the widowhood shock, with pre-trends validating parallel trend assumptions. This research contributes to the literature on economic adjustment to life shocks by highlighting how older adults, even in the absence of labor income, actively restructure spending and adapt to changes in household composition. The findings offer new insights for policy efforts aimed at supporting financial resilience in later life.

Ind-772 The Value of Age, Sex and Disability Level in Decision Strategies for Surgical and Conservative Treatments of Adult Spinal Deformity

PRESENTER: **Alessio Pignatellli**
AUTHORS: Noor Alesawy, Khaled Kebaish, Amit Jain, Tej Azad

Background

Adult Spinal Deformity (ASD) refers to spinal abnormalities that lead to misalignment of the spine, often causing pain, disability, and reduced quality of life. It is increasingly common in an aging population. Surgery generally yields better outcomes than non-surgical treatments, however it is a costly procedure with high rates of complications.

Objective

The goal of this project is to develop treatment guidelines based on age, sex, and disability level to maximize the total net benefits in the US

ASD patient population, and to quantify the value of adopting these demographic-informed strategies. The additional aim is to determine the residual value attainable with perfect information to evaluate the potential for research on other predictors of treatment outcomes.

Methods

Three treatment strategies are considered: surgery, non-operative care, non-surgical care followed by delayed surgery for non-responders. Treatment strategies and outcomes are modeled in a decision tree, using stochastic distributions with demographic-dependent parameters from our dataset or literature. The US ASD population size and composition is estimated from prevalence for subjects aged 40-80. 1,000 Monte Carlo simulations of the whole population are used for estimation. Utility scores (SF6D) were derived from ODI data and converted to QALYs, then translated to monetary benefits using willingness-to-pay (WTP). The net benefit is:

Net benefit = QALY monetary benefit - Direct costs - Opportunity costs + Productivity change

Net benefits are calculated at the population level for each full population treatment strategy, and for the best demographic-based treatment strategy. The value of each strategy is defined as the difference between such strategy and the worst-case scenario of assigning each patient to their least beneficial treatment. The percent value of a strategy is calculated from the ratio of the value of the given strategy and the value of the best-case scenario of assigning each patient to their most beneficial treatment. The difference between the value of the best-case scenario and the best demographic-based treatment strategy is the residual value.

Results

Net benefits are primarily driven by QALY monetary benefits and direct costs. Baseline disability level has the biggest impact on net benefits of different treatments. Within the same disability group, surgery is preferred in younger patients. Exact age cutoffs for treatment preference depend on the WTP per QALY. When treating the US ASD population, the value of the best demographic-based strategy is $1,938 - $2,144 billions (at WTP 91,000 - 140,000 $/QALY). Notably, this is $2 - $72 billions higher than conservative treatment for all, which is the best strategy ignoring demographic covariates. The percent value of the demographic-based strategy is 71% - 61%, which means the residual value is $774 - $1,375 billions.

Conclusions

Demographic covariates such as age, sex, and disability level should inform treatment decisions and have great cost-saving potential. The high residual value illustrates a need to determine additional treatment outcome predictors, especially in younger patients, to reduce variance in predictions and edge closer to ideal treatment allocation. In practice, such research and implementation could lead to better patient outcomes at lower relative cost.

Ind-786 Choosing Wisely: Evaluating Latent Factor Models in the Presence of a Contaminated Instrumental Variable with Differing Strength

PRESENTER: **Souvik Banerjee**, Indian Institute of Technology Bombay
AUTHORS: Anirban Basu, Shubham Das

Background: Causal inference methods are widely used in empirical research; however, there is a paucity of evidence on the use of latent factor methods in the presence of a contaminated instrumental variable (IV) for different strengths of the instrument. Objective: We aim to build on and extend the work of Banerjee and Basu (2021) in multiple ways: (i) we discuss the identification criteria for the shared latent factor (SLF) and SLF+IV models, (ii) we provide a theoretical framework to illustrate how the strength of IV and contamination determine the optimal choice between Two Stage Least Square (2SLS), SLF, and SLF+IV estimators, (iii) we compare the finite sample properties of the Ordinary Least Squares (OLS), SLF, 2SLS, and SLF+IV estimators in terms of percentage bias, standard error, coverage probability, and Mean Squared Error (MSE) for different degrees of contamination and strength of the IV, and (iv) we empirically test the OLS, 2SLS, SLF, and SLF+IV models using survey data. Methods: We present a theoretical formulation to depict how the strength and degree of contamination of the IV contamination simultaneously determine the optimal choice of estimator. We performed Monte Carlo simulations with four outcome variables, with sample sizes of 500 and 1000, and for 1000 iterations. We further applied the OLS, 2SLS, SLF and SLF+IV models to study the causal impact of obesity on various health indicators (diastolic and systolic blood pressure readings, blood glucose level, and haemoglobin count), using the arm circumference as an IV and the 2019-2021 Round 5 of the National Family Health Survey (NFHS-5) data. Results: Findings from the simulations indicate that, for a given level of strength of the IV, the SLF+IV estimator has a lower bias than that of the SLF estimator at lower degrees of contamination. However, beyond a certain threshold degree of contamination, the bias of the SLF+IV estimator becomes greater than that of the SLF estimator. The simulation results further highlight that if the IV is strong, then the SLF+IV estimator has a lower bias than the SLF estimator. However, if the IV is weak, then the SLF+IV estimator may or may not have a lower bias than the SLF estimator. The findings from the simulations are consistent with the theoretical results. In our empirical application, all the models reveal that obesity is associated with higher levels of diastolic and systolic blood pressure readings, blood glucose level and haemoglobin count, which indicates that obesity increases the risk of hypertension and diabetes but lowers the risk of anaemia. Discussions: Both SLF and SLF+IV estimators perform better than the traditional OLS and 2SLS estimators in terms of bias and MSE. A strong and less contaminated IV makes the SLF+IV estimator a better choice than the SLF estimator, while a weak and highly contaminated IV makes the SLF estimator a better choice than the SLF+IV estimator.

Ind-935 Causal Inference with Time-to-Event Outcomes: A Debiased Machine Learning Framework for Treatment Parameters

PRESENTER: **Meimei Chen**
AUTHORS: Henry Cutler, Yuanyuan Gu

Background: Causal inference is crucial in health econometrics for assessing the effectiveness and impact of health interventions. Traditionally, Randomised Controlled Trials are used to identify causal impact. However, advancements in data collection technologies, such as wearable devices and electronic health records, have significantly increased access to complex observational data, presenting new opportunities and challenges for health outcome evaluation. Concurrently, machine learning (ML) has gained recognition for its ability to handle and analyse large, complex datasets. This has led to the development of methods integrating ML with causal inference, including the notable approach of double machine learning (DML).

Objective: This research aims to adapt the DML framework for use with survival data, which are critical in health economics research for understanding survival and duration until events. The proposed method in this research allows for the use of a broad array of state-of-the-art ML methods while ensuring that the estimator remains unbiased and normally distributed asymptotically, which allows for the derivation of valid confidence intervals.

Methodology: This research develops a new framework for causal analysis with right-censored time-to-event data based on DML. In addition to the three fundamental assumptions of Rubin's potential outcome framework (i.e., exchangeability, consistency, and positivity), we assume that censoring is independent of the treatment assignment mechanisms, given all covariates. To remove bias introduced by ML methods, we provide a Neyman orthogonal score function for the parameters of interest, nuisance parameters, and censoring indicator. The Neyman orthogonality ensures that the estimator, which identifies our parameters of interest, is locally insensitive to the values of nuisance parameters. We also prove that estimators given in our research achieve a root-N rate of convergence and are approximately normally distributed.

Results: We used both simulated and real-world datasets to evaluate the accuracy and stability of our method. First, we showed that various state-of-the-art ML models, including random forests, gradient boosting machines, and neural networks, can be integrated into our method to estimate the nuisance parameters without compromising the consistency of our parameters of interest. Second, we compared the performance of our method with several conventional statistical methods on simulated datasets. We showed that as the number of nuisance parameters increases, our method remains stable. Third, we applied our method to a real-world dataset from the Linked Births and Infant Deaths Database (LBIDD). We compared our method to alternatives based on absolute bias, mean squared error, and standard deviation. Our method exhibited relatively smaller bias and lower variance.

Conclusion: Our research successfully extended the causal inference framework DML to incorporate time-to-event outcomes, showing robust performance on both simulated and real-world datasets. This method offers a powerful tool for health economists, enabling more accurate causal inference in studies involving survival data.

Ind-2847 Health Literacy's Effects on Health Outcomes and Healthcare Utilization: A Path Analysis of Tribal and Non-Tribal Populations in India

PRESENTER: **Kripa Nandan**
AUTHOR: Pratap C. Mohanty

Introduction: Health literacy is a crucial determinant of health outcomes and healthcare utilization, encompassing the ability to access, understand, evaluate, and apply health information for informed decision-making. This study examines the effects of health literacy on health outcomes and healthcare utilization among tribal and non-tribal populations in India, using path analysis. The research focuses on two districts in Odisha: Mayurbhanj, predominantly tribal, and Khordha, with a more diverse population. **Methods:** A multi-stage purposive cross-sectional survey was conducted from January to June 2024. The study employed the HLS-EU-Q47 comprehensive health literacy questionnaire, a validated tool with 47 items rated on a 5-point Likert scale. The questionnaire was translated into Hindi, Odia, and Santali, and also administered in English. It assesses four competencies: accessing, understanding, evaluating, and applying health information across healthcare, disease prevention, and health promotion domains. Reliability was confirmed with a Cronbach's alpha of 0.9449 and a split-half reliability of 0.823, indicating high internal consistency. Participants had a mean age of 42.59 years. In Mayurbhanj, 62.43% were aged 18-45, while in Khordha, this group comprised 64.33%. Gender distribution was balanced, with 57.51% male in Mayurbhanj and 55.62% in Khordha. Income and education levels varied significantly between the districts. **Data Analysis:** Path analysis was conducted using SPSS 27 to explore the relationships between health literacy, health outcomes, medical expenditure, interest in health-related activities, and healthcare utilization. The model's fit was evaluated using several fit statistics: the relative Chi-square Model-Fit Statistic, Adjusted Goodness-of-Fit Index (AGFI), Normed Fit Index (NFI), and Root Mean Squared Error of Approximation (RMSEA). A good model fit is indicated by an AGFI greater than 0.90, an RMSEA less than 0.05, and an NFI greater than 0.90. These indices collectively provide a robust assessment of the model's validity. **Results:** The path analysis revealed significant pathways through which health literacy impacts health outcomes and healthcare utilization. Higher health literacy was associated with better health outcomes and more efficient healthcare utilization, reducing unnecessary medical expenditures. The effects were more pronounced in the tribal population of Mayurbhanj, highlighting the critical role of culturally and linguistically tailored health literacy interventions. **Discussion:** The findings underscore the importance of enhancing health literacy to improve health outcomes, optimize healthcare utilization, and increase interest in health-related activities, particularly in tribal communities. The study highlights the need for targeted health literacy programs that consider cultural and linguistic contexts to effectively address health disparities. **Conclusion:** This research provides valuable insights into the role of health literacy in shaping health outcomes and healthcare utilization in diverse populations. By employing a path analysis approach, the study offers a nuanced understanding of the complex interrelationships between health literacy and health-related behaviors, informing policy and practice aimed at improving health literacy and reducing health inequities in India.

Economic Burden of Disease

MODERATOR: **Asih Eka Putri**, Dewan Jaminan Sosial Nasional

Ind-63 Australian Epilepsy Project: Health Economic Perspectives on Epilepsy

PRESENTER: **Gopisankar Mohanannair Geethadevi**
AUTHORS: Patrick Kwan, For the Australian Epilepsy Project Investigators, Graeme Jackson, Zhibin Chen, Emma Foster, Zanfina Ademi

Background: In Australia, approximately 3-4% of the population will develop epilepsy at some point in their lives. European studies indicate that over 75% of the total healthcare costs of epilepsy are indirect, with 80-92% arising from absenteeism. The remainder is attributed to informal care, loss of productivity, and premature mortality. There is currently no robust, national Australian data on absenteeism or presenteeism due to epilepsy. This project utilised baseline data from the Australian Epilepsy Project (AEP), a prospective study that collects health and economic data from individuals with epilepsy, to address this gap.

Methodology: The AEP included three clinical subgroups: (a) focal and drug-resistant epilepsy (DRE), (b) first unprovoked seizure (FUS), and (c) newly diagnosed epilepsy (NDE). The primary objectives of the health economic sub study were to estimate quality of life based on the EQ-5D-5L questionnaire, and disease specific using QOLIE-31, informal care contribution, and presenteeism and absenteeism in a week using the Work Productivity and Activity Impairment (WPAI) questionnaire. Depending on the type and distribution of variables, univariate analyses were conducted to understand their influence on outcomes using generalized linear models, mixed methods models.

Results: A total of 854 people registered at baseline AEP: 46% had DRE, 34% had NDE, and 18% had FUS. The cohort was 47% female, with a mean age of 37 (SD 13). 66% (n = 258) were employed. The median (IQR) number of seizures in the previous 12-month among DRE, FUS and NDE were 50 (13 – 158), 1 (1 – 1) and 4 (2 – 21) ($p<0.001$: DRE vs NDE and FUS) respectively. Median (IQR) EQ-5D-5L values for the cohort was 0.93 (0.14) which did not differ between diagnostic groups. The mean QOLIE-31 score among DRE, FUS and NDE was 49.3 (17), 60.6 (15.4) and 57.1 (17.7) ($p<0.001$; DRE vs both FUS and NDE). The seizure worry sub-question in QOLIE-31, was the highest for individuals with DRE ($p<0.001$; DRE vs both FUS and NDE). The overall informal care requirement was 20% with the higher for DRE (25.3%; $p<0.001$) compared to FUS. Those with DRE were less likely to be employed (58%) compared to 80% of FUS ($p=0.002$), and 71% of NDE ($p= 0.016$) participants being employed. Of those employed, the mean (SD) hours missed due to epilepsy in a week was 5.1 (18). The mean percentage (SD) of absenteeism, presenteeism, work impairment, and impact on regular activities were 11 (24), 18 (26), 24 (32) and 28 (30) respectively. The mean percentage of presenteeism was 22.7 (28.8), 17.1 (22.7) and 13.6 (24.7) for DRE, NDE and FUS respectively ($p= <0.001$: DRE vs NDE). The mean percentage of impairment on daily activities was 35.7 (31.9), 22.6 (27.7) and 20.2 (28.3).

Conclusions and implications: Up to a quarter of a person's weekly work was negatively impacted by epilepsy. People with DRE experienced more seizures, higher rates of unemployment, increased presenteeism, greater worry about seizure recurrence, and a lower quality of life. Additionally, they faced a greater need for informal care.

Ind-147 Evaluating Health Through the Lens of Productivity Gains

PRESENTER: **Zanfina Ademi**, Monash University
AUTHORS: Melanie Lloyd, Maria Arvez, Dina Abushanab

Objectives: Traditional health economic evaluations often use the years of life lived and quality-adjusted life years (QALYs) to assess mortality risk reductions and health improvements. To advance discussions toward more robust prevention strategies and account for broader economic impacts, we developed a new metric, Productivity-Adjusted Life Years (PALYs), aimed at capturing a more comprehensive view of health's societal contribution. Our objective was to conduct a systematic review illustrating the application of PALYs as an outcome measure across various disease contexts.

Methods: We conducted a comprehensive review of studies utilising PALYs to identify effective methods for decision-making and to illustrate their applications. Using a snowball search, we selected studies that applied PALYs to quantify societal health burdens in specific diseases or contexts. Extracted data included health conditions, country setting, timeframe, model type, outcomes, data type (incidence/prevalence), discounting, time horizon, prevention strategies, working-age population, productivity index components, PALY economic value, GDP, and sensitivity analysis details. Income level classifications were based on World Bank standards, and findings were summarized through narrative synthesis.

Results: We identified 34 studies published between 2018 and 2024, with most from 2020–2023. These studies spanned health conditions from chronic diseases, such as cardiovascular and kidney disease, to environmental factors like PM2.5 exposure. Most were conducted in high-income countries (n=20), followed by upper-middle-income (n=9), lower-middle-income (n=4), and low-income (n=1) settings. Life table models (n=23) and dynamic models (n=8) were predominant, with other methods including mathematical projection, questionnaires, and cross-sectional designs. Prevention-focused studies (n=18) outnumbered those on chronic disease management (n=14), with two studies addressing both. From a population perspective, diabetes, hypertension, sleep apnoea, cardiovascular diseases, and non-optimal temperatures imposed the greatest societal burden, while epilepsy resulted in the most significant losses in life years and productivity-adjusted life years. Most studies

included presenteeism and absenteeism (n=26) in their productivity index; four included mortality, eight included labour force participation, and three included absenteeism alone. Productivity loss values ranged from US$1,137 to AU$217,983 per full-time worker.

Conclusion: The diversity of health conditions and economic contexts covered in these studies highlights a broad interest in the determinants of health as measured by the PALY metric. This diversity is essential, as it provides a comprehensive understanding of the economic impacts associated with varied health challenges. Moreover, the emphasis on prevention over chronic disease management suggests a strategic shift toward averting disease onset.

Ind-264 Factors Associated With Sickness Absenteeism and Presenteeism in a Canadian Working Population

PRESENTER: **Wei Zhang**, University of British Columbia
AUTHORS: Hong Qian, Jacynthe L'Heureux, Gary Johns, Mieke Koehoorn, Simon Woodcock

Background

Many economic evaluations conducted from a societal perspective have not considered absenteeism or presenteeism, two important work productivity loss components. One of the reasons is a lack of existing estimates that can be incorporated in the economic evaluations.

Objective

To estimate absenteeism and presenteeism among a representative sample of the Canadian working population, and identify associated factors.

Methods

Questions regarding absenteeism and presenteeism were added to the Canadian Community Health Survey as a rapid response module, which was conducted by Statistics Canada in July to December 2022. Eligibility for this module included 1) aged 15-75 years, 2) working at a job or business as their main activity in the past 12 months, 3) having worked at a job or business in the past 3 months, and 4) not “permanently unable to work”. We excluded some respondents through logic checks, e.g., if their reported absenteeism and presenteeism in the past 7 days were greater than those reported for the past 3 months.

Absenteeism was measured as the number of absent workdays because of health in the past 3 months. Presenteeism was measured as the number of days worked while experiencing health problems in the past 3 months. Linear regression using backward selection method (p value <0.2) was used to identify factors associated with absenteeism and presenteeism. Age, age squared, gender and chronic conditions (14 conditions) were included in the regression models regardless of statistical significance. Other factors included ethnicity/identity, immigrant status, province, education, household income, occupation, industry, self-employment status, full/part-time work status, telework status, work schedule/shift, self-perceived work stress, body mass index classification, type of smoker, and type of alcohol drinker.

Results

There were 9,148 survey respondents meeting our inclusion criteria. Chronic fatigue syndrome (3.14 days), multiple chemical sensitivities (2.27), fibromyalgia (1.92), and mood disorder (1.80) were associated with more absenteeism days in a 3-month recall period, compared to those without the corresponding chronic condition. Lower education was associated with more absenteeism. Compared to public administration industry, some industries, such as accommodation and food services, were associated with lower absenteeism. People who perceived their work as extremely stressful were absent from work for 1.69 more days than those without work stress.

Stroke (13.18 days), chronic fatigue syndrome (10.89), fibromyalgia (10.54), and post-traumatic stress disorder (8.07) were associated with more presenteeism days. People reporting Indigenous identity had 2.63 more presenteeism days than people who did not identify as a visible minority. People working in the health care and social assistance industry had 1.81 fewer presenteeism days than those in public administration industry. More presenteeism days were associated with annual household income <$100,000, being self-employed, working full-time, feeling quite a bit or extremely stressed at work, being underweight, or former daily smokers. Fewer presenteeism days were associated with regular drinkers.

Conclusions

Our results found both similar (e.g., chronic conditions and work stress) and different factors (e.g., household income and self-employment status) associated with absenteeism and presenteeism. The findings are intended to inform the inclusion of absenteeism and presenteeism in future economic analyses.

Ind-616 The Cost of Illness of Three High Burden Sexually Transmissible Infections; Chlamydia, Gonorrhoea and Syphilis in Australia.

PRESENTER: **Caroline Watts**, UNSW Sydney
AUTHORS: Virginia Wiseman, Rebecca Guy, Htein Linn Aung, Christopher K. Fairley, Nicholas Medland, Jane Hocking

Background Estimating the economic burden of priority sexually transmitted infections (STIs), chlamydia, gonorrhoea and syphilis, is important for policy making in regard to prioritising public health interventions and the allocation of resources. In Australia, and many countries globally the rate of STIs has increased considerably over the past decade. If untreated, these STIs are major causes of morbidity in women and men. For women, chlamydia and gonorrhoea can cause pelvic inflammatory disease leading to chronic pain, infertility and ectopic pregnancy. Syphilis can cause severe multi-organ disease, and stillbirth and malformations in babies. There is very little data on the economic

burden of STIs in Australia. **Aims** To estimate the cost of chlamydia, gonorrhoea and syphilis infections to the Australian society in 2019 (pre COVID-19 pandemic) **Methods** A prevalence-based approach was adopted which included all the costs associated with prevalent cases in 12-month period. Direct health system costs included costs of testing, consultations, medications, hospital services. Indirect costs related to productivity losses due to morbidity were also estimated. The analysis also included costs related to STI testing and management in jurisdictions which do receive funding through the universal insurance scheme such as publicly funded sexual health and community clinics, Australian Defence force personal and people who are incarcerated. Because COVID-19 resulted in a decline in the use of sexual and reproductive health service use, 2019 was chosen as the base case. **Results** In 2019, the annual direct health system cost of the STIs chlamydia, gonorrhoea and syphilis in Australia was estimated at $443.9 million of which 68% was for women and 32% for men. By infection type, the total (direct and indirect) annual cost for chlamydia was $192.0 million (SD 6.7) which accounted for 43% of total costs, for gonorrhoea $167.3 million (SD 5.9) which accounted for 38% of total costs and syphilis was $84.7 million (SD 2.9) which accounted for 19% of total costs. Productivity costs accounted for 20% of costs for women, 15% of costs for men. Reflecting that testing and management of STIs is largely conducted by general practitioners in Australia, 41%-47% of direct costs were related to consultations, 36%-49% to pathology, 8%-14% of costs due to hospital related expenditure and 0.2%-2% of expenditure from pharmaceuticals and medical imaging. By sector 67% of costs were funded through Australia's universal health insurance schemes, 15% funded through other government funding mechanisms and 18% of costs were due to productivity losses. **Conclusion** This study highlights the substantial cost of the STIs chlamydia, gonorrhoea to society. Further research is required to quantify the intangible costs associated with STIs. These results can inform economic evaluations to identify cost-effective STI prevention strategies to reduce this burden.

Ind-753 The Early Bird Does Not Get The Worm

PRESENTER: **Marco Bertoni**
AUTHORS: Francesca Meli, Lorenzo Rocco
